PKP-2200-LI

PKP_2200

• – ◦ • – ◦ • – ◦ •

Introduction

PKP_2200 is a global constant for the Blink Marine PowerKey interface. This constant serves as the default value for configuring digital input functionalities in the Blink Marine system.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

No adapters available

Functionality

PKP_2200 defines a global constant of type USINT (Unsigned Short Integer) with the hexadecimal value 16#21 (decimal 33). This constant is used as the default value for the PowerKey configuration.

Technical Specifications

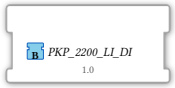
- **Data Type**: USINT (8-bit unsigned integer)
- **Initial Value**: USINT#16#21 (hexadecimal 21, decimal 33)
- **Packet Mapping**: BlinkMarine::io::DI

State Overview

As a global constant, PKP_2200 has no state transitions and retains its fixed value throughout its runtime.

Application Scenarios

- Default configuration for Blink Marine PowerKey interfaces
- Use as a reference value in digital input function blocks
- Configuration of I/O parameters in marine control systems



⚖️ Comparison with Similar Blocks

Unlike function blocks with dynamic behavior, PKP_2200 is a static constant without any behavioral logic. It serves solely to provide a fixed configuration value.

Conclusion

PKP_2200 represents an essential building block for configuring digital input interfaces in the BlinkMarine system. Its use as a global constant enables centralized and consistent configuration across different function blocks.

PKP_2200_LI_DI

• – ◦ • – ◦ • – ◦ •

Introduction

The PKP_2200_LI_DI is a global constant definition for Blink Marine PowerKey Digital Inputs. This constant defines the pin assignments for the digital inputs of a PowerKey system and provides predefined configurations for various keys as well as an invalid state.

Interface Structure

Event Inputs

No event inputs available - this is a global constant definition

Event Outputs

No event outputs available - this is a global constant definition

Data Inputs

No data inputs available - this is a global constant definition

Data Outputs

No data outputs available - this is a global constant definition

Adapters

No adapters available - this is a global constant definition

Functionality

The PKP_2200_LI_DI defines global constants of type `PKP_2200_LI_DI_S`, which specify the pin numbers for digital inputs of a Blink Marine PowerKey system. Each constant represents a specific key configuration with associated hardware pins.

- **Data Type**: All constants use the structure type `PKP_2200_LI_DI_S`
- **Pin Assignments**:
- DigitalInput_Key_1: Pin 1
- DigitalInput_Key_2: Pin 2
- DigitalInput_Key_3: Pin 3
- DigitalInput_Key_4: Pin 4
- Invalid: Pin 255 (invalid state)
- **Package Membership**: BlinkMarine::io::DI

State Overview

No state machine present - this is a static constant definition

Application Scenarios

- Configuration of digital inputs in marine control systems
- Hardware abstraction for PowerKey key assignments
- Simplification of pin mapping in IEC 61499 applications
- Error handling through defined invalid state

⚖️ Comparison with similar components

Unlike Function blocks with active logic are simply constant definitions that do not perform any active processing. They serve solely for the centralized management of hardware configurations.

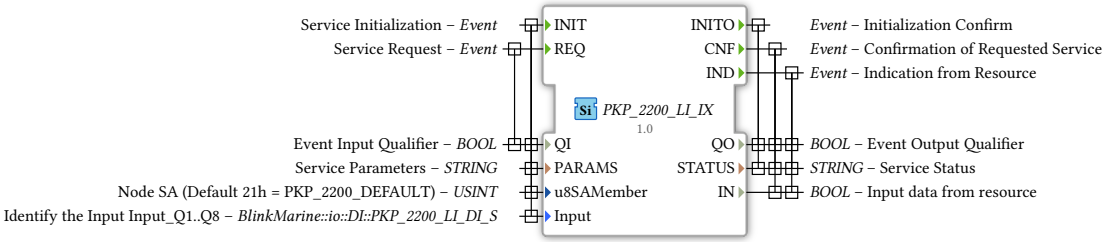
Conclusion

The PKP_2200_LI_DI provides a standardized and maintainable solution for the pin configuration of digital inputs in Blink Marine PowerKey systems. Centralized definition of hardware assignments ensures consistency across different applications and improves code reusability.

PKP_2200_LI_DI_S

Blink Marine PowerKey DI Struct

Structure



Name	Type	Initial Value
Pin	USINT	255

PKP_2200_LI_IX

• – ◦ • – ◦ • – ◦ •

Introduction

The PKP_2200_LI_IX is a service interface function block for Boolean input data. This block serves as an interface for digital inputs and enables communication with corresponding hardware resources.

Interface Structure

Event Inputs

- **INIT**: Service initialization with parameters QI, PARAMS, u8SAMember, and Input
- **REQ**: Service request with parameter QI

Event Outputs

- **INITO**: Initialization acknowledgment with parameters QO and STATUS
- **CNF**: Acknowledgement of the requested service operation with parameters QO, STATUS, and IN
- **IND**: Indication from the resource with parameters QO, STATUS, and IN

Data Inputs

- **QI**: Event input qualifier (BOOL)
- **PARAMS**: Service parameter (STRING)
- **u8SAMember**: Node SA (USINT) - Default value: PKP_2200::PKP_2200_DEFAULT (21h)
- **Input**: Identifies input Input_Q1..Q8 (Type: BlinkMarine::io::DI::PKP_2200_LI_DI_S) - Initial value: Invalid

Data Outputs

- **QO**: Event output qualifier (BOOL)
- **STATUS**: Service status (STRING)
- **IN**: Input data from the resource (BOOL)

Adapter

No adapter interfaces are available.

Functionality

This function block initializes and manages communication with digital input resources. The INIT event initializes the service with the appropriate parameters. The REQ event allows service operations to be requested. The INITO, CNF, and IND output events return acknowledgments and status information.

Technical Features

- Uses specific PKP_2200 communication parameters
- Supports up to 8 digital inputs (Q1-Q8)
- Includes default values for SA members (21h = PKP_2200_DEFAULT)
- Implements invalid initialization for inputs

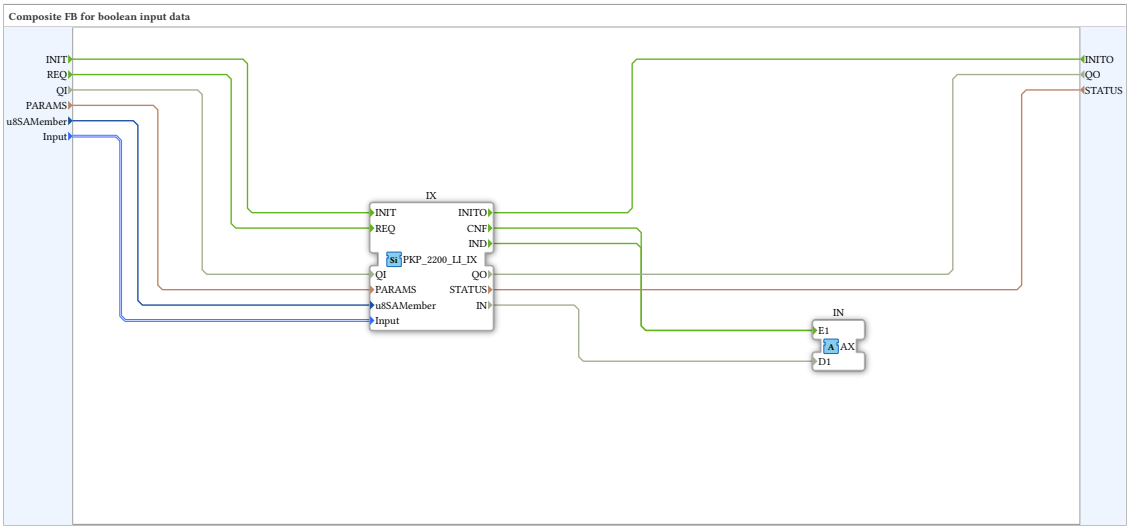
State Transitions

The function block goes through the following states:

1. **Initialization Phase**: INIT event processed, INITO response generated
2. **Service Operation**: REQ event processed, CNF response generated
3. **Resource Indication**: Automatic IND events upon state changes

Application Scenarios

- Connecting digital input sensors in automation systems
- Integration into marine applications (BlinkMarine environment)
- Communication with PKP_2200-compatible hardware
- Monitoring of switching states and signal levels

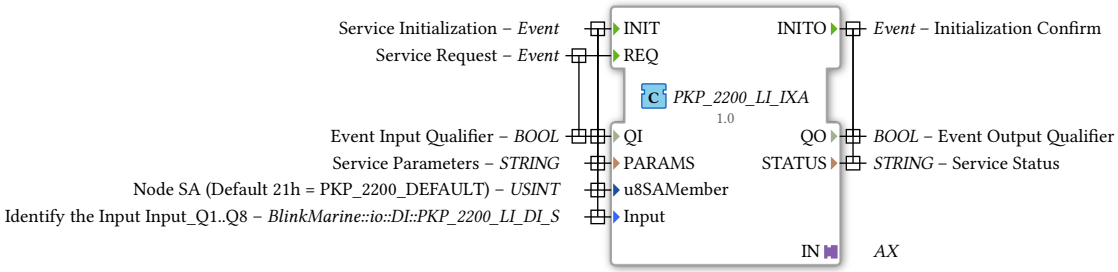


⚖️ Comparison with Similar Function Blocks

Compared to simple The PKP_2200_LI_IX offers enhanced service functionalities for digital input modules, including status feedback and parameterization options. Its specific PKP_2200 integration distinguishes it from generic I/O modules.

Conclusion

The PKP_2200_LI_IX is a specialized service interface module for the reliable connection of digital inputs in industrial automation systems, particularly in marine environments. Its enhanced functionality, including status feedback and parameterization options, makes it a robust solution for demanding I/O applications.



PKP_2200_LI_IXA

• — ○ • — ○ • — ○ •

Introduction

The PKP_2200_LI_IXA is a composite function block for processing Boolean input data. It serves as an interface for digital inputs and provides standardized initialization and query functions for input signals.

Interface Structure

Event Inputs

- **INIT**: Service Initialization (with QI, PARAMS, u8SAMember, Input)
- **REQ**: Service Request (with QI)

Event Outputs

- **INITO**: Initialization Acknowledgement (with QO, STATUS)

Data Inputs

- **QI**: Event Input Qualifier (BOOL)
- **PARAMS**: Service Parameters (STRING)
- **u8SAMember**: Node SA (USINT) - Default Value: PKP_2200::PKP_2200_DEFAULT
- **Input**: Input Identifier (BlinkMarine::io::DI::PKP_2200_LI_DI_S) - Default Value: Invalid

Data Outputs

- **QO**: Event Output Qualifier (BOOL)
- **STATUS**: Service Status (STRING)

Adapters

- **IN**: Unidirectional Adapter of Type AX

Functionality

The function block initializes itself via the INIT event and confirms successful initialization with INITO. Service requests can be made via the REQ event. The input data is processed via the IN adapter, and the results are provided via the corresponding outputs.

Technical Features

- Uses standardized initialization procedures according to EInit type
- Supports configuration via SA member (default: 21h)
- Provides error handling via STATUS output
- Implements qualified event processing

State Overview

The function block goes through the following states:

1. **Not Initialized**: Before INIT event
2. **Initialization**: During INIT processing
3. **Ready**: After successful initialization (INITO)
4. **Service Request**: During REQ processing

Application Scenarios

- Digital input signal processing in automation systems
- I/O communication with PKP-2200-compatible devices
- Integration into distributed control systems
- Boolean signal processing with quality monitoring

⚖️ Comparison with Similar Blocks

Compared to simple digital input blocks, PKP_2200_LI_IXA offers extended functionality through:

- Parameterizable SA Member Configuration
- Detailed status feedback
- Standardized initialization procedures
- Adapter-based interface

Conclusion

The PKP_2200_LI_IXA is a robust and flexible function block for processing digital input signals with advanced configuration and diagnostic capabilities. Its standardized interface enables easy integration into complex automation systems.

Modules with low IO density

DQ

DataPanel_LO_DO

• – ◦ • – ◦ • – ◦ •

Introduction

DataPanel_LO_DO is a global constant definition for low I/O density DataPanel modules for digital outputs (DO). The constant defines a structured mapping of pin numbers to specific digital output channels and provides an invalid state for error handling.

Interface Structure

Event Inputs

Not present - This is a global constant definition

Event Outputs

Not present - This is a global constant definition

Data Inputs

Not present - This is a global constant definition

Data Outputs

Not present - This is a global constant definition

Adapters

Not present - This is a global constant definition

Functionality

The global constant DataPanel_LO_DO defines a collection of structured constants of type `DataPanel_LO_DO_S`, representing digital output channels of a low-I/O-density DataPanel module. Each constant contains a pin assignment for specific output channels.

- **Data Type**: Uses the structured data type `DataPanel_LO_DO_S`
- **Pin Mapping**: Defines 8 digital output channels (1A-4B) with consecutive pin numbers 1-8
- **Error Handling**: Includes a special `Invalid` constant with pin value 255 for invalid states
- **Modular Structure**: Channel naming follows the pattern “DigitalOutput_XY” for clear identification

State Overview

Not applicable - This is a static constant definition without state machines

Application Scenarios

- Configuration of DataPanel modules with low I/O density
- Simplified pin mapping in control programs
- Type-safe use of digital output channels
- Error handling through defined invalid states

⚖️ Comparison with Similar Components

Compared to other I/O constant definitions, this offers DataPanel_LO_DO:

- Specific adaptation for modules with low I/O density
- Structured data types for improved type safety
- Clear naming convention for better readability
- Integrated error constant for more robust programming

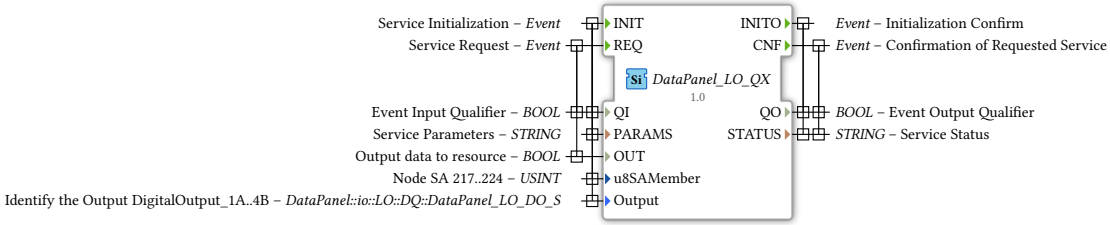
Conclusion

DataPanel_LO_DO provides an efficient and type-safe solution for configuring digital output channels in DataPanel modules with low I/O density. Its structured definition and clear pin assignment enable maintenance-friendly and fault-resistant programming of control applications.

DataPanel_LO_DO_S

DataPanel Modules with low IO density DO Struct

Structure



Name	Type	Initial Value
Pin	USINT	255

DataPanel_LO_QX

• – ◦ • – ◦ • – ◦ •

Introduction

The DataPanel_LO_QX is an output service interface function block for Boolean output data, specifically designed for communication with digital outputs in automation systems. This block enables the safe and controlled output of binary signals to connected hardware resources.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Operation

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters
- **OUT** (BOOL): Output Data for Resource
- **u8SAMember** (USINT): Node SA 217..224 (Initial Value: LO::LO_00)
- **Output** (DataPanel_LO_DO_S): Identifies Digital Output 1A..4B (Initial Value: Invalid)

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service status information

Adapter

No adapter interfaces are present.

Functionality

The function block operates according to a typical service interface pattern. During initialization (INIT event), the service parameters and hardware configuration are passed. The actual data output occurs via the REQ event, with the Boolean value at the OUT input being output to the configured hardware resource. Each operation is acknowledged by corresponding confirmation events (INITO, CNF).

Technical Features

- Supports specific hardware addressing via u8SAMember (SA nodes 217-224)
- Flexible output configuration via output parameters (DigitalOutput_1A to 4B)
- Initialization with default values for quick deployment
- String-based status feedback for detailed fault diagnosis

State Overview

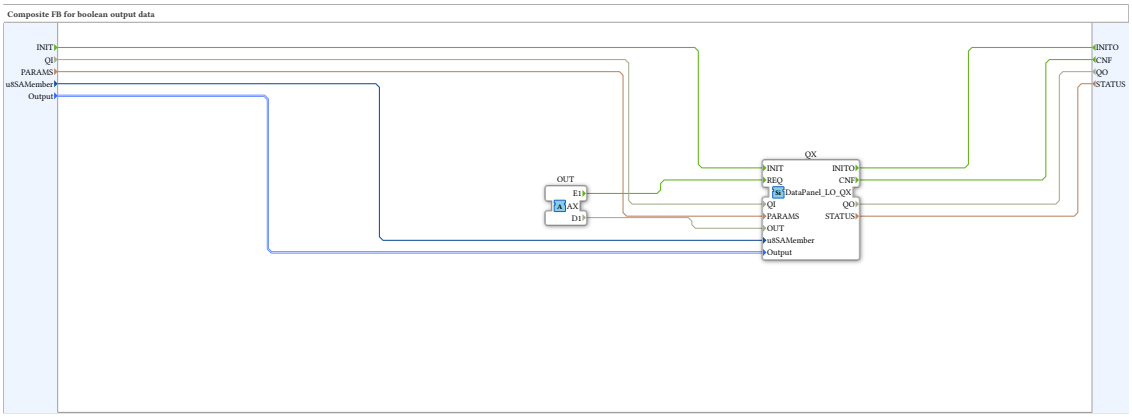
The function block has two main states:

1. **Not Initialized**: Waiting for an INIT event
2. **Initialized**: Ready for REQ operations

After successful initialization, output requests can be processed continuously.

Application Scenarios

- Control of digital outputs in process automation
- Connection of binary signals to field devices
- Integration into distributed control systems
- Safety-critical switching operations

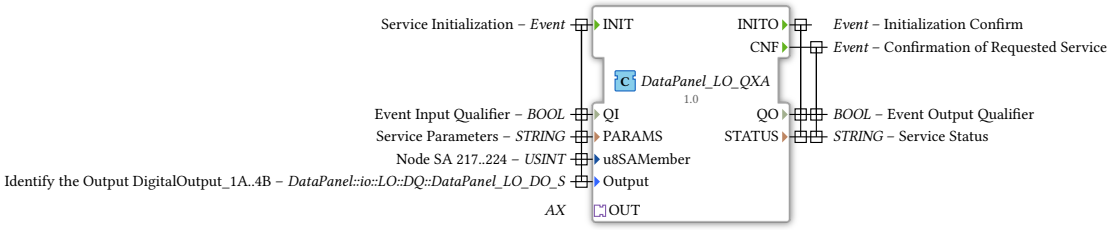


⚖️ Comparison with similar modules

Compared to simple digital output modules, DataPanel_LO_QX offers extended functionalities such as configurable hardware addressing, detailed status feedback, and a structured initialization procedure. Its specific SA member addressing makes it particularly suitable for complex distributed systems.

Conclusion

The DataPanel_LO_QX is a robust and flexible module for controlling digital outputs in industrial automation systems. Its structured interface and extensive configuration options make it particularly suitable for demanding applications with specific hardware requirements.



DataPanel_LO_QXA

• – ○ • – ○ • – ○ •

Introduction

The DataPanel_LO_QXA is a composite function block for outputting Boolean data in automation systems. It serves as an interface for digital output functions and enables the control of outputs via defined service parameters.

Interface Structure

Event Inputs

- **INIT**: Service initialization event with associated data QI, PARAMS, u8SAMember, and Output

Event Outputs

- **INITO**: Initialization acknowledgment with QO and STATUS
- **CNF**: Acknowledgement of the requested service with QO and STATUS

Data Inputs

- **QI** (BOOL): Event input qualifier
- **PARAMS** (STRING): Service parameter
- **u8SAMember** (USINT): Node SA 217..224 with initial value LO::LO_00
- **Output** (DataPanel_LO_DO_S): Identifies the output DigitalOutput_1A..4B with initial value Invalid

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service status

Adapter

- **OUT**: Unidirectional AX-type adapter for output control

Functionality

The function block initializes itself via the INIT event and returns the initialization status via INITO. The actual output control is handled by the OUT adapter, which is connected to the internal QX block. The QX block processes the input data and returns the status of the service request via CNF.

Technical Features

- Uses specific SA member addressing (217-224)
- Supports various digital outputs (1A-4B)
- Implements service parameter passing via STRING
- Includes integrated error handling with invalid initial value

State Overview

1. **Not Initialized**: Before INIT event
2. **Initialization in progress**: During INIT processing
3. **Ready**: After successful INITO confirmation
4. **Active**: During service requests via adapter OUT

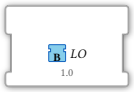
Application Scenarios

- Control of digital outputs in automation systems
- Integration into process control systems with SA addressing
- Connection to higher-level control systems via service parameters
- Boolean signal output in industrial applications

⚖️ Comparison with Similar Blocks

Compared to simple digital output blocks, DataPanel_LO_QXA offers extended functionality through:

- Parameterizable Service Interface
- SA Member-Based Addressing
- Integrated Status Feedback
- Adapter-Based Extensibility



Conclusion

The DataPanel_LO_QXA is a powerful, integrated function block for the professional control of digital outputs in industrial automation systems. Its modular structure and configurable interface make it particularly suitable for complex applications with flexible configuration requirements.

📺 Video

- The Catalog of 1863
- LogiBUS Project Update

Introduction

LO is a global constant definition for modules with low I/O density. These constants define specific address ranges for I/O modules and are used in the 4diac IDE to configure control systems.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

No adapters available

Functionality

LO consists of global constants defined as static values. The constants represent address ranges for low-density I/O modules and are integrated into the application at compile time.

Technical Features

- All constants are of type USINT (Unsigned Short Integer)
- Value range: 217 to 224
- Static initialization at compile time
- Constants are immutable during runtime

State Overview

No state transitions exist, as these are static constants

Application Scenarios

- Addressing low-density I/O modules
- Configuring hardware interfaces
- Use in conjunction with specific I/O drivers
- Simplifying hardware configuration through centralized constant definition

⚖️ Comparison with Similar Blocks

Compared to other global constant blocks, LO provides specific address ranges for low-density I/O modules, while other blocks may define different address ranges or constant types.

Conclusion

LO constants offer a structured and centralized way to define hardware addresses for low-density I/O modules. Using these global constants improves the maintainability and readability of control programs.

u8SAMember	USINT	MI::MI_00	Node SA 224..239
Input	DataPanel::io::MI::AI::DataPanel_MI_AI_S	AI_1	Identify the Input AnalogInput_1A..8B

Output Vars

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Service Status
IN	WORD	Input data from resource

DataPanel_MI_IW_0_10V

• – ○ • – ○ • – ○ •

Introduction

The **DataPanel_MI_IW_0_10V** function block is a service-oriented interface module (SIFB) for acquiring an analog 0-10V input signal. It is designed as part of the **HR Agrartechnik DataPanel MI** system and enables parameterizable initialization as well as cyclical or event-driven retrieval of measured values.

Interface Structure

Event Inputs

Event	Type	Data Carried	Description
`INIT`	`EInit`	`QI`, `PARAMS`, `u8SAMember`, `Input`, `AnalogInput_hysteresis`	Service Initialization: Hardware Connection Configuration
`REQ`	`Event`	`QI`	Service Request: Triggering a Measurement Data Query

Event Outputs

Event	Type	Accompanying Data	Description
`INITO`	`EInit`	`QO`, `STATUS`	Initialization Confirmation

CNF	Event	QO, STATUS, IN	Measurement Query Confirmation
IND	Event	QO, STATUS, IN	Asynchronous display (e.g., spontaneous measurement update from the resource)

Data Inputs

Name	Type	Initial Value	Description
QI	BOOL	–	Input Qualifier (controls execution)
PARAMS	STRING	–	Service Parameter (e.g., communication configuration)
u8SAMember	USINT	MI::MI_00	Node SA Address (valid range 224…239)
Input	DataPanel::io::MI::AI::DataPanel_MI_AI_Slid	AI_1	Analog Input Selection (e.g., AnalogInput_1A … AnalogInput_8B)
AnalogInput_hysteresis	WORD	–	Hysteresis Value for Signal Smoothing

Data Outputs

Name	Type	Description
QO	BOOL	Output Qualifier (indicates valid processing)
STATUS`	STRING	Service Status (Error/Success Message)
IN`	WORD	Digitized Analog Value (0…10V, raw WORD value)

Adapter

No adapters available.

Functionality

1. **Initialization (INIT)**

The function block is configured with the parameters PARAMS, the node address u8SAMember, the selected input Input, and the hysteresis AnalogInput_hysteresis. Upon successful initialization, the output INITO is sent with QO = TRUE and a positive STATUS.

1. **Measurement Query (REQ)**

A new measurement is requested by creating an event at REQ. The result is available at output IN as soon as event CNF is triggered. Qualifiers QO and STATUS indicate the validity of the value.

1. **Asynchronous Display (IND)**

The function block can also receive an event IND from the hardware without an explicit request (e.g., during a spontaneous value change or a periodic update). In this case, IN, QO, and STATUS are also updated.

The digitized analog value is provided as a 16-bit word (WORD) on output IN. The scaling (e.g., 0V ⟶ 0, 10V ⟶ 65535) depends on the connected hardware and must be interpreted in the application.

Technical Features

- **HR Agricultural Technology Specific**: This function block is designed for the DataPanel MI family and uses predefined constants from the packages DataPanel::io::MI::const::MI and DataPanel::io::MI::AI::DataPanel_MI_AI.
- **Hysteresis**: The parameter AnalogInput_hysteresis allows you to configure noise reduction or debouncing of the signal.

- **Addressing**: The bus node is selected via `u8SAMember` (USINT, range 224–239); the default is `MI::MI_00`.
- **Compiler Integration**: The block is integrated into the 4diac IDE ecosystem as a SIFB and has a unique type hash (`eclipse4diac::core::TypeHash`).

State Overview

Since this is a service-oriented block, the internal state machine is controlled by the following events:

- **IDLE** – After successful initialization (or after a reset), the block waits for `REQ` or an external `IND`.
- **BUSY** – After a `REQ`, the hardware query is performed; no further `REQ` is possible during this time. Upon completion, `CNF` is sent, and the state returns to IDLE.
- **ERROR** – If an error occurs during initialization or measurement, `STATUS` is set accordingly, and `QO = FALSE` is signaled.

A detailed state machine (ECC) is not present in the XML model; however, the described behavior is typical for service-oriented SIFBs.

Application Scenarios

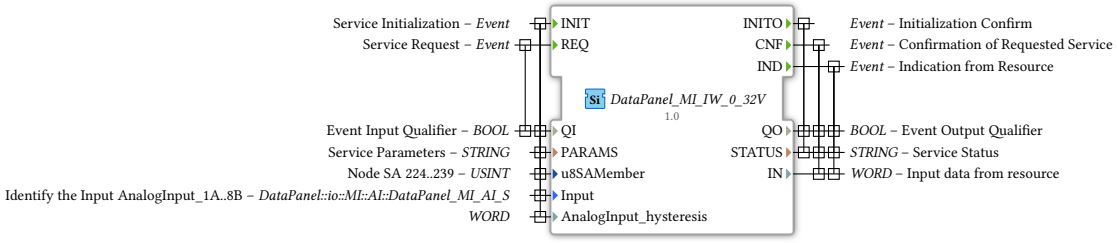
- **Agricultural Technology**: Acquisition of sensor signals (e.g., pressure, temperature, fill level) via 0-10V interfaces on HR data panels.
- **Industrial Control**: Integration of analog measured values into a PLC environment via 4diac applications.
- **Configurable Measuring Points**: Multiple channels of an MI module can be queried using different `Input` values.

Comparison with Similar Function Blocks

Function Block	Voltage Range	Platform	Features
`DataPanel_MI_IW_0_10V`	0-10V	HR DataPanel MI	Hysteresis, SA Addressing
`DataPanel_MI_IW_4_20mA`	4-20mA	HR DataPanel MI	Analog Current Inputs
`GenericAnalogInput`	Variable	Standard IEC 61131	General Input, No Hysteresis

This function block is specifically optimized for DataPanel-MI hardware and offers tight coupling to device-specific parameters.

Conclusion



The **DataPanel_MI_IW_0_10V** function block provides a robust and flexibly configurable interface for acquiring analog 0-10V signals in the HR Agrartechnik DataPanel system. Its channel configuration, addressing, and hysteresis capabilities make it suitable for precise measurement tasks in agricultural automation.

DataPanel_MI_IW_0_32V

• – ○ • – ○ • – ○ •

Introduction

The function block **DataPanel_MI_IW_0_32V** is a Service Interface Function Block (SIFB) according to IEC 61499. It is used to read an analog voltage signal in the range of 0–32V via a DataPanel MI module. The block handles the initialization of the communication channel, the configuration of an analog input (e.g., AnalogInput_1A to 8B), and the cyclical querying or reception of measured values. The output is as a **WORD** value; the status is signaled via **STATUS** and the **CNF** or **IND** event.

Interface Structure

Event Inputs

Event	Comment	With
INIT	Service Initialization	QI, PARAMS, u8SAMember, Input, AnalogInput_hysteresis
REQ	Service Request (Measurement Retrieval)	QI

Event Outputs

Event	Comment	With
INITO	Initialization Acknowledgement	QO, STATUS
CNF	Service Request Acknowledgement	QO, STATUS, IN
IND	Indication of a New Measured Value from the Resource	QO, STATUS, IN

Data Inputs

Name	Type	Initial Value	Comment
QI	BOOL	–	Event input qualifier
PARAMS	STRING	–	Service parameters (e.g., addresses, baud rate)
u8SAMember	USINT	`MI::MI_00`	Node SA address (224..239)
Input	DataPanel::io::MI::AI::DataPanel_MI_AI_In	`Invalid`	Analog input selection (AnalogInput_1A ... 8B)
AnalogInput_hysteresis	WORD	–	Analog value hysteresis (configuration)

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Service Status (e.g., error/success messages)
IN	WORD	Measured Analog Value (0..32V scaled as WORD)

Adapters

No adapters available.

Functionality

The function block is started by the **INIT** event. The passed parameters (node address, analog input selection, and hysteresis) are then passed to the hardware. After successful initialization, **INITO** is triggered with `QO = TRUE`.

A **REQ** event triggers the query of the current analog value. The measured value is provided as a **WORD** via the **IN** output and acknowledged via the **CNF** event. The resource can also spontaneously

send a new value, which is then signaled via the **IND** event – also with the current **IN** and **STATUS** values.

STATUS returns a valid value for `"OK"`; in case of errors (e.g., communication error, invalid channel), an error message is issued and `QO` is set to `FALSE`.

Technical Specifications

- **Voltage Range:** 0V to 32V, represented as a WORD – scaling is hardware-dependent.
- **Hysteresis Configuration:** The parameter `AnalogInput_hysteresis` allows setting a threshold to suppress noise or small voltage fluctuations.
- **Initialization:** The input `u8SAMember` must contain a valid node address (224–239); `Input` selects the specific analog channel. The default settings are `MI::MI_00` (address of the first MI module) and `Invalid`, meaning a valid channel must be set before the first INIT.
- **Service Interface Block:** The FB communicates directly with the hardware and is not modeled by an ECC state machine – event control is event-driven, following the SIFB pattern.

State Overview

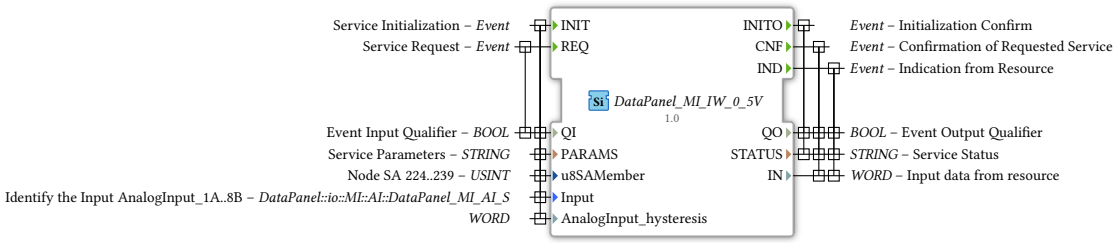
Since this is a Service Interface FB, the internal logic is handled by the hardware. From the perspective of the IEC 61499 model, the following typical phases emerge:

- **IDLE:** After system startup, before an INIT has been triggered.
- **INITIATE:** During INIT processing (hardware parameterization).
- **OPERATIONAL:** After successful INIT – REQ and IND events are processed.
- **ERROR:** In case of faulty initialization or loss of communication – STATUS contains an error message.

Application Scenarios

- **Voltage Monitoring:** Acquisition of sensor signals (e.g., pressure sensors, level sensors) with an output signal of 0…10V or 0…32V.
- **Analog Value Acquisition in Agricultural Technology:** Integration into a DataPanel control system for recording analog values from various machine components.
- **Hysteresis-controlled threshold evaluation:** Direct use of the input value in downstream logic that reacts to thresholds being exceeded or fallen below.

Comparison with similar components



Unlike generic analog input components (e.g., `AI_BASIC`), the **DataPanel_MI_IW_0_32V** is specifically optimized for DataPanel MI hardware. Typical differences:

- **Parameterization:** Specific node address (`u8SAMember`) and channel selection (`Input`) instead of generic configuration strings.
- **Hysteresis:** Explicit input for hysteresis – with standard components, this is often controlled via the communication driver parameterization.
- **Voltage Range:** Fixed at 0–32V; other modules may offer adjustable measurement range.

Conclusion

The **DataPanel_MI_IW_0_32V** is a practical, custom-designed module for the DataPanel platform, enabling the acquisition of analog signals in the 0–32V range. Its clear interface (initialization, retrieval, spontaneous indication) and integrated hysteresis make it ideal for use in agricultural control systems and other industrial applications with DataPanel components. Easy operation via the INIT and REQ events, along with standardized status feedback, allows for rapid integration into IEC 61499 projects.

DataPanel_MI_IW_0_5V

• – ○ • – ○ • – ○ •

Introduction

The function block **DataPanel_MI_IW_0_5V** is a service interface function block (SIFB) for acquiring analog input signals in the voltage range **0 … 5 V**. It provides the interface to an analog input channel of the DataPanel-MI-IW series and enables initialization, cyclic querying, and asynchronous reception of measured values via a bus system. The block is implemented as an IEC 61499-compliant FB and uses system-specific data types from the package `DataPanel::io::MI::AI`.

Interface Structure

Event Inputs

Event	Type	Description	With Variables
`INIT`	EInit	Initializes the service connection	`QI`, `PARAMS`, `u8SAMember`, `Input`, `AnalogInput_hysteresis`
`REQ`	Event	Requests a current measurement value	`QI`

Event Outputs

Event	Type	Description	With Variables
`INITO`	EInit	Initialization Confirmation	`QO`, `STATUS`
`CNF`	Event	Confirmation of a Completed Request	`QO`, `STATUS`, `IN`
`IND`	Event	Asynchronous Indication of a Measured Value from the Resource	`QO`, `STATUS`, `IN`

Data Inputs

Variable	Type	Description	Initial Value
`QI`	BOOL	Qualifier for Event Inputs	–
`PARAMS`	STRING	Service Parameter (e.g., Communication Address)	–
`u8SAMember`	USINT	Node SA Address (224 … 239)	`MI::MI_00`
`Input`	DataPanel::io::MI::AI::DataPanel_MI_AI_Selection	Selection of the analog input channel (e.g., AnalogInput_1A … 8B)	`Invalid`
`AnalogInput_hysteresis`	WORD	Hysteresis value for signal evaluation	–

Data Outputs

Variable	Type	Description
`QO`	BOOL	Output qualifier (indicates valid status)
`STATUS`	STRING	Service status message (e.g., error text)
`IN`	WORD	Measured analog value (raw value) from the resource

Adapter

No adapter interfaces are available.

Functionality

The function block operates according to the **service interface principle**: It communicates with an underlying hardware resource (e.g., a bus system or I/O module) via events.

1. **Initialization (`INIT`)**

A `INIT` event (with `QI` set) initiates the connection. The parameters `PARAMS`, `u8SAMember`, `Input`, and `AnalogInput_hysteresis` define the target address and channel configuration. After successful initialization, `INITO` is triggered, and `QO` is set to `TRUE` and `STATUS` to the corresponding text.

1. **Measurement Request (`REQ`)**

Once the function block (FB) is initialized, a current measurement value can be requested via `REQ`. The function block (FB) sends the request to the resource and signals upon receiving the result with `CNF`. The raw value is provided in the output variable `IN` (type `WORD`).

1. **Asynchronous Indication (`IND`)**

The resource can independently report changes in measured values or alarms. These are reported via the `IND` event with the corresponding value in `IN`.

In case of a negative value (`QI`) or an error, `QO` is set to `FALSE` and `STATUS` to an error description.

Technical Features

- **System-Specific Types**

The function block uses the user-defined structures `DataPanel_MI_AI_S` (channel selection) and the constants `MI::MI_00` (address specification). These are defined in the package `DataPanel::io::MI::AI`.

- **Hysteresis**

A hysteresis value can be specified via the input `AnalogInput_hysteresis` as a `WORD` value to suppress the noise of the analog signal.

- **Channel Addressing**

The analog input channel is selected via the `Input` parameter. Valid values are, for example, `AnalogInput_1A` through `AnalogInput_8B`; the initial value `Invalid` must be replaced with a valid channel before first use.

State Overview

Since the XML definition does not contain an ECC (Execution Control Chart), the state logic is derived from the typical behavior of a SIFB (Single-Integrated Function Block). An abstract state machine can be described as follows:

State	Description	Event	Action
IDLE	Waiting for Initialization	`INIT` (QI=TRUE)	Starting connection
INIT	Initialization in progress	–	Waiting for resource confirmation
READY	Ready for requests	`INITO`	Set QO=TRUE
BUSY	Measurement request in progress	`REQ`	Sending request to resource
DONE	Response received	`CNF`	Loading `IN` and setting QO=TRUE
ERROR	Error status	–	Set QO=FALSE, STATUS=Error text

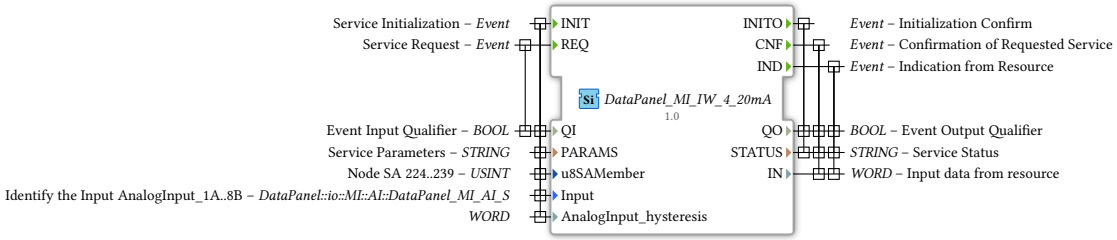
Asynchronous `IND` events can occur in the **READY** or **BUSY** states and result in the immediate availability of the value.

Application Scenarios

- **Agricultural Sensors** (e.g., level sensors, pressure sensors, temperature sensors with 0-5V output)
- **Data Acquisition in Stationary Motors** or **Vehicle Control Units** of the DataPanel family
- **Multi-Channel Analog Value Acquisition** through parallel instances of the FB with different `Input` and `u8SAMember` values

Comparison with Similar Function Blocks

Feature	DataPanel_MI_IW_0_5V	Generic Analog Input (e.g., IEC 61499 standard)
Voltage Range	0 – 5V	Usually configurable (0-10V, 4-20mA, etc.)
Channel Selection	Specific type `DataPanel_MI_AI_S`	Usually `INT` or `STRING` parameter
Hysteresis	Separate Variable (`WORD`)	Often not included



Bus connection	Proprietary (DataPanel-MI-IW)	Abstract communication interface

The function block is highly tailored to the DataPanel hardware and therefore offers less flexibility than a generic analog input, but provides a direct, optimized connection.

Conclusion

The **DataPanel_MI_IW_0_5V** is a specialized service interface function block for acquiring 0–5V analog signals in the DataPanel environment. It encapsulates the complex bus communication and offers a simple, event-driven interface to the application logic. Thanks to its integrated hysteresis and clear channel addressing, it is particularly suitable for robust measurement tasks in agricultural automation.

DataPanel_MI_IW_4_20mA

• – ○ • – ○ • – ○ •

Introduction

The function block **DataPanel_MI_IW_4_20mA** is a service interface function block (SIFB) for acquiring analog input data in the 4-20mA range. It serves as an interface between the automation system and a hardware-level analog input module. The block handles the initialization of communication (e.g., bus connection), the cyclic request for measured values, and the provision of the measured raw data via output events.

• – ○ • – ○ • – ○ •

Interface Structure

Event Inputs

Event	Type	Description	Associated Variables
INIT	EInit	Service Block Initialization	QI, PARAMS, u8SAMember, Input, AnalogInput_hysteresis
REQ	Event	Request for a Measured Value Update	QI

Event Outputs

Event	Type	Description	Carried Variables
INITO	EInit	Confirmation of Successful Initialization	QO, STATUS
CNF	Event	Confirmation of a Requested Measurement	QO, STATUS, IN
IND	Event	Asynchronous Display of an Incoming Measured Value	QO, STATUS, IN

Data Inputs

Variable	Type	Description	Initial Value
QI	BOOL	Qualifier for the Event Input	–
PARAMS	STRING	Parameter for Service Initialization	–

u8SAMember	USINT	Node Address (224...239) of the Slave Device	MI::MI_00 (224)
Input	*DataPanel::io::MI::AI::DataPanel_MI_AI_S*	Analog input channel identification (e.g., AnalogInput_1A..8B)	Invalid
AnalogInput_hysteresis	WORD	Hysteresis value for signal smoothing	–

Data Outputs

Variable	Type	Description
QO	BOOL	Qualifier for event output
STATUS	STRING	Status message (e.g., error, initialization)
IN	WORD	Raw value read from analog input

Adapter

No adapters defined.

• – ◦ • – ◦ • – ◦ •

Functionality

This function block implements asynchronous communication with a slave device (e.g., an analog input module with a 4-20mA interface) via a proprietary bus.

1. **Initialization** (INIT):

The parameters PARAMS (e.g., baud rate, protocol settings), the node address (u8SAMember), and the specific analog input channel (Input) are set. Hysteresis (AnalogInput_hysteresis) can be specified to stabilize the raw value. After a successful connection, INITO is sent along with QO = TRUE.

1. **Measurement Request** (REQ):

This function block requests the current measured value of the configured channel. The response is delivered asynchronously via output CNF (upon successful request) or, if necessary, via IND (in case of spontaneous value changes or cyclical messages from the slave). The read value appears in the output variable IN as a 16-bit raw value.

1. **Asynchronous Indication** (IND):

If the slave device sends data independently (e.g., upon exceeding a threshold), IND is triggered. This allows even unsolicited measurement values to be acquired.

The outputs QO and STATUS provide information about the success of the operations (e.g., initialization error, communication error).

• – ◦ • – ◦ • – ◦ •

Technical Specifications

- **Target Platform**: The module is designed for the "DataPanel" system of HR Agrartechnik GmbH (version 1.0, year 2026).
- **Node Address Range**: The slave addresses u8SAMember are limited to the range 224–239; The initial value MI::MI_00 corresponds to the smallest address (224).
- **Input Channel Identification**: The data type DataPanel_MI_AI_S defines possible channels (AnalogInput_1A … 8B). The initial value Invalid indicates that no channel is selected before the first initialization.
- **Hysteresis**: The AnalogInput_hysteresis value is passed as a 16-bit word and acts as a digital filter to prevent noise or oscillation.
- **Type Hash**: An attribute eclipse4diac::core::TypeHash is included but initialized with an empty string – it can be set later at runtime.

• – ◦ • – ◦ • – ◦ •

State Overview

Since this is a service interface function block (FB), its behavior is determined by the event logic and the underlying communication protocol. An internal state machine is not represented in the XML definition; however, the following phases typically exist:

- **OFF / UNINITIALIZED**: Before the first `INIT` event. No communication is active.
- **INIT** Phase: After receiving `INIT`, until `INITO` is sent. Slave configuration.
- **IDLE** (ready): After successful initialization. The FB can accept `REQ` events.
- **BUSY** (Request in progress): From `REQ` until the response arrives (followed by `CNF`).
- **INDICATION** state: `IND` is triggered when data arrives asynchronously, after which the function block returns to the IDLE state.

Error states (e.g., communication failure) are reported via `STATUS`.

• – ◦ • – ◦ • – ◦ •

Application Scenarios

- **4-20 mA Sensor Connection**: A pressure sensor, level sensor, or temperature sensor with a 4-20 mA output is connected to the DataPanel system. The function block reads the measured value cyclically or on demand.
- **Multi-channel acquisition**: Via different instances of the building block (with different `InputWith` parameters, multiple analog channels can be operated in parallel.
- **Data Logger System**: Combined with a function block for data recording, the `IND` output can be used to log status changes or alarms.
- **Agricultural Control**: In agricultural technology (HR Agrartechnik GmbH), this allows for the recording of fluid levels, flow rates, or axle loads, for example.

• – ◦ • – ◦ • – ◦ •

Comparison with Similar Function Blocks

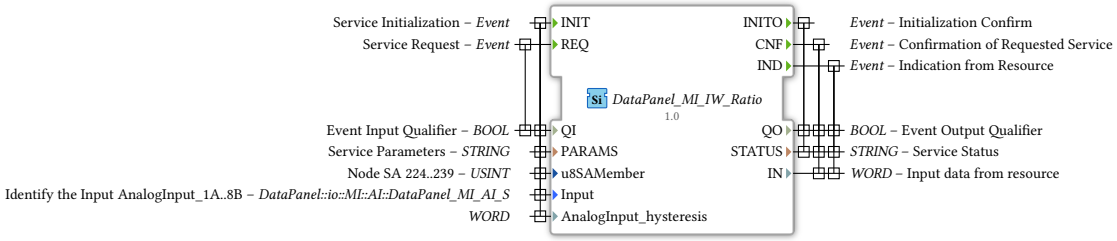
•

Compared to a general analog input function block (e.g., a function block for standardized fieldbuses like PROFIBUS or IO-Link), this block is distinguished by the following features:

- **Specific Hardware Assignment**: It is directly tailored to the "DataPanel::io::MI::AI" protocol.
- **Node Addressing**: The limitation to nodes 224–239 and the predefined constants from `MI::MI_xx` simplify configuration in fixed networks.
- **Event Model**: `IND` alongside `CNF` allows for both synchronous and asynchronous data acquisition – more flexible than a pure polling model.
- **Event Model**: `IND` alongside `CNF` enables both synchronous and asynchronous data acquisition – more flexible than a pure polling model.
- **Node Addressing**: - **Hysteresis Parameter**: Provides simple debouncing at the function block level, a feature not found in many generic function blocks.

• – ◦ • – ◦ • – ◦ •

Conclusion



The **DataPanel_MI_IW_4_20mA** function block offers a robust and compact solution for acquiring 4-20mA signals in a proprietary DataPanel system. The clear separation of initialization, request, and spontaneous indication, along with the integrated hysteresis, makes it suitable for practical use in agricultural technology. Its configurable node address and channel allow for flexible deployment and integration into existing automation networks.

DataPanel_MI_IW_Ratio

• — ○ • — ○ • — ○ •

Introduction

The function block **DataPanel_MI_IW_Ratio** is a service interface function block (SIFB) for acquiring analog input data with ratiometric conversion. It provides the interface to a sensor connected to a node (SA 224..239) whose measured value is output as a 16-bit word (WORD). This block is part of the library `DataPanel::io::MI::AI` and is typically used in automation technology, particularly in agricultural engineering.

Interface Structure

Event Inputs

Event	Type	With Variables	Comment
INIT	EInit	QI, PARAMS, u8SAMember, Input, AnalogInput_hysteresis	Service Initialization
REQ	Event	QI	Service Request

Event Outputs

Event	Type	With Variables	Comment
INITO	EInit	QO, STATUS	Initialization Confirmation
CNF	Event	QO, STATUS, IN	Confirmation of Requested Service
IND	Event	QO, STATUS, IN	Indication from Resource

Data Inputs

Variable	Type	Initial Value	Comment
QI	BOOL	–	Event Input Qualifier
PARAMS	STRING	–	Service Parameters
u8SAMember	USINT	MI::MI_00	Node SA 224..239
Input	DataPanel::io::MI::AI::DataPanel_MI_AI_S	Invalid	Identify the Input AnalogInput_1A..8B
AnalogInput_hysteresis	WORD	–	(no value specified)

Data Outputs

| Variable | Type | Comment | | |-----|--|---| | QO | BOOL | Event Output Qualifier | | STATUS | STRING | Service Status | | IN | WORD | Input data from resource |

Adapter

No adapters available.

Functionality

The function block operates as a state-controlled service interface block:

1. **Initialization (INIT)**:

The function block is configured via the INIT event. The inputs `PARAMS`, `u8SAMember`, `Input`, and `AnalogInput_hysteresis` define the bus/node address, the analog channel, and the hysteresis. The `QI` input must be set to TRUE to start initialization. After successful configuration, the INITO event is output with `QO = TRUE` and `STATUS = "OK"` (or similar).

1. **Measurement Request (REQ)**:

The REQ event requests a new measurement from the sensor. The function block evaluates the hardware and returns the result via the CNF event at output `IN`. Here too, `QO` indicates the validity of the value.

1. **Indication (IND)**:

If the hardware supports asynchronous events (e.g., cyclic updates), the IND event is used to report the current measurement value without prompting.

The measurement value is output as a 16-bit word (WORD) in ratiometric format. This means that the digital value is directly proportional to the ratio of the measured voltage to the reference voltage.

Technical Features

- **Ratiometric Measurement**: The function block is specifically designed for ratiometric sensors where the output is proportional to the supply voltage. This minimizes measurement errors caused by voltage fluctuations.
- **Configuration via constants**: The initial value of `u8SAMember` (`MI::MI_00`) and the data type `DataPanel_MI_AI_S` are derived from imported libraries (`DataPanel::io::MI::const::MI` and `DataPanel::io::MI::AI::DataPanel_MI_AI`). The valid address range for the node is between 224 and 239 (Node SA 224..239).
- **Hysteresis**: Threshold hysteresis behavior can be implemented using `AnalogInput_hysteresis`; the exact effect depends on the underlying driver.
- **TypeHash attribute**: The attribute `eclipse4diac::core::TypeHash` is used for unique type identification in the runtime system.

State Overview

Since the function block is implemented as a service interface function block, it has an internal state machine. The typical states are:

- **IDLE**: Waiting for an INIT event.
- **INIT**: Initialization is being executed (parameterization, hardware access).
- **READY**: Initialization is complete, waiting for REQ or IND.
- **REQ**: Processing a measurement request.
- **IND**: Asynchronous indication is being processed.

In case of an error, `QO = FALSE` is set and `STATUS` contains a corresponding error message.

Application Scenarios

- **Agricultural Machinery**: Acquisition of sensor values (e.g., fill levels, pressure, position) via the ratiometric input of a data panel.
- **Industrial Automation**: Connection of analog sensors with voltage output (0…5V, 0…10V) that operate ratiometrically.
- **Early Prototypes**: The module can be directly integrated into a controller from the 4diac IDE and tested with any parameters.

Comparison with Similar Modules

Module	Feature
`DataPanel_MI_AI`	Standard analog input without explicit ratiometric design.
`DataPanel_MI_IW_Voltage`	Voltage measurement with absolute values (e.g., mV).
DataPanel_MI_IW_Ratio	Specifically optimized for ratiometric sensors.

The module described here differs primarily in its use of the ratiometric measurement principle, which is employed in many modern sensors (e.g., Hall effect sensors, potentiometers).

Conclusion

The `DataPanel_MI_IW_Ratio` is a specialized service interface function block for the reliable acquisition of ratiometric analog signals. With its clearly defined interface (INIT/REQ/IND) and configurable parameters, it is ideally suited for use in agricultural and automation applications. Integration into the 4diac IDE is achieved via the `DataPanel::io::MI::AI` library.

DataPanel_MI_DI

• – ◦ • – ◦ • – ◦ •

Introduction

DataPanel_MI_DI is a global constant definition for medium I/O density DataPanel modules for digital inputs (DI). This constant defines the pin assignments for various digital input channels of a DataPanel system.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

No adapters available

Functionality

DataPanel_MI_DI is a global constant definition that provides fixed values for the pin assignments of the digital inputs. The constant defines structured data of type `DataPanel_MI_DI_S` with PIN numbers for various digital input channels.

Technical Features

- Defines pin assignments for 8 digital input channels (5A, 5B, 6A, 6B, 7A, 7B, 8A, 8B)
- Pin numbers range from 9 to 16
- Includes a special "Invalid" constant with a pin value of 255 for error handling
- Uses the structured data type `DataPanel_MI_DI_S`
- Organized in the package `DataPanel::io::MI::DI`

State Overview

No state transitions are present - this is a static constant definition

Application Scenarios

- Configuration of DataPanel systems with medium I/O density
- Hardware abstraction for digital inputs in control systems
- Simplification of pin assignment in IEC 61499-based applications
- Reusable constant definition for multiple projects

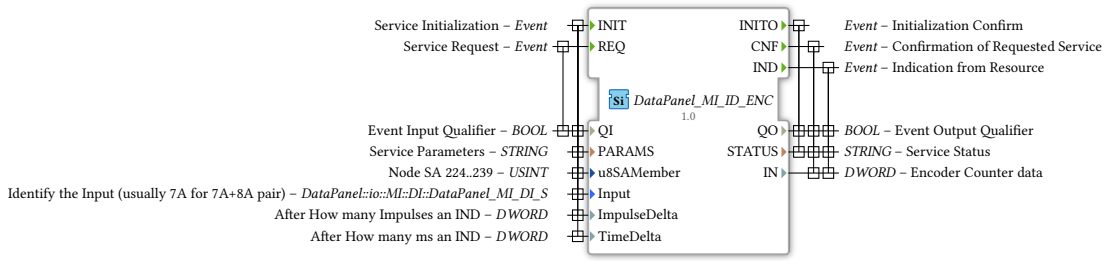
⚖️ Comparison with Similar Components

Compared to other constant definitions, DataPanel_MI_DI offers:

- Specific pin assignments for DataPanel hardware
- Structured data types for improved type safety
- Predefined invalid constant for robustness

Conclusion

DataPanel_MI_DI provides a standardized and type-safe way to configure digital input pins in DataPanel systems with medium I/O density. The use of structured constants increases maintainability and reduces configuration errors in automation projects.



DataPanel_MI_DI_S

DataPanel Modules with medium IO density DI Struct

Structure

Pin	USINT	255

DataPanel_MI_ID_ENC

• – ○ • – ○ • – ○ •

Introduction

The **DataPanel_MI_ID_ENC** function block is an input service interface function block for acquiring encoder pulse data. It is designed to process a 7A+8A encoder pair and outputs the current counter reading and status information. Initialization is performed via parameters such as the node address (SA member), the input configuration, and thresholds for pulse- and time-based event triggering.

Interface Structure

Event Inputs

Event	Description	Accompanying Data
INIT	Service Initialization	QI, PARAMS, u8SAMember, Input, ImpulseDelta, TimeDelta
REQ	Service Request	QI

Event Outputs

Event	Description	Accompanying Data
INITO	Initialization Acknowledgement	QO, STATUS
CNF	Requested Action Acknowledgement	QO, STATUS, IN
IND	Asynchronous Event Display (Pulse or Timeout)	QO, STATUS, IN

Data Inputs

Name	Type	Initial Value	Description
QI	BOOL	–	Event Input Qualifier
PARAMS	STRING	–	Service Parameter
u8SAMember	USINT	MI::MI_00	Node Address (range 224..239)
Input	DataPanel::io::MI::DI::DataPanel_MI_DI_S	Invalid	Input Identifier (usually 7A for a 7A+8A pair)
PulseDelta	DWORD	–	Number of pulses after which an IND is triggered
TimeDelta	DWORD	–	Time in milliseconds after which an IND is triggered

Data Outputs

Name	Type	Description
QO	BOOL	Event Output Qualifier
STATUS	STRING	Service Status
IN	DWORD	Current Encoder Counter Value

Adapter

None.

Functionality

1. **Initialization (INIT → INITO)**

The function block is configured with the parameters `PARAMS`, the node address `u8SAMember`, the input specification `Input`, and the threshold values `ImpulseDelta` and `TimeDelta`. After successful initialization, the event `INITO` is acknowledged with `QO` and `STATUS`.

1. **Request (REQ → CNF)**

The function block `REQ` triggers a targeted query of the current counter reading. The block responds with `CNF` and provides the current encoder value via `IN`, along with status information.

1. **Asynchronous Events (IND)**

Regardless of an explicit request, `IND` is triggered as soon as either the number of encoder pulses specified in `ImpulseDelta` has been exceeded or the time interval defined in `TimeDelta` has expired. This enables event-driven processing without continuous polling.

The output `IN` contains the current 32-bit counter value of the encoder for each event (CNF and IND).

Technical Features

- **User-Defined Types**: The input `Input` is based on the data type `DataPanel_MI_DI_S`, which expects a specific input configuration (e.g., 7A). The constant value `Invalid` serves as a placeholder for undefined inputs.
- **Configurable Event Triggering**: By combining `ImpulseDelta` and `TimeDelta`, the system can trigger an IND either after a specific number of pulses, after a time interval, or after the first event occurring (AND operation).
- **Node Addressing**: The physical node in the bus system is selected via `u8SAMember` (value range 224–239). The initial value `MI::MI_00` refers to a constant in the module `MI`.

State Overview

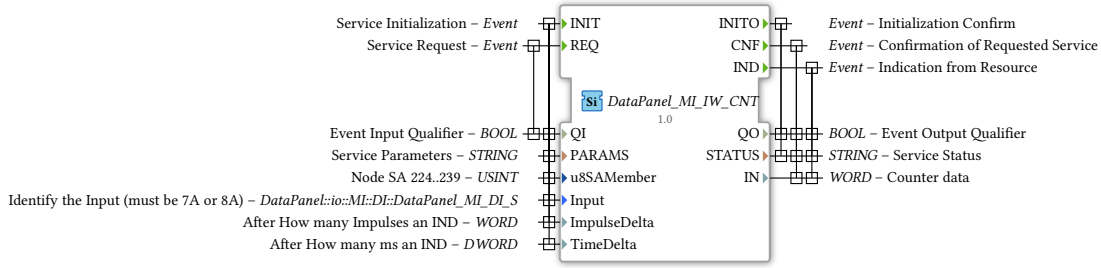
State	Description
IDLE	Waiting for INIT or REQ
INIT	Initialization in progress, parameters are being applied
ACTIVE	Initialization complete, ready for REQ and IND
ERROR	Error state (e.g., failed initialization)

The actual state machine is not explicitly represented in the code shown; the states depicted are derived from the typical behavior of service interface function blocks.

Application Scenarios

- **Agricultural Machinery Control**: Acquisition of rotational speeds on drive shafts via incremental encoders (7A+8A pair) for monitoring and controlling work processes.
- **Position Acquisition**: Use as a pulse counter for position measurement, e.g., for drive systems or actuators.
- **Event-Driven Data Acquisition**: Configurable IND thresholds prevent peak loads in data traffic and optimize logging tasks.

Comparison with Similar Components



Compared to simple encoder counters, the DataPanel_MI_ID_ENC offers:

- **Flexible Trigger Criteria**: Instead of relying solely on polling, pulse or time thresholds can be set.
- **Structured Initialization**: The use of a user-defined type (`DataPanel_MI_DI_S`) enables clear mapping to specific hardware inputs.
- **Event-based output**: The separation of `CNF` (synchronous with the request) and `IND` (asynchronous) allows for decoupled processing at higher control levels.

Conclusion

The **DataPanel_MI_ID_ENC** function block is a powerful service interface module for encoder data acquisition in industrial control systems. Its configurable thresholds and support for both synchronous and asynchronous events make it particularly suitable for real-time applications in agricultural engineering. The clear interface definition and the use of specific data types enable easy integration into existing automation environments.

DataPanel_MI_IW_CNT

• – ○ • – ○ • – ○ •

The **DataPanel_MI_IW_CNT** is a service interface function block from the DataPanel family of HR Agrartechnik GmbH. It is used to acquire **pulse counter data** via the dedicated hardware inputs 7A and 8A of the underlying bus system. The block encapsulates the initialization, cyclic querying, and event-driven output of the counter values. Typical applications include agricultural machinery where pulse generators (e.g., speed, flow, or position sensors) need to be evaluated. The function block is designed for the IEC 61499-compliant 4diac IDE and uses the service interface patterns defined therein.

Event	Type	Description
INIT	EInit	Initializes the channel (sets hardware parameters)
REQ	Event	Requests a current counter value
Event	Type	Description
---	---	----------
INITO	EInit	Acknowledges successful initialization
CNF	Event	Confirmation of a requested REQ operation
IND	Event	Asynchronous indication (triggered by pulse or time interval)
Name	Type	Description
------	-----	----------
QI	BOOL	Qualifies the INIT/REQ event
PARAMS	STRING	Service parameter (vendor-dependent configuration)
u8SAMember	USINT	Node SA (224..239); Default = `MI::MI_00`
Input	DataPanel_MI_DI_S	Input identification (must be “7A” or “8A”); Default = `Invalid`
ImpulseDelta	WORD	Pulse threshold for asynchronous IND triggering (number of pulses)
TimeDelta	DWORD	Time threshold for asynchronous IND triggering (in ms)
Name	Type	Description
----	----	----------
QO	BOOL	Qualifies the event outputs
STATUS	STRING	Status message (e.g., “OK” or error code)
IN	WORD	Current 16-bit counter value (pulse counter)

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters
No adapter interfaces defined.

Functionality
The **DataPanel_MI_IW_CNT** operates as a service interface function block and communicates directly with the hardware interface of the DataPanel system. After startup, the channel must be initialized via the **INIT** event. The parameters (SA address, input number, pulse and time configuration) are passed during this process. The function block attempts to allocate and provide the corresponding hardware channel.

After successful initialization (signaled by **INITO**), the counter value can be queried via the **REQ** event. The response is provided via **CNF**: `IN` contains the current counter value, and `STATUS` contains the operating status.

Additionally, the function block can asynchronously output an **IND** indication when either the set number of pulses (`ImpulseDelta`) has been reached or the time interval (`TimeDelta`) has elapsed. This allows for event-driven processing without cyclical queries.

Error handling is provided via the `STATUS` output and the `QO` flag. If an error occurs (e.g., invalid input configuration, hardware unreachable), `QO` is set to `FALSE`, and a corresponding error message is output in `STATUS`.

- **Input Identification:** The parameter `Input` must be set to a valid DataPanel input type (7A or 8A). The default value `Invalid` prevents incorrect initialization.
- **Node SA (`u8SAMember`):** Defines the slave address of the DataPanel participant. Valid values are 224 to 239. The predefined value `MI::MI_00` represents the first slave.
- **Asynchronous Indication:** The function block can independently generate **IND** events using `ImpulseDelta` and `TimeDelta`. Both thresholds can be active independently. If either value exceeds the configured threshold, an IND event is triggered. This reduces the bus load compared to cyclic polling.
- **Data Format:** The counter value `IN` is a 16-bit word and allows values from 0 to 65535. The counter is reset to 0 upon overflow.
- **Copyright & Version:** This function block is published under version 1.0 for the year 2026 by HR Agrartechnik GmbH.

The FB (Function Block) cycles through classic service interface states:

State	Description
IDLE	Waiting for INIT or REQ. Hardware is not yet assigned.
INIT	INIT received – Parameterization and hardware reservation are in progress.
ACTIVE	Initialization successful – Channel is ready for operation.
REQUEST	REQ received – Querying the current counter value.
INDICATE	Asynchronous condition met – Sending an IND event.
ERROR	Error occurred (e.g., incorrect parameter, hardware error).

After an error, only a new INIT can return the FB to the IDLE state.

1. **Speed Measurement:** A radar sensor or magnetic pulse generator delivers rectangular pulses. The module counts the pulses and outputs the value as CNF or IND. `TimeDelta` can be used for time-based speed calculation.
2. **Flow Measurement:** Pulse flow meters (e.g., Hall effect) are used in agricultural irrigation systems. `ImpulseDelta`Generates an event after each defined quantity of liquid.

3. **Position Detection:** Distances are measured using an incremental encoder. By combining pulse and time monitoring, both position and speed can be determined.

- **DataPanel_MI_DI:** A purely digital input function block (status 0/1) without a counting function. The IW_CNT extends it with pulse counting and asynchronous event triggering.
- **DataPanel_MI_AI:** An analog input function block for voltage or current signals. In contrast, the IW_CNT processes only pulses (discrete) and not a continuous value.
- **CTUD** (IEC 61499 standard counter): This standard function block can count forwards/backwards but does not require low-level initialization. The DataPanel_MI_IW_CNT is specifically connected to the DataPanel hardware and offers the IND function, which is often missing in standard function blocks.

``## Conclusion
The **DataPanel_MI_IW_CNT** is a powerful service interface function block for the flexible acquisition of pulse counter data in agricultural control systems. Its integrated asynchronous indication based on pulse or time thresholds reduces response time and relieves the load on the control system. Thanks to its clearly structured interface and specific configuration options (SA address, input selection), it can be seamlessly integrated into the DataPanel ecosystem. It thus represents a reliable component for applications that require precise pulse evaluation at the system level.

DataPanel_MI_IW_DutyCycle

No image available.

• — ○ • — ○ • — ○ •

Introduction

The function block `DataPanel_MI_IW_DutyCycle` is a service interface function block (FB) for acquiring and processing frequency input signals (type 7A/8A) in the hardware system. It calculates the duty cycle from the incoming frequency signal and outputs it as a percentage. The block supports initial parameterization as well as event-driven outputs upon significant value changes or time-controlled queries.

Interface Structure

Event Inputs

Event	Type	With Variables	Comment
`INIT`	EInit	QI, PARAMS, u8SAMember, Input, FreqDelta, TimeDelta	Service Initialization

REQ	Event	QI	Service Request

Event Outputs

Event	Type	With Variables	Comment
INITO	EInit	QO, STATUS	Initialization Acknowledgement
CNF	Event	QO, STATUS, IN	Requested Action Acknowledgement
IND	Event	QO, STATUS, IN	Resource indication (upon value change/timer)

Data Inputs

Variable	Type	Comment
QI	BOOL	Event input qualifier
PARAMS	STRING	Service parameter (e.g., configuration string)
u8SAMember	USINT	Node address (SA 224..239, default: MI::MI_00)
Input	DataPanel_MI_DI_S	Input identification (must be 7A or 8A, initial value: Invalid)
FreqDelta	WORD	Required value change in %, to trigger an IND
TimeDelta	DWORD	Time interval in ms after which an IND is triggered

Data Outputs

Variable	Type	Comment
QO	BOOL	Event output qualifier
STATUS	STRING	Service status (failure/success message)
IN	WORD	Measured duty cycle in percent (0..100)

Adapter

No adapters defined.

Functionality

The function block initializes itself via the event INIT. The following parameters are passed: QI (activation), PARAMS (general configuration), the node address u8SAMember, the physical input (Input), the change delta FreqDelta, and the time interval TimeDelta. After successful initialization, INITO is output with valid QO and STATUS.

A REQ event triggers an immediate query of the current duty cycle. The result is output via CNF, with the current value displayed in IN.

The function block continuously monitors the input. If the measured duty cycle changes by more than the amount specified in FreqDelta, a IND event is sent with the new value. Additionally, after TimeDelta milliseconds (provided no change has occurred in the meantime), a IND event is also triggered to ensure regular updates.

Technical Specifications

- The function block is designed for connection to 7A or 8A type frequency inputs. The input is identified via the structure DataPanel_MI_DI_S – set to Invalid by default until a valid initialization occurs.
- The node address (SA) is limited to the range 224–239. The default is MI::MI_00.
- The parameters FreqDelta and TimeDelta allow for flexible configuration of the notification behavior: either change-only triggering, time-only triggering, or a combination of both.
- The status QO indicates the validity of the output data; STATUS contains detailed error or success messages.

- – Compiler imports reference the packages `DataPanel::io::MI::const::MI` and `DataPanel::io::MI::DI::DataPanel_MI_DI::Invalid`, as well as `eclipse4diac::core::TypeHash`.

State Overview

An explicit state machine is not defined in the XML. However, the following sequence can be derived from the behavior of the events:

1. **Initialization State** – After `INIT`, the module is configured and transitions to the operating state. Errors result in `INITO` with a negative `QO`.
2. **Operating State** – `REQ` is followed by `CNF` with the current duty cycle. When changes occur or the timer expires, `IND` is sent.
3. **Error State** – In case of invalid parameters or hardware errors, `STATUS` is set accordingly, and `QO` is changed to `FALSE`.

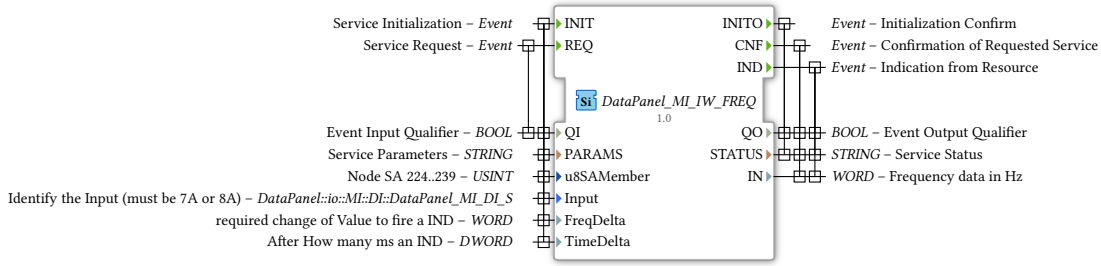
Application Scenarios

- **Speed Measurement in Agricultural Machinery** – Monitoring of frequency signals (e.g., from speed sensors) and output of the duty cycle as an indicator of engine speed or conveying rate.
- **Pulse Width Modulation (PWM) Analysis** – Measurement of the duty cycle of a PWM signal for controlling actuators or for providing feedback on the fill level.
- **Vibration/Frequency Monitoring** – Acquisition of periodic signals with configurable sensitivity (FreqDelta) and update rate (TimeDelta).

Comparison with Similar Components

- **`DataPanel_MI_DI`**: A digital input component without frequency or duty cycle calculation. Provides only binary states.
- **`DataPanel_MI_AI`**: Analog input component for voltage or current signals; not optimized for frequency signals.
- **`DataPanel_MI_IW_Frequency`**: Measures the absolute frequency, not the duty cycle. `DataPanel_MI_IW_DutyCycle` adds the percentage on/off time to this.

Conclusion



The `DataPanel_MI_IW_DutyCycle` function block offers a robust and configurable interface for acquiring duty cycles from frequency inputs in the 7A/8A range. The parameters `FreqDelta` and `TimeDelta` allow the reporting behavior to be flexibly adapted to the application. It is particularly suitable for use in agricultural technology and industrial control systems where reliable duty cycle monitoring is required.

DataPanel_MI_IW_FREQ

No image available.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **DataPanel_MI_IW_FREQ** is a service interface function block (SIFB) that encapsulates access to a frequency input of a data panel (type 7A/8A). It is used for initialization, cyclic or event-driven querying, and asynchronous notification of frequency changes. The FB is part of a modular control environment for agricultural machinery (MI – machine interface).

Interface Structure

Event Inputs

Event	Description	With
INIT	Service Initialization	`QI`, `PARAMS`, `u8SAMember`, `Input`, `FreqDelta`, `TimeDelta`
REQ	Service Request (Read Current Frequency)	`QI`

Event Outputs

Event	Description	With
INITO	Initialization Confirmation	`QO`, `STATUS`
CNF	Confirmation of a requested query	`QO`, `STATUS`, `IN`
IND	Asynchronous indication (frequency change or time elapsed)	`QO`, `STATUS`, `IN`

Data Inputs

Name	Type	Initial Value	Description
`QI`	BOOL	–	Event input qualifier (controls processing)
`PARAMS`	STRING	–	Service parameter (device-specific configuration)
`u8SAMember`	USINT	`MI::MI_00`	Node address (SA) of the data collection module (value range 224…239)
`Input`	`DataPanel::io::MI::DI::DataPanel_MI_DI_Enum`	`Invalid`	Identifies the physical input (must be `7A` or `8A`)
`FreqDelta`	WORD	–	Frequency change threshold [Hz] that triggers a `IND`
`TimeDelta`	DWORD	–	Time interval [ms] after which a `IND` is sent (even without changes)

Data Outputs

Name	Type	Description
`QO`	BOOL	Event output qualifier (indicates successful execution)
`STATUS`	STRING	Service status (e.g., error messages or confirmation texts)
`IN`	WORD	Current frequency in Hz

Adapters

None available.

Functionality

1. **Initialization** – The event `INIT` establishes the connection to the configured frequency input. The parameters `PARAMS`, `u8SAMember`, `Input`, `FreqDelta`, and `TimeDelta` are adopted. After successful initialization, the output event `INITO` is triggered with `QO = TRUE` and a positive `STATUS`.
2. **Query (REQ/CNF)** – An event `REQ` requests the current frequency value. The function block (FB) sends the request to the data panel and, upon response, returns the event `CNF` with the current value in `IN`. `QO` indicates whether the query was successful.
3. **Asynchronous Indication (IND)** – The FB continuously monitors the frequency input. An event `IND` is triggered when:

- the frequency value changes by at least `FreqDelta` [Hz], or
- the time interval specified in `TimeDelta` [ms] has elapsed since the last event `IND`.

This enables both threshold-based and time-based updates.

The events `INIT` and `REQ` are only executed if the corresponding qualifier `QI` has the value `TRUE`. The output qualifier `QO` signals successful execution.

Technical Features

- **Type Dependency**: The function block uses special types from the package `DataPanel::io::MI::DI`, which enable type-safe configuration of the input (e.g., `DataPanel_MI_DI_S`) as well as constants (`MI::MI_00`).
- **Input Initialization**: The data input `Input` is set to `Invalid` by default. Before the first `INIT`, this must be set to a valid value (`7A` or `8A`), otherwise initialization will fail.
- **Frequency Display**: The measured frequency is output as a 16-bit value (`WORD`) in Hz.
- **Event-Driven Retrieval**: The `INIT` service must be successfully executed once before using `REQ` or receiving `IND`.
- **Attribute Hash**: A `eclipse4diac::core::TypeHash` attribute exists but is not set – this is used for runtime optimization in 4diac.

State Overview

The function block (FB) internally cycles through the following logical states:

State	Description
IDLE	Waiting for `INIT` – no connection
INIT	Establish connection to input and apply parameters
RUN	Ready for operation – waiting for `REQ` or sending `IND` upon change/expiration
ERROR	Error state (e.g., incorrect `Input`, communication error) – `STATUS` contains an error message

A transition to the error state occurs when initialization fails. The only way to return from the error state is by sending `INIT` again.

Application Scenarios

- **Speed measurement** on an agricultural machine: A frequency sensor (e.g., a magnetic transducer) provides pulses that are recorded via the data panel. Using `FreqDelta = 5 Hz` and `TimeDelta = 100 ms`, the controller receives current values both during significant speed changes and at regular intervals.
- **Monitoring a constant frequency**: With a low change threshold (`FreqDelta = 1 Hz`) and a short time interval (`TimeDelta = 50 ms`), the function block (FB) is suitable for real-time monitoring of critical processes.
- **Redundant frequency acquisition**: Two parallel instances of the FB on different inputs (7A and 8A) allow for plausibility checks of the measured values.

Comparison with similar function blocks

Function block	Type	Special feature
`DataPanel_MI_IW_FREQ`	Frequency input (SIFB)	Event-driven, asynchronous IND, configurable thresholds and time values

`DataPanel_MI_DI`	Digital input (SIFB)	Binary states only, no frequency-dependent triggers
Generic `SIFB`with INIT/REQ/IND	General	No built-in frequency functions, must be developed in-house

The **DataPanel_MI_IW_FREQ** is specifically optimized for processing frequency signals, while other modules provide either only discrete states or generic interfaces.

Conclusion

The **DataPanel_MI_IW_FREQ** is a powerful and flexible service interface module for acquiring frequency data via a data panel (Type 7A/8A). Its combination of threshold-based and time-based indication makes it suitable for both simple measurement tasks and safety-critical monitoring. The type-safe configuration and clear event interface facilitate integration into agricultural automation solutions.

The **DataPanel_MI_IW_FREQ** is a powerful and flexible service interface module for acquiring frequency data via a data panel (Type 7A/8A). —

DataPanel_MI_IX

• – ◦ • – ◦ • – ◦ •

Introduction

The DataPanel_MI_IX is a service interface function block for Boolean input data, specifically designed for communication with digital inputs in automation systems. This block enables the initialization and querying of digital input signals via standardized service interfaces.

Interface Structure

Event Inputs

- **INIT**: Service initialization with parameters QI, PARAMS, u8SAMember, and Input
- **REQ**: Service request with parameter QI

Event Outputs

- **INITO**: Initialization acknowledgment with parameters QO and STATUS
- **CNF**: Acknowledgement of the requested service operation with parameters QO, STATUS, and IN
- **IND**: Indication from the resource with parameters QO, STATUS, and IN

Data Inputs

- **QI**: BOOL - Event input qualifier
- **PARAMS**: STRING - Service parameter
- **u8SAMember**: USINT - Node SA 224..239 (Initial value: MI::MI_00)
- **Input**: DataPanel_MI_DI_S - Identifies digital input 5A..8B (Initial value: DataPanel_MI_DI::Invalid)

Data Outputs

- **QO**: BOOL - Event output qualifier
- **STATUS**: STRING - Service status
- **IN**: BOOL - Input data from the resource

Adapters

No adapter interfaces available.

Functionality

The function block initializes communication with a specific digital input via the INIT event. After successful initialization, the input state can be queried via the REQ event. The block returns the current state of the digital input and status information via the CNF and IND output events.

Technical Features

- Supports specific SA member addressing in the range 224-239
- Uses structured input identification via the DataPanel_MI_DI_S data type
- Provides both request-based (REQ/CNF) and indication-based (IND) communication
- Initialization with configurable service parameters

State Overview

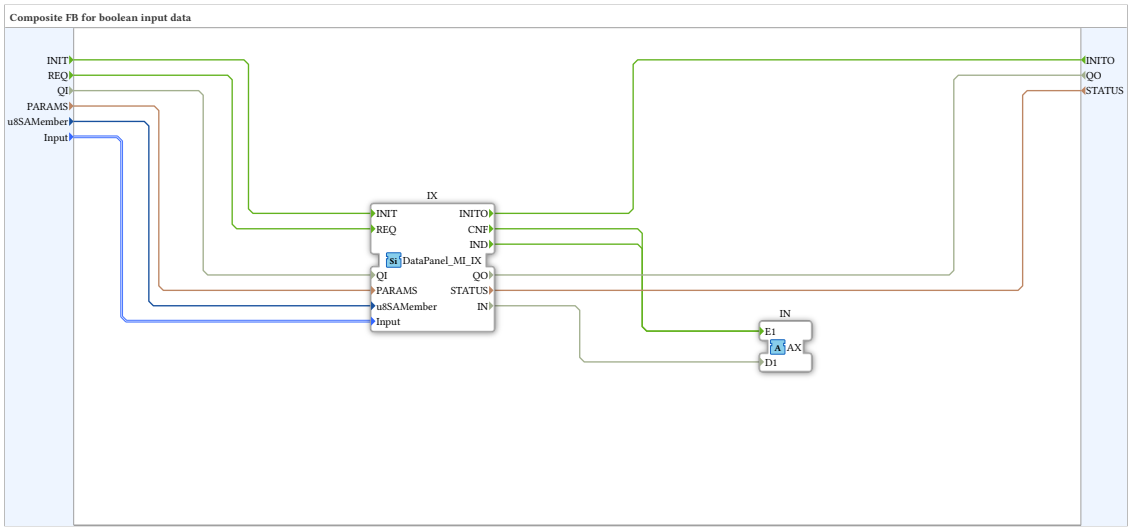
The function block goes through the following states:

1. **Not Initialized**: Before INIT call
2. **Initialized**: After successful INIT/INITO sequence
3. **Ready**: Can process REQ/CNF cycles
4. **Active**: Processes incoming IND events from the resource

Application Scenarios

- Monitoring of digital inputs in control cabinets
- Integration into PLC controllers for binary signal acquisition
- Industrial automation with specific SA addressing requirements
- Plants with distributed I/O systems

⚖️ Comparison with Similar Blocks

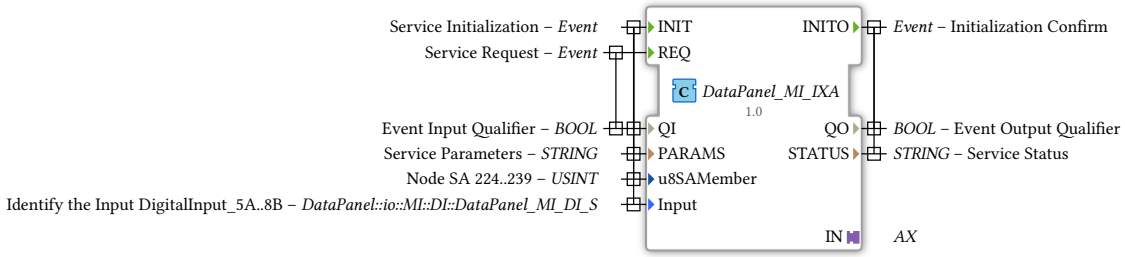


Compared to generic digital input blocks, DataPanel_MI_IX offers:

- Specific addressing for DataPanel systems
- Extended initialization options with parameter strings
- Additional IND functionality for event-based communication
- Structured input identification

Conclusion

DataPanel_MI_IX is a specialized function block for the reliable acquisition of digital input signals in DataPanel environments. Its flexible parameterization and dual operating modes (demand-driven and event-driven) make it ideally suited for demanding automation applications with specific addressing requirements.



DataPanel_MI_IXA

• – ○ • – ○ • – ○ •

Introduction

The DataPanel_MI_IXA is a composite function block for processing Boolean input data. It serves as an interface for digital inputs and enables the initialization and querying of input data via standardized service interfaces.

Interface Structure

Event Inputs

- **INIT**: Service initialization with the associated data QI, PARAMS, u8SAMember, and Input
- **REQ**: Service request with the associated data QI

Event Outputs

- **INITO**: Initialization acknowledgment with the associated data QO and STATUS

Data Inputs

- **QI**: Event input qualifier (BOOL)
- **PARAMS**: Service parameters (STRING)
- **u8SAMember**: Node SA 224..239 (USINT) with initial value MI::MI_00
- **Input**: Identification of the digital input DigitalInput_5A..8B with initial value Invalid

Data Outputs

- **QO**: Event output qualifier (BOOL)
- **STATUS**: Service status (STRING)

Adapter

- **IN**: Unidirectional adapter of type AX for data communication

Functionality

This function block acts as a wrapper for the internal DataPanel_MI_IX block and forwards all events and data accordingly. During INIT initialization, all parameters are passed to the internal block, and confirmation is provided via INITO. REQ requests are forwarded directly to the internal block.

Technical Features

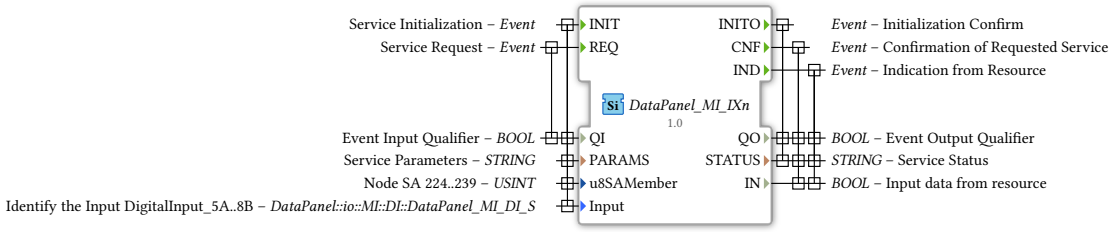
- Uses special types from the DataPanel::io::MI::DI namespace
- Supports SA members in the range 224-239
- Provides initialization with default values for u8SAMember and Input
- Implements error handling via the Invalid initial value

State Overview

The block has an initialized state and an operating state. After successful INIT initialization, the block is operational and can process REQ requests.

Application Scenarios

- Connecting digital inputs in automation systems
- Integration into DataPanel I/O structures
- Use in control systems with SA bus communication
- Abstraction of hardware inputs in standardized interfaces



⚖️ Comparison with similar modules

Compared to simple digital input modules, DataPanel_MI_IXA offers extended initialization options and parameterization via the PARAMS input. SA member numbering enables specific addressing in larger systems.

Conclusion

The DataPanel_MI_IXA is a robust and flexible function block for integrating digital inputs into complex automation systems. Its structured interface and extended parameterization options make it particularly suitable for demanding applications in industrial environments.

DataPanel_MI_IXn

• – ○ • – ○ • – ○ •

Introduction

The DataPanel_MI_IXn function block is a service-oriented input block for digital binary inputs (ground switching / NPN). It is used to read a single Boolean input signal from a DataPanel system via the MI (Module Interface) protocol. The block is typically used in the 4diac IDE to connect field devices such as switches or sensors.

Interface Structure

Event Inputs

- **INIT** (EInit): Initializes the block. The parameters QI, PARAMS, u8SAMember, and Input are passed.
- **REQ** (Event): Requests the current input value to be read. Qualified by QI.

Event Outputs

- **INITO** (EInit): Confirms successful initialization. Returns QO and STATUS.
- **CNF** (Event): Acknowledges a completed request (REQ). Contains QO, STATUS, and the read value IN.

- **IND** (Event): Indicates an asynchronous change in the input signal from the resource driver. Contains QO, STATUS, and IN.

Data Inputs

- **QI** (BOOL): Qualifier for the event inputs; typically set to TRUE to enable processing.
- **PARAMS** (STRING): Service-specific parameters for configuration (e.g., addressing or protocol settings).
- **u8SAMember** (USINT): Node SA (Subscriber Address) of the device in the range 224…239. Initial value: MI::MI_00.
- **Input** (DataPanel::io::MI::DI::DataPanel_MI_DI_S): Identification of the digital input (e.g., DigitalInput_5A…8B). Initial value: Invalid.

Data Outputs

- **QO** (BOOL): Output qualifier; indicates whether the output data is valid.
- **STATUS** (STRING): Service status message (e.g., error or success message).
- **IN** (BOOL): The binary input value read from the connected sensor or switch.

Adapters

No adapters defined.

Functionality

The function block communicates with a DataPanel module via the MI protocol. After startup, the function block is initialized with INIT, during which the communication parameters (PARAMS, u8SAMember, Input) are configured. Upon successful initialization, INITO is triggered. The current state of the configured digital input can then be queried using REQ. The response is provided via CNF with the value IN. Additionally, the function block can receive asynchronous events (IND) when the input state changes without an explicit request (e.g., due to hardware interrupts). The QO output indicates the validity of the data, and STATUS provides diagnostic information.

Technical Features

- The function block is implemented as a Service Interface Function Block (SIFB) and expects a low-level hardware implementation in the 4diac runtime.
- The input configuration uses a user-defined structure type `DataPanel_MI_DI_S`, which enables precise channel assignment.
- The parameter `u8SAMember` is limited to values 224–239; this corresponds to typical SA addresses for MI-based subsystems.
- Initialization can only be performed with valid parameters. Initialization fails if the input is invalid (e.g., Invalid).

State Overview

An explicit state machine is not defined in the XML. Typically, the function block goes through the following states:

1. **IDLE** – After startup, waits for INIT.
2. **INIT** – Initialization is performed, configuring the hardware channel.
3. **OPERATE** – Ready for REQ and receiving IND events.
4. **ERROR** – In case of failed initialization or communication errors.

Alternative states may vary depending on the communication driver implementation.

Application Scenarios

- **Field Device Connection**: A binary proximity sensor (npn) is connected to a DataPanel input. The function block reads the switching state and makes it available in the control application.
- **Switch Monitoring**: A manually operated switch (ground switching) is monitored via the function block; Changes are reported asynchronously via IND.
- **Diagnostics**: Errors such as wire breaks or address conflicts can be detected via STATUS.

Comparison with similar function blocks

Similar function blocks such as `DataPanel_MI_DI_Xn` (for other input groups) or `DataPanel_MI_DO_Xn` (outputs) share the same interface but differ in the number of channels or the data direction. This function block focuses on a single digital input and is suitable for precise monitoring.

Conclusion

The `DataPanel_MI_IXn` function block provides a standardized interface for reading a binary input in DataPanel systems via the MI protocol. Its service-oriented structure (INIT/REQ/IND) allows for flexible integration into event-driven automation solutions. Configuration via dedicated parameters ensures simple and robust connectivity.

Not present - This is a global constant definition

Functionality

The global constant DataPanel_MI_DO defines fixed pin assignments for a medium I/O density DataPanel module. Each constant represents a specific output channel or power supply port and assigns it a fixed pin value. The structure is based on the data type `DataPanel_MI_DO_S` with a pin array.

Technical Features

- Defines 16 digital output channels (1A-8B) with pin assignments 1-16
- Includes 4 power supply ports (Input_Power_Port_5-8) with pin assignments 17-20
- Provides an invalid constant with a pin value of 255 for error handling
- Structured organization in pairs (A/B) for improved clarity
- Fixed pin assignments guarantee consistent hardware control

State Overview

Not applicable - These are static constant definitions

Application Scenarios

- Hardware configuration of DataPanel modules with medium I/O density
- Simplifying pin mapping in control programs
- Reusable constant definitions in larger automation projects
- Hardware-abstract programming using symbolic pin names

⚖️ Comparison with Similar Components

Compared to individual pin definitions, this global Constants:

- Centralized management of all pin assignments
- Typed access via structured data types
- Improved maintainability and code readability
- Consistent naming conventions across the entire project

Conclusion

DataPanel_MI_DO provides an efficient and structured way to manage pin assignments for DataPanel modules with medium digital output density. The use of global constants improves code maintainability and allows for centralized management of hardware changes.

DataPanel_MI_IW_AMP

• — ○ • — ○ • — ○ •

Introduction

The DataPanel_MI_IW_AMP function block is an input interface function block (Service Interface Function Block) for acquiring the current feedback (amperage) of a single channel. It serves to integrate current measurements into the 4diac IDE and enables communication with a higher-level controller or a data panel. The block initializes the hardware-level communication and returns the current measurement value as a WORD upon each request.

Interface Structure

Event Inputs

- `INIT (EInit)` – Service initialization. Triggered to configure the function block and establish the connection to the hardware. This event transfers the parameters QI, PARAMS, u8SAMember, Input, and AnalogInput_hysteresis.

- `REQ (Event)` – Service request. Triggers a new measurement query. The function block responds with the CNF event and provides the current amperage value on the IN output.

Event Outputs

- `INITO (EInit)` – Initialization confirmation. Sent after successful initialization. Outputs the QO and STATUS status.
- `CNF (Event)` – Service request confirmation. Sent in response to REQ and contains the current measurement value IN as well as the status information QO and STATUS.
- `IND (Event)` – Resource indication. Triggered by asynchronous events from the hardware (e.g., spontaneous value changes). Also provides the current measurement value IN.

Data Inputs

- `QI (BOOL)` – Input Qualifier. Controls whether the FB is active (TRUE) or not (FALSE).
- `PARAMS (STRING)` – Service Parameter. Contains configuration data for initialization, e.g., bus interface or addressing.
- `u8SAMember (USINT)` – Node SA (Source Address) in the range 224..239. Defines the unique address of the connected device. Initial value: `MI::MI_00`.
- `Input (DataPanel_MI_DO_S)` – Identifies the digital output whose current is to be measured (e.g., DigitalOutput_1A..8B). Initial value: `Invalid`.
- `AnalogInput_hysteresis (WORD)` – Hysteresis for the analog input. Can be used to prevent edge detection during small fluctuations.

Data Outputs

- `QO (BOOL)` – Output qualifier. Indicates whether the function block is operating correctly (TRUE) or if an error has occurred (FALSE).
- `STATUS (STRING)` – Service status. Contains error messages or information about the operating status.
- `IN (WORD)` – Measured current value in units of mA or 0.1A (depending on the configuration). Provides the current amperage value of the selected channel.

Adapters

No adapters defined.

Functionality

The function block acts as a service interface between the application and the hardware level. When `INIT` is triggered, the configuration parameters (address, channel assignment, hysteresis) are passed to the hardware. After successful initialization, `INITO` is sent. A `REQ` event triggers an immediate query of the current measurement value, which is provided on the output `IN` and acknowledged with `CNF`. Additionally, the hardware can generate a `IND` event upon changes to asynchronously inform the application.

`IND`` The values of QIandQOcontrol the activity state: The function block (FB) can only deliver data ifQI=TRUE and QO=TRUE. In case of an error, QOis set to FALSE and an error message is stored inSTATUS`.

Technical Features

- The FB is designed as a generic service interface block and requires a hardware-dependent implementation of the service functions.
- Addressing via `u8SAMember` follows a predefined set of constants (e.g., `MI::MI_00` … `MI::MI_15`), which allows for easy configuration of multiple channels.
- The output type `DataPanel_MI_DO_S` is used to select a specific digital output; the function block will only operate correctly if this value is valid (not `Invalid`).
- Hysteresis (`AnalogInput_hysteresis`) can be used to suppress measurement noise and avoid unnecessary events.
- The amperage output is a WORD, depending on the configuration, in mA (e.g., 0–65535 mA) or in 0.1 A increments.

State Overview

The function block typically goes through the following states:

1. **IDLE** – Idle state after startup, waiting for INIT.
2. **INIT** – Initialization is performed; after success, transition to OPERATIONAL, then INITO.

3. **OPERATIONAL** – Ready for operation; REQ events are processed, measured values are delivered via CNF; asynchronous IND is possible.
4. **ERROR** – Error state (e.g., communication error, invalid parameters); QO = FALSE, STATUS contains error text; reset only by re-INIT.

A detailed state machine is embedded in the service implementation.

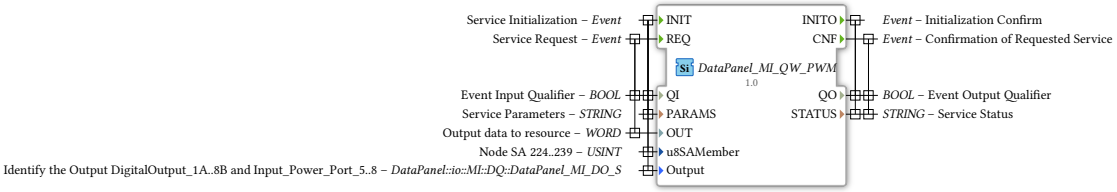
Application Scenarios

- **Current monitoring of individual outputs** in a machine controller, e.g., for detecting load changes or defects.
- **Integration of analog input modules** of a data panel to measure the current consumption per channel.
- **Parameterization via INIT** enables flexible use in various hardware configurations.

Comparison with Similar Function Blocks

Compared to a purely digital input function block, this block offers analog measured value feedback (amperage), which provides more information about the load state. Similar modules for voltage or temperature measurement use a comparable interface scheme (INIT/REQ/IND) with other physical units. The advantage of `DataPanel_MI_IW_AMP` lies in its specific optimization for current measurement and its integration into the DataPanel family.

Conclusion



The `DataPanel_MI_IW_AMP` function block provides a standardized and flexible interface for acquiring current values in automation systems. Its clearly defined events and parameters allow for easy integration into 4diac projects and offer both synchronous and asynchronous notifications of measured value changes. Detailed configuration via address, channel, and hysteresis enables adaptable use in diverse hardware environments.

DataPanel_MI_QX

• – ◦ • – ◦ • – ◦ •

Introduction

The DataPanel_MI_QX is a Service Interface Function Block for outputting Boolean data to a resource. This block serves as an interface between the control logic and the physical outputs of a DataPanel MI system and enables the configuration and control of digital outputs.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Operation

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters
- **OUT** (BOOL): Output Data for Resource
- **u8SAMember** (USINT): Node SA 224..239, Initial Value: MI::MI_00
- **Output** (DataPanel_MI_DO_S): Identifies the output (DigitalOutput_1A..8B and Input_Power_Port_5..8), Initial Value: Invalid

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status

Adapters

No adapter interfaces are available.

Functionality

The DataPanel_MI_QX function block manages communication with the digital outputs of a DataPanel MI system. During initialization (INIT event), the service parameters are configured and the hardware interface is set up. The REQ event triggers the output of Boolean data to the specified resource. The function block acknowledges both initialization and service operations via the corresponding output events.

Technical Features

- Supports the configuration of SA nodes in the 224-239 range
- Enables the identification of specific digital outputs (1A to 8B) and power ports (5-8)
- Uses a special data type (DataPanel_MI_DO_S) for output identification
- Implements robust error handling through STATUS output

State Overview

The Function Block goes through the following states:

1. **Not Initialized**: Waiting for an INIT event
2. **Initialized**: Ready for service requests
3. **Service Execution**: Processing REQ events
4. **Acknowledgement**: Sending CNF/INITO events with status information

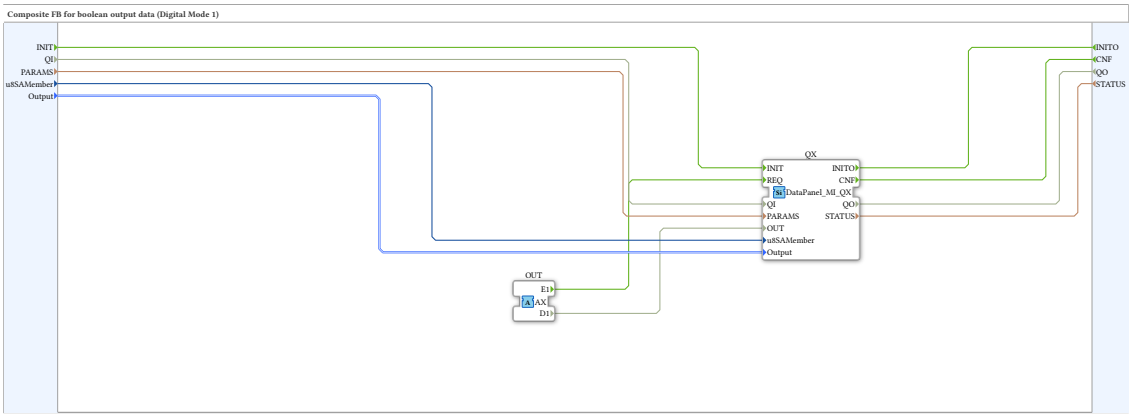
Application Scenarios

- Control of digital outputs in industrial automation systems
- Connection of DataPanel MI hardware components
- Implementation of secure output protocols
- Integration into larger control systems with multiple output channels

⚖️ Comparison with Similar Function Blocks

Compared to simple digital output blocks, DataPanel_MI_QX offers advanced functionalities such as:

- Configurable SA node configuration
- Specific hardware identification for DataPanel MI systems
- Detailed status feedback
- Flexible output configuration via the output parameter

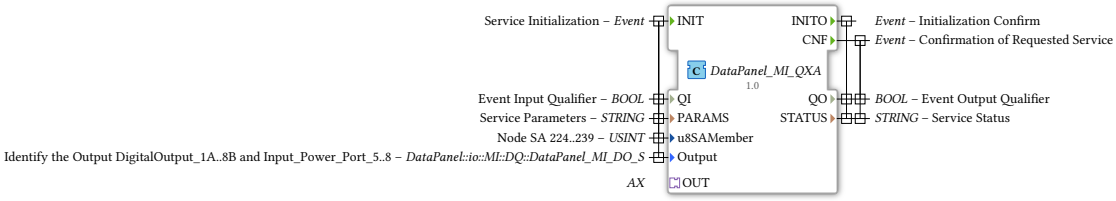


🛠️ Related Exercises

- Exercise_003b2_sub
- Exercise_010a4

Conclusion

The DataPanel_MI_QX Function Block represents a powerful and flexible solution for controlling digital outputs in DataPanel MI systems. Its extensive parameterization and detailed status feedback make it particularly suitable for complex automation applications that require a reliable and configurable output interface.



DataPanel_MI_QXA

• – ○ • – ○ • – ○ •

Introduction

The DataPanel_MI_QXA is a composite function block for controlling Boolean output data in automation systems. This block serves as an interface for digital outputs and enables the configuration and control of output channels via standardized service parameters.

Interface Structure

Event Inputs

- **INIT**: Service initialization event with associated data QI, PARAMS, u8SAMember, and Output

Event Outputs

- **INITO**: Initialization acknowledgment with QO and STATUS
- **CNF**: Acknowledgement of the requested service with QO and STATUS

Data Inputs

- **QI** (BOOL): Event input qualifier
- **PARAMS** (STRING): Service parameter
- **u8SAMember** (USINT): Node SA address in the range 224-239, initialized with MI::MI_00
- **Output** (DataPanel_MI_DO_S): Output identification (DigitalOutput_1A..8B and Input_Power_Port_5..8), initialized with Invalid

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status

Adapters

- **OUT**: Unidirectional AX-type adapter for output control

Functionality

The DataPanel_MI_QXA composite function block encapsulates the functionality of the DataPanel_MI_QX block and extends it with an adapter interface. Upon initialization, the configuration parameters are passed to the internal QX block. The OUT adapter enables external control of the output functions via standardized interfaces.

Technical Features

- Supports SA addresses in the range 224-239
- Uses specific output identification for digital outputs and power ports
- Integrated error handling through invalid initialization
- Unidirectional adapter architecture for clean interface separation

State Overview

The function block goes through the following states:

1. **Initialization Phase**: The INIT event processes configuration parameters
2. **Ready State**: Waits for control requests via adapter OUT
3. **Active Operation**: Processes output commands and generates CNF acknowledgments

Application Scenarios

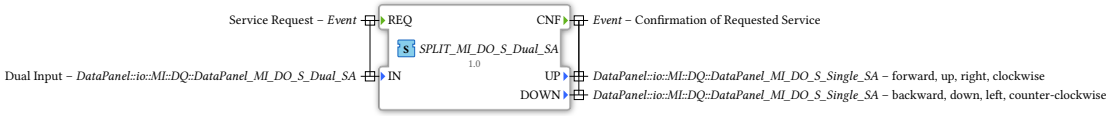
- Control of digital outputs in industrial automation
- Connection of power port controllers
- Integration into modular control systems with SA addressing

- Use in distributed automation systems

⚖️ Comparison with Similar Function Blocks

Compared to simple digital output function blocks, DataPanel_MI_QXA offers:

- Extended parameterization options via STRING Parameters
- SA Addressing Support for Network Integration
- Composite Architecture with Adapter Interface
- Comprehensive Status Feedback



🛠️ Related Exercises

- Exercise_003b2_sub_AX
- Exercise_010a4_AX

Conclusion

The DataPanel_MI_QXA is a powerful composite function block for controlling Boolean output data in complex automation environments. Its modular architecture and standardized interfaces make it ideal for use in distributed control systems with high demands on flexibility and maintainability.

SPLIT_MI_DO_S_Dual_SA

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SPLIT_MI_DO_S_Dual_SA** is used to split a single data panel input of type `DataPanel_MI_DO_S_Dual_SA` into two separate outputs of type `DataPanel_MI_DO_S_Single_SA`. The drive information contained in the dual structure for forward/reverse movement (or up/down, right/left, clockwise/counterclockwise) is distributed to two independent outputs.

Interface Structure

Event Inputs

Event	Description
REQ	Service Request: The block processes the current value of the data input IN.

Event Outputs

Event	Description
CNF	Confirmation of processing completed. Sent after the algorithm has finished executing.

Data Inputs

Name	Type	Description
IN	`DataPanel::io::MI::DQ::DataPanel_MI_DO_S_Dual_SA`	Dual input carrying both forward (UP) and backward (DOWN) information.

Data Outputs

Name	Type	Description
UP	`DataPanel::io::MI::DQ::DataPanel_MI_DO_S_Single_SA`	Output for forward, upward, clockwise, or counterclockwise rotation.

DOWN	DataPanel::io::MI::DQ::DataPanel_MI_DO_S_Single_SA	Output for reverse, downward, counterclockwise, or counterclockwise rotation.

Adapter

None.

Functionality

The function block is activated by the **REQ** event. The associated algorithm performs the following assignments:

- The common control value `u8SAMember` of the dual structure is passed unchanged to both outputs (`UP.u8SAMember` and `DOWN.u8SAMember`).
- The direction information is separated: Output `UP.Port` receives the value of field `IN.Up`, and output `DOWN.Port` receives the value of field `IN.Down`.
- After the algorithm executes, the acknowledgment event **CNF** is sent.

Technical Features

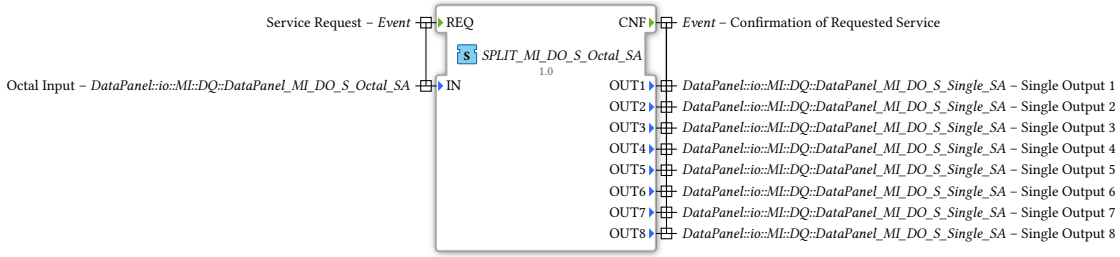
- The function block is implemented as a simple function block (SimpleFB), meaning the logic is executed within a single algorithm without a state machine.
- The data types used are from the `DataPanel::io::MI::DQ` package. They are declared as implicit imports in the function block.
- The output data is valid at the time of the **CNF** event.

State Overview

The function block has only a single EC state, **REQ**, in which the algorithm is executed and the output event **CNF** is subsequently set. There are no other states or branches.

Application Scenarios

- Splitting a combined drive signal for a bidirectional motor into two separate control lines (e.g., for direction control).
- Separating forward and reverse signals in a machine control system when downstream function blocks expect separate inputs for each direction of movement.
- Preparing data for two independent actuators that operate in the same mode (e.g., power level) but control different directions.



Comparison with Similar Function Blocks

A possible alternative approach would be to use a general-purpose splitter function block that splits arbitrary compound data types. **SPLIT_MI_DO_S_Dual_SA** is specifically tailored to the aforementioned data types and directly handles the correct assignment of the direction fields, reducing the potential for errors and improving the readability of the control code.

Conclusion

SPLIT_MI_DO_S_Dual_SA offers a simple and reliable way to split a dual data panel control command into two separate outputs for opposite directions of movement. Thanks to its clearly defined interface and direct processing from an event call, it is particularly well-suited for use in modular control systems where a clean separation of the direction signals is required.

SPLIT_MI_DO_S_Octal_SA

• — ○ • — ○ • — ○ •

The function block **SPLIT_MI_DO_S_Octal_SA** is used to split a single data value of type DataPanel_MI_DO_S_Octal_SA into eight separate outputs of type DataPanel_MI_DO_S_Single_SA. The common portion (u8SAMember) is retained unchanged, and the respective port information from the octal input is distributed to the individual outputs.

Event	Comment	
REQ	Service Request; Processing starts as soon as the event occurs. The user must first validate the data input IN.	
Event	Comment	
-----	-----	
CNF	Confirmation of completed processing. Indicates that all eight outputs have been updated.	
Name	Type	Comment
--	----------	----------
IN	DataPanel_MI_DO_S_Octal_SA	Octal input value (Port 1...8 and common u8SAMember)
Name	Type	Comment
--	----------	----------
OUT1	DataPanel_MI_DO_S_Single_SA	Single Output 1
OUT2	DataPanel_MI_DO_S_Single_SA	Single Output 2
OUT3	DataPanel_MI_DO_S_Single_SA	Single Output 3
OUT4	DataPanel_MI_DO_S_Single_SA	Single Output 4
OUT5	DataPanel_MI_DO_S_Single_SA	Single Output 5
OUT6	DataPanel_MI_DO_S_Single_SA	Single Output 6
OUT7	DataPanel_MI_DO_S_Single_SA	Single Output 7
OUT8	DataPanel_MI_DO_S_Single_SA	Single Output 8

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters available.

Functionality

This function block implements a simple, event-driven process:

1. An incoming REQ event triggers the execution of the algorithm REQ.

No adapters available.

This function block implements a simple, event-driven sequence:

1. Each output also receives the corresponding port value from the octal input:

- `OUT1.Port := IN.Port1`
- `OUT2.Port := IN.Port2`
- ...
- `OUT8.Port := IN.Port8`

1. Upon completion, the event `CNF` is sent, indicating that all eight outputs are valid.

- The function block is implemented as a **SimpleFB** (simple function block) and operates without a state machine with multiple states – processing occurs in a single step.
- There is no concurrency or time-critical processes; the partitioning occurs synchronously with the `REQ` event.
- The types `DataPanel_MI_DO_S_Octal_SA` and `DataPanel_MI_DO_S_Single_SA` must be defined in the same data namespace (here, `DataPanel::io::MI::DQ`).

The function block has exactly one state, `REQ`:

- **Entry** via the `REQ` event.
- **Action**: Execution of the algorithm `REQ`.
- **Output**: Sending the `CNF` event (all outputs are carried out simultaneously).

There are no other states that indicate delay or error handling.

- Splitting an octal data bus (e.g., a module with eight identical digital outputs) into individual logical channels.
- Interface between an octal sensor/actuator panel and a controller that processes individual outputs separately.
- Preprocessing in automation technology when a data packet contains multiple ports that need to be forwarded separately.

Comparable components exist for other data structures (e.g., `SPLIT_MI_DO_S_Octal_SA` for specific panel types). The basic mechanism—splitting a composite data type into its components—is universal but differs depending on the data field name and type.

The `SPLIT_MI_DO_S_Octal_SA` is a compact and clearly structured function block for decomposing an octal data packet into eight individual signals. It facilitates the modularization of automation software by dividing complex data types into manageable units and directly inheriting the port assignment from the source structure.

Introduction

The MI Global Constants represent a collection of constants for medium I/O density modules. These constant definitions are used in the 4diac IDE to provide consistent and reusable addressing information for I/O modules.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

No adapters available

Functionality

MI Global Constants are purely constant declarations without any active functionality. The constants define address ranges for 16 different I/O modules (MI_00 to MI_15), each with a unique numeric value in the range of 224 to 239.

Technical Features

- All constants are of type USINT (Unsigned Short Integer)
- The values form a continuous range from 224 to 239
- Constants are declared as global and constant
- Package assignment: DataPanel::io::MI::const

State Overview

No state transitions are present, as these are static constant definitions

Application Scenarios

- Addressing I/O modules in control applications
- Reuse in various function blocks
- Centralized management of module addresses
- Simplified project configuration

⚖️ Comparison with Similar Blocks

Compared to other constant definitions, MI provides specific addresses for modules with medium I/O density. Other constant sets might cover different address ranges or module types.

Conclusion

The MI Global Constants offer a convenient and centralized way to manage address information for I/O modules. Using these constants improves the maintainability and readability of control programs, as module address changes can be made centrally.

Radio_DI

• – ◦ • – ◦ • – ◦ •

Introduction

Radio_DI is a GlobalConstants package for the 4diac IDE that defines constants for digital inputs in radio systems. The package provides predefined pin configurations for various digital input signals that can be used in control applications.

Interface Structure

Because Radio_DI is a GlobalConstants package, it does not have traditional function block interfaces. Instead, it provides global constants.

Event Inputs

Not available - GlobalConstants package

Event Outputs

Not available - GlobalConstants package

Data Inputs

Not available - GlobalConstants package

Data Outputs

Not available - GlobalConstants package

Adapters

Not available - GlobalConstants package

Functionality

The Funk_DI package defines a collection of global constants of type `Funk_DI_S`, representing digital input pins. Each constant contains a pin number that identifies the physical or logical input. The constants can be used in other function blocks to reference specific digital inputs.

Technical Features

- **Pin Assignments**: The pin numbers follow a specific scheme:
- Standard Inputs: Pins 1-15
- Special Functions: Pin 0 (STOP), Pin 25 (START)
- System Functions: Pin −1 (STATUS), Pin −6 (COUNTER)
- Invalid Value: Pin 127 (Invalid)
- **Data Type**: All constants use the structured data type `Funk_DI_S`
- **Package Structure**: Organized in the namespace `Funk::io::DI`

State Overview

Since this is a constant package, there are no state transitions. All values are hard-coded at compile time and are unchangeable.

Application Scenarios

- **Digital Input Configuration**: Simplified configuration of digital inputs in control applications
- **Standardization**: Ensuring consistent pin assignments across different projects
- **Maintainability**: Centralized management of all digital input configurations
- **Wireless Systems**: Specifically designed for applications in wireless control systems

⚖️ Comparison with Similar Components

Compared to other digital input constant packages, Funk_DI offers:

- Specific pin assignments for wireless systems
- Predefined constants for special functions (START, STOP, STATUS, COUNTER)
- Structured organization within the I/O area of the Funk namespace

Conclusion

The Funk_DI GlobalConstants package provides a convenient collection of predefined constants for digital inputs in wireless systems. Its standardized pin assignments and clear naming conventions enable efficient and easy-to-maintain configuration of control applications. The special functions such as START, STOP, and STATUS make it particularly suitable for industrial control applications with wireless components.

Funk_IX

• – ◦ • – ◦ • – ◦ •

Introduction

The Funk_IX is a Service Interface Function Block for Boolean input data. It serves as an interface for communication with digital inputs in distributed automation systems and enables the initialization, querying, and asynchronous notification of input signals.

Interface Structure

Event Inputs

- **INIT**: Service Initialization
- Linked to: QI, PARAMS, Input
- **REQ**: Service Request
- Linked to: QI

Event Outputs

- **INITO**: Initialization Acknowledgement
- Linked to: QO, STATUS
- **CNF**: Acknowledgement of Requested Service
- Linked to: QO, STATUS, IN
- **IND**: Indication from Resource
- Linked to: QO, STATUS, IN

Data Inputs

- **QI**: Event Input Qualifier (BOOL) - Qualifier for event inputs
- **PARAMS**: Service Parameters (STRING) - Service parameters
- **Input**: Identifies the input (Funk::io::DI::Funk_DI_S) - Identifies the digital input (e.g., DigitalInput_Key_01)

Data Outputs

- **QO**: Event Output Qualifier (BOOL) - Qualifier for event outputs
- **STATUS**: Service Status (STRING) - Service status
- **IN**: Input data from resource (BOOL) - Input data from the resource

Adapter

No adapter interfaces are available.

Functionality

The Funk_IX Function Block implements a Service Interface Pattern for digital inputs. During initialization (INIT event), the service parameters are configured and the specific digital input is identified. Input values can be queried via the REQ event, resulting in a CNF response with the current input value. Additionally, the block supports asynchronous IND events, which are triggered by changes in the input signal's state.

Technical Features

- Uses the special data type `Funk::io::DI::Funk_DI_S` to identify digital inputs
- Initial value for input is set to "Invalid"
- Supports both synchronous queries (REQ/CNF) and asynchronous notifications (IND)
- Includes comprehensive status feedback via the STATUS output

State Overview

The Function Block goes through the following states:

1. **Not Initialized**: Before INIT event
2. **Initialized**: After successful INIT/INITO sequence
3. **Query Ready**: Ready for REQ/CNF cycles
4. **Notification Ready**: Ready for asynchronous IND events

Application Scenarios

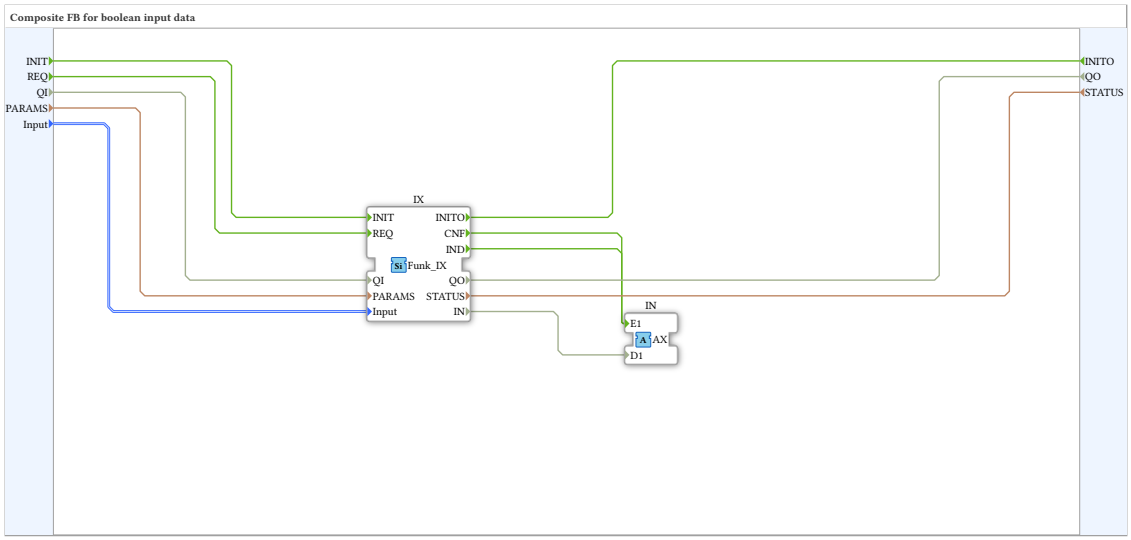
- Monitoring of digital sensors and switches
- Integration into distributed control systems
- Connection of field devices in industrial automation
- Condition monitoring of machines and systems

⚖️ Comparison with Similar Function Blocks

Compared to Funk_IX offers simple digital input blocks with enhanced service functionality, including parameterization, status feedback, and asynchronous notifications. Its unique input identification enables precise addressing in complex systems.

🛠️ Related Exercises

- Exercise_003b2_sub



Conclusion

The Funk_IX Function Block provides a powerful and flexible solution for integrating digital inputs into 4diac-based automation systems. Its service-oriented architecture, with initialization, query, and notification functions, makes it particularly suitable for demanding industrial applications.

Funk_IXA

• – ○ • – ○ • – ○ •

Introduction

The **Funk_IXA** function block is a composite function block for processing Boolean input data. It serves as an interface for digital inputs and enables the initialization and querying of input signals via a standardized interface.

Interface Structure

Event Inputs

- **INIT**: Service Initialization (with QI, PARAMS, Input)
- **REQ**: Service Request (with QI)

Event Outputs

- **INITO**: Initialization Acknowledgement (with QO, STATUS)

Data Inputs

- **QI**: Event Input Qualifier (BOOL)
- **PARAMS**: Service Parameters (STRING)
- **Input**: Digital Input Identification (Funk_DI_S, Initial Value: Invalid)

Data Outputs

- **QO**: Event Output Qualifier (BOOL)
- **STATUS**: Service Status (STRING)

Adapters

- **IN**: Unidirectional Adapter Type AX

Functionality

The The Funk_IXA block acts as a wrapper for the underlying Funk_IX block. During INIT initialization, the parameters QI, PARAMS, and Input are passed to the internal IX block. The REQ request triggers a query of the current input state. The IN adapter enables communication with external systems.

Funk_IXA acts as a wrapper for the underlying Funk_IX block.

Technical Features

- Uses the specific data type Funk_DI_S to identify digital inputs
- Implements invalid initialization for the input parameter
- Supports string-based parameter passing for flexible configuration
- Provides status feedback via the STATUS output

State Overview

The block goes through the following states:

1. **Not Initialized**: Before INIT call
2. **Initialized**: After successful INIT processing
3. **Ready**: Can process REQ requests
4. **Active**: During REQ processing

Application Scenarios

- Connecting digital inputs in automation systems
- Integration into distributed control systems
- Use in agricultural machinery controls
- Interface for sensor data acquisition

⚖️ Comparison with Similar Blocks

Compared to simple digital input blocks, Funk_IXA offers:

- Extended parameterization options
- Status feedback
- Adapter interface for extended communication
- Typed Input Identification

🛠️ Related Exercises

- Exercise_003b2_sub_AX

Conclusion

The Funk_IXA function block represents a robust and flexible solution for processing digital input signals. Its composite structure and the use of standardized interfaces make it particularly suitable for complex automation applications that require reliable data acquisition and status monitoring.

A2X2_ILOCK_SWITCH_PROTECT

• — ○ • — ○ • — ○ •

Introduction

The **A2X2_ILOCK_SWITCH_PROTECT** subapplication bundles a bidirectional A2X2 network round-trip with a last-wins arbitration mechanism including a protective dead time. It combines three logical functions in a single composite component: a bidirectional-to-unidirectional adapter bridge, an interlock switch protector operating on the paired adapter channels, and a splitter that duplicates the interlocked state both to the write-back return path and to an external plug for physical output driving.

The subapplication follows a “SUB style” architecture where the bridge, interlock, and splitter reside inside the composite (subapplication), rather than being placed in the device resource. This encapsulation hides the internal complexity and makes the component reusable across different hardware configurations.

Interface Structure

The subapplication interface consists of one data input, one bidirectional socket adapter, and one unidirectional plug adapter. No explicit event inputs or event outputs are exposed at the composite boundary; all event flow is carried implicitly through the adapter connections.

Event Inputs

None. All event handling is encapsulated within the adapter-based communication flow.

Event Outputs

None. Results propagate through the adapter channels.

Data Inputs

Name	Type	Initial Value	Comment
`DT_PROTECT`	`TIME`	`T#50ms`	Protective dead time before direction change is permitted.

`DT_PROTECT` defines the minimum time period that must elapse before a direction reversal is accepted, suppressing rapid toggling and mechanical bounce effects.

Data Outputs

None.

Adapters

Direction	Name	Type	Comment
Socket	`IO`	`adapter::types::bidirectional::A2X2`	Bundled network round-trip: button state enters, write-back state exits.

Plug	OUT	adapter::types::unidirectional::A2X	Interlocked UP/DOWN state, intended for physical output drivers.

- **IO** is the bidirectional A2X2 socket receiving the raw operator button states (up/down) from the network and sending back the acknowledged/interlocked state.
- **OUT** is a unidirectional A2X plug that provides the interlocked UP/DOWN output signals to be connected to actual output hardware (e.g., relays, contactors, motor drivers).

Functionality

The subapplication implements a complete interlock-protected switching chain for two-directional actuators (e.g., a lift, a slide, a directional valve). The logic flow is as follows:

1. **Bridge stage** – The internally instantiated A2X2_TO_A2X function block splits the bidirectional A2X2 socket into two unidirectional A2X channels: one acting as the input (button state reception) and one as the output (write-back transmission).
2. **Interlock stage** – The ILOCK_SWITCH_PROTECT_A2X block receives the raw input from the bridge and applies a **last-wins arbitration** algorithm. When a direction change is requested, the protection logic enforces a dead time (DT_PROTECT) during which the new direction cannot be activated. This prevents simultaneous activation of both directions and guards against rapid switching.
3. **Time-out stage** – An internal E_TimeOut event block is triggered by the interlock's timeout mechanism. It provides the temporal reference signal that controls when the protection window expires and the new direction is accepted.
4. **Split stage** – The A2X_SPLIT_2 block takes the interlocked output from the interlock stage and duplicates it:
   - The first copy (OUT1) is routed to the subapplication's external OUT plug for driving physical outputs.
   - The second copy (OUT2) is fed back into the bridge's input channel (A2X_IN), which propagates the state back through the IO socket as the acknowledged write-back signal.

This closed-loop structure ensures that the state acknowledged to the network always matches the state physically commanded at the output, while the interlock prevents hazardous direction conflicts.

Technical Features

- **Bidirectional round-trip support**: Uses the A2X2 bidirection adapter, carrying both the incoming operator request and the outgoing acknowledged state on a single combined channel.
- **Last-wins arbitration**: Implements priority handling where the most recent button command takes precedence, with a time-based guard against rapid reversals.
- **Configurable protective dead time**: The DT_PROTECT input allows the user to tune the minimum time between direction changes (default 50 ms) per application requirements.
- **Integrated time-out generation**: The internal E_TimeOut block functions as the watchdog/timing engine, eliminating the need for external timing resources.
- **Internal state duplication**: The splitter stage generates two synchronized output copies—one for the external physical world, one for the network write-back—guaranteeing consistency.
- **Composite encapsulation**: All three functional stages (bridge, interlock, splitter) are contained within the subapplication, simplifying resource integration and promoting reuse.
- **No explicit event interface**: The subapplication relies entirely on adapter-based event propagation, reducing interface complexity at the composite level.

State Overview

Although the subapplication does not expose an explicit state machine, the internal interlock behavior implies the following logical states:

State	Condition	Output Behavior
Idle	No button pressed, or both buttons released	Both UP and DOWN outputs are inactive (off).
UP Active	UP button pressed, no active DOWN conflict	UP output active; DOWN output inactive.

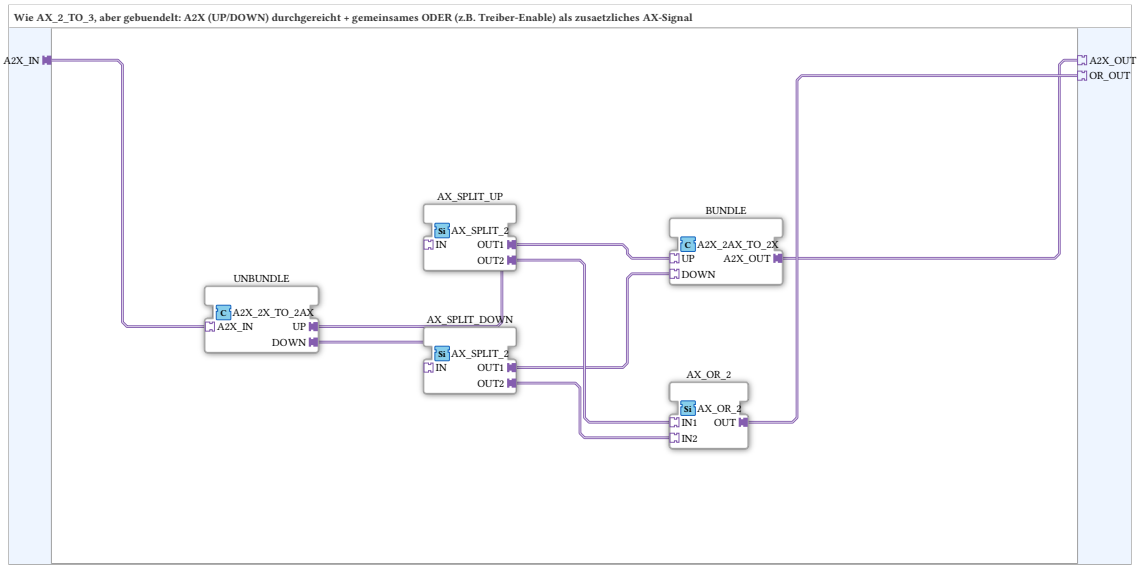
DOWN Active	DOWN button pressed, no active UP conflict	DOWN output active; UP output inactive.
Blocked / Switching	A direction change was requested during the dead time (`DT_PROTECT` still running)	The previous direction is maintained until the dead time expires; the new direction is then applied (last-wins).
Timeout Expired	`E_TimeOut` fires after the configured delay	The pending direction change is committed; the output state transitions accordingly.

The `E_TimeOut` block acts as a flip-flop reset mechansim: it triggers the transition from "Blocked" to the new active direction once the protection window has elapsed.

Application Scenarios

- **Lift / elevator control**: Interlocking the UP and DOWN commands of a hoist drive to prevent simultaneous activation, with a dead time to suppress bounce from mechanical limit switches.
- **Directional valve control** in hydraulic or pneumatic systems: Ensures that a spool valve is not commanded to two opposite positions at once.
- **Electric actuator control** (e.g., sliding gates, blinds, awnings): Protects the drive motor from rapid reversals that could cause overheating or mechanical wear.
- **Remote push-button panels**: Used as a central safety proxy between a network-based control panel (A2X2) and the local power electronics.
- **Machine safety circuits**: Provides a configurable switching delay between directions where a mandatory cool-down or mechanical settling period is required.

Comparison with Similar Blocks



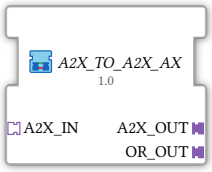
Feature	A2X2_ILOCK_SWITCH_PROTECT	ILOCK_SWITCH_PROTECT_A2X (standalone)	Simple interlock without dead time
Adapter interface	Bidirectional A2X2 + unidirectional A2X	Already operates on a bundled pair (A2X)	Typically discrete Boolean inputs
Dead-time protection	Yes, configurable via `DT_PROTECT`	Yes (if configured directly)	No
Network round-trip support	Yes, internal bridge handles A2X2 splitting	Requires external bridging	Not applicable
Output duplication	Internal splitter provides output + write-back	Output only, write-back must be added externally	Output only
Integration complexity	Low (single composite component)	Medium (requires external bridging and splitting)	High (requires external logic)
Encapsulation level	Complete (bridge + interlock + splitter)	Partial	None

The key advantage of this composite over using `ILOCK_SWITCH_PROTECT_A2X` alone is the integrated handling of the bidirectional A2X2 adapter channel and the automatic duplication of the result for both physical output and write-back feedback. This reduces wiring errors and external block count.

Conclusion

The **A2X2_ILOCK_SWITCH_PROTECT** subapplication provides a complete, encapsulated solution for interlocked, direction-protected switch control over a bidirectional A2X2 network connection. By combining the adapter conversion, last-wins arbitration with protective dead time, and feedback duplication into a single composite, it simplifies system integration, reduces external dependencies, and ensures consistent state propagation between the network and the physical output stage. Its configurable `DT_PROTECT` parameter makes it adaptable to a wide range of machinery and automation applications where safe directional switching is critical.

A2X_TO_A2X_AX



• – ○ • – ○ • – ○ •

Introduction

`A2X_TO_A2X_AX` is the bundled counterpart to `AX_2_TO_3`: Instead of two separate `AX` sockets/plugs (`UP_IN`/`DOWN_IN`, `UP_OUT`/`DOWN_OUT`), this block receives UP/DOWN signals bundled together as a single `A2X` signal, passes it through unchanged, and additionally provides a single `AX` signal that is the OR of both directions (e.g., for a common driver enable).

Gebuendeltes UP/DOWN Eingangssignal – *A2X*

A2X – Gebuendeltes UP/DOWN Ausgangssignal (unveraendert durchgereicht)
AX – ODER aus UP und DOWN

Function Blocks (FBs) Used

Sub-Blocks: A2X_TO_A2X_AX

- **Type**: SubAppType
- **Internal FBs Used**:
  - **UNBUNDLE**: `adapter::conversion::unidirectional::A2X_2X_TO_2AX` — splits the incoming `A2X_IN` into two separate `AX` signals (UP, DOWN).
  - **AX_SPLIT_UP** / **AX_SPLIT_DOWN**: each `adapter::events::unidirectional::AX_SPLIT_2` — each branch into a return path (back to the bundled output signal) and a branch for OR operation.
  - **BUNDLE**: `adapter::conversion::unidirectional::A2X_2AX_TO_2X` — re-bundles UP/DOWN into a single `A2X_OUT`.
  - **AX_OR_2**: `adapter::booleanOperators::AX_OR_2` — returns on `OR_OUT` whether the actuator is currently moving in either direction.
- **Functionality**: `A2X_IN` is unbundled, each direction is split (once back into the bundle, once into the OR operation), UP/DOWN are bundled again (`A2X_OUT`), and the OR operation of both directions is additionally located on `OR_OUT`.

Program Flow and Connections

1. `A2X_IN` ⟶ `UNBUNDLE.A2X_IN` ⟶ `UNBUNDLE.UP` ⟶ `AX_SPLIT_UP.IN`; `UNBUNDLE.DOWN` ⟶ `AX_SPLIT_DOWN.IN`.
2. `AX_SPLIT_UP.OUT1` ⟶ `BUNDLE.UP`; `AX_SPLIT_DOWN.OUT1` ⟶ `BUNDLE.DOWN`; `BUNDLE.A2X_OUT` ⟶ `A2X_OUT`.
3. `AX_SPLIT_UP.OUT2` ⟶ `AX_OR_2.IN1`; `AX_SPLIT_DOWN.OUT2` ⟶ `AX_OR_2.IN2`; `AX_OR_2.OUT` ⟶ `OR_OUT`.

Technical Features

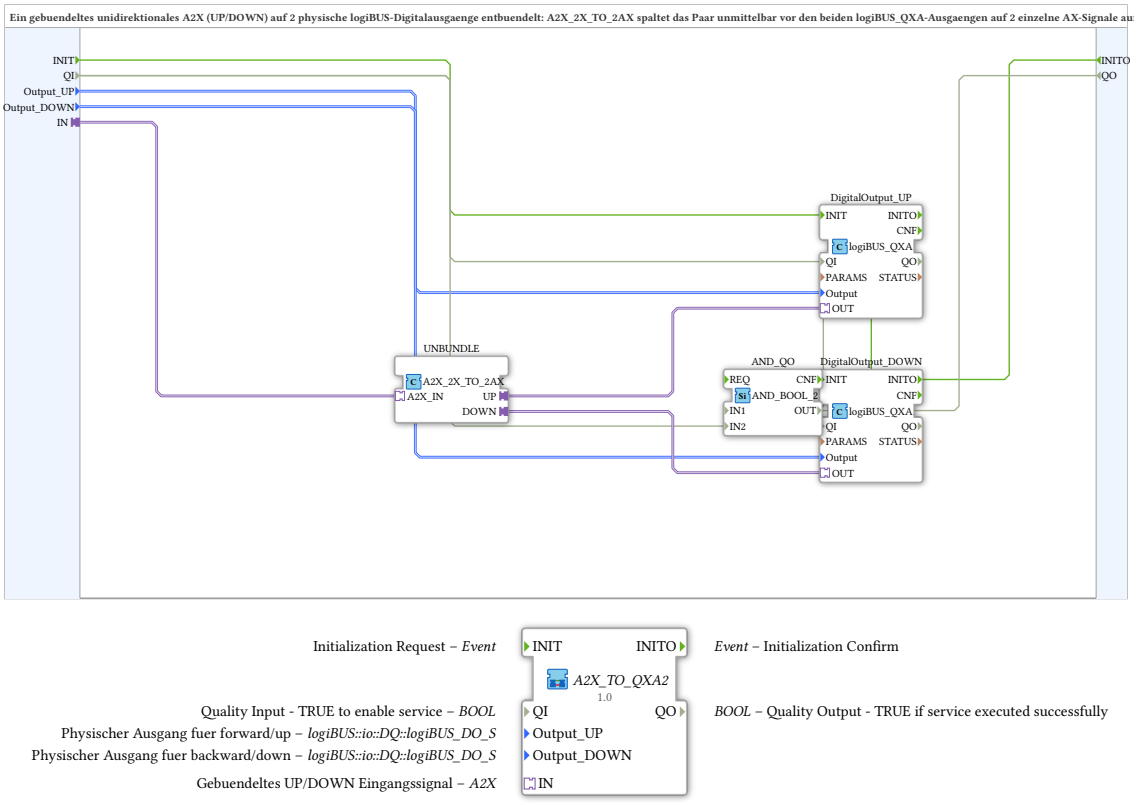
- **Unchanged passthrough despite bundling**: Externally, `A2X` remains bundled; internally, UP/DOWN is passed through unchanged, as with `AX_2_TO_3`.
- **One split per direction**: Necessary because each of the two unbundled signals must go to two destinations—back into the bundling and into the OR gate.

Application Scenarios

- Circuits where UP/DOWN are already implemented as a single `A2X` signal (e.g., direction on a double-action valve) and should not be split into two separate `AX` signals.

Comparison with Similar Components

If UP/DOWN are already implemented individually as `AX`, `AX_2_TO_3` should be used instead—functionally identical (pass-through plus OR as a third signal), but with an unbundled interface.



Summary

`A2X_TO_A2X_AX` passes a bundled `A2X` signal through unchanged and adds an additional `AX` OR signal—the bundled counterpart to `AX_2_TO_3`.

A2X_TO_QXA2

• – ○ • – ○ • – ○ •

Introduction

The **A2X_TO_QXA2** subapplication (composite type) acts as a bundling/unbundling adapter between a single bidirectional A2X signal (UP/DOWN) and two physical logicBUS digital outputs. It takes a bundled A2X adapter input and splits it into two separate AX signals, which are then routed to two independent logicBUS QXA digital output function blocks. The unbundling logic is encapsulated within the composite itself, so the device resource remains simple and does not need to handle the separation. This design

follows a “sub style” approach: the composite contains the unbundling and output mapping, making it reusable and modular.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization Request

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Confirm

Data Inputs

Name	Type	Initial Value	Comment
QI	BOOL	TRUE	Quality Input - TRUE to enable service.
Output_UP	logiBUS::io::DQ::logiBUS_DO_S	Invalid	Physical output for forward/up direction.
Output_DOWN	logiBUS::io::DQ::logiBUS_DO_S	Invalid	Physical output for backward/ down direction.

These data inputs are directly connected to the Output parameter of the internal logicBUS QXA function blocks.

Data Outputs

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if service executed successfully.

Adapters

Direction	Name	Type	Comment
Socket	IN	adapter::types::unidirectional::A2X	Bundled UP/DOWN input signal.

Functionality

The subapplication receives a bundled A2X adapter signal (IN). Internally, this signal is fed into an instance of the A2X_2X_TO_2AX conversion adapter (named UNBUNDLE), which splits the bundled A2X into two separate AX signals: UP and DOWN. These two signals are then individually connected to the OUT adapter ports of two logiBUS_QXA function blocks (DigitalOutput_UP and DigitalOutput_DOWN). Each of these QXA blocks drives a physical logicBUS digital output, whose configuration is provided via the subapplication’s data inputs Output_UP and Output_DOWN.

The internal data connections directly assign the subapplication data inputs to the respective QXA block’s Output parameter, while the adapter connections carry the signal flow from the input through the unbundler and to the two QXA outputs.

Initialization is passed through the event chain INIT → DigitalOutput_UP.INIT, DigitalOutput_UP.INITO → DigitalOutput_DOWN.INIT, DigitalOutput_DOWN.INITO → INITO. QI is forwarded to the QI inputs of both QXA blocks. The QO outputs of both QXA blocks are combined by the AND_QO block (type iec61131::booleanOperators::AND_BOOL_2) and output as QO; AND_QO is triggered via REQ by DigitalOutput_DOWN.INITO.

Technical Features

- **Composite encapsulation**: All unbundling and output-driving logic is contained within the subapplication, simplifying the upper-level resource design.
- **Modularity**: The subapplication can be reused wherever a single A2X input must control two separate physical outputs (e.g., a forward/reverse motor drive).
- **Initialization events only**: Apart from `INIT`/`INITO` there are no events; signal processing operates purely on data and adapter connections, which keeps the interface simple and suitable for cyclic or continuous processing.
- **Aggregated status**: `QO` is the AND (`AND_QO`) of the `QO` outputs of `DigitalOutput_UP` and `DigitalOutput_DOWN`.
- **Parameterization**: The QXA function blocks receive their `QI` input from the subapplication's `QI` input (initial value `TRUE`).
- **Type compatibility**: Uses standard 4diac adapter types (`adapter::types::unidirectional::A2X` and `adapter::conversion::unidirectional::A2X_2X_TO_2AX`) and logicBUS I/O types.

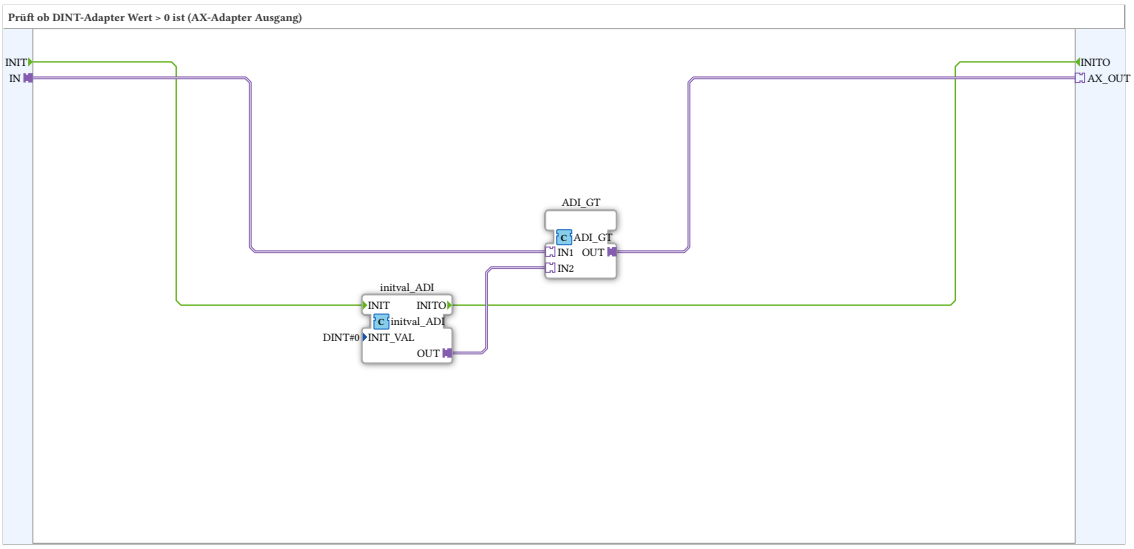
State Overview

The subapplication itself does not maintain any internal state. The state behavior is entirely determined by the underlying QXA output blocks and the conversion adapter. No explicit state machine is defined in this composite.

Application Scenarios

- **Motor control**: When a single control signal (e.g., from a PLC) provides a direction command (UP/DOWN), the subapplication distributes the command to separate output channels for forward and reverse operation.
- **Actuator redundancy**: In systems where two independent physical outputs are required for the same logical signal (e.g., for safety or redundancy), this block provides a clean separation.
- **Interface adaptation**: When a device has a bundled A2X interface but the physical actuators require individual AX signals, this subapplication bridges the gap without additional glue logic.

Comparison with Similar Blocks

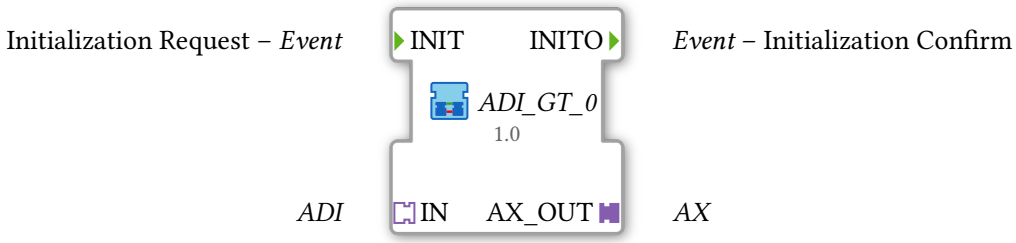


Compared to a direct wiring of the A2X signal to two QXA outputs, this subapplication encapsulates the unbundling step. Other possible approaches:

- **Direct use of `A2X_2X_TO_2AX`**: This would require the developer to manually instantiate the conversion adapter and connect the outputs to QXA blocks in the resource. The `A2X_TO_QXA2` subapplication simplifies this by pre-configuring the connections and parameter values.
- **Similar subapplications**: If other subapplications exist for different unbundling ratios (e.g., A2X to two separate AX outputs), they would differ in the number of outputs and the internal mapping. This specific variant is optimized for two independent physical outputs.

Conclusion

The `A2X_TO_QXA2` subapplication provides a clear, reusable solution for splitting a bundled A2X signal into two physical logicBUS digital outputs. Its composite nature keeps the device resource clean and promotes system modularity. With only initialization events and straightforward data/adapter connections, it integrates easily into control applications that require directional output separation.



ADI_GT_0

• – ◦ • – ◦ • – ◦ •

Introduction

`ADI_GT_0` checks whether a DINT adapter value is greater than 0 and outputs the result as a boolean AX adapter signal. A typical input is a signed 32-bit value. The block is built identically for every numeric type (`AS`, `AI`, `ADI`, `ALI`, `AUS`, `AUI`, `AUDI`, `AULI`, `AR`, `ALR`).

Interface

- **Event input**: `INIT` (initialization)
- **Event output**: `INITO` (initialization finished, comes from the internal `initval_ADI`)
- **Socket**: `IN` (`ADI`) — the value compared against 0
- **Plug**: `AX_OUT` (`AX`) — TRUE when `IN > 0`

Function Blocks (FBs) Used

Sub-blocks: ADI_GT_0

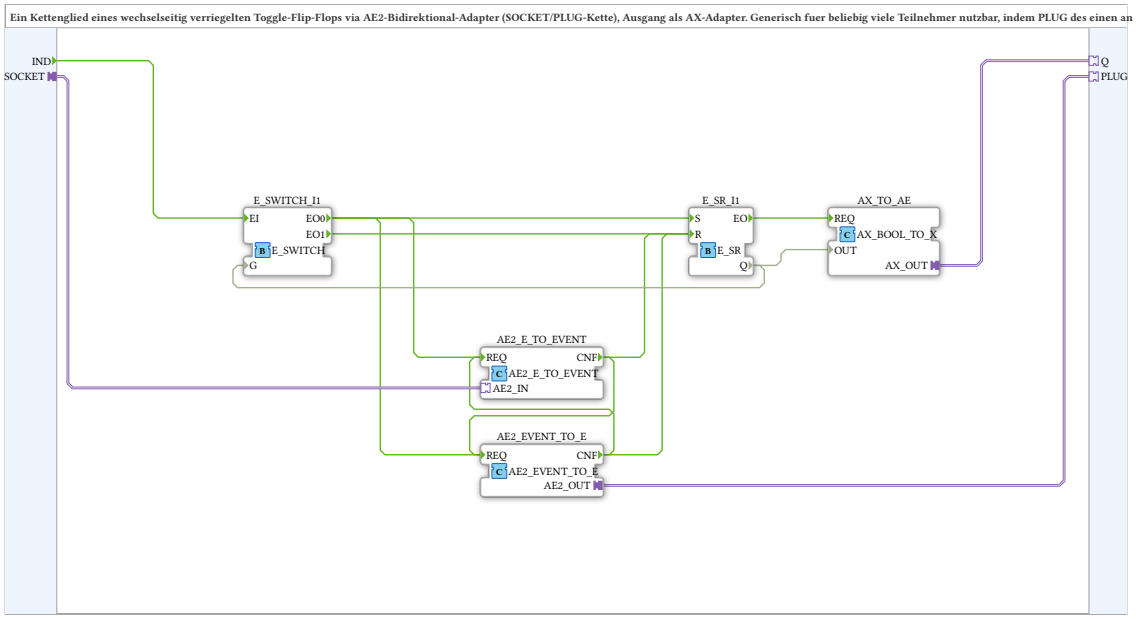
- **Type**: SubAppType
- **Internal FBs used**:
  - **initval_ADI**: `adapter::types::unidirectional::ADI::initval::initval_ADI` — supplies the fixed comparison constant `DINT#0` as an adapter value (`INIT_VAL=DINT#0`). An adapter socket cannot take the constant as a parameter, so it is fed in through this block.
  - **ADI_GT**: `adapter::iec61131::comparison::ADI_GT` — adapter-native comparison `IN1 > IN2`.
- **Functionality**: `IN` ⟶ `ADI_GT.IN1`; constant 0 ⟶ `ADI_GT.IN2`; result ⟶ `AX_OUT`.

Program Flow and Connections

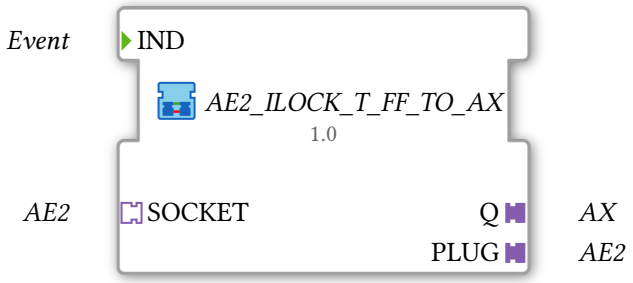
1. `INIT` ⟶ `initval_ADI.INIT`; `initval_ADI.INITO` ⟶ `INITO`.
2. `IN` (adapter) ⟶ `ADI_GT.IN1`.
3. `initval_ADI.OUT` (constant `DINT#0`) ⟶ `ADI_GT.IN2`.
4. `ADI_GT.OUT` ⟶ `AX_OUT` (adapter).

Application Scenarios

- Converting a signed 32-bit value into a simple boolean adapter signal for VT status displays or enable logic.



Summary



`ADI_GT_0` is a compact wrapper around the adapter-native comparison `ADI_GT` — converts “DINT > 0” directly into an AX adapter signal, so the caller does not have to create and wire the zero constant itself.

AE2_ILOCK_T_FF_TO_AX

• – ○ • – ○ • – ○ •

Introduction

`AE2_ILOCK_T_FF_TO_AX` is a reusable subapplication that implements a single link of a **mutually interlocked toggle flip-flop chain**. It is designed to be used in a network where multiple instances are connected in series via standard bidirectional AE2 adapters. The subapp guarantees that at any time only one output in the entire chain is active. A click (event) on the local input toggles the state of that link, while simultaneously forcing all other links to become inactive through a propagating reset signal sent along the chain.

The block is generic and can be used for any number of participants. It provides an AX adapter as the output interface, making it compatible with unidirectional adapter consumers.

Interface Structure

Event Inputs

Name	Type	Description
IND	Event	Toggle trigger. When a rising edge occurs, the internal state changes (set if currently inactive, reset if currently active), and the reset signal is sent to neighboring links.

Event Outputs

The subapplication has **no dedicated event output** interfaces. All communication with other links is performed via the AE2 adapters.

**Data Inputs

There are **no direct data inputs** exposed to the user. The internal logic relies solely on the event input and the data carried by the AE2 adapters.

**Data Outputs

There are **no direct data outputs**. The result is available via the Q adapter (AX type), which carries a boolean value.

Adapters

Name	Type	Direction	Purpose
SOCKET	AE2 (bidirectional)	Socket (input side)	Receives reset signals from the previous link in the chain.
PLUG	AE2 (bidirectional)	Plug (output side)	Sends reset signals to the next link in the chain.
Q	AX (unidirectional)	Plug (output side)	Provides the current state as a boolean value (true = active, false = inactive).

Functionality

The subapp implements a **toggle flip-flop with mutual exclusion**. Its internal network consists of:

- An E_SR set/reset flip-flop storing the current state.
- An E_SWITCH that routes the incoming IND event based on the current state.
- Two bidirectional adapter-conversion blocks (AE2_EVENT_TO_E and AE2_E_TO_EVENT) that translate between regular events and AE2 adapter events.
- A unidirectional converter (AX_BOOL_TO_X) that maps the internal boolean state to the output adapter Q.

Operation:

1. **Toggle action:** When an IND event arrives, E_SWITCH checks the current state Q.
   - If Q = false (inactive), the event is routed to the S (set) input of E_SR, causing the state to become active. Simultaneously, an event is sent to the AE2_EVENT_TO_E block, which emits a reset signal on the PLUG adapter.
   - If Q = true (active), the event is routed to the R (reset) input of E_SR, causing the state to become inactive. No reset signal is propagated in this case.
2. **Interlock propagation:** When a reset signal is received from the previous link via the SOCKET adapter, the AE2_E_TO_EVENT block converts it to a regular event. This event resets the local E_SR (forcing Q to false) and also sends a new event to AE2_EVENT_TO_E, which forwards the reset signal to the next link via PLUG. Thus the reset propagates down the chain, ensuring all other links become inactive.
3. **Output:** The internal state Q is directly fed to the AX_BOOL_TO_X converter, which produces the boolean value on the Q adapter.

The combination of the toggle action and the reset propagation guarantees that after any IND event, exactly one link in the chain is active – the link that received the event (if it was inactive) – and all others are reset.

Technical Features

- **Modularity:** The subapp is designed as a self-contained chain element. Multiple instances can be connected by linking `PLUG` of one to `SOCKET` of the next.
- **Synchronisation:** The AE2 adapter conversions handle event propagation with minimal delay, and the internal SR flip-flop ensures state stability.
- **Scalability:** The chain length is unlimited; the propagation delay grows linearly with the number of elements, but the interlock logic remains correct.
- **Output compatibility:** The `AX` output allows direct connection to unidirectional consumers (e.g., indicators, control words) without additional conversion.
- **Event-driven:** All operations are triggered by events; no cyclic polling is required.

State Overview

The subapp has two distinct states:

State	`Q` value	Description
Inactive	`false`	The link is not active. An incoming `IND` event will toggle it to active and propagate a reset signal.
Active	`true`	The link is the only active one in the chain. An incoming `IND` event toggles it back to inactive.

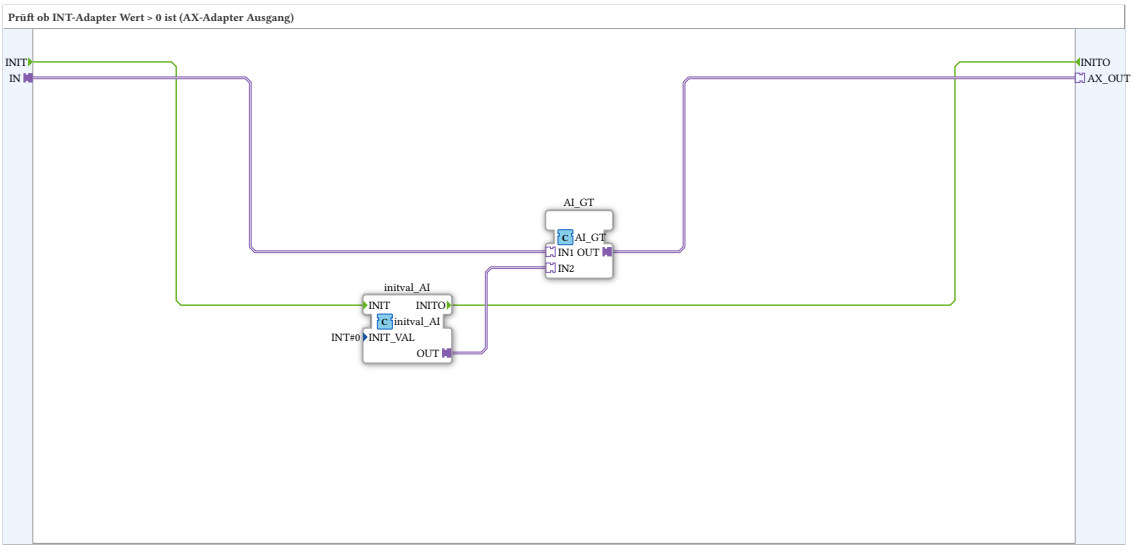
Transitions:

- **Inactive → Active:** Triggered by `IND` when `Q = false`.
- **Active → Inactive:** Triggered by `IND` when `Q = true`, or by a reset signal received from the chain (via `SOCKET`).

Internal reset signals do not change the state if the link is already inactive; they are simply forwarded.

Application Scenarios

- **Exclusive mode selection:** A set of mutually exclusive operating modes in a machine. Each mode is represented by one subapp instance; clicking a button selects the corresponding mode and deactivates all others.
- **Priority-free resource allocation:** A group of clients that must share a single resource. The first client that requests the resource gets it, and all others are automatically denied.
- **Single-active workflow steps:** A sequence of steps in a production system where only one step may run at a time, with manual triggering to advance.

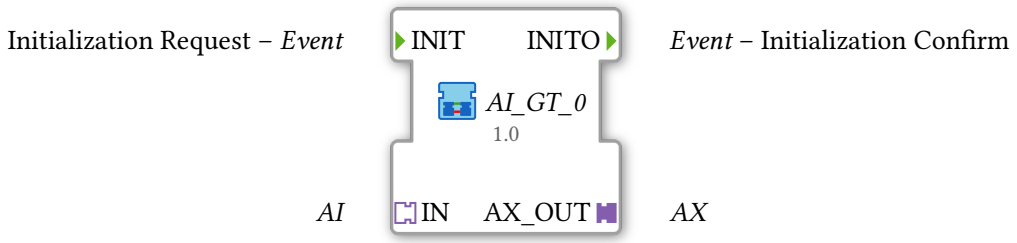


Comparison with Similar Blocks

- **Standard Toggle Flip-Flop (`E_T`):** A simple toggle changes state on every event but has no interlock capability. Multiple toggles can be active simultaneously.
- **Independent SR Latches:** Without a chain, each latch would need explicit external logic to enforce mutual exclusion. This subapp encapsulates the necessary interlock in a reusable and scalable manner.
- **Centralised Arbiter:** A central arbiter could be used, but it would require additional wiring and a different communication pattern. `AE2_ILOCK_T_FF_TO_AX` provides a decentralised solution with a simple daisy-chain topology.

Conclusion

`AE2_ILOCK_T_FF_TO_AX` is a compact and reusable subapplication that provides toggling behaviour with guaranteed mutual exclusion. Its chain-based design automatically propagates resets, making it suitable for any number of participants without additional logic. The use of standard AE2 adapters ensures easy integration into IEC 61499 systems, and the AX output simplifies connection to ordinary boolean consumers. This block is ideal for scenarios where a single active state among many must be maintained with minimal wiring and high reliability.



AI_GT_0

• – ○ • – ○ • – ○ •

Introduction

`AI_GT_0` checks whether a INT adapter value is greater than 0 and outputs the result as a boolean AX adapter signal. A typical input is a signed 16-bit value. The block is built identically for every numeric type (`AS`, `AI`, `ADI`, `ALI`, `AUS`, `AUI`, `AUDI`, `AULI`, `AR`, `ALR`).

Interface

- **Event input**: `INIT` (initialization)
- **Event output**: `INITO` (initialization finished, comes from the internal `initval_AI`)
- **Socket**: `IN` (`AI`) — the value compared against 0
- **Plug**: `AX_OUT` (`AX`) — TRUE when `IN > 0`

Function Blocks (FBs) Used

Sub-blocks: AI_GT_0

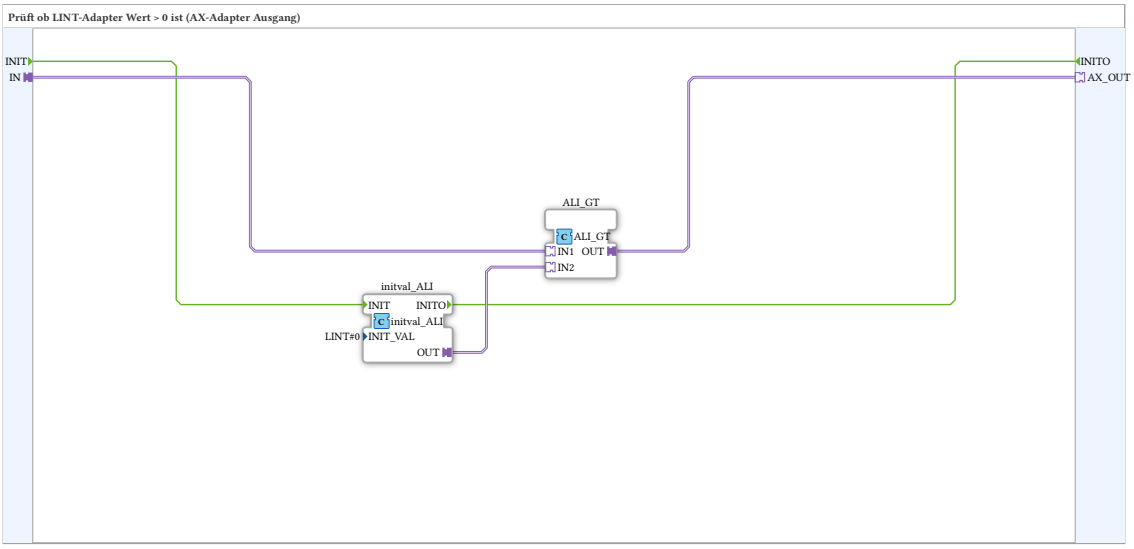
- **Type**: SubAppType
- **Internal FBs used**:
  - **initval_AI**: `adapter::types::unidirectional::AI::initval::initval_AI` — supplies the fixed comparison constant `INT#0` as an adapter value (`INIT_VAL=INT#0`). An adapter socket cannot take the constant as a parameter, so it is fed in through this block.
  - **AI_GT**: `adapter::iec61131::comparison::AI_GT` — adapter-native comparison `IN1 > IN2`.
- **Functionality**: `IN` ⟶ `AI_GT.IN1`; constant 0 ⟶ `AI_GT.IN2`; result ⟶ `AX_OUT`.

Program Flow and Connections

1. `INIT` ⟶ `initval_AI.INIT`; `initval_AI.INITO` ⟶ `INITO`.
2. `IN` (adapter) ⟶ `AI_GT.IN1`.
3. `initval_AI.OUT` (constant `INT#0`) ⟶ `AI_GT.IN2`.
4. `AI_GT.OUT` ⟶ `AX_OUT` (adapter).

Application Scenarios

- Converting a signed 16-bit value into a simple boolean adapter signal for VT status displays or enable logic.



Summary

`AI_GT_0` is a compact wrapper around the adapter-native comparison `AI_GT` — converts "INT > 0" directly into an AX adapter signal, so the caller does not have to create and wire the zero constant itself.

ALI_GT_0

• – ○ • – ○ • – ○ •

Introduction

`ALI_GT_0` checks whether a LINT adapter value is greater than 0 and outputs the result as a boolean AX adapter signal. A typical input is a signed 64-bit value. The block is built identically for every numeric type (`AS`, `AI`, `ADI`, `ALI`, `AUS`, `AUI`, `AUDI`, `AULI`, `AR`, `ALR`).

Interface

- **Event input**: `INIT` (initialization)
- **Event output**: `INITO` (initialization finished, comes from the internal `initval_ALI`)
- **Socket**: `IN` (`ALI`) — the value compared against 0
- **Plug**: `AX_OUT` (`AX`) — TRUE when `IN > 0`

Function Blocks (FBs) Used

Sub-blocks: ALI_GT_0

- **Type**: SubAppType
- **Internal FBs used**:

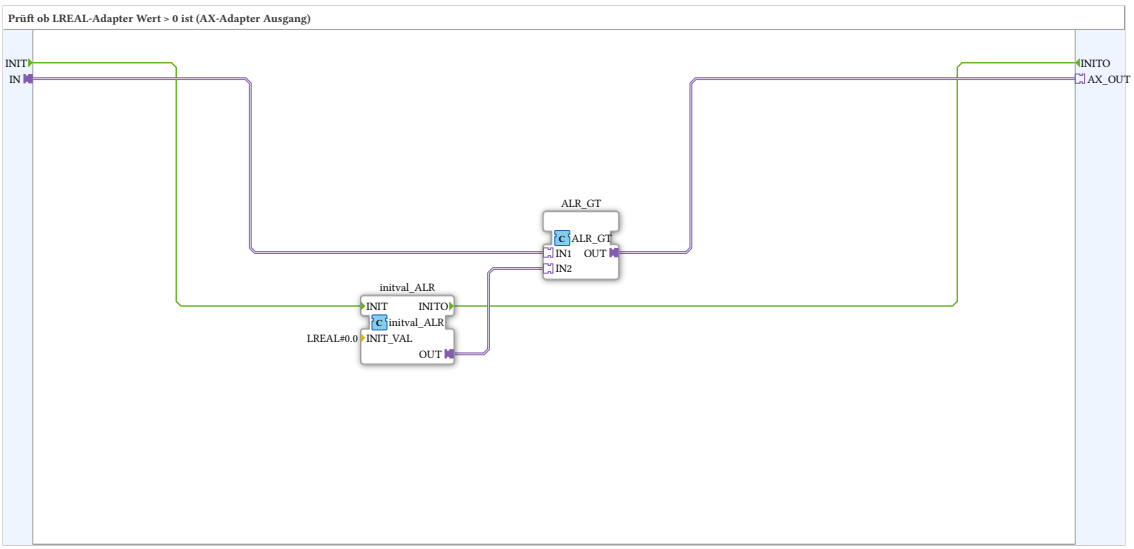
  - **initval_ALI**: `adapter::types::unidirectional::ALI::initval::initval_ALI` — supplies the fixed comparison constant `LINT#0` as an adapter value (`INIT_VAL=LINT#0`). An adapter socket cannot take the constant as a parameter, so it is fed in through this block.
  - **ALI_GT**: `adapter::iec61131::comparison::ALI_GT` — adapter-native comparison `IN1 > IN2`.
- **Functionality**: `IN` ⟶ `ALI_GT.IN1`; constant 0 ⟶ `ALI_GT.IN2`; result ⟶ `AX_OUT`.

Program Flow and Connections

1. `INIT` ⟶ `initval_ALI.INIT`; `initval_ALI.INITO` ⟶ `INITO`.
2. `IN` (adapter) ⟶ `ALI_GT.IN1`.
3. `initval_ALI.OUT` (constant `LINT#0`) ⟶ `ALI_GT.IN2`.
4. `ALI_GT.OUT` ⟶ `AX_OUT` (adapter).

Application Scenarios

- Converting a signed 64-bit value into a simple boolean adapter signal for VT status displays or enable logic.



Summary

`ALI_GT_0` is a compact wrapper around the adapter-native comparison `ALI_GT` — converts "LINT > 0" directly into an AX adapter signal, so the caller does not have to create and wire the zero constant itself.

ALR_GT_0

• – ○ • – ○ • – ○ •

Introduction

`ALR_GT_0` checks whether a LREAL adapter value is greater than 0 and outputs the result as a boolean AX adapter signal. A typical input is a floating-point value (LREAL). The block is built identically for every numeric type (`AS`, `AI`, `ADI`, `ALI`, `AUS`, `AUI`, `AUDI`, `AULI`, `AR`, `ALR`).

Interface

- **Event input**: `INIT` (initialization)
- **Event output**: `INITO` (initialization finished, comes from the internal `initval_ALR`)
- **Socket**: `IN` (`ALR`) — the value compared against 0
- **Plug**: `AX_OUT` (`AX`) — TRUE when `IN > 0`

Function Blocks (FBs) Used

Sub-blocks: ALR_GT_0

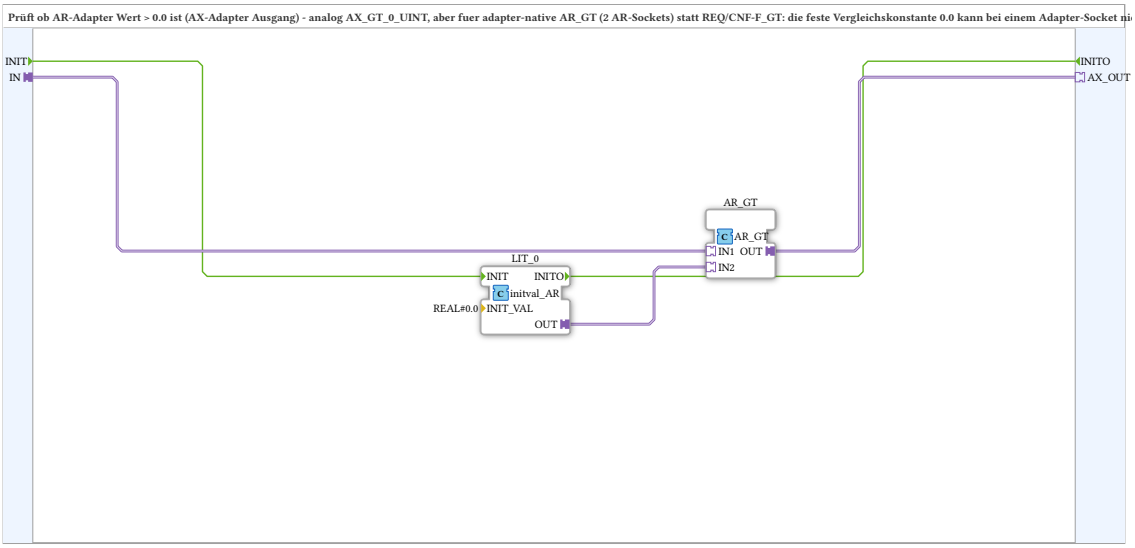
- **Type**: SubAppType
- **Internal FBs used**:
  - **initval_ALR**: `adapter::types::unidirectional::ALR::initval::initval_ALR` — supplies the fixed comparison constant `LREAL#0.0` as an adapter value (`INIT_VAL=LREAL#0.0`). An adapter socket cannot take the constant as a parameter, so it is fed in through this block.
  - **ALR_GT**: `adapter::iec61131::comparison::ALR_GT` — adapter-native comparison `IN1 > IN2`.
- **Functionality**: `IN` ⟶ `ALR_GT.IN1`; constant 0 ⟶ `ALR_GT.IN2`; result ⟶ `AX_OUT`.

Program Flow and Connections

1. `INIT` ⟶ `initval_ALR.INIT`; `initval_ALR.INITO` ⟶ `INITO`.
2. `IN` (adapter) ⟶ `ALR_GT.IN1`.
3. `initval_ALR.OUT` (constant `LREAL#0.0`) ⟶ `ALR_GT.IN2`.
4. `ALR_GT.OUT` ⟶ `AX_OUT` (adapter).

Application Scenarios

- Converting a floating-point value (LREAL) into a simple boolean adapter signal for VT status displays or enable logic.



Summary

`ALR_GT_0` is a compact wrapper around the adapter-native comparison `ALR_GT` — converts "LREAL > 0" directly into an AX adapter signal, so the caller does not have to create and wire the zero constant itself.

AR_GT_0

• – ◦ • – ◦ • – ◦ •

Introduction

AR_GT_0 checks whether a REAL adapter value is greater than 0 and outputs the result as a boolean AX adapter signal. A typical input is a floating-point value (REAL), e.g. a speed. The block is built identically for every numeric type (AS, AI, ADI, ALI, AUS, AUI, AUDI, AULI, AR, ALR).

Interface

- **Event input**: INIT (initialization)
- **Event output**: INITO (initialization finished, comes from the internal LIT_0)
- **Socket**: IN (AR) — the value compared against 0
- **Plug**: AX_OUT (AX) — TRUE when IN > 0

Function Blocks (FBs) Used

Sub-blocks: AR_GT_0

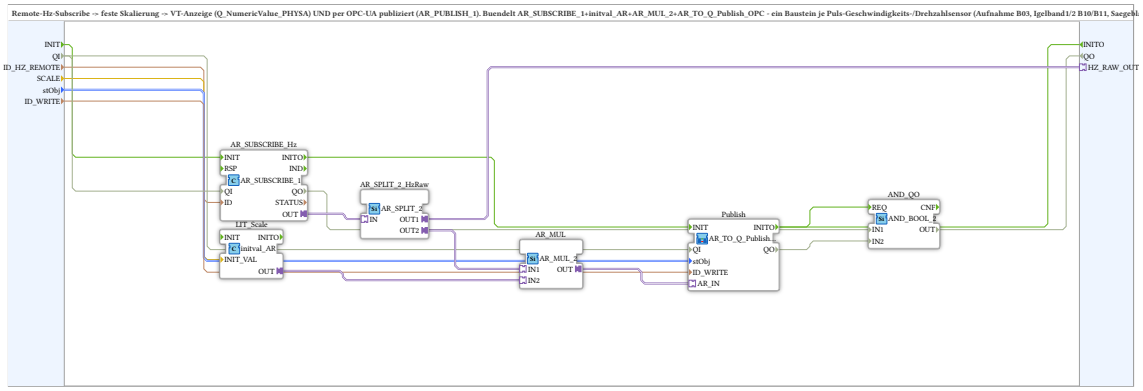
- **Type**: SubAppType
- **Internal FBs used**:
  - **LIT_0**: adapter::types::unidirectional::AR::initval::initval_AR — supplies the fixed comparison constant 0.0 as an adapter value (INIT_VAL=0.0). An adapter socket cannot take the constant as a parameter, so it is fed in through this block.
  - **AR_GT**: adapter::iec61131::comparison::AR_GT — adapter-native comparison IN1 > IN2.
- **Functionality**: IN ⟶ AR_GT.IN1; constant 0 ⟶ AR_GT.IN2; result ⟶ AX_OUT.

Program Flow and Connections

1. INIT ⟶ LIT_0.INIT; LIT_0.INITO ⟶ INITO.
2. IN (adapter) ⟶ AR_GT.IN1.
3. LIT_0.OUT (constant 0.0) ⟶ AR_GT.IN2.
4. AR_GT.OUT ⟶ AX_OUT (adapter).

Application Scenarios

- Converting a floating-point value (REAL), e.g. a speed into a simple boolean adapter signal for VT status displays or enable logic.



Summary

AR_GT_0 is a compact wrapper around the adapter-native comparison AR_GT — converts "REAL > 0" directly into an AX adapter signal, so the caller does not have to create and wire the zero constant itself.

AR_HZ_TO_Q_Publish_OPC

• – ○ • – ○ • – ○ •

Introduction

`AR_HZ_TO_Q_Publish_OPC` bundles the chain **remote subscribe of a frequency (Hz) → fixed scaling → VT display (`Q_NumericValue_PHYSA`) and OPC-UA publish** into one reusable SubApp. It combines `AR_SUBSCRIBE_1`, `initval_AR`, `AR_MUL_2` and `AR_TO_Q_Publish_OPC` - one block per pulse speed/rotation sensor (pickup B03, hedgehog belt 1/2 B10/B11, saw blade B08), only the parameters differ. It was extracted from `Inputs_STG1.SUB`, where four nearly identical chains existed.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; starts the initialization chain (`AR_SUBSCRIBE_Hz` → `Publish`)

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `Publish.INITO` after the chain has completed

Data Inputs

- **QI** (`BOOL`): quality input, service enable (initial value `TRUE`), passed on to `AR_SUBSCRIBE_Hz.QI` and `Publish.QI`
- **ID_HZ_REMOTE** (`WSTRING`): Remote subscribe address of the published frequency (Hz), e.g. `FBs::Ventilsteuerung::Venti`
- **SCALE** (`REAL`): Scale factor Hz → physical unit (e.g. `3.6/53` for km/h, `60.0` for rpm at 1 pulse/revolution)
- **stObj** (`logiBUS::utils::conversion::phys::NumericObjectPool_S`): Object pool properties of the VT numeric variable (`u16ObjId`, `scale`, `offset`, `decimals`), e.g. `FBs::const::DefaultPool_Numeric::NumberVariable_X_N`
- **ID_WRITE** (`WSTRING`): Local publish address (REAL, physical value) for web mirror/dashboard/self-subscribe

Data Outputs

- **QO** (`BOOL`): quality output, `AND` of the `QO` outputs of `AR_SUBSCRIBE_Hz` and `Publish` (via `AND_QO`)

Adapters

- **HZ_RAW_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::AR` - optional read-only mirror of the still unscaled raw value (Hz) before the `SCALE` multiplication. Leave unconnected if not needed.

Function Blocks (FBs) Used

- **AR_SUBSCRIBE_Hz**: `adapter::net::AR_SUBSCRIBE_1` (`QI` comes from the SubApp interface), subscribes to the remote address `ID_HZ_REMOTE`
- **LIT_Scale**: `adapter::types::unidirectional::AR::initval::initval_AR`, provides `SCALE` as an AR value

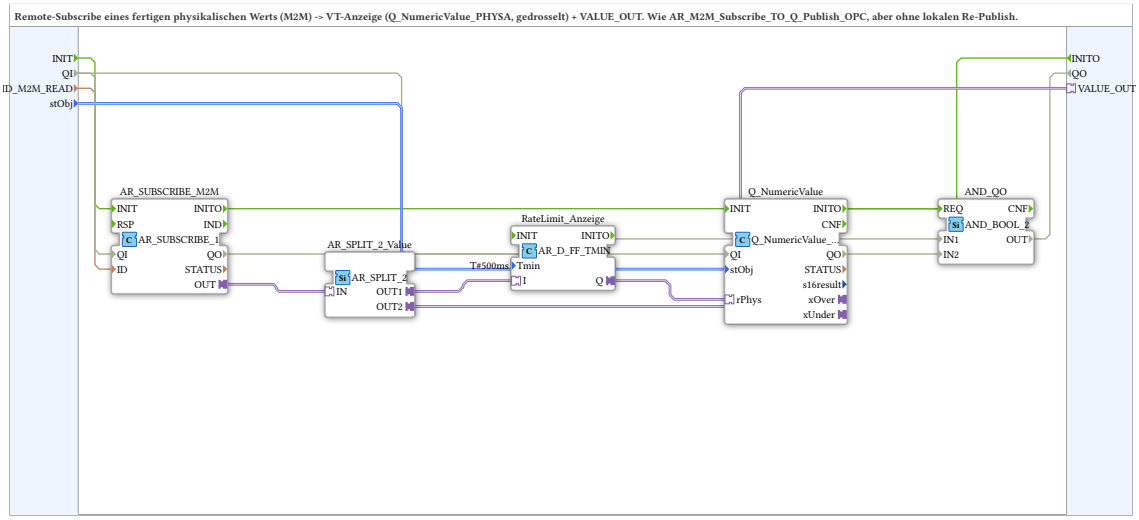
- **AR_SPLIT_2_HzRaw**: `adapter::events::unidirectional::AR_SPLIT_2`, branches the raw value
- **AR_MUL**: `adapter::iec61131::arithmetic::AR_MUL_2`, multiplies the raw value by `SCALE`
- **Publish**: SubApp `MyLib::sys::AR_TO_Q_Publish_OPC`, shows the value on the VT (`stObj`) and publishes it via OPC-UA (`ID_WRITE`)
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2`, combines the `QO` outputs of `AR_SUBSCRIBE_Hz` and `Publish` into the SubApp output `QO`

Program Flow and Connections

1. `ID_HZ_REMOTE` ⟶ `AR_SUBSCRIBE_Hz.ID`; the output `AR_SUBSCRIBE_Hz.OUT` leads to `AR_SPLIT_2_HzRaw.IN`.
2. `AR_SPLIT_2_HzRaw.OUT1` ⟶ plug `HZ_RAW_OUT` (unscaled raw value, optional).
3. `AR_SPLIT_2_HzRaw.OUT2` ⟶ `AR_MUL.IN1`; `SCALE` ⟶ `LIT_Scale.INIT_VAL`, `LIT_Scale.OUT` ⟶ `AR_MUL.IN2`.
4. `AR_MUL.OUT` ⟶ `Publish.AR_IN`.
5. `stObj` ⟶ `Publish.stObj`, `ID_WRITE` ⟶ `Publish.ID_WRITE`.
6. Initialization: `INIT` ⟶ `AR_SUBSCRIBE_Hz.INIT`; `AR_SUBSCRIBE_Hz.INITO` ⟶ `Publish.INIT`; `Publish.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`.
7. Quality: `QI` ⟶ `AR_SUBSCRIBE_Hz.QI` and `Publish.QI`; `AR_SUBSCRIBE_Hz.QO` ⟶ `AND_QO.IN1`, `Publish.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.

Technical Details

- **`HZ_RAW_OUT` (version 1.1)**: The optional plug mirrors the raw value (Hz) for a diagnostic display without needing a second, independent remote subscribe of the same node (FORTE reports `Cannot add another one` on a duplicate self-subscribe).
- **INIT/INITO and QI/QO**: initialization is passed through the chain `INIT` ⟶ `AR_SUBSCRIBE_Hz` ⟶ `Publish` ⟶ `INITO`; `QO` is the `AND` of the `QO` outputs of both blocks.
- Pure wiring of existing blocks; apart from the `AND_QO` combination, no logic of its own.

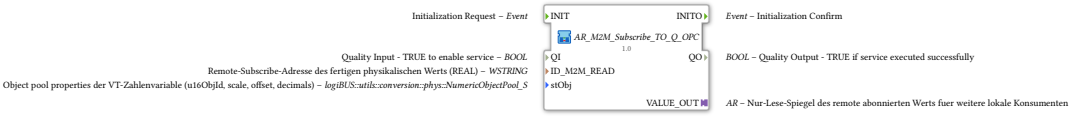


Application Scenarios

- Displaying and publishing speed or rotation from a pulse sensor frequency value (e.g. pickup, hedgehog belts, saw blade)

Summary

`AR_HZ_TO_Q_Publish_OPC` replaces the fourfold duplicated chain of subscribe, scaling and publish with a single parameterizable block.



AR_M2M_Subscribe_TO_Q_OPC

• – ○ • – ○ • – ○ •

Introduction

`AR_M2M_Subscribe_TO_Q_OPC` subscribes remotely (M2M) to a finished physical value (`REAL`) and shows it on the VT (`Q_NumericValue_PHYSA`, throttled to at most one update per 500 ms). The value is also available as a read-only mirror on the plug `VALUE_OUT` for further local consumers. The block corresponds to `AR_M2M_Subscribe_TO_Q_Publish_OPC`, but without local re-publish (no `ID_WRITE`) - the lean library variant.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; starts the chain `AR_SUBSCRIBE_M2M` ⟶ `Q_NumericValue`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `Q_NumericValue.INITO`

Data Inputs

Variable	Type	Default	Comment
`QI`	BOOL	TRUE	Quality input: enables the service; passed on to `AR_SUBSCRIBE_M2M` and `Q_NumericValue`.
`ID_M2M_READ`	WSTRING		Remote subscribe address of the finished physical value (`REAL`).
`stObj`	`logiBUS::utils::conversion::phys::NumericObjectPool_S`	`(u16ObjId := ID_NULL, r32Scale := 1.0, i32Offset := 0, u8Decimals := 0)`	Object pool properties of the VT number variable (`u16ObjId`, scale, offset, decimals).

Data Outputs

Variable	Type	Default	Comment
`QO`	BOOL		Quality output: AND of `AR_SUBSCRIBE_M2M.QO` and `Q_NumericValue.QO`.

Adapters

Adapter	Type	Direction	Comment
`VALUE_OUT`	`adapter::types::unidirectional::AR`	Plug	Read-only mirror of the remotely subscribed value for further local consumers (unthrottled).

Function Blocks (FBs) Used

- **AR_SUBSCRIBE_M2M** (`adapter::net::AR_SUBSCRIBE_1`): remote subscribe of the value
- **AR_SPLIT_2_Value** (`adapter::events::unidirectional::AR_SPLIT_2`): splits the value into the display branch and `VALUE_OUT`
- **RateLimit_Anzeige** (`adapter::events::unidirectional::AR_D_FF_TMIN`, `Tmin = T#500ms`): throttles only the VT display to at most one update per `Tmin`
- **Q_NumericValue** (`isobus::UT::Q::Q_NumericValue_PHYSA`): writes the value to the VT number variable
- **AND_QO** (`iec61131::booleanOperators::AND_BOOL_2`): combines the two `QO` outputs

Program Flow and Connections

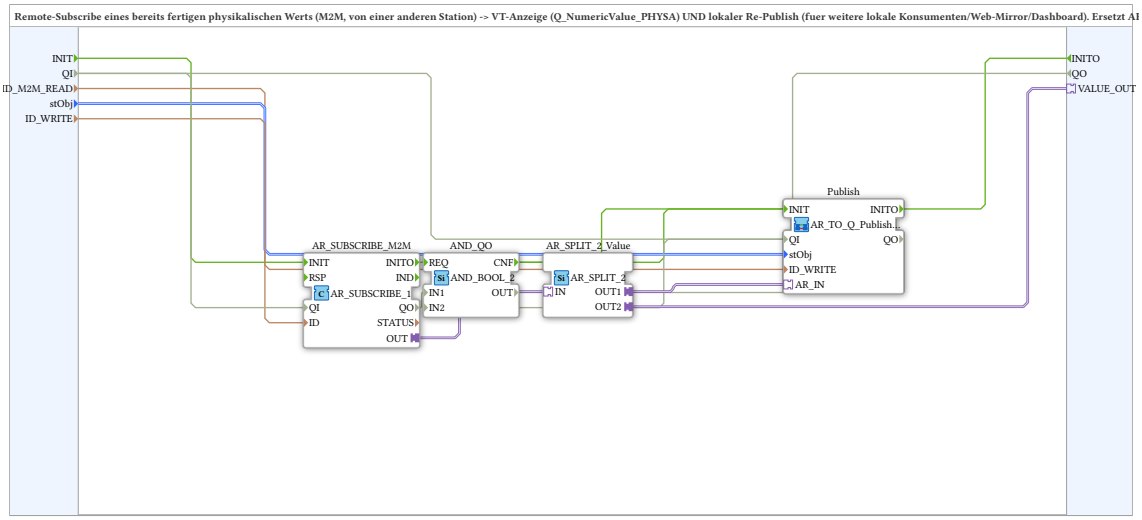
1. Initialization: `INIT` -> `AR_SUBSCRIBE_M2M.INIT`; `AR_SUBSCRIBE_M2M.INITO` -> `Q_NumericValue.INIT`; `Q_NumericValue.INITO` -> `INITO` and -> `AND_QO.REQ`.
2. Data: `ID_M2M_READ` -> `AR_SUBSCRIBE_M2M.ID`; `stObj` -> `Q_NumericValue.stObj`.
3. Quality: `QI` -> `AR_SUBSCRIBE_M2M.QI` and `Q_NumericValue.QI`; `AR_SUBSCRIBE_M2M.QO` -> `AND_QO.IN1`; `Q_NumericValue.QO` -> `AND_QO.IN2`; `AND_QO.OUT` -> `QO`.
4. Value path: `AR_SUBSCRIBE_M2M.OUT` -> `AR_SPLIT_2_Value.IN`.
5. Display branch: `AR_SPLIT_2_Value.OUT1` -> `RateLimit_Anzeige.I`; `RateLimit_Anzeige.Q` -> `Q_NumericValue.rPhys`.
6. Mirror branch: `AR_SPLIT_2_Value.OUT2` -> `VALUE_OUT`.

Technical Features

- The throttling (`T#500ms`) only acts on the display branch; `VALUE_OUT` remains unthrottled as in the original.
- Compared with `AR_M2M_Subscribe_TO_Q_Publish_OPC` the local publish and `ID_WRITE` are omitted.

Application Scenarios

- Displaying an already physically scaled value delivered by another station on the VT when no local re-publish is needed.
- Passing the subscribed value on via `VALUE_OUT` to further local consumers.



Summary

`AR_M2M_Subscribe_TO_Q_OPC` subscribes to a finished physical value remotely, shows it throttled on the VT and additionally provides it via `VALUE_OUT` - without local re-publish.

AR_M2M_Subscribe_TO_Q_Publish_OPC

• – ○ • – ○ • – ○ •

Introduction

`AR_M2M_Subscribe_TO_Q_Publish_OPC` subscribes to an already converted physical value (REAL) from another station via OPC-UA (M2M), shows it on the VT (`Q_NumericValue_PHYSA`) and republishes it locally so that further local consumers, web mirror or dashboard can read it. In addition, the value is available at the plug `VALUE_OUT` for local adapter consumers. The block is the lean successor of `AR_HZ_TO_Q_Publish_OPC` without its own scaling, because the Hz-to-unit conversion now runs on the sensor station (see `logiBUS_PI_Speed_Publish_OPC`).

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; passed on to `AR_SUBSCRIBE_M2M.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `Publish.INITO`

Data Inputs

- **QI** (BOOL, initial value `TRUE`): quality input, enables the service; passed on to `AR_SUBSCRIBE_M2M.QI` and `Publish.QI`
- **ID_M2M_READ** (WSTRING): remote subscribe address of the finished physical value (REAL), e.g. `FBs::Ventilsteuerung::`
- **stObj** (`logiBUS::utils::conversion::phys::NumericObjectPool_S`): object pool properties of the VT number variable (`u16ObjId`, scale, offset, decimals), e.g. `FBs::const::DefaultPool_Numeric::NumberVariable_X_N`
- **ID_WRITE** (WSTRING): local publish address (REAL, physical value) for web mirror, dashboard and self-subscribe of further local consumers

Data Outputs

- **QO** (BOOL): quality output, AND combination (`AND_QO`) of the `QO` outputs of `AR_SUBSCRIBE_M2M` and `Publish`

Adapters

- **VALUE_OUT** (plug, `adapter::types::unidirectional::AR`): read-only mirror of the remotely subscribed value for further local consumers; avoids a duplicate OPC-UA self-subscribe of the same remote node on this station

Functionality

The network consists of four parts:

- `AR_SUBSCRIBE_M2M` (`adapter::net::AR_SUBSCRIBE_1`, `QI` comes from the input `QI`): subscribes to the address `ID_M2M_READ` (`ID_M2M_READ` ⟶ `AR_SUBSCRIBE_M2M.ID`) and outputs the value as an AR adapter.
- `AR_SPLIT_2_Value` (`adapter::events::unidirectional::AR_SPLIT_2`): distributes the subscribed value to two destinations (`AR_SUBSCRIBE_M2M.OUT` ⟶ `AR_SPLIT_2_Value.IN`).
- `Publish` (`MyLib::sys::AR_TO_Q_Publish_OPC`): displays the value on the VT and publishes it locally (`AR_SPLIT_2_Value.OUT1` ⟶ `Publish.AR_IN`, `stObj` ⟶ `Publish.stObj`, `ID_WRITE` ⟶ `Publish.ID_WRITE`).
- `AND_QO` (`iec61131::booleanOperators::AND_BOOL_2`): combines `AR_SUBSCRIBE_M2M.QO` and `Publish.QO` into the output `QO`.

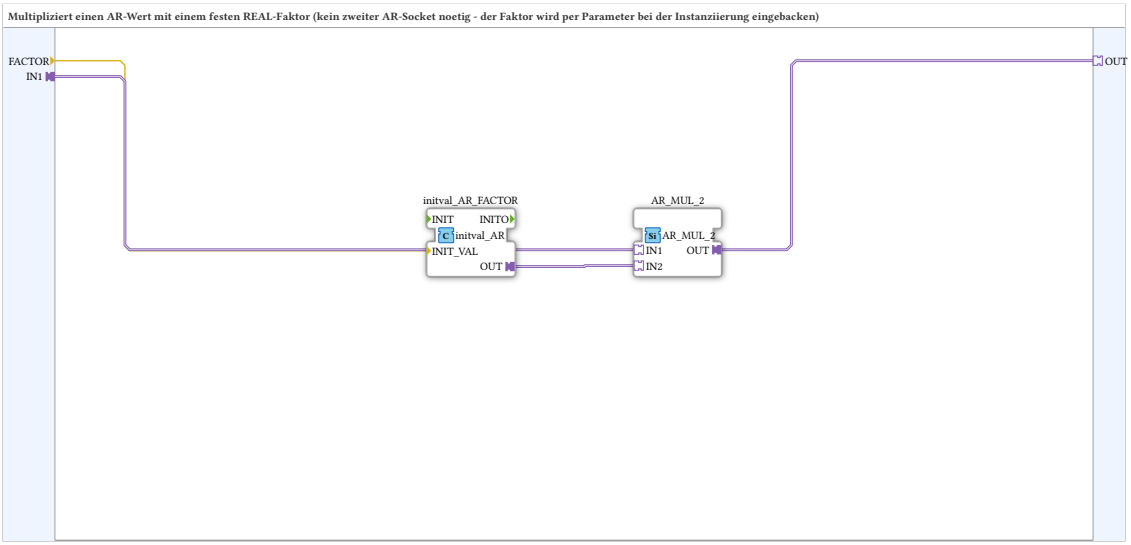
`AR_SPLIT_2_Value.OUT2` is routed to the plug `VALUE_OUT`.

Initialization and quality: `INIT` ⟶ `AR_SUBSCRIBE_M2M.INIT`, `AR_SUBSCRIBE_M2M.INITO` ⟶ `Publish.INIT`, `Publish.INITO` ⟶ `INITO` and `AND_QO.REQ`. `QI` is passed on to `AR_SUBSCRIBE_M2M.QI` and `Publish.QI`; `AR_SUBSCRIBE_M2M.QO` ⟶ `AND_QO.IN1`, `Publish.QO` ⟶ `AND_QO.IN2`, `AND_QO.OUT` ⟶ `QO`.

Technical Details

- No more `SCALE`/`AR_MUL_2`: the subscribed value is already in the physical unit
- The `AR_SPLIT_2` in front of `Publish.AR_IN` was inserted instead of wiring `AR_SUBSCRIBE_M2M.OUT` directly, so that an adapter is never branched without a split
- `VALUE_OUT` supplies the subscribed value to consumers such as automatic filling or filling belt detection without creating a second subscribe on the same remote node

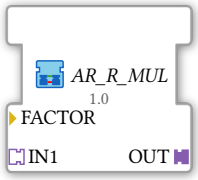
Application Scenarios



- Displaying a value measured by another station (e.g. speed) on the VT while making it available locally to dashboard and web client

- Passing the remote value on to local control or automation blocks via `VALUE_OUT`

Conclusion



The block bundles remote subscribe, VT display and local republish of a finished physical value into one SubApp and additionally provides the value as an AR plug.

AR_R_MUL

Fester Multiplikator, ueber Parameter bei der Instanziierung gesetzt – *REAL*

Zu skalierender Wert – *AR*

AR – IN1 x FACTOR

• – ◦ • – ◦ • – ◦ •

Introduction

The **AR_R_MUL** function block is a subapplication designed to multiply an AR (Analog/Real) value by a fixed REAL factor. Unlike a generic multiplier that requires two AR inputs, this block uses a constant factor that is set once during instantiation via the `FACTOR` parameter. This simplifies usage in scenarios where the multiplication factor is known ahead of time and does not need to be changed dynamically.

Interface Structure

The subapplication provides the following interface elements:

Event Inputs

None.

Event Outputs

None.

Data Inputs

Name	Type	Initial Value	Description
`FACTOR`	REAL	`REAL#1.0`	Fixed multiplier applied to the input AR value. This value is set as a parameter when the subapplication is instantiated.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Socket	IN1	adapter::types::unidirectional::AR	AR value to be scaled.
Plug	OUT	adapter::types::unidirectional::AR	Result of IN1 × FACTOR.

Functionality

The subapplication multiplies the AR value received at the IN1 socket by the constant FACTOR and provides the result at the OUT plug. Internally, the FACTOR data input is converted into a constant AR value using an initval_AR_FACTOR function block. This constant AR value is then used as the second operand in an AR_MUL_2 multiplication block, together with the incoming IN1 AR value. The product is forwarded to the output.

Since the factor is embedded as a parameter, the subapplication behaves like a fixed-gain amplifier for AR signals.

Technical Features

- **Parameter-driven constant**: The multiplication factor is defined once at design time via the FACTOR input, eliminating the need for a second dynamic AR source.
- **Reusability**: The subapplication encapsulates the initialization and multiplication logic, making the overall function easy to instantiate and maintain.
- **Type uniformity**: Both operands are AR type, ensuring compatibility with standard AR signal processing chains.
- **No event involvement**: The block operates purely on data and adapter connections; no event inputs or outputs are required.

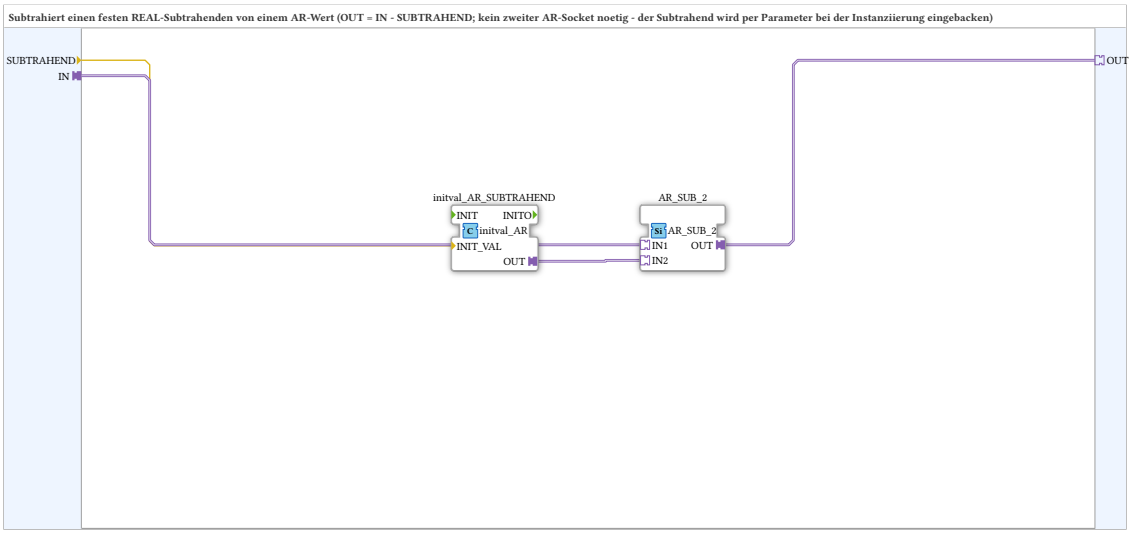
State Overview

The AR_R_MUL subapplication does not maintain any internal state. It processes data continuously: as soon as an AR value arrives at IN1, it is multiplied by the constant factor and the result is made available at OUT. The only relevant state is the fixed FACTOR value, which is set during instantiation and remains unchanged during runtime.

Application Scenarios

- **Sensor scaling**: Convert a raw analog measurement (e.g., 0–10 V) to an engineering unit by applying a fixed scale factor.
- **Unit conversion**: Multiply AR values by a constant to switch between units (e.g., meters to feet).
- **Signal conditioning**: Apply a constant gain to an AR signal for amplification or attenuation.
- **Static calibration**: Incorporate a fixed offset or gain correction in an existing AR processing chain.

Comparison with Similar Blocks

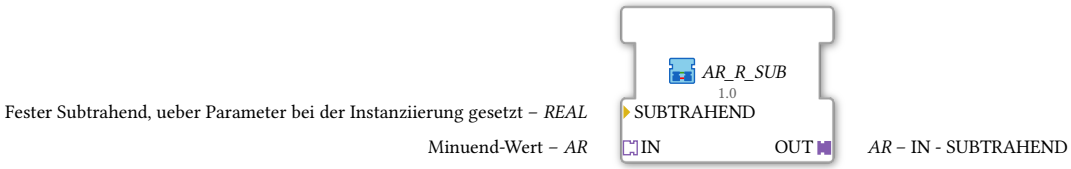


Block	Description	Key Difference
AR_R_MUL	Multiplies an AR value by a fixed REAL factor.	Only one AR input required; factor is static.
AR_MUL_2	Multiplies two AR values dynamically.	Requires two AR inputs; factor can vary at runtime.
AR_ADD_2	Adds two AR values.	Performs addition instead of multiplication.

The main advantage of AR_R_MUL over AR_MUL_2 is its simplicity when the multiplier is a constant – it saves the effort of creating and maintaining a separate constant source, and reduces wiring complexity.

Conclusion

AR_R_MUL provides a clean and efficient way to apply a fixed scaling factor to an AR signal. By embedding the factor as a parameter in the instantiation, it simplifies the design of control and measurement applications where a constant gain is required. Its straightforward interface and lack of event handling make it easy to integrate into larger 4diac systems.



AR_R_SUB

• – ◦ • – ◦ • – ◦ •

Introduction

`AR_R_SUB` is a SubApp that subtracts a fixed `REAL` subtrahend from an `AR` value (`OUT = IN - SUBTRAHEND`). The subtrahend is baked in as a parameter at instantiation, so no second `AR` socket has to be wired. It is the subtraction counterpart of `AR_R_MUL`.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

- **SUBTRAHEND** (`REAL`): Fixed subtrahend, set as a parameter at instantiation. Initial value `REAL#0.0`.

Data Outputs

None.

Adapters

- **IN** (socket, `adapter::types::unidirectional::AR`): minuend value
- **OUT** (plug, `adapter::types::unidirectional::AR`): `IN - SUBTRAHEND`

Function Blocks (FBs) Used

- **`initval_AR_SUBTRAHEND`** (`adapter::types::unidirectional::AR::initval::initval_AR`): creates a constant `AR` value from `SUBTRAHEND`
- **`AR_SUB_2`** (`adapter::iec61131::arithmetic::AR_SUB_2`): subtracts two `AR` values

Functionality

- `SUBTRAHEND` ⟶ `initval_AR_SUBTRAHEND.INIT_VAL`
- `IN` ⟶ `AR_SUB_2.IN1` (minuend)
- `initval_AR_SUBTRAHEND.OUT` ⟶ `AR_SUB_2.IN2` (subtrahend)

- `AR_SUB_2.OUT` ⟶ `OUT`

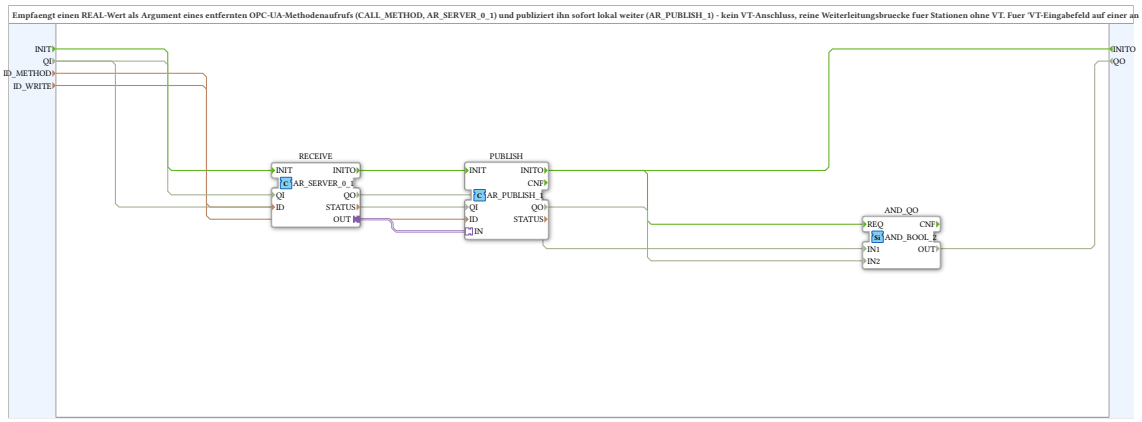
The block has no events of its own; the calculation follows the data flow of the `AR` adapter.

Technical Details

- No second `AR` socket needed, the subtrahend is baked into the instance
- No change of the subtrahend at runtime is intended
- Pure wiring of existing blocks, no logic of its own

Application Scenarios

- Subtracting a constant offset from a scaled or physical `AR` value



Summary

`AR_R_SUB` subtracts a fixed, parameterised `REAL` value from an `AR` signal.

AR_SERVER_0_1_TO_Publish_OPC

• — ○ • — ○ • — ○ •

Introduction

`AR_SERVER_0_1_TO_Publish_OPC` receives a `REAL` value as the argument of a remote OPC-UA method call (`AR_SERVER_0_1`) and immediately publishes it locally (`AR_PUBLISH_1`). The block has no VT connection and is a pure forwarding bridge for stations without a VT: a VT input field on another station or a web dashboard calls the same method - and only on real input. A typical example is pressure reference values (B20).

Function Blocks (FBs) Used

Sub-blocks: AR_SERVER_0_1_TO_Publish_OPC

- **Type**: SubAppType
- **Internal FBs used**:
  - **RECEIVE**: `adapter::net::AR_SERVER_0_1` (`QI` from outside) - creates the OPC-UA method and provides the received `REAL` argument on the adapter `OUT`
  - **PUBLISH**: `adapter::net::AR_PUBLISH_1` (`QI` from outside) - publishes the value under the local address
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` - combines the `QO` of `RECEIVE` and `PUBLISH`
- **Functionality**: The value from the method call is passed directly to the publisher without intermediate logic.

Interface Structure

Event Inputs

- **INIT** (EInit): initialization request; goes to RECEIVE.INIT

Event Outputs

- **INITO** (EInit): initialization confirm; comes from PUBLISH.INITO

Data Inputs

- **QI** (BOOL, default TRUE): Quality Input - TRUE enables the service; goes to RECEIVE.QI and PUBLISH.QI
- **ID_METHOD** (WSTRING): Locally created OPC-UA method (ACTION=CREATE_METHOD, 1 REAL argument) - callable from another station (AR_CLIENT_1_0) and/or directly from the OPC dashboard
- **ID_WRITE** (WSTRING): Local publish address (REAL, ACTION=PUBLISH) for the received value - typically read back by a local self-subscribe

Data Outputs

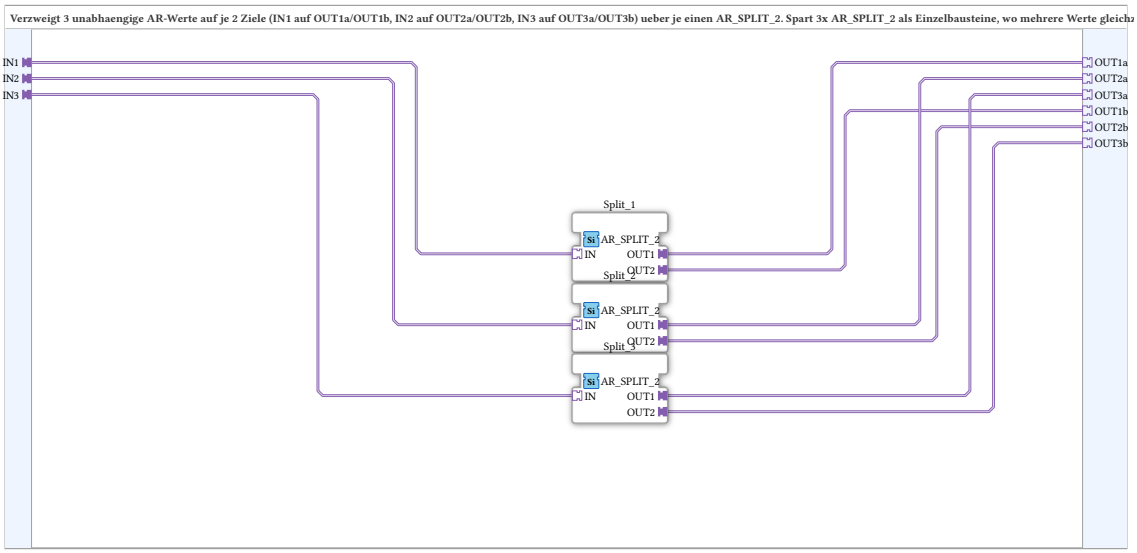
- **QO** (BOOL): Quality Output - TRUE if the service was executed successfully (AND of RECEIVE.QO and PUBLISH.QO)

Program Flow and Connections

- ID_METHOD ⟶ RECEIVE.ID
- ID_WRITE ⟶ PUBLISH.ID
- INIT ⟶ RECEIVE.INIT
- RECEIVE.INITO ⟶ PUBLISH.INIT (the publisher is initialised as soon as the method has been created)
- PUBLISH.INITO ⟶ INITO and ⟶ AND_QO.REQ
- QI ⟶ RECEIVE.QI and PUBLISH.QI
- RECEIVE.QO ⟶ AND_QO.IN1, PUBLISH.QO ⟶ AND_QO.IN2, AND_QO.OUT ⟶ QO
- RECEIVE.OUT ⟶ PUBLISH.IN (adapter connection of the REAL value)

Technical Details

- No VT connection: intended for sensor stations without their own VT (e.g. STG4) that should nevertheless accept editable reference values from another station (VT) or from the dashboard
- The method is called only on real input, there is no cyclic synchronisation
- Version 1.0 (2026-09-23): bundles AR_SERVER_0_1 (receive) and AR_PUBLISH_1 (local forwarding)

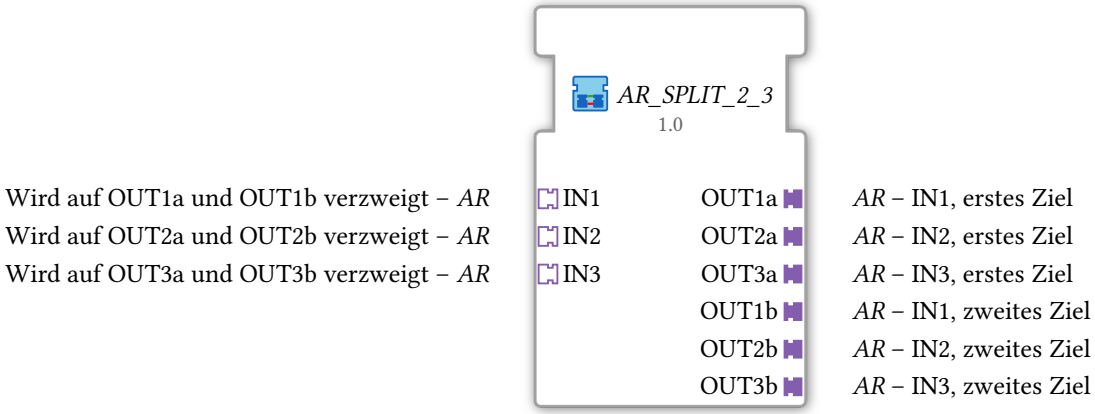


Application Scenarios

- Pressure reference values (B20) of a station without a VT, set by another station or by the web dashboard
- In general: accepting a REAL setpoint via an OPC-UA method call and providing it locally as a publish value

Summary

AR_SERVER_0_1_TO_Publish_OPC encapsulates AR_SERVER_0_1 and AR_PUBLISH_1 into a forwarding bridge that publishes a REAL value received via an OPC-UA method locally.



AR_SPLIT_2_3

• – ○ • – ○ • – ○ •

Introduction

`AR_SPLIT_2_3` branches **three independent AR values** onto two targets each (`IN1` ⟶ `OUT1a`/`OUT1b`, `IN2` ⟶ `OUT2a`/`OUT2b`, `IN3` ⟶ `OUT3a`/`OUT3b`) using one `AR_SPLIT_2` each. It saves three individual `AR_SPLIT_2` blocks wherever several values must be distributed simultaneously to two independent consumers (e.g. threshold/dead band/hysteresis to control logic and to position/display logic, as in the automatic filling).

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

All adapters are unidirectional of type `adapter::types::unidirectional::AR`.

- **IN1** (socket): branched to `OUT1a` and `OUT1b`
- **IN2** (socket): branched to `OUT2a` and `OUT2b`
- **IN3** (socket): branched to `OUT3a` and `OUT3b`
- **OUT1a**, **OUT2a**, **OUT3a** (plugs): first target of `IN1`/`IN2`/`IN3` respectively
- **OUT1b**, **OUT2b**, **OUT3b** (plugs): second target of `IN1`/`IN2`/`IN3` respectively

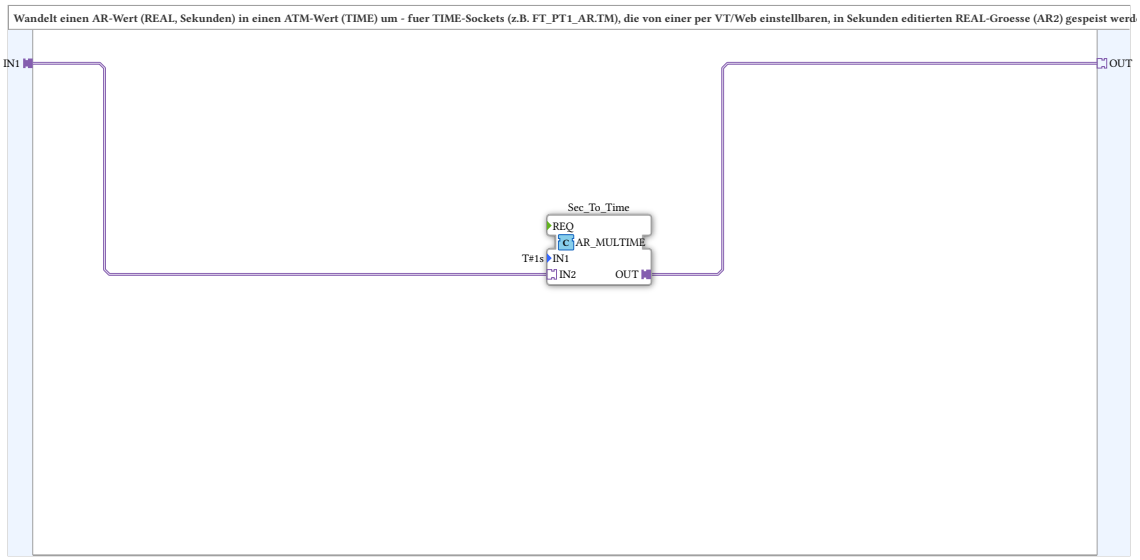
Function Blocks (FBs) Used

- **Split_1**, **Split_2**, **Split_3**: each `adapter::events::unidirectional::AR_SPLIT_2`

Program Flow and Connections

- `IN1` ⟶ `Split_1.IN`; `Split_1.OUT1` ⟶ `OUT1a`; `Split_1.OUT2` ⟶ `OUT1b`
- `IN2` ⟶ `Split_2.IN`; `Split_2.OUT1` ⟶ `OUT2a`; `Split_2.OUT2` ⟶ `OUT2b`
- `IN3` ⟶ `Split_3.IN`; `Split_3.OUT1` ⟶ `OUT3a`; `Split_3.OUT2` ⟶ `OUT3b`

The three branches are completely independent of each other.



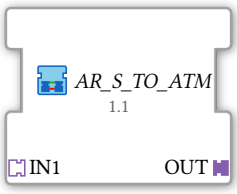
Application Scenarios

- Distributing several parameters (threshold, dead band, hysteresis) to two independent consumers at the same time

Summary

`AR_SPLIT_2_3` bundles three `AR_SPLIT_2` blocks in one SubApp and thus keeps the calling block's network tidy.

AR_S_TO_ATM



• – ○ • – ○ • – ○ •

Introduction

`AR_S_TO_ATM` converts an `AR` value (REAL, seconds) into an `ATM` value (TIME). It is needed for TIME sockets (e.g. `FT_PT1_AR.TM`) that are to be fed by a REAL quantity (AR2) that is editable via VT or web and edited in seconds.

Zeit in Sekunden (REAL) – *AR*

ATM – IN1, umgerechnet von Sekunden (REAL) auf TIME

Interface Structure

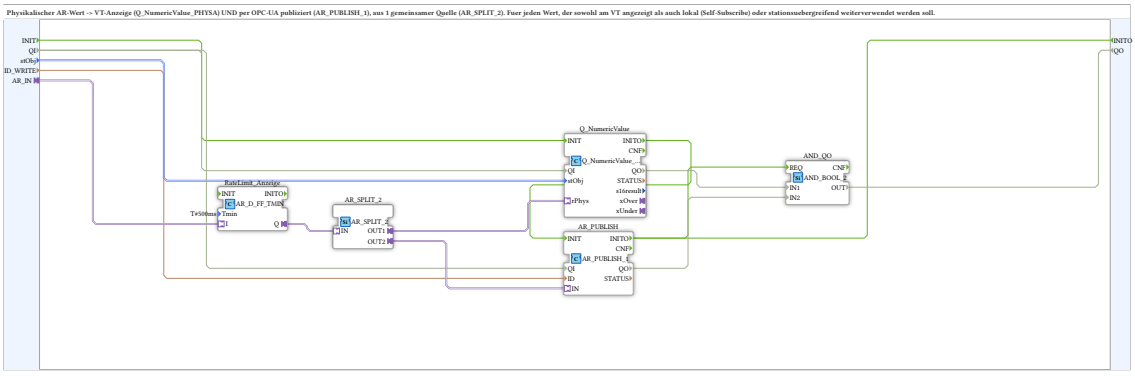
Event Inputs
The function block has no direct event inputs.

Event Outputs
The function block has no direct event outputs.

Data Inputs
The function block has no direct data inputs.

Data Outputs
The function block has no direct data outputs.

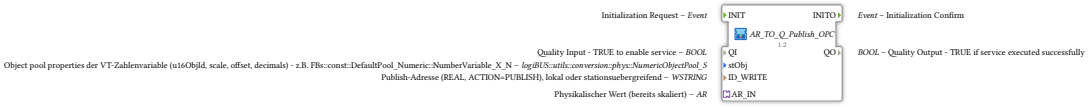
Adapters
- **IN1** (socket, `adapter::types::unidirectional::AR`): time in seconds (REAL)
- **OUT** (plug, `adapter::types::unidirectional::ATM`): `IN1`, converted from seconds (REAL) to TIME



Functionality
Internally a single instance `Sec_To_Time` of type `adapter::iec61131::arithmetic::AR_MULTIME` is used with the parameter `IN1 = T#1s`. The socket `IN1` is routed to `Sec_To_Time.IN2` and the result `Sec_To_Time.OUT` to the plug `OUT`. Thus `OUT = T#1s * IN1`, i.e. true IEC 61131-3 TIME arithmetic: an input of `2.5` yields `T#2s500ms`.

Technical Details
- The earlier variant (`AR_R_MUL` × 1000 ⟶ `AR_TO_ADI` ⟶ `ADI_TO_ATM`) was replaced because it relied on a non-existent function `iec61131::conversion::F_DINT_TO_TIME`
- Stateless; events travel via the adapters (`E1` of `IN1` triggers the calculation)

Application Scenarios
- Adjustable PT1 filter time of the pulse frequency sensors (see `logiBUS_PI_Speed_Publish_OPC`): edited in seconds, routed as TIME to `FT_PT1_AR.TM`
- Any place where a quantity entered in seconds has to be passed to a TIME socket



Conclusion
`AR_S_TO_ATM` is a small adapter SubApp that converts second values to TIME using `T#1s * seconds`.

AR_TO_Q_Publish_OPC

• – ○ • – ○ • – ○ •

Introduction
`AR_TO_Q_Publish_OPC` routes a physical `AR` value from **one common source** both to a VT numeric display (`Q_NumericValue_PHYSA`) and to an OPC-UA publish (`AR_PUBLISH_1`). It is intended for values that are shown on the VT and additionally reused locally (self-subscribe) or across stations. Extracted from `TECU_Speeds/TECU_RPTO`, where the combination `AR_SPLIT_2` + `Q_NumericValue_PHYSA` + `AR_PUBLISH_1` occurred frequently.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialisation request

Event Outputs

- **INITO** (`EInit`): initialisation confirmation

Data Inputs

- **stObj** (`logiBUS::utils::conversion::phys::NumericObjectPool_S`): object pool properties of the VT number variable (`u16ObjId`, scale, offset, decimals), e.g. `FBs::const::DefaultPool_Numeric::NumberVariable_X_N`
- **ID_WRITE** (`WSTRING`): publish address (REAL, `ACTION=PUBLISH`), local or cross-station
- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE to enable the service (VT display and publish)

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service was executed successfully (AND of `Q_NumericValue.QO` and `AR_PUBLISH.QO`)

Adapters

- **AR_IN** (socket, `adapter::types::unidirectional::AR`): physical value (already scaled)

Function Blocks (FBs) Used

- **`RateLimit_Anzeige`** (`adapter::events::unidirectional::AR_D_FF_TMIN`, `Tmin = T#500ms`): limits the update rate
- **`AR_SPLIT_2`** (`adapter::events::unidirectional::AR_SPLIT_2`): distributes the value to two targets
- **`Q_NumericValue`** (`isobus::UT::Q::Q_NumericValue_PHYSA`): writes the physical value into the VT number variable
- **`AR_PUBLISH`** (`adapter::net::AR_PUBLISH_1`): publishes the value via OPC-UA
- **`AND_QO`** (`iec61131::booleanOperators::AND_BOOL_2`): combines the `QO` outputs of `Q_NumericValue` and `AR_PUBLISH` into the `QO` of the SubApp

Functionality

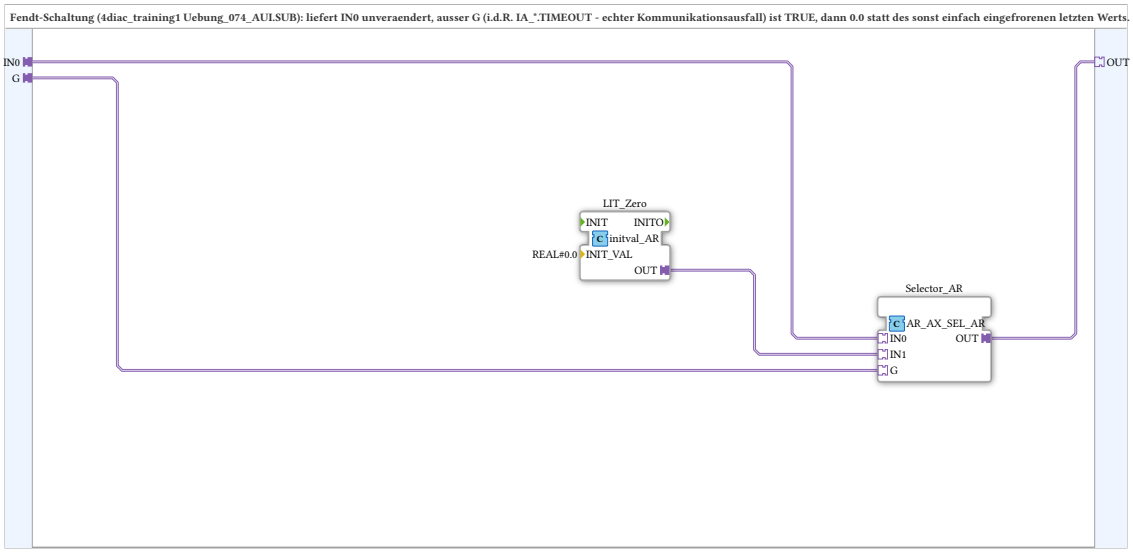
- `AR_IN` ⟶ `RateLimit_Anzeige.I`; `RateLimit_Anzeige.Q` ⟶ `AR_SPLIT_2.IN`
- `AR_SPLIT_2.OUT1` ⟶ `Q_NumericValue.rPhys` (VT display); `stObj` ⟶ `Q_NumericValue.stObj`
- `AR_SPLIT_2.OUT2` ⟶ `AR_PUBLISH.IN`; `ID_WRITE` ⟶ `AR_PUBLISH.ID`
- `INIT` ⟶ `Q_NumericValue.INIT`; `Q_NumericValue.INITO` ⟶ `AR_PUBLISH.INIT`; `AR_PUBLISH.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`)
- `QI` ⟶ `Q_NumericValue.QI` and `QI` ⟶ `AR_PUBLISH.QI`
- `Q_NumericValue.QO` ⟶ `AND_QO.IN1`; `AR_PUBLISH.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`

Technical Details

- **Rate limiting before the split (intentional):** Since v1.2 `RateLimit_Anzeige` sits in front of `AR_SPLIT_2` and therefore throttles **both** branches (VT display and publish/self-subscribe consumers such as `CTRL_PID_AR.AR_ACT`) to at most one update per 500 ms. In v1.1 the throttle was only in the VT display branch. The motivation was sluggish behaviour with many quickly changing displays at the same time (suspected VT bus load).
- An adapter must not fan out to two targets, hence the explicit `AR_SPLIT_2`.

Application Scenarios

- Speed or other measured values that are shown on the VT and at the same time published locally or to other stations



Summary

`AR_TO_Q_Publish_OPC` bundles rate limiting, splitting, VT display and OPC-UA publish of an `AR` value in one SubApp; `INIT`/`INITO` are chained through both services, `QO` is the AND of both services.

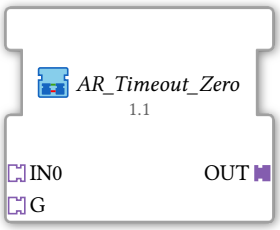
AR_Timeout_Zero



• – ○ • – ○ • – ○ •

Introduction

`AR_Timeout_Zero` passes the `REAL` value `IN0` through unchanged, unless the `AX` signal `G` (usually `IA_*.TIMEOUT`, a real communication failure) is `TRUE`: then `0.0` is output instead of the last value, which would otherwise simply stay frozen. The circuit originates from the Fendt exercise `Uebung_074_AUI`.

Live-Wert, z.B. FIELDBUS_*_SCALED.OUT – *AR*
TRUE = Timeout, liefert 0.0 statt IN0 – *AX*

AR – IN0, oder 0.0 bei G=TRUE

Function Blocks (FBs) Used

Sub-blocks: AR_Timeout_Zero

- **Type**: SubAppType
- **Internal FBs used**:
  - **LIT_Zero**: `adapter::types::unidirectional::AR::initval::initval_AR` with `INIT_VAL=0.0` - provides the constant `0.0`
  - **Selector_AR**: `adapter::iec61131::selection::AR_AX_SEL_AR` - selects between `IN0` and `IN1` depending on `G`
- **Functionality**: With `G=FALSE` the selector outputs the live value `IN0`, with `G=TRUE` the constant `0.0`.

Interface Structure

Event Inputs / Event Outputs

None - the SubApp has no event ports of its own; events travel via the adapters.

Data Inputs / Data Outputs

No direct data ports.

Adapters

- **IN0** (socket): `adapter::types::unidirectional::AR` - live value, e.g. `FIELDBUS_*_SCALED.OUT`
- **G** (socket): `adapter::types::unidirectional::AX` - `TRUE` = timeout, outputs `0.0` instead of `IN0`
- **OUT** (plug): `adapter::types::unidirectional::AR` - `IN0`, or `0.0` if `G=TRUE`

Program Flow and Connections

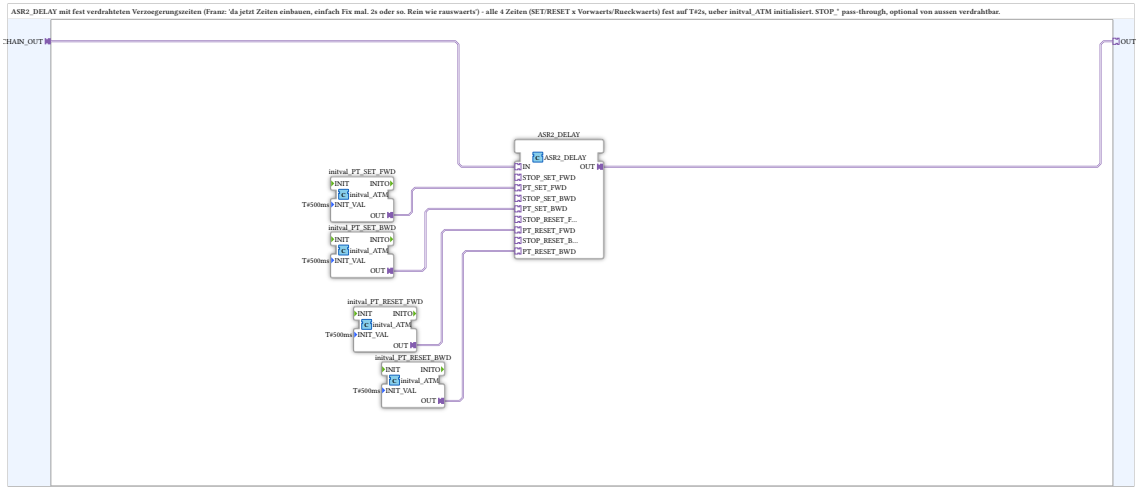
- `IN0` ⟶ `Selector_AR.IN0`
- `LIT_Zero.OUT` ⟶ `Selector_AR.IN1`
- `G` ⟶ `Selector_AR.G`
- `Selector_AR.OUT` ⟶ `OUT`

Technical Details

- The block replaces a frequently recurring wiring (`AR_AX_SEL_AR` with `initval_AR=0`) that had previously been built individually in the TECU blocks (`TECU_RPTO`, `TECU_FPTO`, `TECU_COGSOG`, `TECU_GBSD`, `TECU_WBSD`, `TECU_VDS`, `TECU_FHS`, `TECU_RHS`, `TECU_MSS`)
- Version 1.1 (2026-09-16): moved to `MyLib_AX-1.0.0::sys`, as it is generic and not TECU-specific

Application Scenarios

- Forcing a measured value to zero on communication failure (timeout) instead of freezing the last value
- In general: substitute value `0.0` for an `AR` value, controlled by an `AX` signal



Summary

`AR_Timeout_Zero` encapsulates an `AR` selector with the constant `0.0` into a reusable block that sets the value to zero on timeout.

ASR2_DELAY_SUB

• — ○ • — ○ • — ○ •

Introduction

`ASR2_DELAY_SUB` is `ASR2_DELAY` with hard-wired delay times: the four times (set and reset, each forward and backward) are preset through `initval_ATM` instances so that the block can be inserted into an ASR2 chain as a delay element without any time wiring of its own.

Interface Structure

Event Inputs

The function block has no direct event inputs.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **CHAIN_OUT** (socket, `adapter::types::bidirectional::ASR2`): input of the chain; routed to `ASR2_DELAY.IN`
- **OUT** (plug, `adapter::types::bidirectional::ASR2`): delayed chain; comes from `ASR2_DELAY.OUT`

Functionality

The network consists of one `ASR2_DELAY` instance (`adapter::events::bidirectional::ASR2_DELAY`) and four `initval_ATM` instances (`adapter::types::unidirectional::ATM::initval::initval_ATM`):

- `CHAIN_OUT` ⟶ `ASR2_DELAY.IN` and `ASR2_DELAY.OUT` ⟶ `OUT`
- `initval_PT_SET_FWD.OUT` ⟶ `ASR2_DELAY.PT_SET_FWD`
- `initval_PT_SET_BWD.OUT` ⟶ `ASR2_DELAY.PT_SET_BWD`
- `initval_PT_RESET_FWD.OUT` ⟶ `ASR2_DELAY.PT_RESET_FWD`
- `initval_PT_RESET_BWD.OUT` ⟶ `ASR2_DELAY.PT_RESET_BWD`

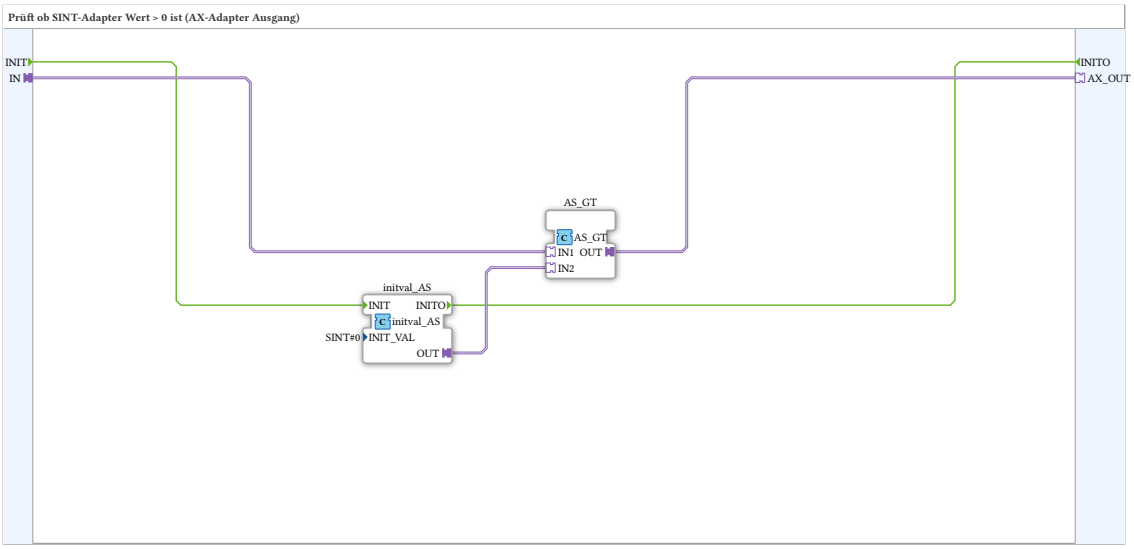
All four `initval_ATM` instances are parameterised with `INIT_VAL = T#500ms`.

Technical Details

- The times are placeholder fixed values without functional requirement and can be made configurable later if needed; the type comment mentions `T#2s` as an example, the instances are currently set to `T#500ms`
- The interface consists only of the input `CHAIN_OUT` and the output `OUT`; the `STOP_*` sockets of `ASR2_DELAY` remain unwired in this SubApp
- Stateless at SubApp level; the state (running timers) resides in `ASR2_DELAY`

Application Scenarios

- Time-staggered control of outputs in a set/reset chain (e.g. belt sequencing) when fixed delays are sufficient

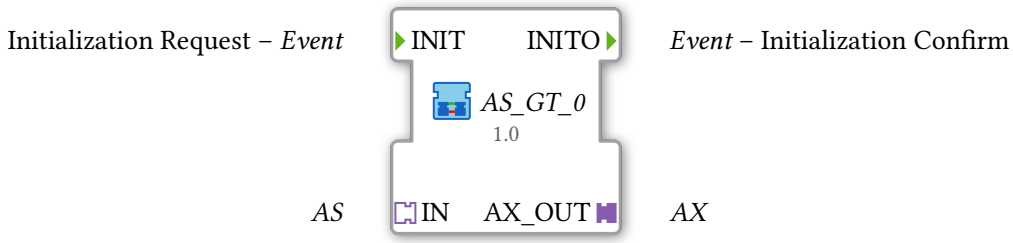


⚖️ Comparison with Similar Blocks

For freely adjustable times, `ASR2_DELAY` is wired directly with your own `ATM` sources; `ASR2_DELAY_SUB`, in contrast, encapsulates the fixed values. For a single event per direction see `AE2_DELAY`.

Conclusion

`ASR2_DELAY_SUB` is a plug-in delay element for ASR2 chains with preset times.



AS_GT_0

• – ○ • – ○ • – ○ •

Introduction

`AS_GT_0` checks whether a SINT adapter value is greater than 0 and outputs the result as a boolean AX adapter signal. A typical input is a signed 8-bit value. The block is built identically for every numeric type (`AS`, `AI`, `ADI`, `ALI`, `AUS`, `AUI`, `AUDI`, `AULI`, `AR`, `ALR`).

Interface

- **Event input**: `INIT` (initialization)
- **Event output**: `INITO` (initialization finished, comes from the internal `initval_AS`)
- **Socket**: `IN` (`AS`) — the value compared against 0
- **Plug**: `AX_OUT` (`AX`) — TRUE when `IN > 0`

Function Blocks (FBs) Used

Sub-blocks: AS_GT_0

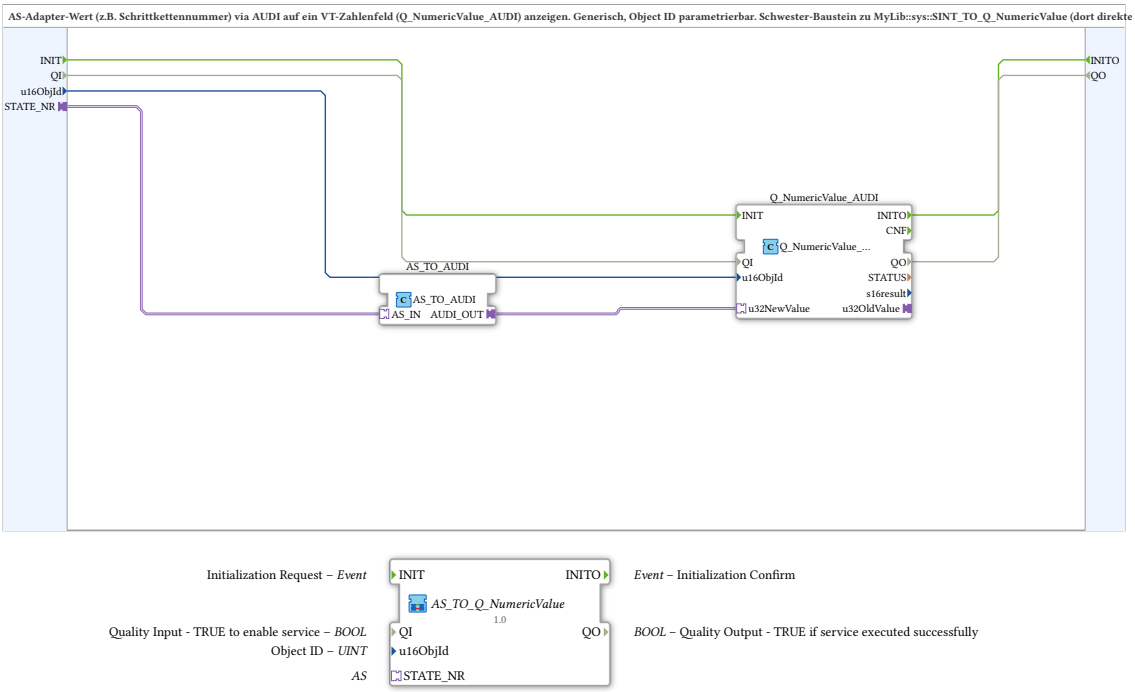
- **Type**: SubAppType
- **Internal FBs used**:
  - **initval_AS**: `adapter::types::unidirectional::AS::initval::initval_AS` — supplies the fixed comparison constant `SINT#0` as an adapter value (`INIT_VAL=SINT#0`). An adapter socket cannot take the constant as a parameter, so it is fed in through this block.
  - **AS_GT**: `adapter::iec61131::comparison::AS_GT` — adapter-native comparison `IN1 > IN2`.
- **Functionality**: `IN` ⟶ `AS_GT.IN1`; constant 0 ⟶ `AS_GT.IN2`; result ⟶ `AX_OUT`.

Program Flow and Connections

1. `INIT` ⟶ `initval_AS.INIT`; `initval_AS.INITO` ⟶ `INITO`.
2. `IN` (adapter) ⟶ `AS_GT.IN1`.
3. `initval_AS.OUT` (constant `SINT#0`) ⟶ `AS_GT.IN2`.
4. `AS_GT.OUT` ⟶ `AX_OUT` (adapter).

Application Scenarios

- Converting a signed 8-bit value into a simple boolean adapter signal for VT status displays or enable logic.



Summary

`AS_GT_0` is a compact wrapper around the adapter-native comparison `AS_GT` — converts "SINT > 0" directly into an AX adapter signal, so the caller does not have to create and wire the zero constant itself.

AS_TO_Q_NumericValue

• — ○ • — ○ • — ○ •

Introduction

`AS_TO_Q_NumericValue` is a reusable subapplication designed to display an AS adapter value (e.g., a step number from a sequencer) on a Visualization Terminal (VT) numeric field. It generically uses an Object ID to select the target field and leverages the `Q_NumericValue_AUDI` function block from the `isobus::UT::Q` library. The block acts as a cleaner interface by accepting an AS adapter input instead of a raw numeric signal, making it suitable for integration into Industrial Automation systems.

Interface Structure

The subapplication exposes a minimal interface: the initialization events `INIT`/`INITO`, the quality signals `QI`/`QO`, one further data input and one adapter socket.

Event Inputs

- **INIT** (`EInit`): initialization request - passed through to `Q_NumericValue_AUDI.INIT`.

Event Outputs

- **INITO** (`EInit`): initialization confirmation - comes from `Q_NumericValue_AUDI.INITO`.

Data Inputs

Name	Type	Initial Value	Comment

QI	BOOL	TRUE	Quality Input - TRUE to enable the service.
u16ObjId	UINT	ID_NULL	Object ID for the VT numeric field (target).

Data Outputs

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if the service was executed successfully (from Q_NumericValue_AUDI.QO).

Adapters

Name	Type	Direction	Comment
STATE_NR	adapter::types::unidirectional::AS	Socket	AS adapter input carrying the value to display.

Functionality

The subapplication performs a unidirectional data conversion and transfer:

1. STATE_NR (AS adapter) carries the value (e.g., a step number) as an AS type.
2. The internal AS_TO_AUDI block converts the AS adapter value into an AUDI-compatible data stream (AUDI_OUT).
3. The converted AUDI value is then fed into Q_NumericValue_AUDI as u32NewValue.
4. Simultaneously, the u16ObjId input is passed directly to Q_NumericValue_AUDI to define which VT numeric field should be updated.

In addition, initialization and the quality signals are passed through: INIT → Q_NumericValue_AUDI.INIT, Q_NumericValue_AUDI.INITO → INITO, QI → Q_NumericValue_AUDI.QI and Q_NumericValue_AUDI.QO → QO.

In essence, the block bridges an AS signaling network with a VT display, making the object ID externally configurable without changing internal wiring.

Technical Features

- **Generic Object ID**: The u16ObjId input is fully parametrizable, allowing the same subapplication to control different VT fields without duplication.
- **Reusability**: Designed for reuse across multiple projects or instances; it was extracted from a larger exercise for modularity.
- **Leverages Standard Library Blocks**: Utilizes isobus::UT::Q::Q_NumericValue_AUDI and adapter::conversion::unidirectional::AS_TO_AUDI, ensuring compatibility with IEC 61499-2 and the 4diac IDE.
- **Simple Wiring**: Only one adapter input and one data input are required (QI defaults to TRUE, INIT is optional); no internal logic or state variables are exposed.
- **Quality Pattern**: QI (default TRUE) enables the service, QO reports the success of the inner Q_NumericValue_AUDI.

State Overview

This subapplication is **stateless** in its own right. It does not maintain any internal state variables or sequencing logic. All data flows are purely combinational from the adapter input and the object ID to the output of the internal Q_NumericValue_AUDI block. The functionality is deterministic and does not depend on execution order or history.

Application Scenarios

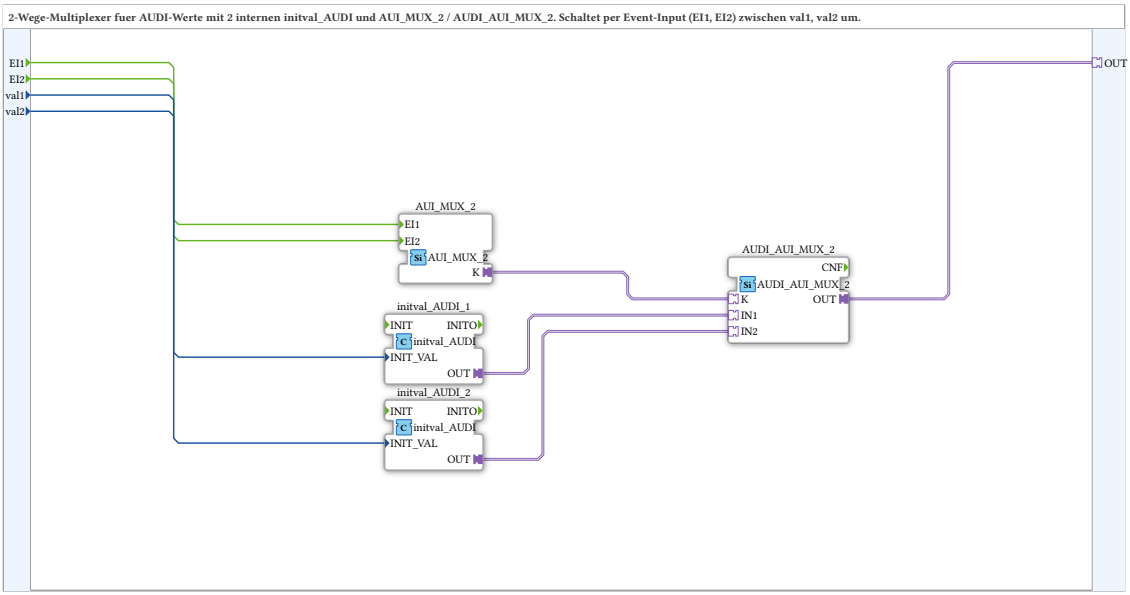
Typical use cases include:

- Displaying the current step number of a sequencer on an HMI or VT.
- Indicating the active recipe or status code from a machine as a numeric readout.
- Updating a numeric field on a VT based on a value from an AS-connected device, without requiring direct signal wiring.

- Serving as a drop-in replacement in systems that previously used a direct `SINT` input, now adding the flexibility of an AS adapter.

Comparison with Similar Blocks

The sister block `MyLib::sys::SINT_TO_Q_NumericValue` provides the same functionality but expects a direct `SINT` value as input instead of an AS adapter. The main differences:



- **Input Type**: `SINT_TO_Q_NumericValue` takes a plain `SINT` data signal; `AS_TO_Q_NumericValue` requires an AS adapter.
- **Flexibility**: The AS adapter version is better suited for environments already using AS-communication patterns, while the SINT version may be simpler for purely data-oriented connections.
- **Wiring**: The AS variant adds an extra conversion layer (`AS_TO_AUDI`), which is transparent to the user and handled internally.

Choosing one over the other depends on the surrounding system architecture and the availability of AS adapter connections.

Conclusion

`AS_TO_Q_NumericValue` is a compact, reusable subapplication that effectively translates an AS adapter value into a numeric display on a VT, with an externally configurable object ID. Its stateless design and use of standard library blocks make it straightforward to integrate into IEC 61499-based projects. By reusing this block, developers can avoid duplicating conversion logic and ensure consistency across automation projects that require numeric visualization of AS signals.

AUDI_AUI_MUX_2_VAL

• – ○ • – ○ • – ○ •

Introduction

The **AUDI_AUI_MUX_2_VAL** is a composite application block (SubApp) that implements a two-channel multiplexer for AUDI data values. It selects between two initialization values (`val1` and `val2`) based on incoming event triggers (`EI1` and `EI2`). The selected value is provided as an AUDI adapter output. Inter-

nally, the block combines an event-driven selector (AUI_MUX_2) with a dedicated adapter multiplexer (AUDI_AUI_MUX_2) and two initial-value generators (initval_AUDI). This design allows clean orchestration of event-controlled value switching while maintaining the structure of AUDI adapters.

Interface Structure

The block is a SubApp with the following interface elements:

Event Inputs

Name	Type	Description
`EI1`	Event	Triggers selection of `val1`
`EI2`	Event	Triggers selection of `val2`

Event Outputs

The block has no explicit event outputs. Internal event handling is entirely contained within the subapplication.

Data Inputs

Name	Type	Description
`val1`	UDINT	First value to be output when `EI1` is triggered
`val2`	UDINT	Second value to be output when `EI2` is triggered

Data Outputs

The block does not provide direct data outputs. The result is delivered through the adapter output.

Adapters

Name	Type	Description
`OUT`	`adapter::types::unidirectional::AUDI`	Output adapter carrying the currently selected AUDI value

Functionality

The internal network consists of three functional parts:

1. **Event decoding** – The incoming events `EI1` and `EI2` are routed to the internal FB `AUI_MUX_2` (type `adapter::events::unidirectional::AUI_MUX_2`). This FB acts as an event selector, forwarding the corresponding selection signal to the adapter multiplexer.
2. **Value preparation** – The two input values `val1` and `val2` are fed to two instances of `initval_AUDI` (type `adapter::types::unidirectional::AUDI::initval::initval_AUDI`). These FBs convert the primitive UDINT data into AUDI adapter format, making them suitable for the adapter-based multiplexing stage.
3. **Adapter multiplexing** – The internal FB `AUDI_AUI_MUX_2` (type `adapter::selection::unidirectional::AUDI_AUI_MUX_2`) receives the selection control from `AUI_MUX_2` and the two prepared AUDI-formatted values from the `initval_AUDI` instances. Based on the control signal, it passes either `IN1` or `IN2` to its output `OUT`, which is then propagated to the block's external adapter output.

In summary, when `EI1` arrives, `val1` is output; when `EI2` arrives, `val2` is output. The output remains at the last selected value until the other event is received.

Technical Features

- **Modular composition** – Uses event-, data-, and adapter-oriented FBs in a clear separation of concerns.
- **Adapter-based data flow** – All AUDI data is handled through dedicated adapter types, ensuring type-safe connections.

- **Initial value handling** – The `initval_AUDI` FBs ensure that the UDINT input values are correctly wrapped into the AUDI adapter format before multiplexing.
- **Event-driven selection** – Selection is performed via event inputs, allowing precise timing control.
- **Unidirectional output** – Only one AUDI output adapter is provided; no feedback or bidirectional interfaces are used.

State Overview

The block does not maintain a persistent internal state machine; it is purely combinatorial with respect to data, while events drive the selection process. However, the output effectively "latches" the last selected value until an opposite event occurs. In that sense, the block can be considered to have two stable output states:

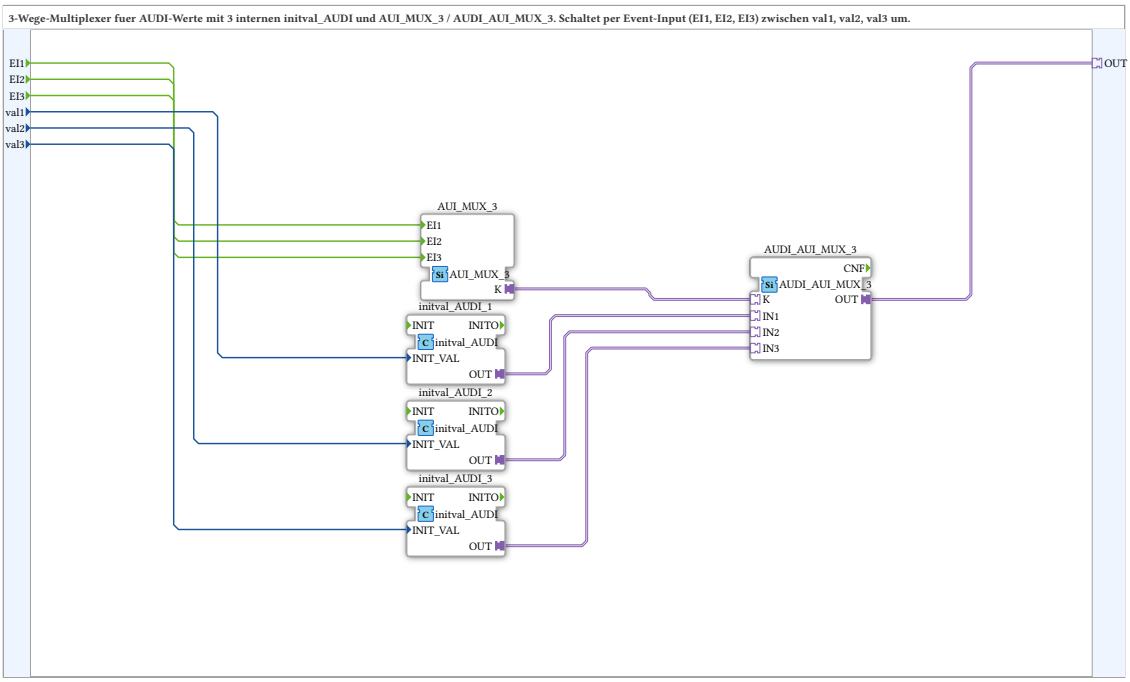
- **State A**: `val1` is active (after `EI1` has been received)
- **State B**: `val2` is active (after `EI2` has been received)

Since no internal memory elements are present, the state is determined solely by the most recent event that has been processed.

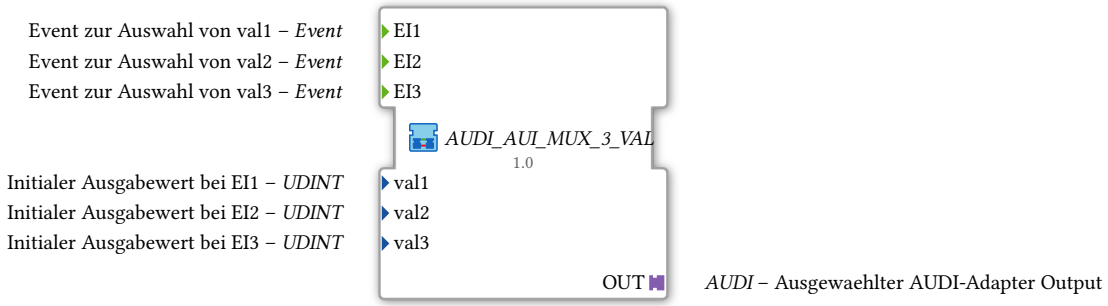
Application Scenarios

This block is particularly useful in automation and control systems where a single AUDI-type data stream must be switched between two different source values based on discrete events. Typical applications include:

- **Mode switching** – Selecting between different operating parameters (e.g., speed or temperature setpoints) based on operational mode events.
- **Redundant value selection** – Choosing between a primary and a backup measurement value depending on failure detection events.
- **Commanded swapping** – Alternating between two preset values (e.g., for test or calibration purposes) via digital triggers.



Comparison with Similar Blocks



The `AUDI_AUI_MUX_2_VAL` is a specialized variant of a generic multiplexer. Unlike a plain data multiplexer (e.g., `MUX`), it works with AUDI adapter data and incorporates the necessary initial-value conversion. Compared to a three-channel version (`AUDI_AUI_MUX_3_VAL`), this block offers only two inputs, making it more compact for simple two-source scenarios. The internal separation into event selector and adapter selector allows reuse of the individual components in other contexts, but for an end-user the block behaves as a single, ready-to-use entity.

Conclusion

The `AUDI_AUI_MUX_2_VAL` subapplication provides a clean and efficient way to switch between two AUDI-formatted values based on event triggers. Its internal architecture leverages existing dedicated FBs, ensuring robustness and reusability. With its simple event-driven interface and adapter-based output, it integrates seamlessly into larger 4diac projects that require controlled data selection.

AUDI_AUI_MUX_3_VAL

• – ○ • – ○ • – ○ •

Introduction

The **AUDI_AUI_MUX_3_VAL** is a subapplication that implements a 3-way multiplexer for AUDI adapter values. It combines three internal `initval_AUDI` function blocks, an `AUI_MUX_3` event selection block, and an `AUDI_AUI_MUX_3` adapter multiplexer. Depending on which event input (`EI1`, `EI2`, or `EI3`) is triggered, one of the three UDINT input values (`val1`, `val2`, `val3`) is selected and made available as an AUDI adapter output. The subapp enables direct wiring of raw numeric values into the AUDI adapter domain without requiring pre-initialized adapter instances externally.

Interface Structure

Event Inputs

Event	Description
`EI1`	Event to select `val1` as the active output
`EI2`	Event to select `val2` as the active output
`EI3`	Event to select `val3` as the active output

Event Outputs

No event outputs are provided by this subapplication.

Data Inputs

Data	Type	Description
`val1`	UDINT	Initial output value when `EI1` is triggered
`val2`	UDINT	Initial output value when `EI2` is triggered
`val3`	UDINT	Initial output value when `EI3` is triggered

Data Outputs

No data outputs are provided by this subapplication.

Adapters

Adapter	Type	Description
`OUT`	`adapter::types::unidirectional::AUDI`	Selected AUDI adapter output carrying the multiplexed value

Functionality

The subapplication operates as a complete selection chain for AUDI values:

1. The three raw UDINT values `val1`, `val2`, and `val3` are passed to three internal `initval_AUDI` function blocks (`initval_AUDI_1`, `initval_AUDI_2`, `initval_AUDI_3`). Each block converts the corresponding UDINT value into an AUDI adapter initial-value stream.
2. The internal `AUI_MUX_3` block receives the event inputs `EI1`, `EI2`, and `EI3` and performs event-based selection logic.
3. The selection information is forwarded via the adapter connection `AUI_MUX_3.K` to the internal `AUDI_AUI_MUX_3` block.
4. The `AUDI_AUI_MUX_3` block multiplexes the three AUDI adapter inputs (`IN1`, `IN2`, `IN3`) originating from the `initval_AUDI` blocks and routes the chosen adapter stream to the output adapter `OUT`.

The entire chain is event-driven: only when an event is raised on `EI1`, `EI2`, or `EI3` does the output adapter reflect the corresponding input value.

Technical Features

- **Three-way selection** via dedicated event inputs (`EI1`, `EI2`, `EI3`), providing explicit and deterministic switching behavior.
- **UDINT input type** for `val1`, `val2`, and `val3`, allowing direct connection of unsigned double integer values from the application logic.
- **Adapter-based output** using the unidirectional `AUDI` adapter type, enabling seamless integration with other AUDI-compatible blocks.
- **Internal composition** combines `initval_AUDI` (value conversion), `AUI_MUX_3` (event selection), and `AUDI_AUI_MUX_3` (adapter multiplexing) into a single reusable subapplication.
- **No additional event or data outputs**, keeping the interface clean and focused on the multiplexing purpose.

State Overview

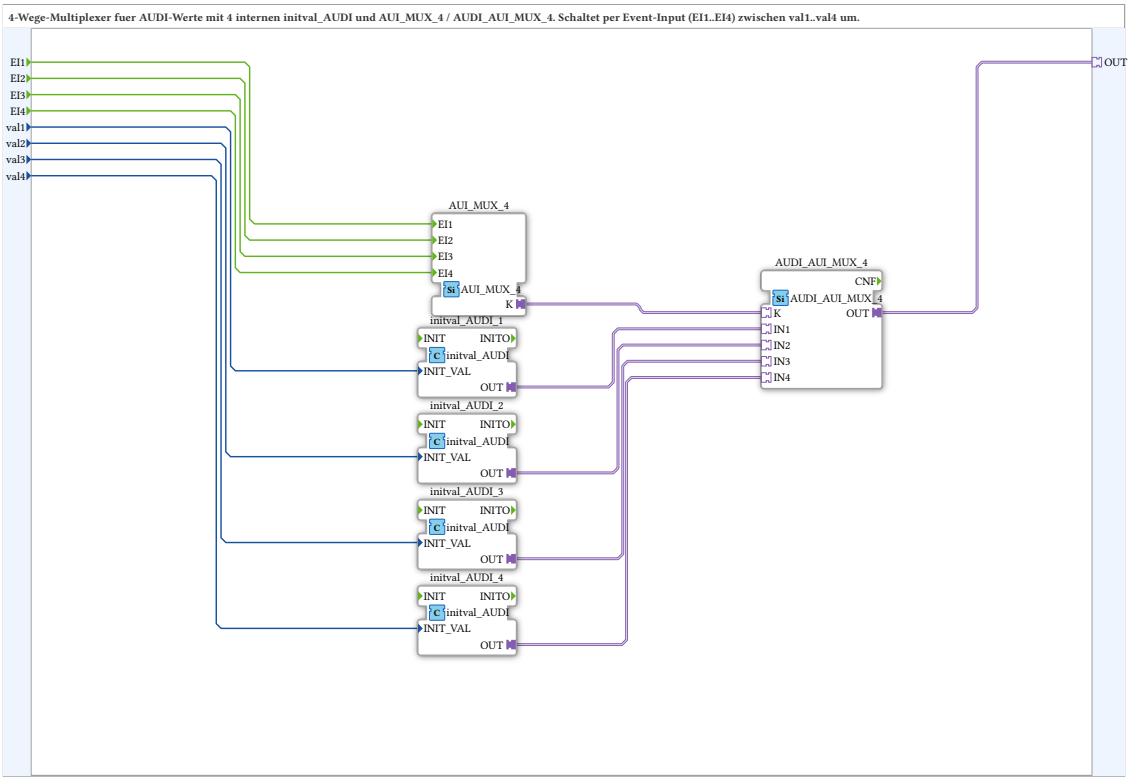
The subapplication does not maintain an explicit internal state machine. Selection behavior is purely event-driven: each trigger on `EI1`, `EI2`, or `EI3` immediately determines which of the three values is propagated to the output. Consequently, the active output corresponds to the most recently triggered event input, and no intermediate states are exposed to the user.

Application Scenarios

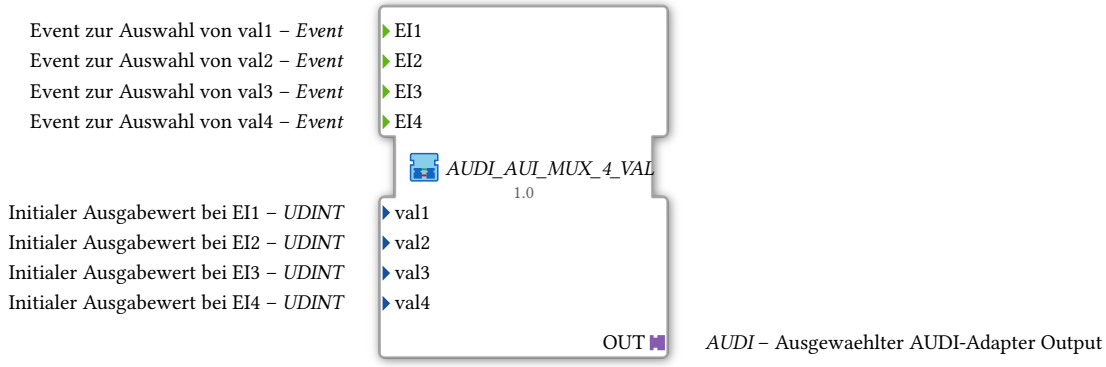
Typical use cases for the `AUDI_AUI_MUX_3_VAL` include:

- **Mode or channel selection** in automation processes where one of three preconfigured AUDI values must be chosen based on external events (e.g., operating mode switches, recipe selection).
- **Parameter switching** in control systems, enabling dynamic changes between different setpoints or configuration values that are supplied as raw UDINT values.

- **Redundant value handling** in safety-critical applications, where a fallback or alternative value can be selected via specific event triggers.
- **Integration into larger adapter-based networks**, providing a convenient bridge between raw numeric inputs and AUDI adapter streams without manual adapter initialization.



Comparison with Similar Blocks



Compared to the standard `AUDI_AUI_MUX_3` block, the `AUDI_AUI_MUX_3_VAL` introduces an integrated initialization layer through the `initval_AUDI` blocks. This eliminates the need for the user to create and configure adapter instances beforehand; raw UDINT values can be wired directly. In contrast to a generic multiplexer without adapter support, this subapplication provides a complete, self-contained solution tailored to the AUDI adapter type, reducing external wiring complexity and improving reusability.

Conclusion

The `AUDI_AUI_MUX_3_VAL` subapplication offers a compact and practical solution for three-way multiplexing of AUDI adapter values driven by event inputs. By internally combining value initialization, event selection, and adapter multiplexing, it simplifies the integration of numeric data into AUDI-based communication chains. Its clear interface, event-driven behavior, and adapter-oriented design make it suitable for a wide range of automation and control scenarios where flexible value switching is required.

AUDI_AUI_MUX_4_VAL

• – ○ • – ○ • – ○ •

Introduction

AUDI_AUI_MUX_4_VAL is a composite subapplication that implements a 4-way multiplexer for AUDI adapter values. It selects between four internal AUDI values using the event inputs EI1 to EI4. Each data input val1 to val4 provides the initial value for one internal AUDI channel. The selected value is made available through a single AUDI adapter output plug.

Interface Structure

The subapplication has four event inputs, four data inputs, and one adapter output. It does not provide any event outputs or data outputs.

Event Inputs

Name	Type	Comment
EI1	Event	Event for selecting val1
EI2	Event	Event for selecting val2
EI3	Event	Event for selecting val3
EI4	Event	Event for selecting val4

Event Outputs

There are no event outputs.

Data Inputs

Name	Type	Comment
val1	UDINT	Initial output value for EI1
val2	UDINT	Initial output value for EI2
val3	UDINT	Initial output value for EI3
val4	UDINT	Initial output value for EI4

Data Outputs

There are no data outputs.

Adapters

Direction	Name	Type	Comment
Plug	OUT	adapter::types::unidirectional::AUDI	Selected AUDI adapter output

Functionality

AUDI_AUI_MUX_4_VAL combines four internal `initval_AUDI` instances with two adapter-based multiplexing elements. Each `initval_AUDI` instance receives one of the UDINT data inputs and converts it into an internal AUDI adapter value. The four resulting AUDI channels are connected to the selection block `AUDI_AUI_MUX_4`.

The event inputs EI1 to EI4 are forwarded to the internal event multiplexer `AUI_MUX_4`. Its control output `K` drives `AUDI_AUI_MUX_4` to select the corresponding AUDI input. When an event occurs on EIn, the AUDI value associated with valn is propagated to the `OUT` adapter plug.

This architecture allows the subapplication to switch between four different AUDI values purely by event control, without requiring additional data selection logic on the outside.

Technical Features

- 4-way event-driven selection of AUDI adapter values.
- Four independent UDINT input values.
- No event outputs or data outputs.
- Output provided as a unidirectional AUDI adapter plug.

- Built from standard adapter-based function blocks:
  - `AUI_MUX_4`
  - `AUDI_AUI_MUX_4`
  - Four `initval_AUDI` instances
- Uses an internal control connection `K` between the event multiplexer and the AUDI selection block.

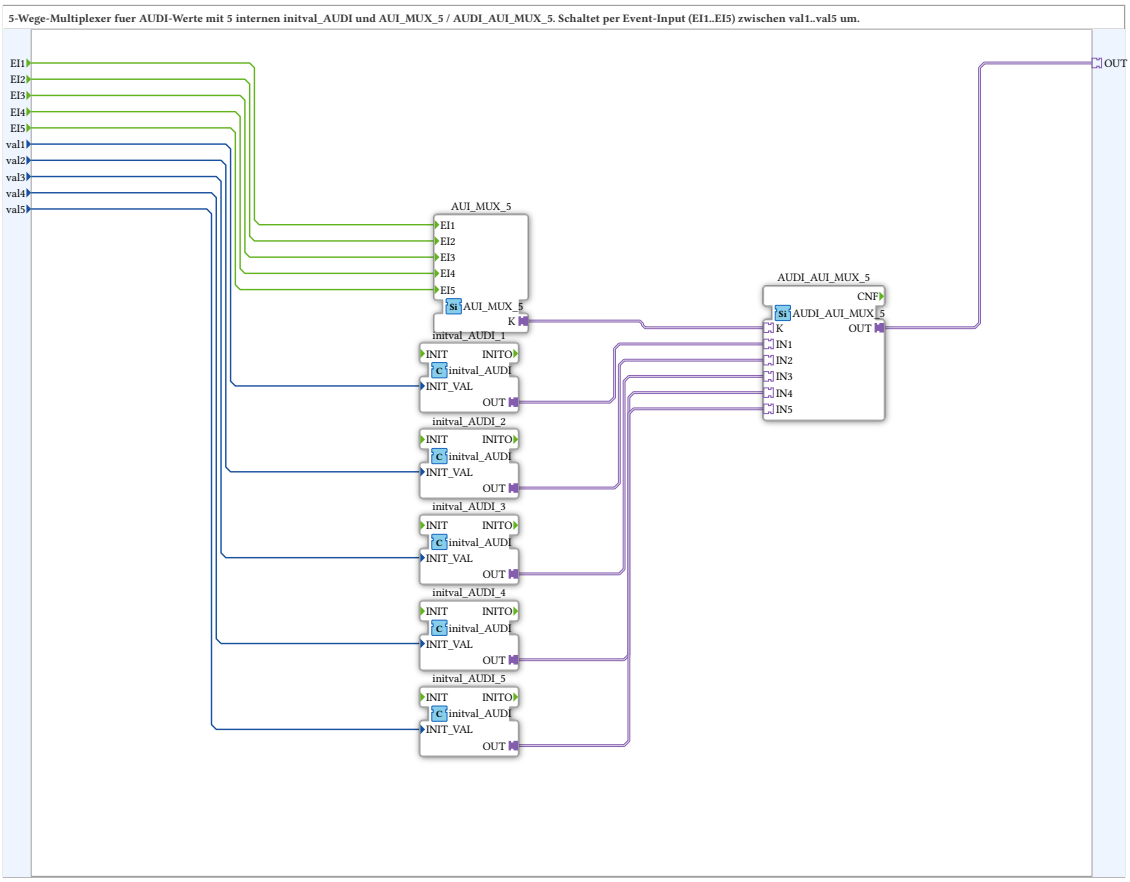
State Overview

The subapplication is defined as a composite network and does not contain its own explicit ECC state machine. Its behavior is event-driven: the active AUDI output value depends on the most recently triggered event input. The internal blocks handle the selection and forwarding of the adapter values.

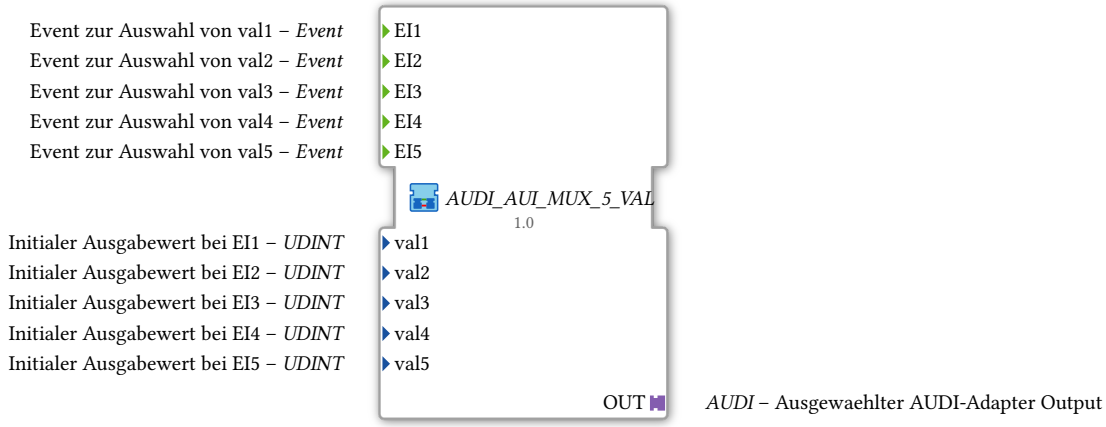
Application Scenarios

AUDI_AUI_MUX_4_VAL is suitable for applications that need to select one out of four AUDI adapter values at runtime. Typical use cases include:

- Switching between four preconfigured AUDI parameter sets.
- Event-based routing of AUDI data channels.
- Selecting initialization values for different operating modes.
- Multiplexing AUDI values in automation or control networks.



Comparison with Similar Blocks



AUDI_AUI_MUX_4_VAL is the 4-way variant of the 3-way subapplication `AUDI_AUI_MUX_3_VAL`. Compared to that block, it provides one additional event input, one additional data input, and a fourth internal AUDI value channel. This makes it useful when exactly four alternatives must be handled. For applications with fewer inputs, the 3-way variant may be more compact; for larger selections, additional variants or cascaded multiplexers are required.

Conclusion

AUDI_AUI_MUX_4_VAL provides a clean and reusable way to multiplex four UDINT-based AUDI adapter values through a single output. Its event-driven interface is simple to integrate into 4diac applications, and the internal composition hides the adapter selection complexity from the surrounding logic.

AUDI_AUI_MUX_5_VAL

• – ○ • – ○ • – ○ •

Introduction

The **AUDI_AUI_MUX_5_VAL** is a composite subapplication that implements a 5-way multiplexer for AUDI values. It combines an event-based selection mechanism with five independent initial value generators, allowing the user to select one of five AUDI data streams via dedicated event inputs. The block is designed to be used in scenarios where multiple AUDI sources need to be switched to a single output line based on control events.

Interface Structure

Event Inputs

Event Name	Description

EI1	Event to select val1 as the active input
EI2	Event to select val2 as the active input
EI3	Event to select val3 as the active input
EI4	Event to select val4 as the active input
EI5	Event to select val5 as the active input

Event Outputs

None.

Data Inputs

Data Name	Type	Description
val1	UDINT	Initial value used when EI1 is triggered
val2	UDINT	Initial value used when EI2 is triggered
val3	UDINT	Initial value used when EI3 is triggered
val4	UDINT	Initial value used when EI4 is triggered
val5	UDINT	Initial value used when EI5 is triggered

Data Outputs

None.

Adapters

Plug Name	Type	Description
OUT	adapter::types::unidirectional::AUDI	Selected AUDI adapter output

Functionality

The subapplication is built around three functional blocks:

- **AUI_MUX_5** – receives the five event inputs and generates a selection signal (K) based on which event has occurred.
- **initval_AUDI_1 ... initval_AUDI_5** – each of these blocks holds one of the UDINT input values and converts it into an AUDI adapter output.
- **AUDI_AUI_MUX_5** – a dedicated AUDI multiplexer that takes the five AUDI inputs and the selection signal K, and routes the selected input to the output adapter.

When an event (EI1 ... EI5) is triggered, the corresponding `val1 … val5` value is propagated via the internal initval block to the multiplexer, and the output adapter `OUT` provides the selected AUDI data stream.

Technical Features

- **Composite subapplication** – encapsulates the entire logic in a single reusable block.
- **Five independent input channels** – each with its own event and data value.
- **UDINT data type** – supports 32-bit unsigned integer values for the initial value parameters.
- **AUDI adapter interface** – output is a standard unidirectional AUDI adapter, enabling easy integration with other AUDI-based components.
- **Event-driven selection** – the output is updated only when one of the selection events occurs.
- **No event or data outputs** – all outputs are carried via the adapter plug.

State Overview

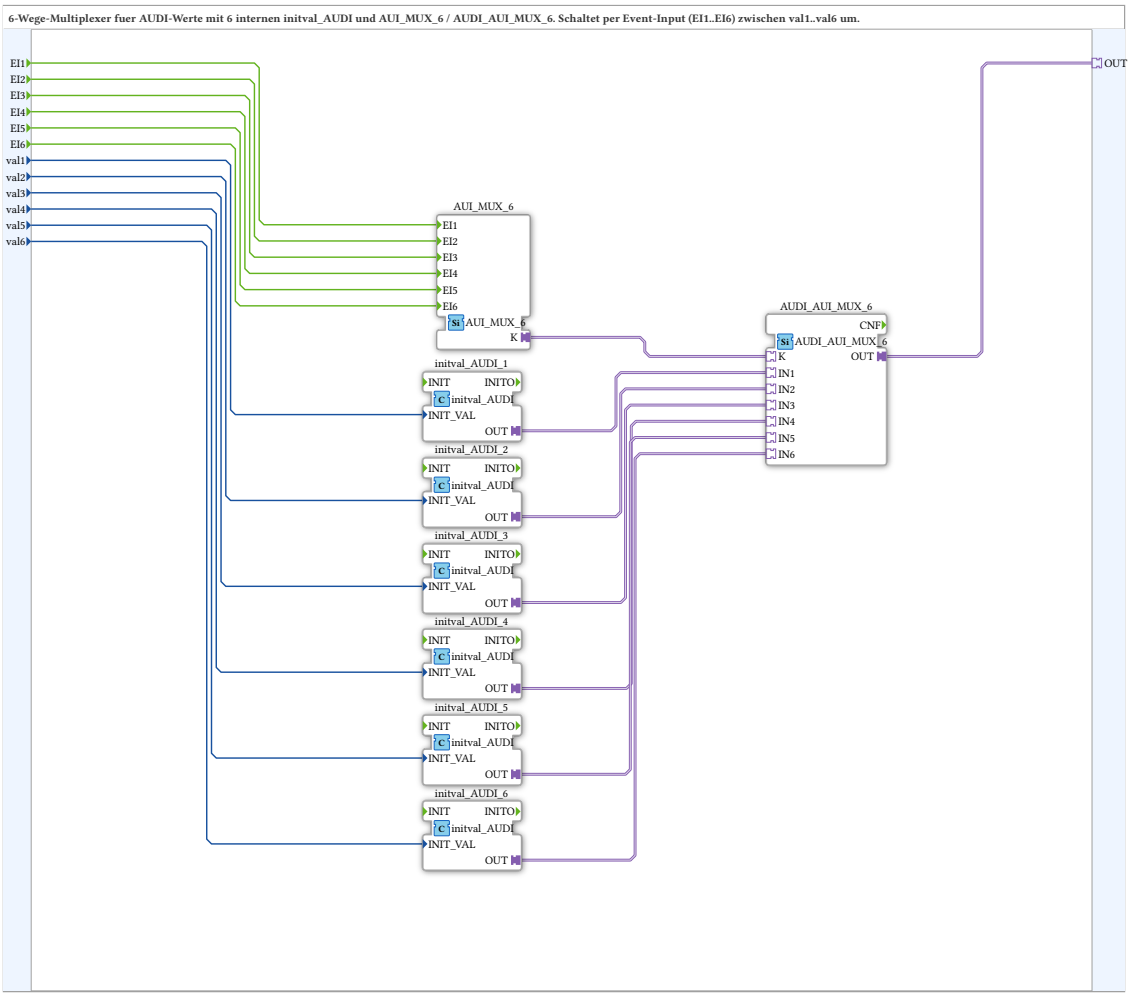
The block does not have an explicit state machine, but its behavior can be described as:

- **Idle** – no event has been received; the output adapter holds the last selected value.
- **Selection** – upon receiving one of the five events, the corresponding input is latched and the output adapter is updated accordingly.

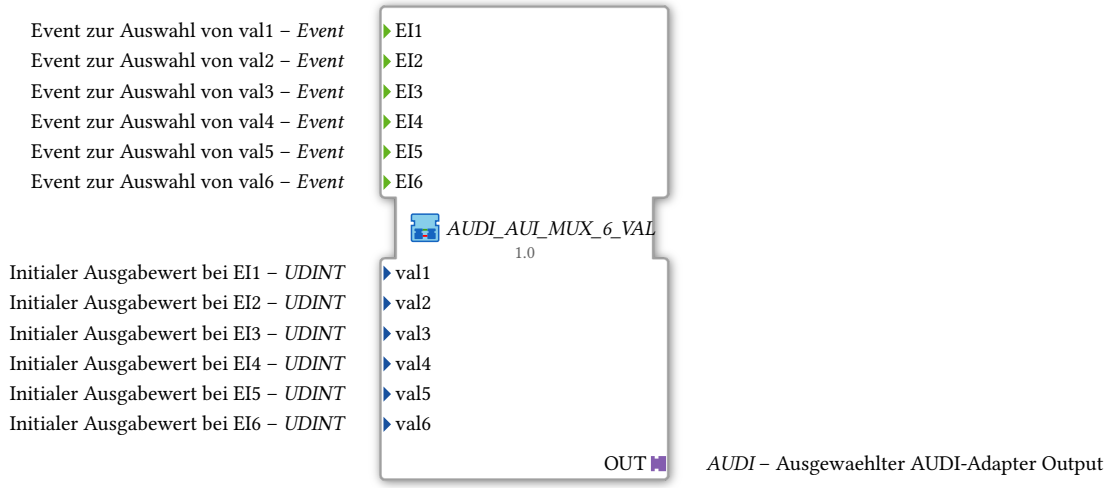
The internal AUI_MUX_5 and AUDI_AUI_MUX_5 ensure that exactly one input is routed to the output at any time.

Application Scenarios

- **Industrial control** – switching between different sensor values (e.g., temperature, pressure) based on operational modes.
- **Automation** – selecting different recipe data for a production line.
- **Test and measurement** – multiplexing multiple measurement channels into a single acquisition system.
- **Component integration** – providing a unified AUDI interface to a higher-level controller while allowing channel selection via events.



Comparison with Similar Blocks



The block is a **5-input variant** of the `AUDI_AUI_MUX_3_VAL` subapplication. Compared to a basic `AUI_MUX_5` (which only provides the selection signal), this block adds the initial value generation and the AUDI multiplexing in a single package, making it more self-contained. It also differs from a simple `AUDI_MUX_5` (which works on pre-configured AUDI inputs) by taking raw UDINT values as input and automatically converting them to the AUDI format.

Conclusion

The `AUDI_AUI_MUX_5_VAL` subapplication provides a clean, event-driven solution for multiplexing up to five AUDI channels. Its internal structure isolates the selection and conversion logic, making it easy to integrate into larger systems. The use of standard AUDI adapter interfaces ensures compatibility with existing 4diac components and simplifies wiring.

AUDI_AUI_MUX_6_VAL

• – ◦ • – ◦ • – ◦ •

Introduction

The AUDI_AUI_MUX_6_VAL is a 6-way multiplexer subapplication designed for selecting AUDI values. It combines six internal initval_AUDI blocks with an AUI_MUX_6 event multiplexer and an AUDI_AUI_MUX_6 selection adapter. The subapp switches between six UDINT input values (val1 to val6) based on event inputs EI1 to EI6, providing the selected value as an AUDI adapter output.

Interface Structure

Event Inputs

Event	Type	Comment
EI1	Event	Event to select val1
EI2	Event	Event to select val2
EI3	Event	Event to select val3
EI4	Event	Event to select val4
EI5	Event	Event to select val5
EI6	Event	Event to select val6

Event Outputs

No event outputs are provided by this subapplication.

Data Inputs

Data	Type	Comment
val1	UDINT	Initial output value at EI1
val2	UDINT	Initial output value at EI2
val3	UDINT	Initial output value at EI3
val4	UDINT	Initial output value at EI4
val5	UDINT	Initial output value at EI5
val6	UDINT	Initial output value at EI6

Data Outputs

No data outputs are provided by this subapplication.

Adapters

Adapter	Type	Comment
OUT	adapter::types::unidirectional::AUDI	Selected AUDI adapter output

Functionality

The subapplication implements a 6-to-1 multiplexer for AUDI values. Internally, it contains:

- Six initval_AUDI instances (initval_AUDI_1 to initval_AUDI_6) that convert the UDINT input values (val1 to val6) into AUDI adapter format. Each initval block receives its corresponding value via the INIT_VAL data input.
- An AUI_MUX_6 event multiplexer block that receives the six event inputs (EI1 to EI6).
- An AUDI_AUI_MUX_6 selection adapter that combines the multiplexed event output (K) and the six initialized AUDI values (IN1 to IN6).

When an event arrives on one of the event inputs (EI1 to EI6), the AUI_MUX_6 block routes the corresponding selection signal to the AUDI_AUI_MUX_6 block. The AUDI_AUI_MUX_6 then forwards the corresponding initialized AUDI value to the OUT adapter.

Technical Features

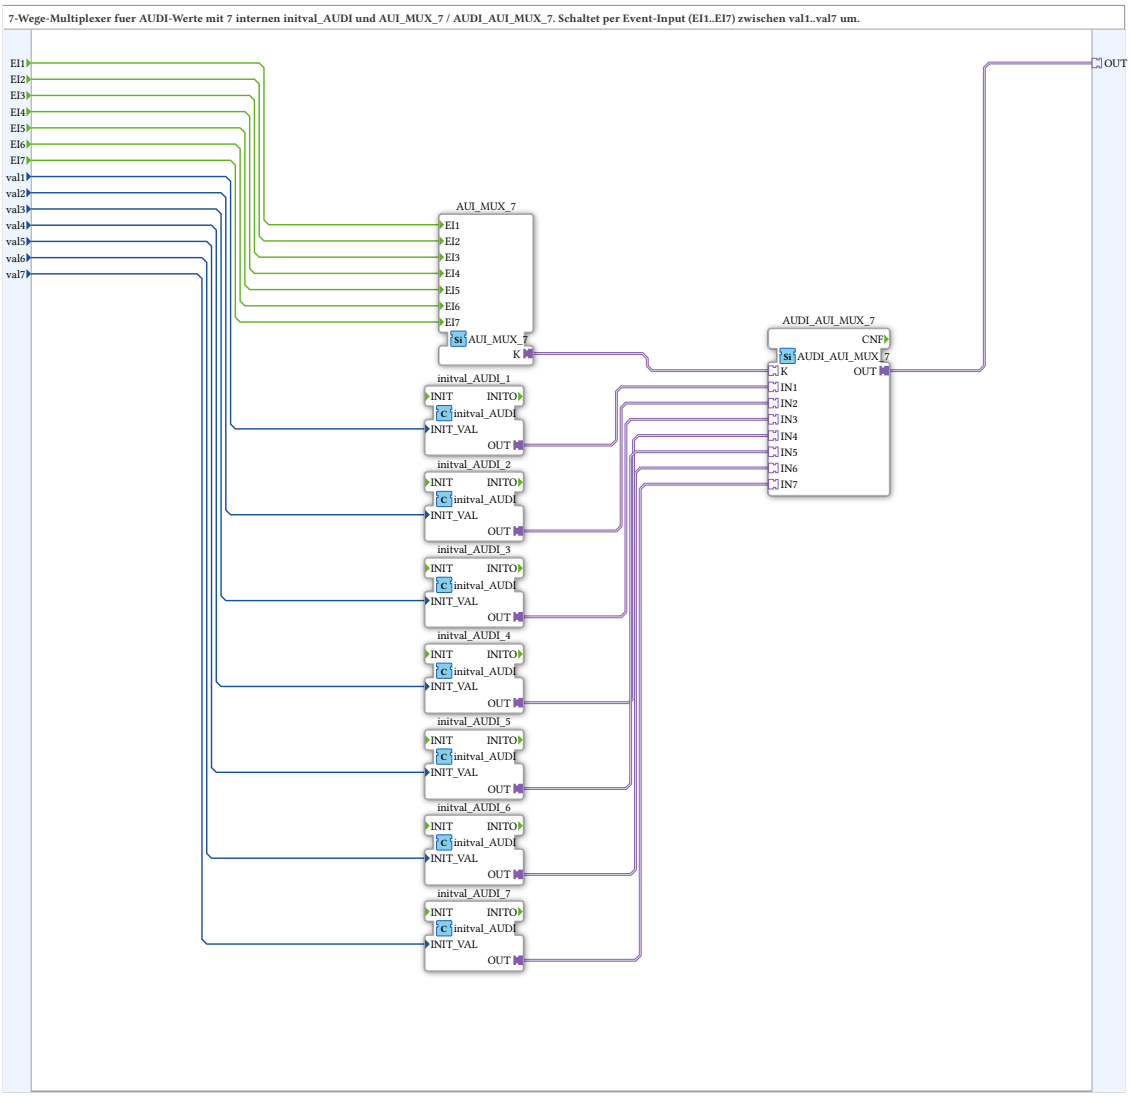
- Six-channel event-driven selection
- UDINT input values converted to AUDI adapter values
- Unidirectional AUDI adapter output
- Clean separation of event selection and data routing
- Scalable design based on the 3-way variant

State Overview

The subapplication itself does not maintain an explicit state machine. The selection behavior is determined by the internal AUI_MUX_6 block, which reacts to the incoming events. After initialization, the output reflects the AUDI value associated with the most recently triggered event input.

Application Scenarios

- Selecting between multiple sensor values represented as AUDI data
- Switching between different preset AUDI configurations
- Multiplexing AUDI data streams in an IEC 61499-based control application



Comparison with Similar Blocks

This block is a 6-way extension of the 3-way variant (AUDI_AUI_MUX_3_VAL). Compared to its smaller counterpart, it provides two additional event inputs and data inputs (EI4/EI5/EI6 and val4/val5/val6), enabling the selection between six different AUDI values. The internal architecture follows the same pattern, using initval_AUDI blocks and a shared AUDI_AUI_MUX_6 selection adapter.

Conclusion

The AUDI_AUI_MUX_6_VAL subapplication provides a convenient, event-driven way to select between six UDINT values and output the corresponding AUDI adapter value. Its modular design makes it suitable for applications requiring multiple selectable AUDI data sources.

AUDI_AUI_MUX_7_VAL

Event zur Auswahl von val1 – *Event* EI1

OUT – *AUDI* – Ausgewaehlter AUDI-Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AUDI_AUI_MUX_7_VAL** is a 7-way multiplexer subapplication designed to select one of seven AUDI values based on an event input. It extends the concept of a 3-channel variant to support seven independent input channels. The block integrates event-based selection with adapter-based data transfer, making it suitable for scenarios where a single AUDI output must be dynamically switched among multiple pre-configured values.

Interface Structure

Event Inputs

Name	Type	Comment
EI1	Event	Event zur Auswahl von val1
EI2	Event	Event zur Auswahl von val2
EI3	Event	Event zur Auswahl von val3
EI4	Event	Event zur Auswahl von val4
EI5	Event	Event zur Auswahl von val5
EI6	Event	Event zur Auswahl von val6
EI7	Event	Event zur Auswahl von val7

Event Outputs

None – the subapplication does not provide any event outputs.

Data Inputs

Name	Type	Comment
val1	UDINT	Initialer Ausgabewert bei EI1
val2	UDINT	Initialer Ausgabewert bei EI2
val3	UDINT	Initialer Ausgabewert bei EI3
val4	UDINT	Initialer Ausgabewert bei EI4
val5	UDINT	Initialer Ausgabewert bei EI5
val6	UDINT	Initialer Ausgabewert bei EI6
val7	UDINT	Initialer Ausgabewert bei EI7

Data Outputs

None – all output data is provided through the adapter interface.

Adapters

Name	Type	Comment
OUT	adapter::types::unidirectional::AUDI	Ausgewählter AUDI-Adapter Output

Functionality

The subapplication operates as an event-driven selector. When one of the event inputs (EI1…EI7) receives a rising edge or a trigger, the corresponding data value (val1…val7) is made available at the output adapter **OUT**. Internally, the following components work together:

- Seven **initval_AUDI** function blocks are used to convert the UDINT input values into the AUDI adapter format. Each block receives one of the `val` inputs and provides an AUDI-typed output.

- The **AUI_MUX_7** event multiplexer forwards the incoming event from the selected input to a corresponding internal selection signal.
- The **AUDI_AUI_MUX_7** data multiplexer then routes the AUDI value from the selected channel to the output adapter.

The selection is purely event-based; no additional control input is required. The output continuously reflects the value of the most recently triggered input channel until another event changes it.

Technical Features

- **IEC 61499-compliant** subapplication structure.
- **Event-driven selection** – no polling or cycle-based updates.
- **UDINT data type** for the input values, providing 32-bit unsigned integer range.
- **Adapter-based output** (AUDI) enabling seamless integration with other components of an AUDI-based system.
- **Scalable design** – the internal architecture can be extended to support more channels if needed.
- **No explicit state variables** the behaviour is deterministic and purely reactive.

State Overview

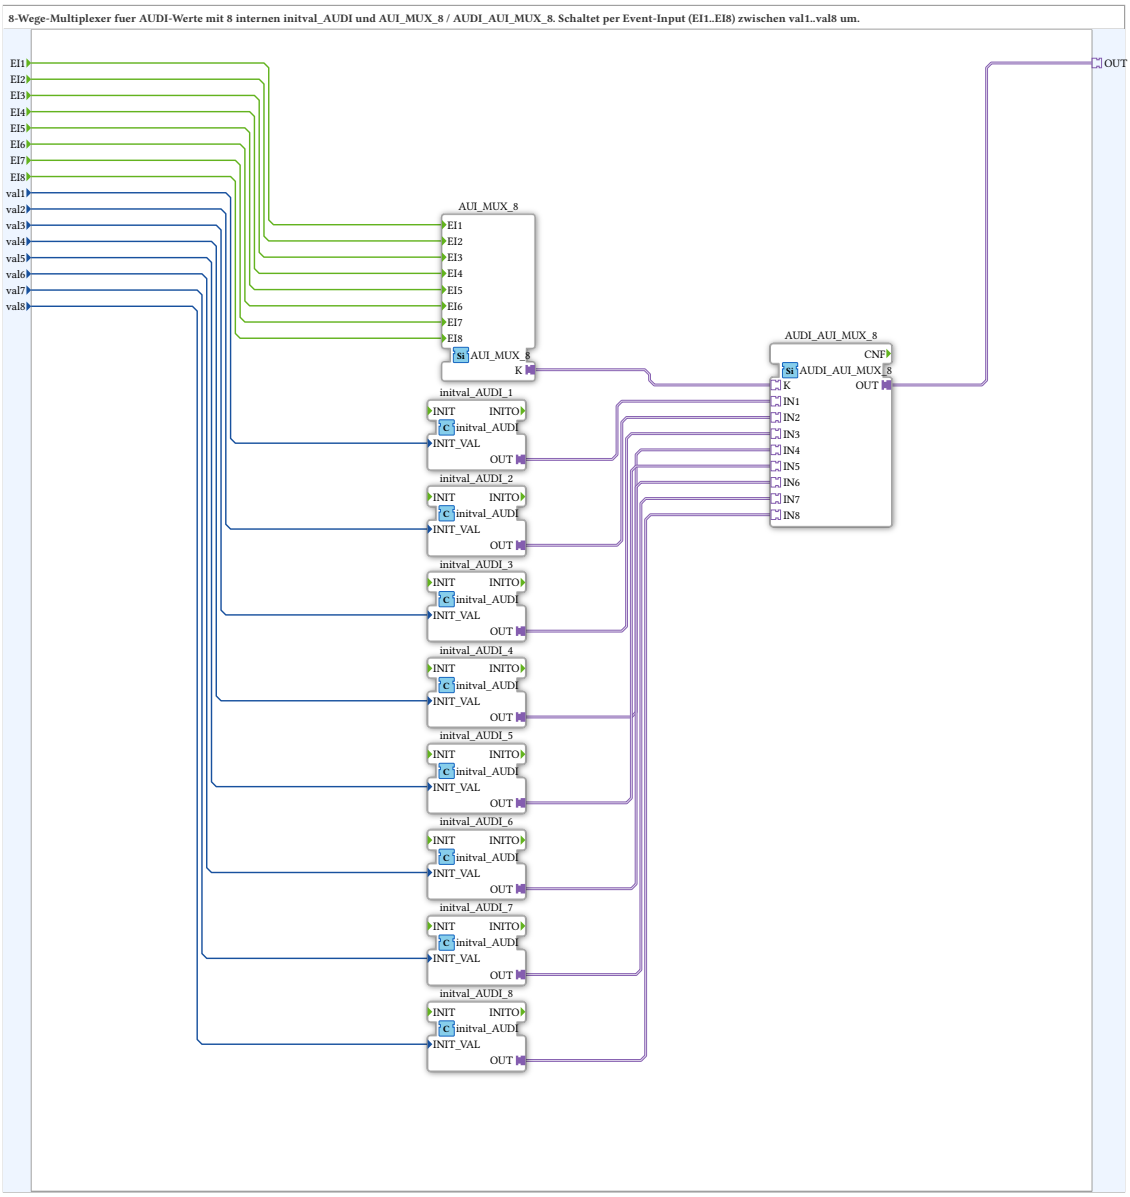
The subapplication does not maintain an internal state machine. Its behaviour is purely combinatorial with respect to the last received event. The active channel is determined solely by the most recent occurrence of an event on EI1…EI7. Consequently, there is no hysteresis or memory beyond the current output value.

Application Scenarios

- **Audio/video switching** – selecting among up to seven different audio sources (e.g., in a multimedia system).
- **Industrial control** – choosing one of several sensor values (encoded as AUDI) for further processing.
- **Configuration management** – switching between preset parameter sets at runtime.
- **Redundancy handling** – selecting a backup value if the primary becomes unavailable.

Comparison with Similar Blocks

Compared to the -3-channel version (`AUDI_AUI_MUX_3_VAL`), this block:



- Provides **seven input channels** instead of three.
- Has a **larger input data port set** (val1…val7).
- Uses a **seven-fold internal replication** of the initialization logic.
- Fulfils the same functional role but for applications requiring more selection options.

Other multiplexer blocks might use a numeric selector input (e.g., QW_INT) instead of multiple event inputs; this variant excels when each channel is triggered by a distinct event (e.g., individual buttons or sensor events).

Conclusion

The **AUDI_AUI_MUX_7_VAL** subapplication is a robust and flexible solution for event-driven selection among up to seven AUDI values. By combining standard IEC 61499 elements with a clear event-based interface, it offers a simple yet powerful mechanism to switch data sources in distributed automation and media systems. Its design ensures high reusability and easy integration into existing AUDI-based architectures.

AUDI_AUI_MUX_8_VAL

• – ◦ • – ◦ • – ◦ •

Introduction

AUDI_AUI_MUX_8_VAL is a composite subapplication that implements an 8-channel multiplexer for values of type `UDINT`. It provides eight event inputs (`EI1` … `EI8`) and eight corresponding data inputs (`val1` … `val8`). When an event is triggered, the associated data value is routed through an internal adapter network and made available at the single AUDI adapter output. The subapplication combines an event multiplexer (`AUI_MUX_8`), an adapter selection block (`AUDI_AUI_MUX_8`), and eight initializer blocks (`initval_AUDI_1` … `initval_AUDI_8`) to achieve a clean, event-driven selection of up to eight `UDINT` values.

Interface Structure

The subapplication exposes a simple, purpose-oriented interface: eight event inputs, eight data inputs, and one adapter output. There are no event outputs, data outputs, or additional adapters.

Event Inputs

Event Name	Description
`EI1`	Event to select `val1` as the output value.
`EI2`	Event to select `val2` as the output value.
`EI3`	Event to select `val3` as the output value.
`EI4`	Event to select `val4` as the output value.
`EI5`	Event to select `val5` as the output value.
`EI6`	Event to select `val6` as the output value.
`EI7`	Event to select `val7` as the output value.
`EI8`	Event to select `val8` as the output value.

Event Outputs

None.

Data Inputs

Data Name	Type	Description

val1	UDINT	Value to be output when EI1 is triggered.
val2	UDINT	Value to be output when EI2 is triggered.
val3	UDINT	Value to be output when EI3 is triggered.
val4	UDINT	Value to be output when EI4 is triggered.
val5	UDINT	Value to be output when EI5 is triggered.
val6	UDINT	Value to be output when EI6 is triggered.
val7	UDINT	Value to be output when EI7 is triggered.
val8	UDINT	Value to be output when EI8 is triggered.

Data Outputs

None.

Adapters

Adapter Name	Type	Description
OUT	adapter::types::unidirectional::AUDI	Adapter output carrying the selected AUDI value.

Functionality

The subapplication operates purely in an event-driven manner. Each of the eight event inputs is directly connected to the corresponding event input of the internal AUI_MUX_8 block. That block uses the active event to produce a selector index K (an integer value) on its output. Simultaneously, each val input is passed to a dedicated initval_AUDI block, which converts the raw UDINT value into an AUDI-typed adapter instance. The eight adapter outputs of the initializers are fed into the eight input channels of the AUDI_AUI_MUX_8 block. Using the selector index K provided by AUI_MUX_8, the selection block forwards exactly one of the eight incoming AUDI adapters to its output, which is then directly connected to the subapplication's OUT adapter.

In summary, triggering any event EI<n> causes the value val<n> to appear at the AUDI output, with no additional data processing. The internal structure ensures that the selection is synchronous with the triggering event and that only one value is active at a time.

Technical Features

- **8-Channel Selection**: Supports up to eight independent input values.
- **Pure Event-Driven Operation**: No continuous polling; each selection is activated by an explicit event.
- **Adapter-Based Output**: The result is provided as a typed AUDI adapter, allowing seamless integration with other AUDI-compatible function blocks.
- **Internal Value Conversion**: The initval_AUDI blocks encapsulate the conversion from UDINT to the AUDI adapter type, keeping the interface simple.
- **Modular Composition**: Uses separate blocks for event multiplexing and adapter selection, which improves reusability and maintainability.
- **No Internal State**: The subapplication is stateless; output selection is fully determined by the most recent event.

State Overview

The subapplication does not maintain any persistent internal state. Its behavior is purely combinational with respect to the triggering event:

- After a reset or at initial startup, no output is selected until one of the events EI1...EI8 is raised.
- When an event EI<n> occurs, the corresponding val<n> is immediately routed to OUT and remains there until another event is triggered.
- The output value is only updated on event edges; data input changes without an associated event do not alter the output.

Because no explicit state variables exist, the subapplication is inherently safe and deterministic.

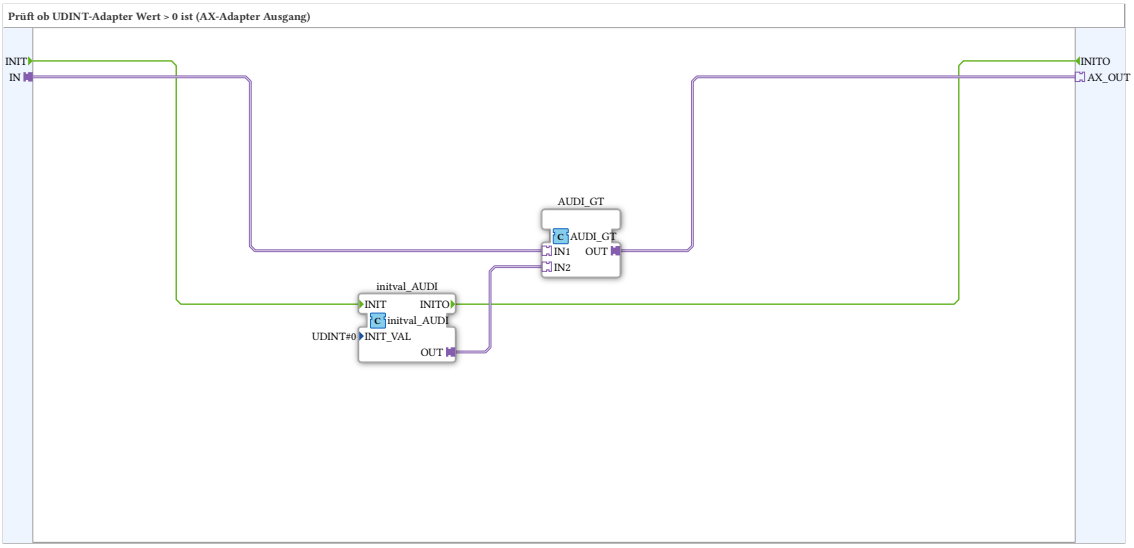
Application Scenarios

This subapplication is particularly useful in control and automation systems where a single AUDI-typed signal must be selected from a set of predefined values based on asynchronous events. Typical use cases include:

- **Mode Selection**: Switching between different operational parameter sets in a machine controller.
- **Recipe Management**: Selecting a recipe (as a `UDINT` code) and forwarding it to a downstream AUDI-based processor.
- **Test Bench Configuration**: Choosing a test profile for a device under test.
- **Event-Driven Calibration**: Changing calibration constants on the fly by sending the appropriate event.

Because the interface is minimal (only events and `UDINT` inputs), it can be easily integrated into larger IEC 61499 applications.

Comparison with Similar Blocks

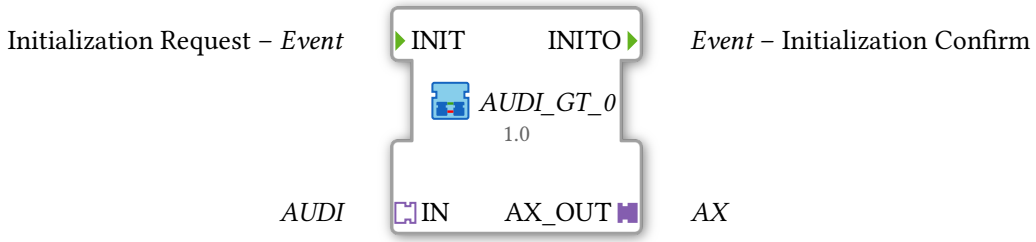


- **AUDI_AUI_MUX_3_VAL**: A three-channel version of the same subapplication. The 8-channel variant offers a larger selection count, making it suitable for applications with more options, but consumes more input events and data ports.
- **Standard MUX Function Blocks**: Typical multiplexers (e.g., based on a selector input) are not event-driven and often require a permanent selector value. This subapplication, in contrast, uses events to trigger the selection, which simplifies integration in event-oriented designs.
- **Simple Selector Adapters**: Some libraries provide direct adapter multiplexers without event synchronization. Here, the event input ensures that the output only changes at explicit trigger points, avoiding glitches or race conditions.

The key advantage of this subapplication is the combination of event-based triggering, typed AUDI adapter output, and the internal separation of event and adapter logic.

Conclusion

AUDI_AUI_MUX_8_VAL is a compact yet powerful subapplication that provides clean, event-driven multiplexing of up to eight `UDINT` values into a single AUDI adapter output. Its modular internal structure and stateless behaviour make it both reliable and easy to integrate into complex IEC 61499 systems. With a simple interface and clear semantics, it is an excellent choice for any application requiring event-synchronised signal selection in AUDI-based environments.



AUDI_GT_0

• – ○ • – ○ • – ○ •

Introduction

`AUDI_GT_0` checks whether a UDINT adapter value is greater than 0 and outputs the result as a boolean AX adapter signal. A typical input is an unsigned 32-bit counter value. The block is built identically for every numeric type (`AS`, `AI`, `ADI`, `ALI`, `AUS`, `AUI`, `AUDI`, `AULI`, `AR`, `ALR`).

Interface

- **Event input**: `INIT` (initialization)
- **Event output**: `INITO` (initialization finished, comes from the internal `initval_AUDI`)
- **Socket**: `IN` (`AUDI`) — the value compared against 0
- **Plug**: `AX_OUT` (`AX`) — TRUE when `IN > 0`

Function Blocks (FBs) Used

Sub-blocks: AUDI_GT_0

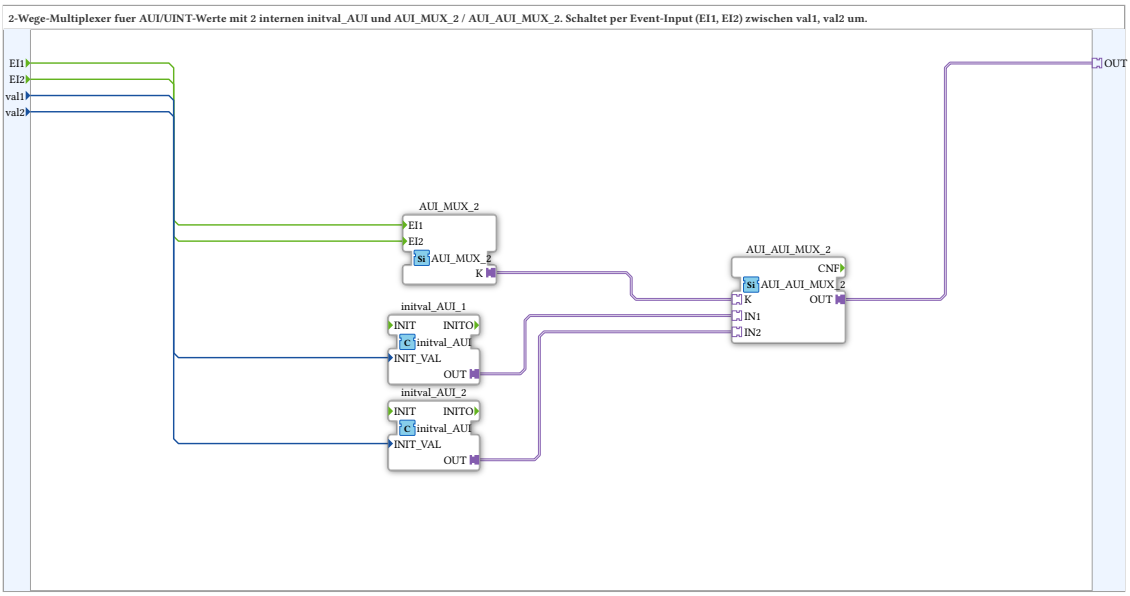
- **Type**: SubAppType
- **Internal FBs used**:
  - **initval_AUDI**: `adapter::types::unidirectional::AUDI::initval::initval_AUDI` — supplies the fixed comparison constant `UDINT#0` as an adapter value (`INIT_VAL=UDINT#0`). An adapter socket cannot take the constant as a parameter, so it is fed in through this block.
  - **AUDI_GT**: `adapter::iec61131::comparison::AUDI_GT` — adapter-native comparison `IN1 > IN2`.
- **Functionality**: `IN` ⟶ `AUDI_GT.IN1`; constant 0 ⟶ `AUDI_GT.IN2`; result ⟶ `AX_OUT`.

Program Flow and Connections

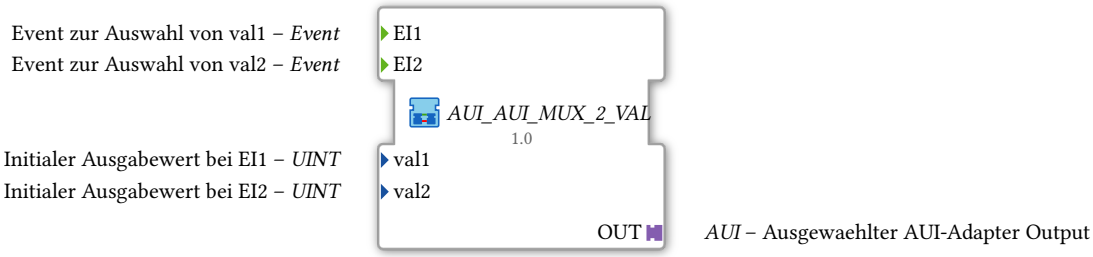
1. `INIT` ⟶ `initval_AUDI.INIT`; `initval_AUDI.INITO` ⟶ `INITO`.
2. `IN` (adapter) ⟶ `AUDI_GT.IN1`.
3. `initval_AUDI.OUT` (constant `UDINT#0`) ⟶ `AUDI_GT.IN2`.
4. `AUDI_GT.OUT` ⟶ `AX_OUT` (adapter).

Application Scenarios

- Converting an unsigned 32-bit counter value into a simple boolean adapter signal for VT status displays or enable logic.



Summary



`AUDI_GT_0` is a compact wrapper around the adapter-native comparison `AUDI_GT` — converts "UDINT > 0" directly into an AX adapter signal, so the caller does not have to create and wire the zero constant itself.

AUI_AUI_MUX_2_VAL

• – ○ • – ○ • – ○ •

Introduction

The **AUI_AUI_MUX_2_VAL** subapplication implements a 2-way multiplexer for AUI adapter values. It accepts two `UINT` input values and two event inputs. Depending on which event is triggered, one of the two input values is converted into an AUI value and provided at the `OUT` adapter plug.

The internal structure combines:

- two `initval_AUI` instances to convert `UINT` values into AUI adapter outputs,
- an `AUI_MUX_2` block for event handling,
- an `AUI_AUI_MUX_2` block for selecting between two AUI input values.

This makes the subapplication a convenient, encapsulated solution for selecting between two AUI values based on events.

• – ○ • – ○ • – ○ •

Interface Structure

Event Inputs

Name	Type	Comment
`EI1`	`Event`	Event to select `val1`
`EI2`	`Event`	Event to select `val2`

Event Outputs

None.

Data Inputs

Name	Type	Comment
`val1`	`UINT`	Initial output value when `EI1` is triggered
`val2`	`UINT`	Initial output value when `EI2` is triggered

Data Outputs

None.

Adapters

Name	Type	Comment
`OUT`	`adapter::types::unidirectional::AUI`	Selected AUI adapter output

• – ◦ • – ◦ • – ◦ •

Functionality

The subapplication acts as a 2-input multiplexer for AUI adapter values:

1. The `UINT` values `val1` and `val2` are connected to two internal `initval_AUI` blocks. These blocks convert the `UINT` values into internal AUI adapter signals.
2. The event inputs `EI1` and `EI2` are connected to the internal `AUI_MUX_2` block. This block determines which input should be selected.
3. The selection information is forwarded to `AUI_AUI_MUX_2`, which receives the two prepared AUI values on its `IN1` and `IN2` adapter inputs.
4. The selected AUI value is routed to the external `OUT` adapter plug.

In practice:

- Triggering `EI1` routes `val1` to `OUT`.
- Triggering `EI2` routes `val2` to `OUT`.

• – ◦ • – ◦ • – ◦ •

Technical Features

- Implements a 2-way multiplexer for AUI adapter values.
- Accepts simple `UINT` values instead of requiring the caller to provide AUI adapter inputs.
- Uses internal `initval_AUI` blocks for `UINT`-to-AUI conversion and initialization.
- Uses `AUI_MUX_2` for event-controlled selection.
- Uses `AUI_AUI_MUX_2` for final adapter output selection.
- Provides a single unidirectional AUI adapter output.
- Encapsulates the complete multiplexing logic inside a reusable subapplication.

• – ◦ • – ◦ • – ◦ •

State Overview

The subapplication does not expose an explicit state machine, but its behavior can be described as a two-state selector:

Event	Selected Input	Output
`EI1`	`val1`	AUI representation of `val1` via `OUT`
`EI2`	`val2`	AUI representation of `val2` via `OUT`
None	Last selection remains active	Depends on the last received event

After one event has been processed, the selected AUI value remains available at `OUT` until the other event is triggered.

• – ◦ • – ◦ • – ◦ •

Application Scenarios

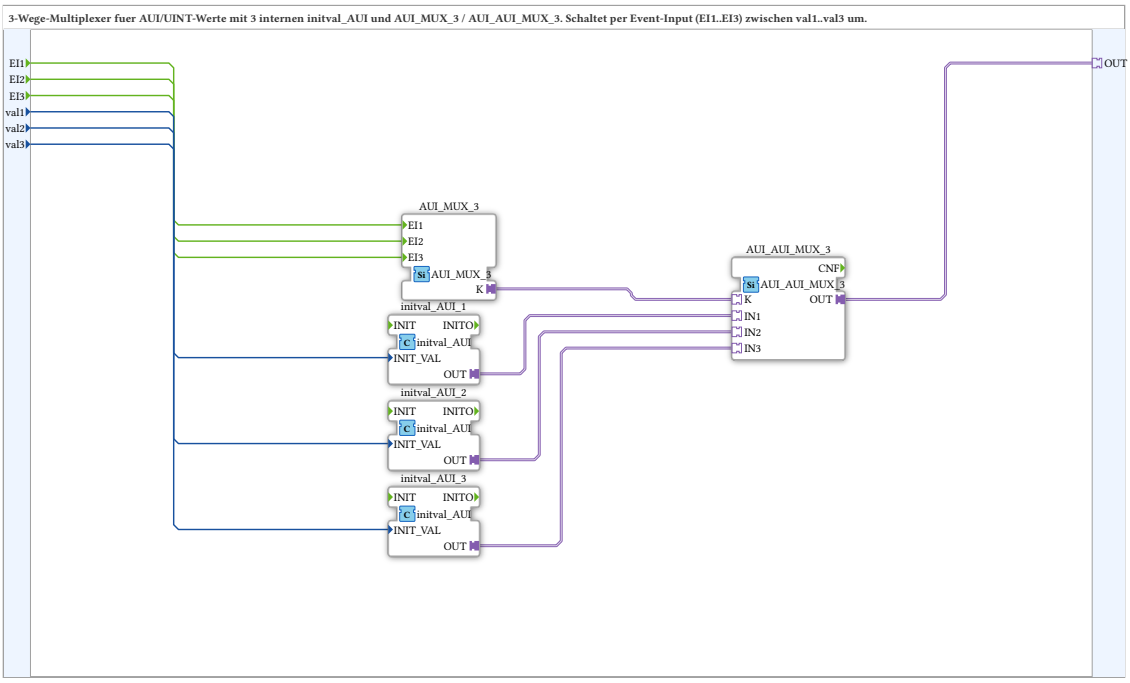
The AUI_AUI_MUX_2_VAL subapplication is useful in IEC 61499 applications where:

- Two predefined UINT values must be selected dynamically by events.
- AUI adapter connections are used for data exchange between function blocks.
- A compact and reusable multiplexer is needed for AUI-based signals.
- Two alternative configuration values must be switched, such as:
  - manual and automatic setpoints,
  - normal and backup values,
  - two operating modes with different parameters.

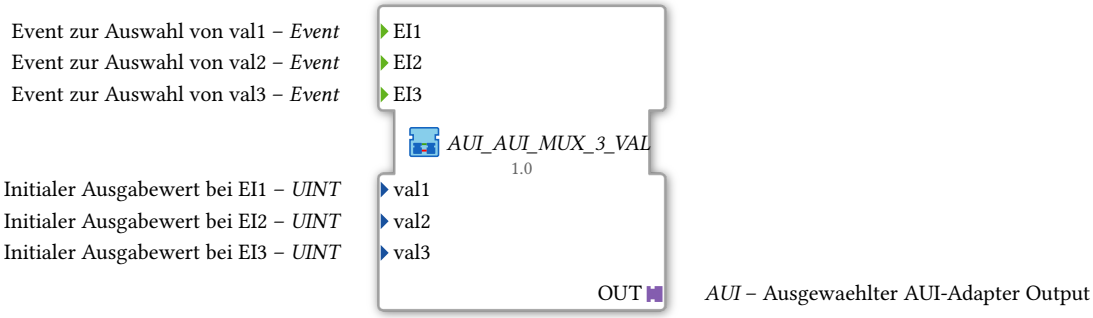
• – ◦ • – ◦ • – ◦ •

Comparison with Similar Blocks

Block / Subapplication	Data Type	Selection Mechanism	Additional Features
Standard MUX	Basic data types	Boolean or event selection	No AUI adapter support
AUI_MUX_2	AUI	Event inputs	Handles AUI event selection
AUI_AUI_MUX_2	AUI	Internal AUI selection	Requires already available AUI inputs
AUI_AUI_MUX_2_VAL	UINT inputs, AUI output	EI1 / EI2 events	Converts UINT values to AUI internally



Compared to a direct AUI multiplexer, this subapplication adds the convenience of using plain UINT values while keeping the AUI adapter interface at the output.



• – ◦ • – ◦ • – ◦ •

Conclusion

AUI_AUI_MUX_2_VAL is a compact and reusable subapplication for event-driven selection between two AUI values. It hides the internal AUI initialization and selection logic behind a simple interface consisting of two events, two UINT inputs, and one AUI adapter output. It is particularly suitable for applications that require fast switching between two predefined values within an AUI-based IEC 61499 environment.

AUI_AUI_MUX_3_VAL

• – ○ • – ○ • – ○ •

Introduction

The **AUI_AUI_MUX_3_VAL** is a composite subapplication that implements a 3-way multiplexer for AUI (Asynchronous Unified Interface) values. It allows selecting one of three AUI input channels via event triggers, while also providing the ability to set initial output values using standard UINT data inputs. The subapplication encapsulates the logic of a dedicated AUI multiplexer and three initial-value adapters, simplifying the integration of AUI-based selection logic into larger systems.

Interface Structure

Event Inputs

- **EI1** – Event to select the first input channel (val1).
- **EI2** – Event to select the second input channel (val2).
- **EI3** – Event to select the third input channel (val3).

Each event triggers the multiplexer to route the corresponding AUI value to the output.

Event Outputs

No explicit event outputs are defined. The subapplication operates purely on event-driven selection; the result is reflected on the AUI output adapter.

Data Inputs

- **val1** (UINT) – The initial value for the first AUI channel.

- **val2** (UINT) – The initial value for the second AUI channel.
- **val3** (UINT) – The initial value for the third AUI channel.

These values are converted to AUI format internally and serve as the default outputs for each corresponding selection event.

Data Outputs

No direct data outputs are exposed. The result is delivered via the AUI output adapter.

Adapters

- **OUT** (AUI, unidirectional) – The selected AUI output. This adapter carries the active channel's value after an event is received.

Functionality

The subapplication combines three main internal components:

1. **AUI_MUX_3** – An event-driven multiplexer control block that accepts the three event inputs (EI1, EI2, EI3) and generates a single control signal (K) indicating which channel is active.
2. **initval_AUI (×3)** – Three instances that accept a UINT initial value (`INIT_VAL`) and convert it into an AUI-compatible output (OUT). Each instance is fed with one of the `val1..val3` inputs.
3. **AUI_AUI_MUX_3** – The core AUI multiplexer that receives three AUI inputs (IN1, IN2, IN3) and the control signal (K). Depending on the control value, it selects one of the inputs and forwards it to the output (OUT).

The internal flow is as follows:

- The UINT values (`val1`, `val2`, `val3`) are passed to the respective `initval_AUI` blocks, which convert them into AUI signals.
- The event inputs (`EI1`, `EI2`, `EI3`) are fed into `AUI_MUX_3`, which produces a control signal based on which event was triggered.
- The control signal and the three AUI inputs are routed to `AUI_AUI_MUX_3`, which selects the appropriate channel and passes it to the external `OUT` adapter.

Thus, upon receiving an event, the subapplication immediately outputs the AUI representation of the corresponding `valN` value.

Technical Features

- **Modular design** – Reuses standard AUI and initval blocks, ensuring interoperability and ease of maintenance.
- **Event-driven selection** – No continuous polling; output changes only when one of the three events occurs.
- **Initial value support** – The UINT inputs allow the subapplication to be initialised with specific values that are converted and made available as AUI signals.
- **Unidirectional AUI output** – The OUT adapter is unidirectional, suitable for simple point-to-point data transfer.
- **Standardised interfaces** – All inputs and outputs adhere to the 61499-2 standard, making the block compatible with other IEC 61499-compliant tools.

State Overview

The subapplication does not maintain internal state beyond the current selection. It behaves as a combinational selector once an event is received:

- **Idle state** – No event has occurred; output holds its last value.
- **Selection states** – After EI1, EI2, or EI3, the output reflects the corresponding AUI value.

There is no explicit reset or default selection; the output remains on the last selected channel until a new event arrives.

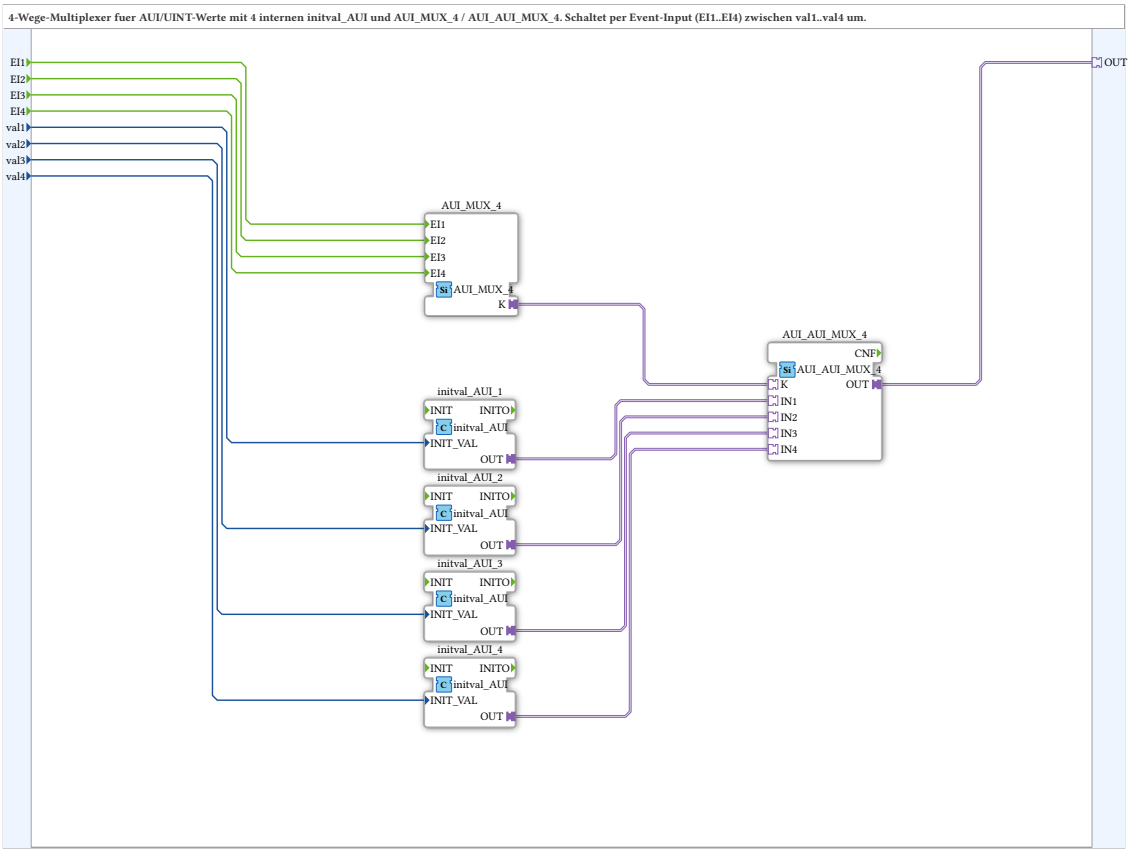
Application Scenarios

- **Process control** – Selecting one of several sensor values (converted to AUI) based on external trigger events.
- **User-interface routing** – Choosing between different data streams (e.g., from different sources) based on operator inputs.

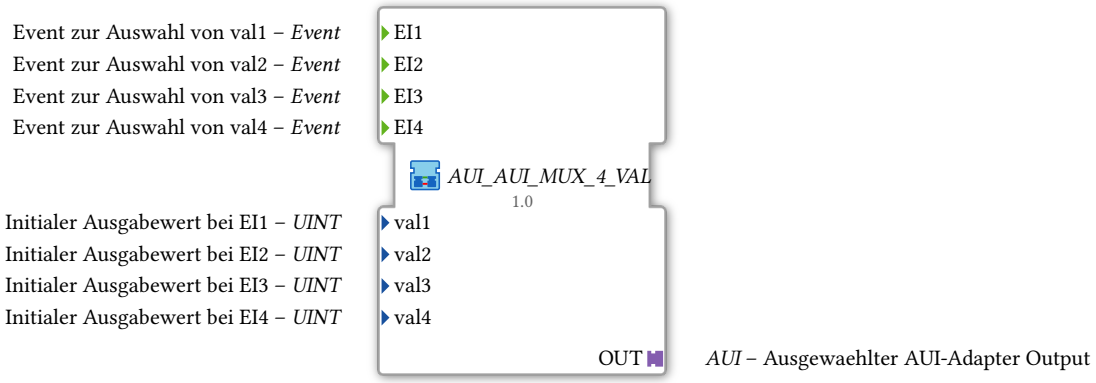
- **Initialization and failover** – Providing a pre-defined default value on each channel, with the ability to switch quickly when events occur.
- **System diagnostics** – Multiplexing diagnostic data from multiple subsystems into a single monitoring point.

Comparison with Similar Blocks

Compared to a simple multiplexer that directly takes UINT inputs and outputs a UINT, this block introduces AUI conversion and event-driven behaviour. It differs from a basic selector in that it:



- Operates on AUI adapters rather than raw data types.
- Includes explicit initial value handling via `initval_AUI`, allowing each channel to have a predefined starting value.
- Is fully event-driven, whereas some multiplexers may use continuous data inputs or a selection input.



When compared to a standalone `AUI_MUX_3` block, this subapplication adds the UINT-to-AUI initialisation layer, making it easier to use in systems that work with standard integer values while still maintaining an AUI output.

Conclusion

The **AUI_AUI_MUX_3_VAL** subapplication provides a clean, event-driven solution for multiplexing AUI signals while supporting UINT-based initial values. Its modular internal structure leverages standard 4diac blocks, ensuring reliability and compatibility. With its simple interface and flexible configuration, it is well suited for a wide range of industrial automation and control applications where AUI communication and event-based selection are required.

AUI_AUI_MUX_4_VAL

• – ◦ • – ◦ • – ◦ •

Introduction

AUI_AUI_MUX_4_VAL is a composite subapplication that implements a 4-way multiplexer specifically for AUI (Application User Interface) adapter values of type UINT. It combines a set of internal initial value generators (`initval_AUI`) with an event-driven selection mechanism (`AUI_MUX_4`) and a final adapter switch (`AUI_AUI_MUX_4`). The subapplication is designed to select one of four UINT input values and route it to a single AUI output adapter based on which of the four event inputs is activated.

Interface Structure

Event Inputs

Event	Description
`EI1`	Event to select the value `val1`
`EI2`	Event to select the value `val2`
`EI3`	Event to select the value `val3`
`EI4`	Event to select the value `val4`

Event Outputs

None – the subapplication does not provide event outputs.

Data Inputs

Data Input	Type	Description
`val1`	UINT	UINT value to be output on `EI1`
`val2`	UINT	UINT value to be output on `EI2`
`val3`	UINT	UINT value to be output on `EI3`
`val4`	UINT	UINT value to be output on `EI4`

Data Outputs

None – all data is passed through the adapter interface.

Adapters

Adapter	Type	Description
`OUT`	`adapter::types::unidirectional::AUI`	Selected UINT value as an AUI adapter output

Functionality

The subapplication operates as follows:

1. The four UINT input values (`val1` ... `val4`) are fed into four internal `initval_AUI` blocks, which convert them into AUI adapter values (likely by wrapping the UINT into the AUI adapter structure).
2. The internal `AUI_MUX_4` block receives the event inputs (`EI1` ... `EI4`) and, based on the event that occurs, generates a selection signal (`K`) that indicates which input channel is to be chosen.
3. The `AUI_AUI_MUX_4` comparator/switch uses this selection signal to forward the corresponding AUI adapter value from the four internal `initval_AUI` blocks to the single output adapter `OUT`.

Thus, whenever an event `EIx` is triggered, the value `valx` becomes available on the output adapter `OUT`. Only one event is processed at a time; the last event received determines the active output.

Technical Features

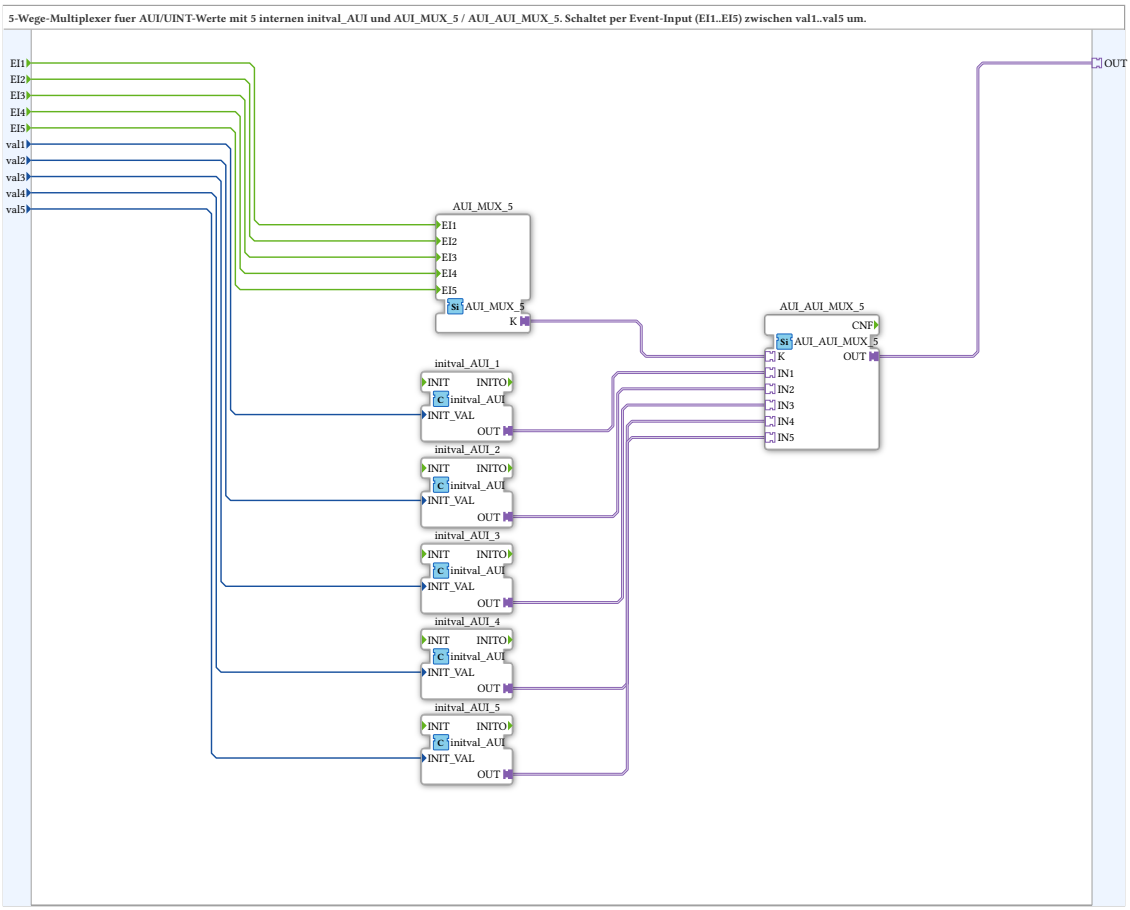
- **Event-driven selection:** The output is only updated when one of the four event inputs is activated, avoiding continuous polling.
- **Internal initial value handling:** The `initval_AUI` blocks ensure that each input value is properly converted to the AUI adapter format before multiplexing.
- **Adapter-based output:** The result is provided as an AUI adapter, allowing seamless integration with other AUI-compatible components.
- **Modular structure:** The subapplication is built from reusable blocks (`AUI_MUX_4`, `AUI_AUI_MUX_4`, `initval_AUI`), promoting maintainability and reusability.

State Overview

The subapplication does not maintain an internal state machine in the traditional sense. Its behavior is purely combinational with respect to the most recent event: the output reflects the value corresponding to the last event that was received. There is no explicit state storage; the selection is performed asynchronously by the internal adapter switch.

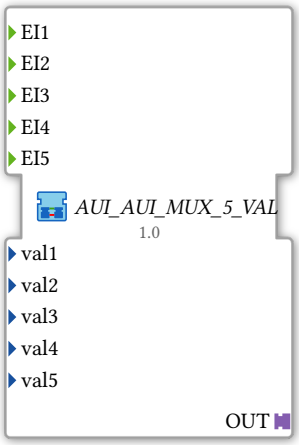
Application Scenarios

- **Multi-source data selection:** When a system must choose between several UINT-based data streams (e.g., sensor readings, configuration values) and output the selected one via an AUI adapter.
- **Control scenario switching:** In an automation environment where different parameter sets (val1...val4) are applied based on discrete control events (EI1...EI4).
- **AUI integration:** For systems already using AUI adapters, this subapp provides a convenient way to multiplex UINT values without leaving the AUI paradigm.



Comparison with Similar Blocks

- **AUI_AUI_MUX_4** (the internal selection block) itself is a plain adapter multiplexer that requires an additional selection signal. This subapplication **adds event inputs** and **automatic conversion from UINT to AUI**, simplifying the user interface.
- **Standard demultiplexer/multiplexer blocks** often work with plain data types and separate selection inputs; here the selection is embedded in the events, making the component self-contained and event-oriented.
- **Similar subapplications** may combine the same internal blocks but offer fewer inputs (e.g., 2-way), whereas this version supports four independent channels.



Conclusion

AUI_AUI_MUX_4_VAL provides a compact and efficient solution for selecting one of four UINT values and forwarding it as an AUI adapter output, driven entirely by events. Its internal structure reuses proven building blocks, ensuring reliability and ease of integration in IEC 61499 automation systems. The subapplication is particularly suited for scenarios where several value sources need to be switched dynamically without overcomplicating the application logic.

AUI – Ausgewaehlter AUI-Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AUI_AUI_MUX_5_VAL** is a composite subapplication (SubAppType) that implements a 5-way multiplexer for AUI (Application Interconnection Unit) adapter values with UINT-based initial configuration. It allows the selection of one out of five incoming AUI data streams based on a corresponding event trigger. Internally, the subapp combines three functional building blocks: an event-driven multiplexer (`AUI_MUX_5`), a data-path selection adapter (`AUI_AUI_MUX_5`), and five initialization adapters (`initval_AUI`) that convert UINT values into AUI adapter outputs. This structure provides a clean and reusable way to route AUI data in IEC 61499-based automation systems, especially in scenarios where a single output adapter must be switched between multiple sources.

Interface Structure

The subapplication exposes the following interface elements to the outside world:

Event Inputs

Name	Type	Description
EI1	Event	Event to select input value `val1`
EI2	Event	Event to select input value `val2`
EI3	Event	Event to select input value `val3`
EI4	Event	Event to select input value `val4`
EI5	Event	Event to select input value `val5`

Each event input corresponds to a dedicated selection action. Triggering one of these events causes the internal multiplexer to route the associated data value to the output.

Event Outputs

There are no event outputs in this subapplication. The selection process is purely input-driven; no completion or acknowledgment events are generated.

Data Inputs

Name	Type	Description
val1	UINT	Initial output value when EI1 is triggered
val2	UINT	Initial output value when EI2 is triggered
val3	UINT	Initial output value when EI3 is triggered
val4	UINT	Initial output value when EI4 is triggered
val5	UINT	Initial output value when EI5 is triggered

These UINT values are forwarded to the internal `initval_AUI` adapters, which convert them into AUI adapter data structures. The values are applied whenever the corresponding event input is activated.

Data Outputs

There are no direct data outputs in the interface list. The result of the multiplexing operation is delivered exclusively via the AUI adapter output.

Adapters

Name	Type	Description
OUT	`adapter::types::unidirectional::AUI`	Selected AUI adapter output containing the active data stream

The `OUT` adapter is a unidirectional AUI interface that carries the data of the currently selected input channel.

Functionality

The subapplication works as a data-selection switch with event-based control. Upon receiving an event at one of the five event inputs (`EI1` to `EI5`), the internal `AUI_MUX_5` block decodes the event and forwards a corresponding selection signal through its `K` adapter connection to the `AUI_AUI_MUX_5` block. Simultaneously, the UINT value associated with the triggered event (e.g., `val1` for `EI1`) is passed to the respective `initval_AUI` instance, which converts it into an AUI data structure. The `AUI_AUI_MUX_5` block then chooses the corresponding input (`IN1` to `IN5`) and routes its data to the `OUT` adapter.

The internal wiring is organized as follows:

- Each event input `EI1`–`EI5` is directly connected to the corresponding event input of the `AUI_MUX_5` block.
- Each UINT data input `val1`–`val5` feeds the `INIT_VAL` input of a dedicated `initval_AUI` instance.

- The five `initval_AUI` outputs (`OUT`) are connected to the `IN1`–`IN5` adapter ports of the `AUI_AUI_MUX_5` selection block.
- The selection event from `AUI_MUX_5` is transferred via its `K` adapter to the `K` port of `AUI_AUI_MUX_5`.
- The `OUT` port of the selection block is connected to the subapplication's external `OUT` adapter.

Thus, the overall behavior is a synchronous event-driven multiplexer: only one output is active at any time, and the active channel is determined exclusively by the most recent event input.

Technical Features

- **Composite subapplication**: Encapsulates a complete multiplexing logic into a single reusable component.
- **Event-driven selection**: Selection is controlled via five discrete event inputs, making the block suitable for cyclic or edge-triggered control schemas.
- **UINT-to-AUI conversion**: The internal `initval_AUI` adapters handle the conversion from simple UINT data to the compound AUI adapter format, simplifying the external interface.
- **Modular internal design**: The subapp is built from three different block types (`AUI_MUX_5`, `AUI_AUI_MUX_5`, and `initval_AUI`), each with a clear and focused responsibility, improving maintainability and testability.
- **Unidirectional AUI output**: The external adapter interface is unidirectional, which fits well in publish-subscribe or point-to-point data flow architectures.
- **No explicit state variables**: The subapp relies entirely on the internal blocks' behavior; no additional state management is required in the composite layer.

State Overview

The subapplication itself does not define an explicit state machine; its behavior is derived from the internal blocks. However, the effective operational states can be described as follows:

State	Trigger	Description
Idle	No event received	The output retains the last selected value; no switching occurs.
Channel 1 active	Event EI1	Input `val1` is converted and routed to the `OUT` adapter.
Channel 2 active	Event EI2	Input `val2` is converted and routed to the `OUT` adapter.
Channel 3 active	Event EI3	Input `val3` is converted and routed to the `OUT` adapter.
Channel 4 active	Event EI4	Input `val4` is converted and routed to the `OUT` adapter.
Channel 5 active	Event EI5	Input `val5` is converted and routed to the `OUT` adapter.

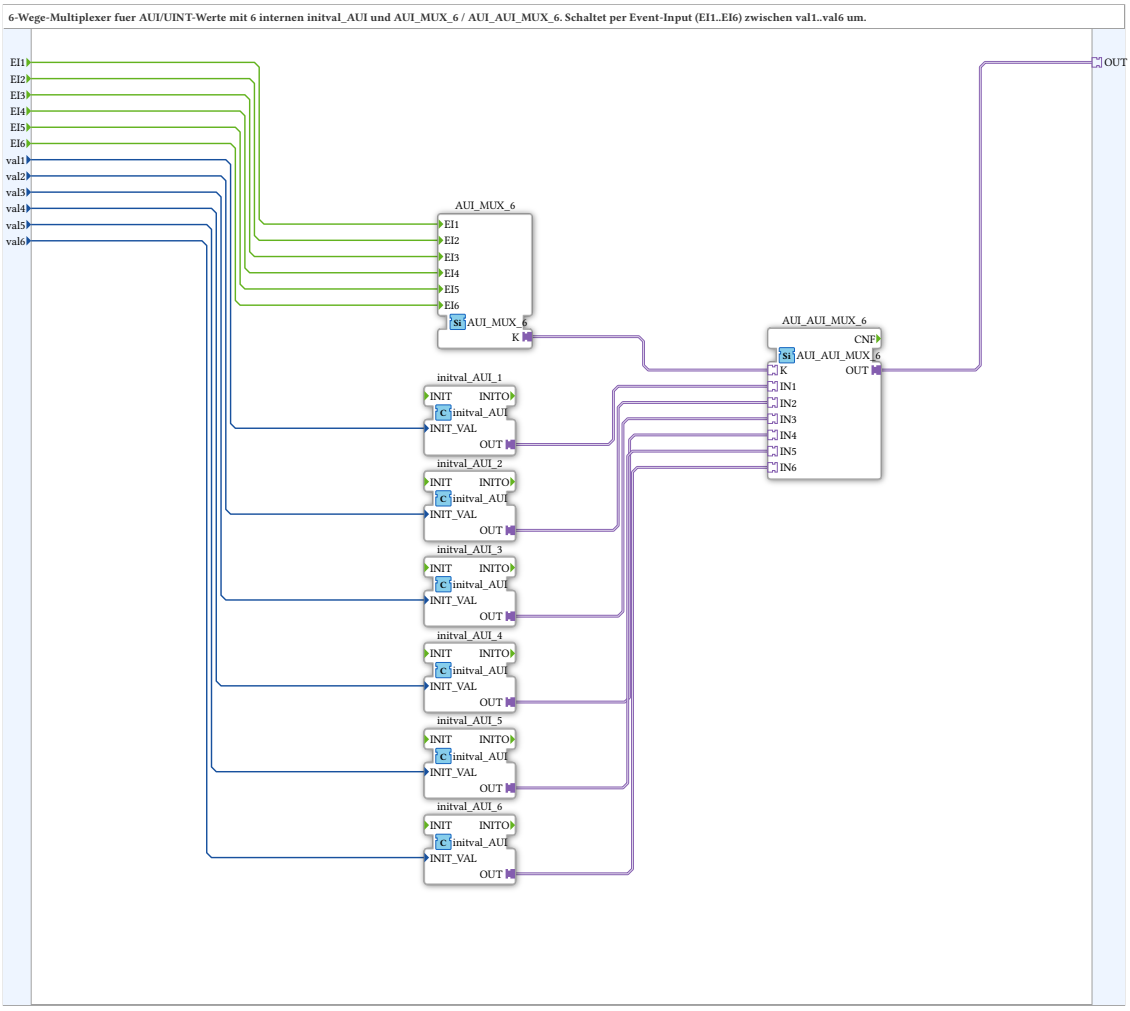
Each state transition is triggered by a rising edge of the corresponding event input. The output remains stable in the absence of new events.

Application Scenarios

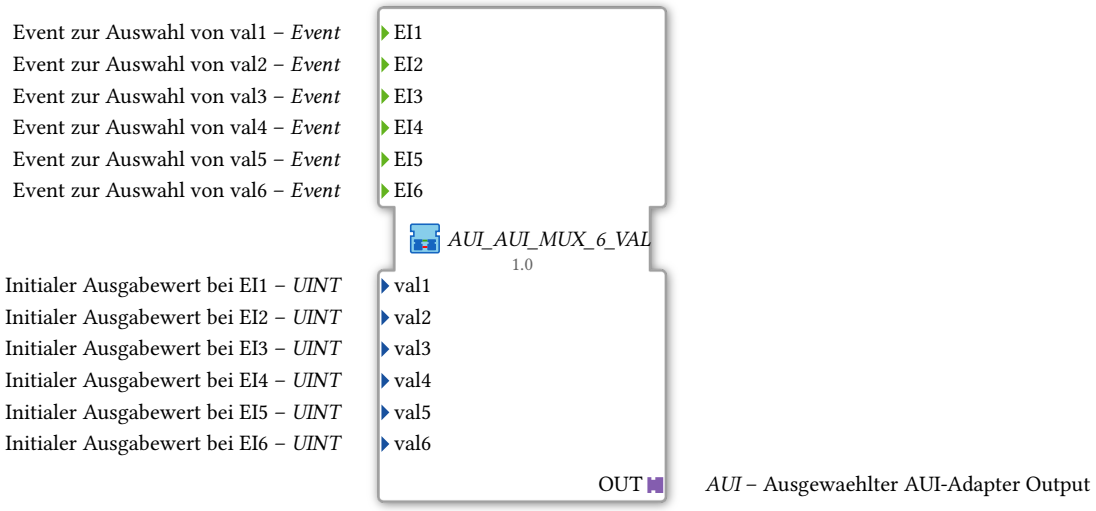
- **Multi-source data routing**: In distributed automation systems where a single consumer must receive data from one out of several producers, this block can serve as a central selection switch.
- **Parameterizable initialization**: When different startup values are required for different operational modes, the UINT inputs allow runtime or configuration-time initialization of each channel.
- **Mode switching**: In machine control applications, the block can switch between different reference values (e.g., speed, position, temperature) based on operator events.
- **Test and simulation environments**: The subapp can be used to inject different test values into a processing chain by simply toggling the event inputs.

Comparison with Similar Blocks

Feature	AUI_AUI_MUX_5_VAL	Simple UINT MUX	Generic AUI MUX (without init)
Input data type	UINT (converted internally to AUI)	UINT only	AUI (requires pre-configured sources)
Output data type	AUI adapter	UINT	AUI adapter



Event inputs	5 (EI1–EI5)	Typically 1 (with selector input)	5 (EI1–EI5)
Internal initialization	Yes, via `initval_AUI` blocks	No	No
Type conversion handling	Integrated, transparent to the user	Not applicable	Not applicable
Use case complexity	Medium – suitable for composite control	Low – simple data selection	Medium – requires external AUI sources



Compared to a plain UINT multiplexer, this subapp adds the advantage of AUI adapter compatibility. Compared to a generic AUI mux, it offers built-in UINT initialization, which reduces external wiring and makes it easier to configure values at design time or from HMI/PLC variables.

Conclusion

The `AUI_AUI_MUX_5_VAL` subapplication provides a robust and modular solution for selecting between five AUI data streams based on event triggers. Its internal architecture cleanly separates event decoding, data conversion, and data selection, resulting in a highly reusable component. The integration of UINT-based initialization values simplifies configuration and makes the block particularly useful in applications where parameterized startup values or dynamic channel switching are required. By maintaining a purely unidirectional external interface and relying on standard 4diac adapter patterns, the block fits seamlessly into IEC 61499-compliant engineering workflows and can be deployed across a wide range of automation scenarios.

AUI_AUI_MUX_6_VAL

• – ◦ • – ◦ • – ◦ •

Introduction

AUI_AUI_MUX_6_VAL is a composite subapplication that implements a 6-way multiplexer for UINT values, converting them into AUI adapter outputs. It combines six input events (EI1…EI6) with six data inputs (val1…val6) and a single AUI output adapter. Internally, it uses three functional blocks: an event-driven multiplexer (AUI_MUX_6), an AUI selection unit (AUI_AUI_MUX_6), and six instances of the initialiser block initval_AUI. This design allows the selection of one of six UINT values via event triggers and provides the selected value as an AUI adapter output.

Interface Structure

Event Inputs

Event	Type	Comment
EI1	Event	Event to select val1
EI2	Event	Event to select val2
EI3	Event	Event to select val3
EI4	Event	Event to select val4
EI5	Event	Event to select val5
EI6	Event	Event to select val6

Event Outputs

No event outputs are defined.

Data Inputs

Data Input	Type	Comment
val1	UINT	Initial output value when EI1 is triggered
val2	UINT	Initial output value when EI2 is triggered
val3	UINT	Initial output value when EI3 is triggered
val4	UINT	Initial output value when EI4 is triggered
val5	UINT	Initial output value when EI5 is triggered
val6	UINT	Initial output value when EI6 is triggered

Data Outputs

No direct data outputs are present; all output data is carried through the AUI adapter.

Adapters

Adapter	Type	Comment
OUT	AUI (adapter::types::unidirectional::AUI)	Selected AUI adapter output

Functionality

The subapplication operates as a 6-to-1 selector for AUI-encoded UINT values. When an event input (e.g., EI1) is activated, the corresponding UINT value (val1) is loaded into the respective internal initval_AUI block. These initval_AUI blocks convert the plain UINT data into an AUI adapter stream. The event multiplexer (AUI_MUX_6) forwards the triggering event to the selection block (AUI_AUI_MUX_6), which then switches the appropriate input adapter (from one of the six initval_AUI blocks) to the output adapter. Thus, the selected UINT value becomes available on the OUT adapter only after the corresponding event fires.

Technical Features

- **Modular design**: Combines dedicated multiplexer, selection, and initialisation blocks.
- **Adapter-based I/O**: All data exchange uses AUI type adapters, ensuring type safety and compatibility with other AUI-compatible blocks.
- **Event-driven selection**: Each input event directly controls the multiplexer, resulting in deterministic switching behaviour.
- **Parameterised initial values**: All six data inputs are UINT and are internally converted to AUI via initval_AUI blocks.
- **Scalable architecture**: The pattern can be extended to more channels by adding parallel blocks and events.

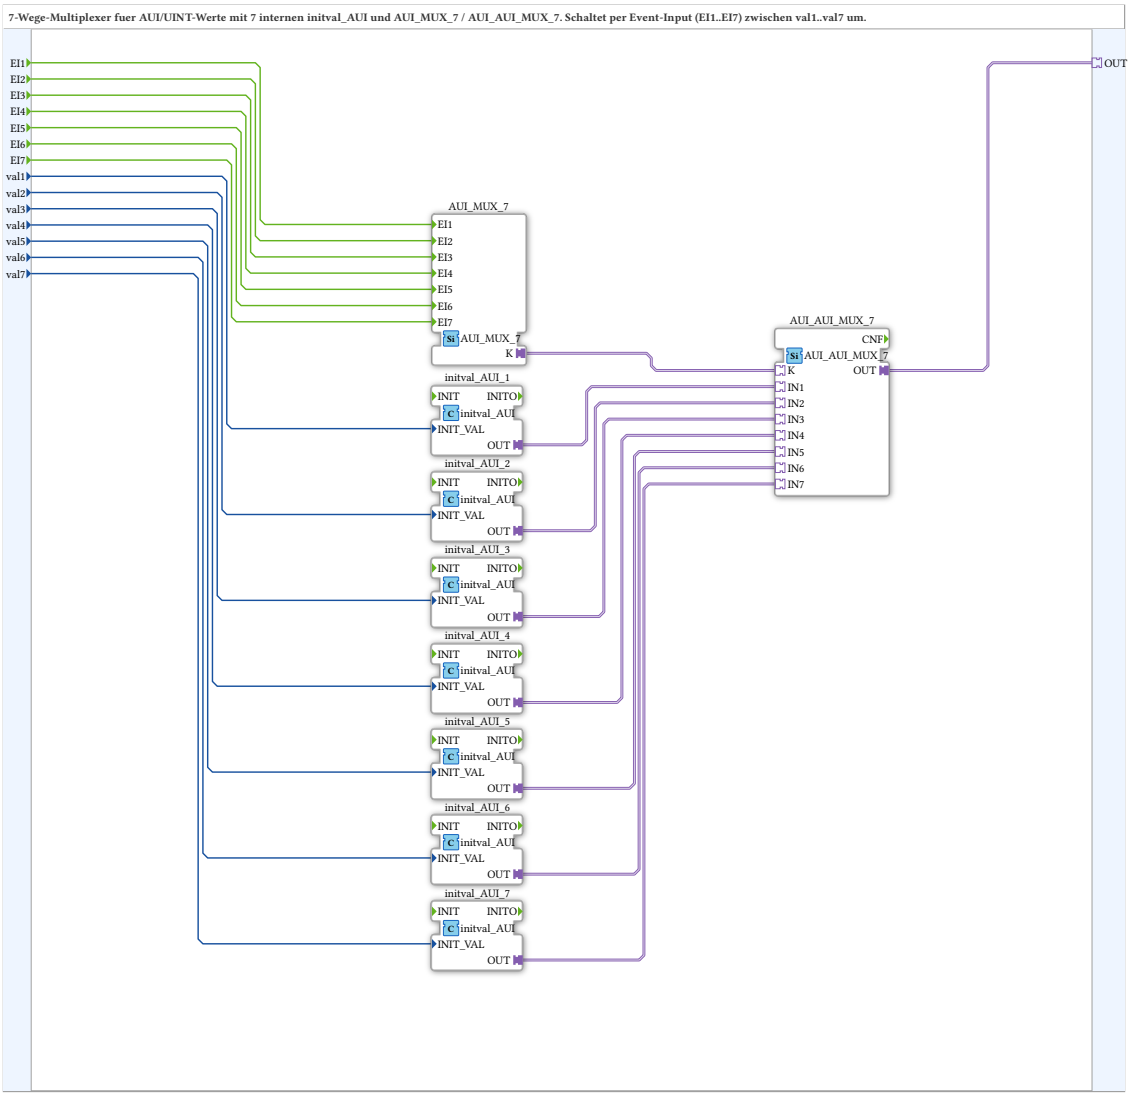
State Overview

The subapplication does not expose an explicit state machine. Its behaviour is purely combinational and event-driven: the state is implicitly defined by which event has been most recently received. Each event latches the corresponding UINT value into the AUI output. There is no internal persistent state beyond the current selection; however, the initval_AUI blocks hold the converted AUI values until overwritten by a new event.

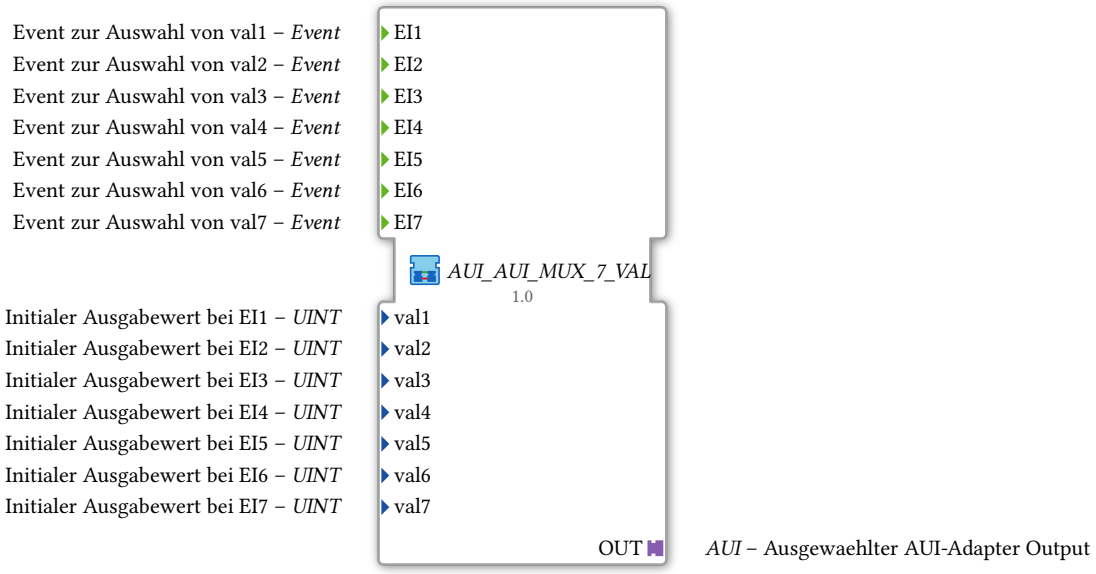
Application Scenarios

- **Control systems**: Selecting between multiple preset speeds, pressures, or setpoints based on discrete control signals.
- **Data routing**: Forwarding one of several measured UINT values to a common monitoring adapter.
- **Configuration management**: Loading predefined parameter sets into an AUI-based process.
- **Test benches**: Simulating multi-channel sensor selection for validation purposes.

Comparison with Similar Blocks



Feature	AUI_AUI_MUX_6_VAL	AUI_MUX_6 (standalone)	AUI_AUI_MUX_6 (standalone)
Input data type	UINT (converted to AUI internally)	UINT (via events)	AUI (direct adapters)
Output type	AUI adapter	AUI adapter	AUI adapter
Number of channels	6	6	6
Internal initialisers	Yes (initval_AUI blocks)	No	No
Event handling	Yes (EI1…EI6)	Yes (EI1…EI6)	(depends on implementation)



The combined subapplication integrates the initialisation and selection logic, simplifying external wiring and ensuring consistent AUI conversion for all input values.

Conclusion

AUI_AUI_MUX_6_VAL is a compact and reusable subapplication that provides a reliable 6-way AUI multiplexer with UINT inputs. By encapsulating the conversion and selection logic, it reduces complexity for application developers and promotes clear, event-driven control. Its design aligns with IEC 61499 standards and is well suited for industrial automation scenarios where multiple analogue or digital values must be selectively routed to a common adapter output.

AUI_AUI_MUX_7_VAL

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUI_AUI_MUX_7_VAL** is a composite subapplication that implements a 7-way multiplexer for AUI (Adapter Unified Interface) values derived from UINT inputs. It selects one of seven UINT values (`val1` ... `val7`) based on a corresponding event input (`EI1` ... `EI7`) and provides the selected value as a unidirectional AUI adapter output (`OUT`). Internally, the subapplication uses pre-built function blocks to convert the UINT data to AUI format and to perform the actual selection, offering a ready-to-use, reusable component for scenarios requiring event-driven data selection in IEC 61499-based systems.

Interface Structure

The subapplication exposes a clean interface comprising event inputs, data inputs, and an adapter output. No event outputs or additional adapters are present.

Event Inputs

Name	Type	Comment
EI1	Event	Event to select `val1`
EI2	Event	Event to select `val2`
EI3	Event	Event to select `val3`
EI4	Event	Event to select `val4`
EI5	Event	Event to select `val5`
EI6	Event	Event to select `val6`
EI7	Event	Event to select `val7`

Event Outputs

None.

Data Inputs

Name	Type	Comment
val1	UINT	Value to be output when `EI1` occurs
val2	UINT	Value to be output when `EI2` occurs

val3	UINT	Value to be output when EI3 occurs
val4	UINT	Value to be output when EI4 occurs
val5	UINT	Value to be output when EI5 occurs
val6	UINT	Value to be output when EI6 occurs
val7	UINT	Value to be output when EI7 occurs

Data Outputs

None.

Adapters

Name	Type	Direction	Comment
OUT	adapter::types::unidirectional::AUI	Output (Plug)	Selected AUI adapter output

Functionality

The subapplication acts as an event-driven selector. When an event arrives on one of the event inputs (EI1 … EI7), the corresponding UINT data input (val1 … val7) is converted into an AUI adapter value and propagated to the output adapter OUT. The selection is entirely event-driven; no continuous data sampling occurs—the output is only updated upon the arrival of a triggering event.

Internally, the subapplication is composed of:

- Seven initval_AUI function blocks that convert each UINT input into an AUI value.
- An AUI_MUX_7 block that handles the event selection logic (likely routing the triggering event to the appropriate internal channel).
- An AUI_AUI_MUX_7 block that performs the final selection of the AUI values from the seven converted inputs and forwards the chosen one to the output adapter OUT.

The event input is mapped directly to the selection mechanism, ensuring that a single event selects exactly one data source. The combination of these internal blocks yields a robust, reusable multiplexer with a simple external interface.

Technical Features

- **Event-driven selection**: Only one event determines the active input; no polling or continuous evaluation.
- **UINT to AUI conversion**: Each UINT value is converted internally to an AUI adapter type, enabling seamless integration with AUI-based communication patterns.
- **7-channel multiplexing**: Supports up to seven distinct input values, each selectable via its own event.
- **Unidirectional AUI output**: The output is a unidirectional adapter, suitable for scenarios where data flows from the subapplication to a connected consumer.
- **Reuse of standard blocks**: The subapplication leverages existing, tested function blocks (initval_AUI, AUI_MUX_7, AUI_AUI_MUX_7) to reduce development and verification effort.
- **No hidden state**: The subapplication is stateless; the output depends solely on the most recent event and the current input values.

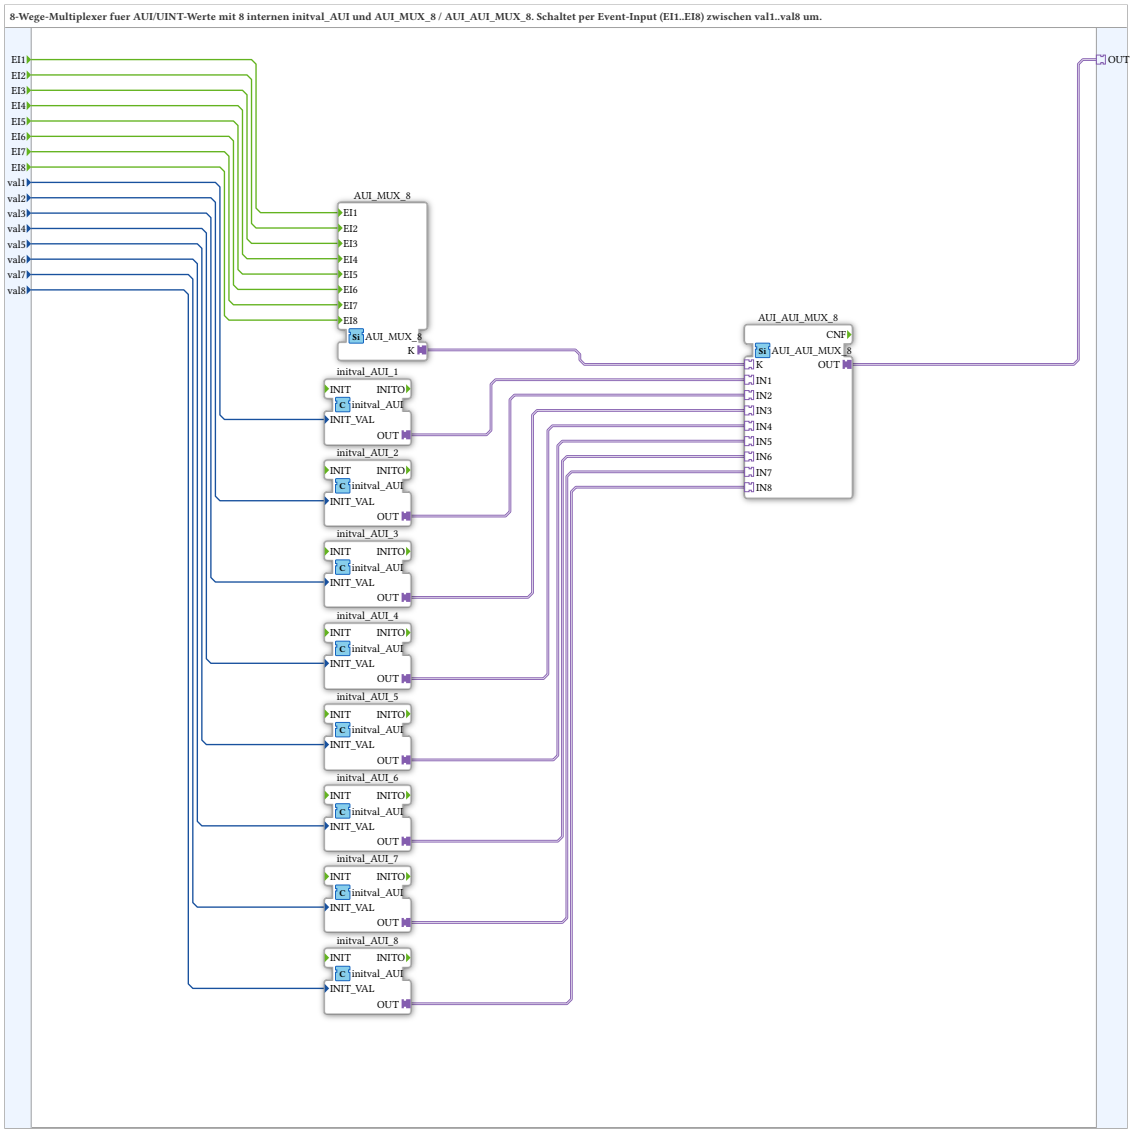
State Overview

The subapplication does not maintain any internal state. Its behaviour is purely combinatorial with respect to the event inputs—the output is updated synchronously when an event occurs. There is no startup, idle, or error state; the block is always ready to respond to events. This simplifies integration and testing, as no re-initialisation is required.

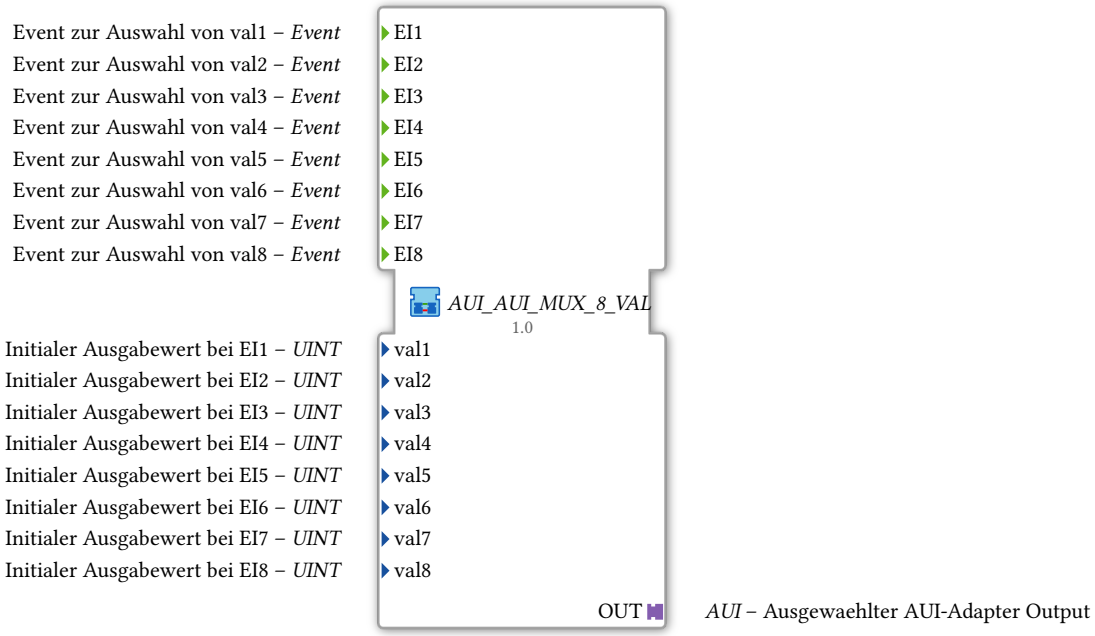
Application Scenarios

- **Multi-source data selection**: In systems where multiple data sources (e.g., sensor readings, configuration values) must be chosen on demand, this subapplication provides a clean event-driven interface.
- **AUI-based communication**: When the surrounding application uses AUI adapters for data exchange, this component bridges the gap between simple UINT values and the AUI data type.

- **Rapid prototyping**: Because the subapplication encapsulates the conversion and selection logic, it can be dropped into a 4diac-based design with minimal configuration.
- **Distributed control systems**: The event-driven nature aligns well with IEC 61499 event-based execution models, making the subapplication suitable for distributed automation and process control.



Comparison with Similar Blocks



- **vs. Standard MUX blocks**: Typical multiplexer FBs in IEC 61499 often use a data input as the selector (e.g., a K input) and do not provide per-event selection. This subapplication uses individual event inputs, which is more natural for event-driven control flows.
- **vs. AUI-only multiplexers**: Some multiplexers operate entirely within the AUI domain, but they may not offer the UINT-to-AUI conversion. Here, the conversion is intrinsic, simplifying the user interface.
- **vs. Single-value selectors**: For fewer channels, a simpler selector might suffice, but the 7-channel configuration provides a scalable solution without needing multiple instances.

Conclusion

The **AUI_AUI_MUX_7_VAL** subapplication is a well-designed, reusable component for selecting one of seven UINT values based on event triggers and exposing the result as a unidirectional AUI adapter. Its event-driven nature, combined with built-in UINT-to-AUI conversion, makes it a practical building block for IEC 61499 applications needing flexible and reliable data multiplexing. With its clear interface and absence of internal state, it is easy to integrate, test, and maintain.

AUI_AUI_MUX_8_VAL

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUI_AUI_MUX_8_VAL** is a composite subapplication that provides an 8-way multiplexer for **UINT** values, which are presented on an **AUI** adapter interface. It selects one of eight input values based on an incoming event and forwards the selected value as an AUI output. This block is especially useful when a control system needs to switch between different parameter sets or configuration values in a structured, event-driven manner.

Interface Structure

Event Inputs

Name	Type	Comment
EI1	Event	Event to select val1
EI2	Event	Event to select val2
EI3	Event	Event to select val3
EI4	Event	Event to select val4
EI5	Event	Event to select val5
EI6	Event	Event to select val6
EI7	Event	Event to select val7
EI8	Event	Event to select val8

Event Outputs

None.

Data Inputs

Name	Type	Comment
val1	UINT	Initial output value for EI1
val2	UINT	Initial output value for EI2

val3	UINT	Initial output value for EI3
val4	UINT	Initial output value for EI4
val5	UINT	Initial output value for EI5
val6	UINT	Initial output value for EI6
val7	UINT	Initial output value for EI7
val8	UINT	Initial output value for EI8

Data Outputs

None.

Adapters

Name	Type	Comment
OUT	adapter::types::unidirectional::AUI	Selected AUI adapter output

Functionality

The subapplication acts as a demultiplexer/selector for AUI-encapsulated values. Internally, it combines three functional elements:

1. **AUI_MUX_8** – an event-driven multiplexer block that receives the eight event inputs and converts them into a single selection signal (available on its `K` adapter output).
2. **initval_AUI_1 ... initval_AUI_8** – eight instances of an AUI initialisation block. Each block accepts a UINT value (`INIT_VAL`) and provides it as an AUI output.
3. **AUI_AUI_MUX_8** – a selection block that receives the selection signal `K` from the first block and the eight AUI inputs from the initval blocks. It forwards exactly one of these inputs to the subapplication's `OUT` adapter, depending on the active event.

When an event is received on `EIx` (x = 1 ... 8), the corresponding input value `valx` is propagated to the output adapter. The internal architecture ensures that only the selected value is presented on `OUT`, while all other values remain isolated.

Technical Features

- **8-channel selection** – up to eight independent UINT input values can be managed.
- **Event-driven switching** – selection occurs only upon an event, providing deterministic behaviour.
- **AUI adapter output** – the selected value is provided as an AUI type, allowing seamless integration with other adapter-based components in the 4diac environment.
- **Internal initialisation** – each input value is converted to an AUI representation using dedicated initval blocks, simplifying the connection to the selection logic.
- **Modular design** – built from reusable standard blocks, making the subapplication easy to maintain and extend.

State Overview

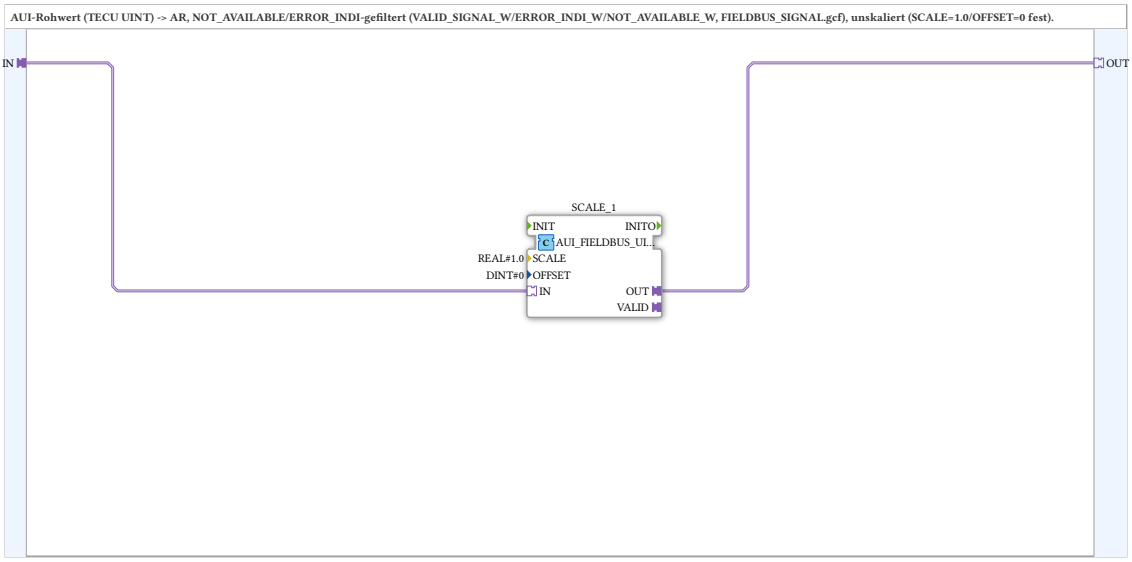
The subapplication does not maintain a persistent state. It is purely combinational with respect to the event inputs: after the reception of an event on `EIx`, the output reflects the value of `valx`. No internal state variables are used, and the block behaves identically for every execution cycle.

Application Scenarios

Typical use cases for the `AUI_AUI_MUX_8_VAL` include:

- **Parameter switching** – selecting between different configuration sets (e.g., different motor profiles, sensor calibration values) based on external control events.
- **Mode selection** – choosing between operating modes in a machine or process, where each mode has its own set of parameters.
- **Test and simulation** – dynamically feeding different test values into a component without reconfiguring the network.

- **Redundancy management** – switching between primary and backup values in case of failure detection.

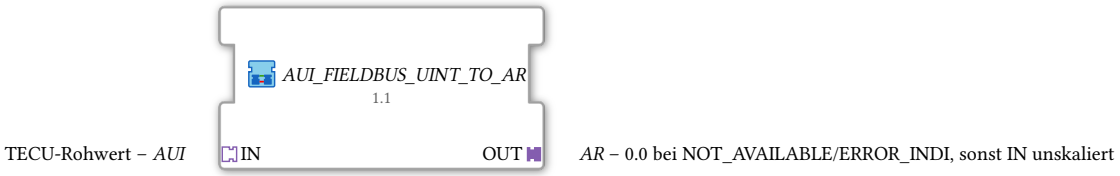


Comparison with Similar Blocks

Compared to simpler multiplexers that operate directly on UINT data, `AUI_AUI_MUX_8_VAL` provides an **AUI-typed output**, which is essential when the downstream components expect an adapter interface. Unlike a conventional event-driven multiplexer that may require additional conversion steps, this subapplication integrates the conversion and selection in one block. It also supports eight channels, while many standard multiplexers are limited to fewer inputs. However, it does not offer an explicit "no selection" or invalid event state – only the eight defined event inputs are accepted.

Conclusion

The `AUI_AUI_MUX_8_VAL` is a compact and reusable subapplication for event-based selection among eight UINT values, presented as an AUI output. Its internal structure leverages proven building blocks, resulting in a clean and deterministic behaviour. It is suitable for a wide range of industrial automation and control applications where multiple parameter sets or modes need to be switched dynamically.



AUI_FIELDBUS_UINT_TO_AR

• – ○ • – ○ • – ○ •

Introduction

`AUI_FIELDBUS_UINT_TO_AR` converts an `AUI` raw value (TECU, `UINT`) into an `AR` value and filters out the fieldbus special values `NOT_AVAILABLE` and `ERROR_INDI` on the way. The conversion is unscaled (`SCALE = 1.0`, `OFFSET = 0` fixed). The block was extracted because the same parameterisation was previously set individually in `TECU_RPTO`, `TECU_FPTO`, `TECU_COGSOG`, `TECU_GBSD`, `TECU_WBSD`, `TECU_VDS`, `TECU_FHS` and `TECU_RHS`. It lives in `MyLib_AX::sys` because it is generic and not TECU-specific.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

- **IN** (socket, `adapter::types::unidirectional::AUI`): TECU raw value
- **OUT** (plug, `adapter::types::unidirectional::AR`): `0.0` on `NOT_AVAILABLE/ERROR_INDI`, otherwise `IN` unscaled

Function Blocks (FBs) Used

- **`SCALE_1`** (`logiBUS::signalprocessing::fieldbus::AUI_FIELDBUS_UINT_TO_SIGNAL_SCALED`): parameters `SCALE = 1.0`, `OFFSET = 0`

Functionality

`IN` ⟶ `SCALE_1.IN` and `SCALE_1.OUT` ⟶ `OUT`. The filtering of the fieldbus special values (`VALID_SIGNAL_W`/`ERROR_INDI_W`/`NOT_AVAILABLE_W`, defined in `FIELDBUS_SIGNAL.gcf`) is done by the internal block; the SubApp only fixes scale and offset.

Technical Details

- No event or data ports of its own, adapters only
- Fixed scale factor 1.0 and offset 0 (generic, unscaled variant)

Application Scenarios

- Taking TECU raw values (e.g. speeds) from the fieldbus as an `AR` signal without scaling

Summary

`AUI_FIELDBUS_UINT_TO_AR` wraps `AUI_FIELDBUS_UINT_TO_SIGNAL_SCALED` with `SCALE = 1.0`/`OFFSET = 0` as a reusable SubApp.

AUI_GT_0

• – ○ • – ○ • – ○ •

Introduction

`AUI_GT_0` checks whether a UINT adapter value is greater than 0 and outputs the result as a boolean AX adapter signal. A typical input is an object-ID or counter value (e.g. "how many channels are active"). The block is built identically for every numeric type (`AS`, `AI`, `ADI`, `ALI`, `AUS`, `AUI`, `AUDI`, `AULI`, `AR`, `ALR`).

Interface

- **Event input**: `INIT` (initialization)
- **Event output**: `INITO` (initialization finished, comes from the internal `initval_AUI`)
- **Socket**: `IN` (`AUI`) — the value compared against 0
- **Plug**: `AX_OUT` (`AX`) — TRUE when `IN > 0`

Function Blocks (FBs) Used

Sub-blocks: AUI_GT_0

- **Type**: SubAppType
- **Internal FBs used**:
  - **initval_AUI**: `adapter::types::unidirectional::AUI::initval::initval_AUI` — supplies the fixed comparison constant `UINT#0` as an adapter value (`INIT_VAL=UINT#0`). An adapter socket cannot take the constant as a parameter, so it is fed in through this block.
  - **AUI_GT**: `adapter::iec61131::comparison::AUI_GT` — adapter-native comparison `IN1 > IN2`.
- **Functionality**: `IN` ⟶ `AUI_GT.IN1`; constant 0 ⟶ `AUI_GT.IN2`; result ⟶ `AX_OUT`.

Program Flow and Connections

1. `INIT` ⟶ `initval_AUI.INIT`; `initval_AUI.INITO` ⟶ `INITO`.
2. `IN` (adapter) ⟶ `AUI_GT.IN1`.
3. `initval_AUI.OUT` (constant `UINT#0`) ⟶ `AUI_GT.IN2`.
4. `AUI_GT.OUT` ⟶ `AX_OUT` (adapter).

Application Scenarios

- Converting an object-ID or counter value (e.g. "how many channels are active") into a simple boolean adapter signal for VT status displays or enable logic.

Summary

`AUI_GT_0` is a compact wrapper around the adapter-native comparison `AUI_GT` — converts "UINT > 0" directly into an AX adapter signal, so the caller does not have to create and wire the zero constant itself.

AULI_GT_0

• – ◦ • – ◦ • – ◦ •

Introduction

`AULI_GT_0` checks whether a ULINT adapter value is greater than 0 and outputs the result as a boolean AX adapter signal. A typical input is an unsigned 64-bit counter value. The block is built identically for every numeric type (`AS`, `AI`, `ADI`, `ALI`, `AUS`, `AUI`, `AUDI`, `AULI`, `AR`, `ALR`).

Interface

- **Event input**: `INIT` (initialization)
- **Event output**: `INITO` (initialization finished, comes from the internal `initval_AULI`)
- **Socket**: `IN` (`AULI`) — the value compared against 0
- **Plug**: `AX_OUT` (`AX`) — TRUE when `IN > 0`

Function Blocks (FBs) Used

Sub-blocks: AULI_GT_0

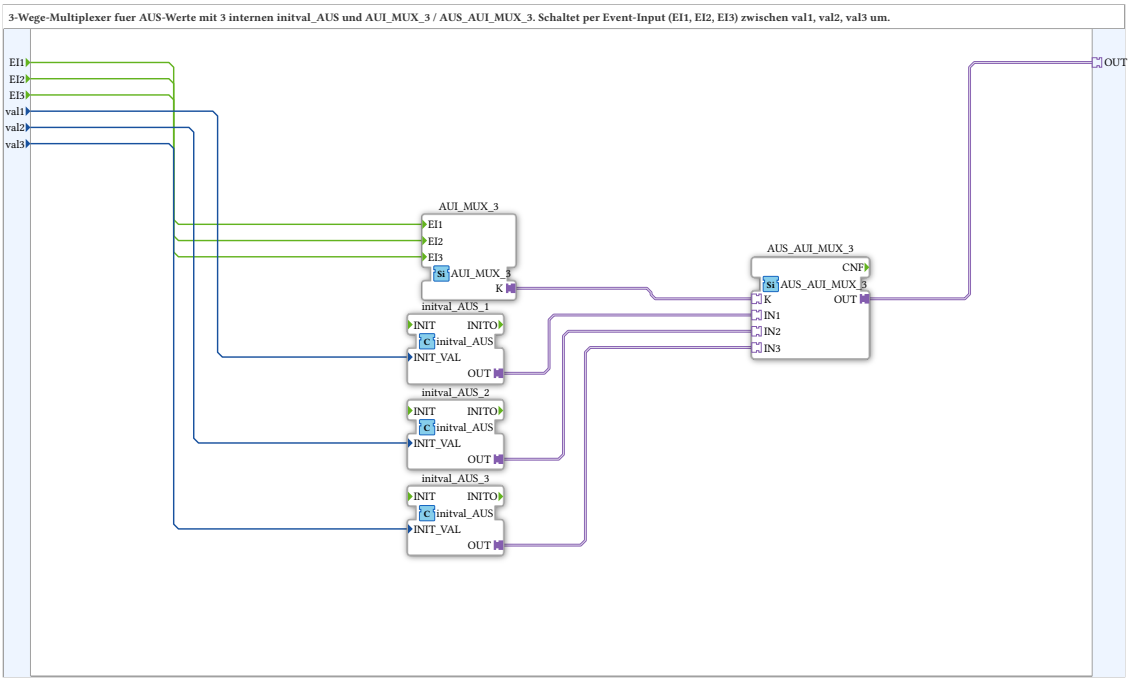
- **Type**: SubAppType
- **Internal FBs used**:
  - **initval_AULI**: `adapter::types::unidirectional::AULI::initval::initval_AULI` — supplies the fixed comparison constant `ULINT#0` as an adapter value (`INIT_VAL=ULINT#0`). An adapter socket cannot take the constant as a parameter, so it is fed in through this block.
  - **AULI_GT**: `adapter::iec61131::comparison::AULI_GT` — adapter-native comparison `IN1 > IN2`.
- **Functionality**: `IN` ⟶ `AULI_GT.IN1`; constant 0 ⟶ `AULI_GT.IN2`; result ⟶ `AX_OUT`.

Program Flow and Connections

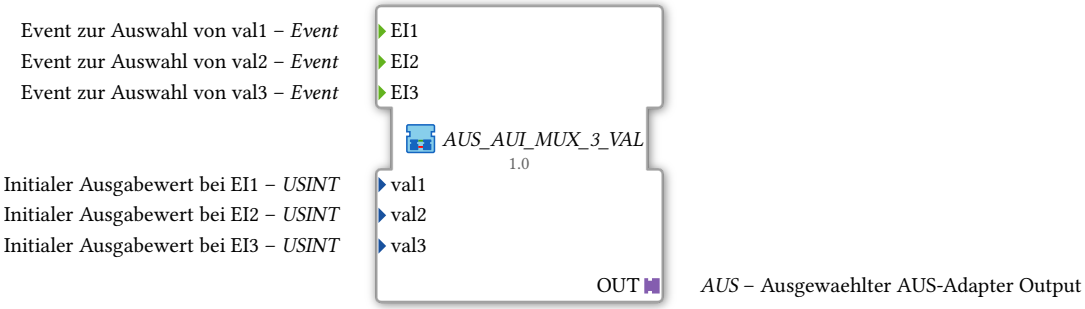
1. `INIT` ⟶ `initval_AULI.INIT`; `initval_AULI.INITO` ⟶ `INITO`.
2. `IN` (adapter) ⟶ `AULI_GT.IN1`.
3. `initval_AULI.OUT` (constant `ULINT#0`) ⟶ `AULI_GT.IN2`.
4. `AULI_GT.OUT` ⟶ `AX_OUT` (adapter).

Application Scenarios

- Converting an unsigned 64-bit counter value into a simple boolean adapter signal for VT status displays or enable logic.



Summary



`AULI_GT_0` is a compact wrapper around the adapter-native comparison `AULI_GT` — converts "ULINT > 0" directly into an AX adapter signal, so the caller does not have to create and wire the zero constant itself.

AUS_AUI_MUX_3_VAL

• – ○ • – ○ • – ○ •

Introduction

`AUS_AUI_MUX_3_VAL` is a composite subapplication that implements a three-way multiplexer for AUS (Automation Unit Service) values. It provides three independent USINT input values (`val1`, `val2`, `val3`) and, based on which of the three event inputs (`EI1`, `EI2`, `EI3`) is triggered, routes the corresponding value to a unidirectional AUS adapter output (`OUT`).

Internally, the subapplication combines three initial-value adapters (`initval_AUS`) with an event selection block (`AUI_MUX_3`) and an adapter multiplexer (`AUS_AUI_MUX_3`). This allows the user to supply plain numeric values on the subapplication interface while internally converting them to the required AUS adapter representation.

Interface Structure

Event Inputs

Name	Type	Comment
EI1	Event	Event to select val1 as active output
EI2	Event	Event to select val2 as active output
EI3	Event	Event to select val3 as active output

Event Outputs

None. The subapplication does not provide any event outputs.

Data Inputs

Name	Type	Comment
val1	USINT	Initial output value used when EI1 is triggered
val2	USINT	Initial output value used when EI2 is triggered
val3	USINT	Initial output value used when EI3 is triggered

Data Outputs

None. The result of the multiplexing is delivered via the adapter plug OUT.

Adapters

Name	Direction	Type	Comment
OUT	Plug	adapter::types::unidirectional::AUS	Carries the currently selected AUS value

Functionality

The subapplication is composed of five internal function blocks that work together to perform the multiplexing task:

1. **initval_AUS_1, initval_AUS_2, initval_AUS_3** – Each of these blocks (type adapter::types::unidirectional::AUS::initval::initval_AUS) receives one of the USINT data inputs (val1, val2, val3) on its INIT_VAL input and exposes it as a unidirectional AUS adapter on its OUT output. This converts the plain numeric value into the AUS adapter form required by the downstream selection block.
2. **AUI_MUX_3** – An event multiplexer (type adapter::events::unidirectional::AUI_MUX_3) that receives the three event inputs. When an event is received, it sets the selection signal on its adapter output K to indicate which channel has been requested.
3. **AUS_AUI_MUX_3** – An adapter selection block (type adapter::selection::unidirectional::AUS_AUI_MUX_3) that takes the three prepared AUS adapter inputs (IN1, IN2, IN3) plus the selection signal K. Based on the value of K, it forwards the corresponding input to its OUT adapter.

Signal flow summary:

- EI1/EI2/EI3 ⟶ AUI_MUX_3.EI1/2/3 ⟶ AUI_MUX_3.K (selection)
- val1/val2/val3 ⟶ initval_AUS_1/2/3.INIT_VAL ⟶ initval_AUS_1/2/3.OUT ⟶ AUS_AUI_MUX_3.IN1/2/3
- AUS_AUI_MUX_3.OUT ⟶ subapplication plug OUT

When, for example, EI1 is triggered, AUI_MUX_3 encodes this on K, which instructs AUS_AUI_MUX_3 to pass the AUS value generated from val1 to the OUT adapter.

Technical Features

- **Three independent event-triggered channels** – Each input value is selected exclusively by its corresponding event.
- **USINT data type** – All three input values are unsigned short integers (0–255), suitable for small control values, addresses, or counters.
- **Adapter-based output** – The result is provided through a unidirectional AUS adapter, enabling direct connection to other AUS-compatible blocks in the application.
- **Internal value conversion** – The `initval_AUS` blocks transparently convert raw USINT values into the AUS adapter format, hiding internal representation details from the user.
- **Modular composition** – The subapplication reuses standard blocks (`AUI_MUX_3`, `AUS_AUI_MUX_3`, `initval_AUS`) and can be easily adapted or extended.
- **No data or event outputs** – Simplicity; the only external result is the selected AUS adapter value.
- **Deterministic selection** – The selection logic is purely event-driven; the most recently triggered event determines the active output.

State Overview

The subapplication does not contain an explicit state machine with multiple persistent states. Instead, it behaves as a **one-hot selection logic**:

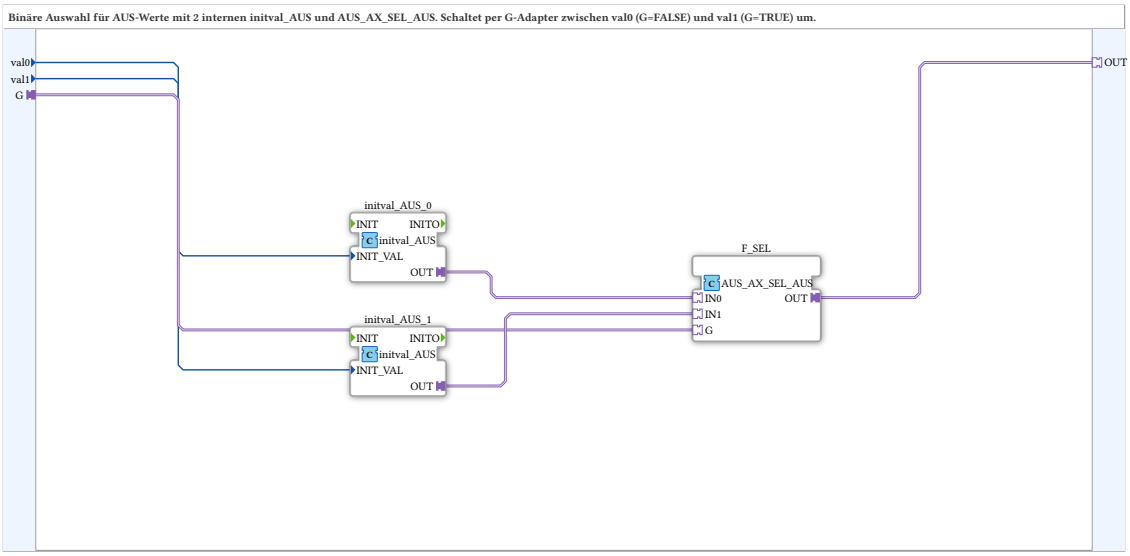
- After receipt of `EI1`, the output presents the AUS value derived from `val1`.
- After receipt of `EI2`, the output presents the AUS value derived from `val2`.
- After receipt of `EI3`, the output presents the AUS value derived from `val3`.

The "current state" can be described as the identity of the last received event (or the corresponding selected channel). The output is updated immediately upon the event, without additional data processing steps. Because the selection is event-triggered, no polling or continuous evaluation of the data inputs is required.

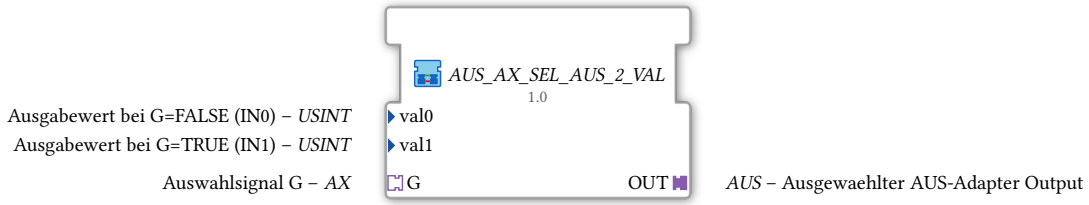
Application Scenarios

- **Mode / profile selection** – Selecting among three pre-defined parameter sets (e.g., operating modes, speed profiles) via discrete event signals.
- **Input routing in process control** – Redirecting a control value from one of three sources to a common output depending on external triggers.
- **Value presets for automation units** – Supplying a fixed value to an AUS-consuming block (e.g., a setpoint or limit) and switching between presets on demand.
- **Testing and simulation** – Switching between different simulation values in a test environment without reconfiguration.
- **HMI or master control integration** – Where operator actions (buttons, commands) generate events that select the corresponding operation value.

Comparison with Similar Blocks



Feature	`AUS_AUI_MUX_3` (standalone)	`AUS_AUI_MUX_3_VAL` (this subapplication)
Input handling	Requires already-prepared AUS adapters on `IN1`, `IN2`, `IN3`	Accepts plain USINT values and converts them internally
Value provisioning	External blocks must supply AUS values	Self-contained; values are provided directly on the subapp interface
Number of external connections	More complex wiring (multiple AUS plugs)	Simplified – only three numeric inputs and one event per channel
Use of `initval_AUS`	Not included	Integrated internally
Ease of use	Lower – requires in-depth adapter knowledge	Higher – user only provides simple values and events



Compared to a generic IEC 61499 MUX function block, this subapplication adds the AUS **adapter conversion layer**, making it directly interoperable with AUS-based components while keeping the interface numeric. Unlike a binary-coded multiplexer, selection here is **event-driven** rather than address-driven.

Conclusion

`AUS_AUI_MUX_3_VAL` provides a clean, self-contained solution for selecting one of three AUS values via discrete events. By wrapping the `initval_AUS`, `AUI_MUX_3`, and `AUS_AUI_MUX_3` blocks into a single composite, it hides the internal adapter transformations and offers a simple numeric interface. This makes it an ideal building block for applications that need to switch between preset values in an event-oriented manner, while remaining compatible with the 4diac adapter ecosystem.

AUS_AX_SEL_AUS_2_VAL

• – ○ • – ○ • – ○ •

Introduction

The **AUS_AX_SEL_AUS_2_VAL** is a subapplication that implements a binary selection of two `AUS` (output) adapter values based on a select signal carried by an `AX` adapter. It encapsulates two internal `initval_AUS` blocks that convert raw `USINT` values into valid `AUS` adapter data, and a central `AUS_AX_SEL_AUS` selection block. Depending on the state of the select input `G`, the subapp forwards one of the two configured values (`val0` or `val1`) to its output adapter `OUT`.

Interface Structure

The subapplication provides no direct event inputs or outputs; all interaction takes place through data inputs and adapter connections.

Event Inputs

None.

Event Outputs

None.

Data Inputs

Name	Type	Comment
`val0`	`USINT`	Output value when `G = FALSE` (IN0)

val1	USINT	Output value when G = TRUE (IN1)

Data Outputs

None.

Adapters

Direction	Name	Type	Comment
Socket (Input)	G	adapter::types::unidirectional::AX	Selection signal G
Plug (Output)	OUT	adapter::types::unidirectional::AUS	Selected AUS adapter output

Functionality

The internal network consists of three function blocks and the associated connections:

1. **initval_AUS_0** – Takes the val0 data input and generates an AUS adapter value as its output.
2. **initval_AUS_1** – Takes the val1 data input and generates an AUS adapter value as its output.
3. **F_SEL** (type AUS_AX_SEL_AUS) – Receives the two AUS values on its IN0 and IN1 inputs, and the selection signal G (type AX) on its G input. It forwards the selected AUS value to its OUT output, which is connected to the subapplication's OUT plug.

The selection logic is straightforward: when G is FALSE, the value from val0 (via initval_AUS_0) is forwarded; when G is TRUE, the value from val1 (via initval_AUS_1) is forwarded.

Technical Features

- **Encapsulated initialization** – The raw USINT values are wrapped into AUS adapter objects by the two internal initval_AUS blocks, keeping the subapp interface clean and adapter-based.
- **Adapters only interface** – External communication is performed exclusively through unidirectional adapters (AX for selection, AUS for the output), making the block compatible with adapter-based system designs.
- **Combinational behavior** – The output follows the selection input without internal state memory; changes on val0, val1, or G are directly reflected.
- **No event dependencies** – The subapp works without event triggers, simplifying its integration in cyclic or continuous processing environments.

State Overview

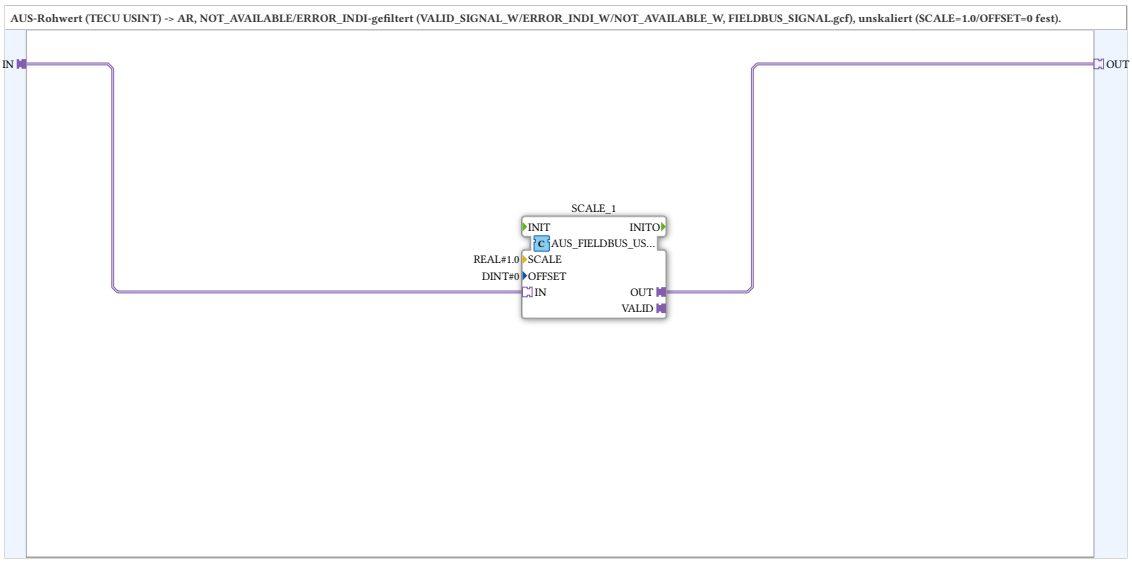
This subapplication is purely combinational and does not maintain an internal state. The output is determined solely by the current values of the data inputs val0, val1, and the adapter input G. No initialization sequence, reset handling, or state transition logic is required.

Application Scenarios

- **Preset value switching** – Selecting between two predefined AUS output values (e.g., two different speed commands or configuration codes) based on a binary control signal.
- **Redundant parameter selection** – Switching between a primary and a fallback value in automation systems where an AUS adapter delivers the active parameter.
- **Adapter-based I/O routing** – In systems that standardize on unidirectional AUS/AX adapters, this subapp provides a reusable, interface-compatible selection element.
- **Configuration time setting** – Used to map static configuration values into adapter-formatted outputs, as the initval blocks convert constants or externally provided values.

Comparison with Similar Blocks

Feature	AUS_AX_SEL_AUS_2_VAL	Standard SEL / MUX (IEC 61131)
Interface type	Adapter-based (AX / AUS)	Direct data pins (e.g., USINT)
Value initialization	Implicit via internal initval_AUS blocks	Requires external value preparation
Output type	Adapter (AUS)	Raw data type



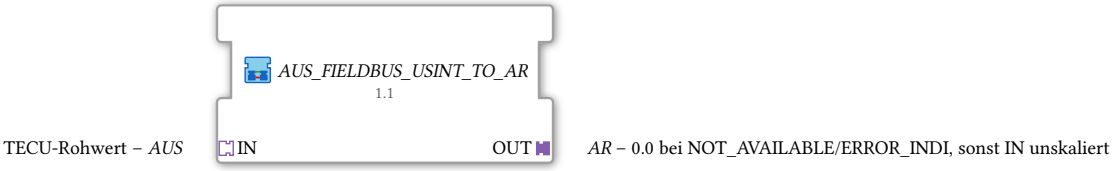
Use in adapter-heavy designs	Fully compatible	Requires additional conversion blocks

Unlike a plain SEL function block, this subapp encapsulates both the value initialization and the adapter connection logic, reducing the wiring effort and increasing reusability in adapter-oriented architectures.

Conclusion

AUS_AX_SEL_AUS_2_VAL provides a clean, adapter-based solution for selecting between two AUS values under the control of an AX selection signal. Its internal use of initval_AUS blocks hides the conversion complexity from the application programmer and ensures that the subapp can be dropped directly into 4diac projects relying on unidirectional adapters. With its combinational nature and simple interface, it is a practical building block for binary configuration and routing in IEC 61499-based automation systems.

AUS_FIELDBUS_USINT_TO_AR



• – ○ • – ○ • – ○ •

Introduction

AUS_FIELDBUS_USINT_TO_AR converts an **AUS raw value** (TECU USINT) into an AR value. The values NOT_AVAILABLE/ERROR_INDI are filtered (VALID_SIGNAL_W/ERROR_INDI_W/NOT_AVAILABLE_W, FIELDBUS_SIGNAL.gcf); the scaling is fixed to SCALE=1.0 and OFFSET=0, so the value remains unscaled.

The SubApp was extracted from AUS_FIELDBUS_USINT_TO_SIGNAL_SCALED because SCALE=1.0/OFFSET=0 had to be parameterized individually every time in TECU_FHS/TECU_RHS; it lives in MyLib_AX::sys because it is generic and not TECU-specific.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

- **IN** (socket): Unidirectional adapter of type `adapter::types::unidirectional::AUS` - TECU raw value
- **OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::AR` - `0.0` on `NOT_AVAILABLE/ERROR_INDI`, otherwise `IN` unscaled

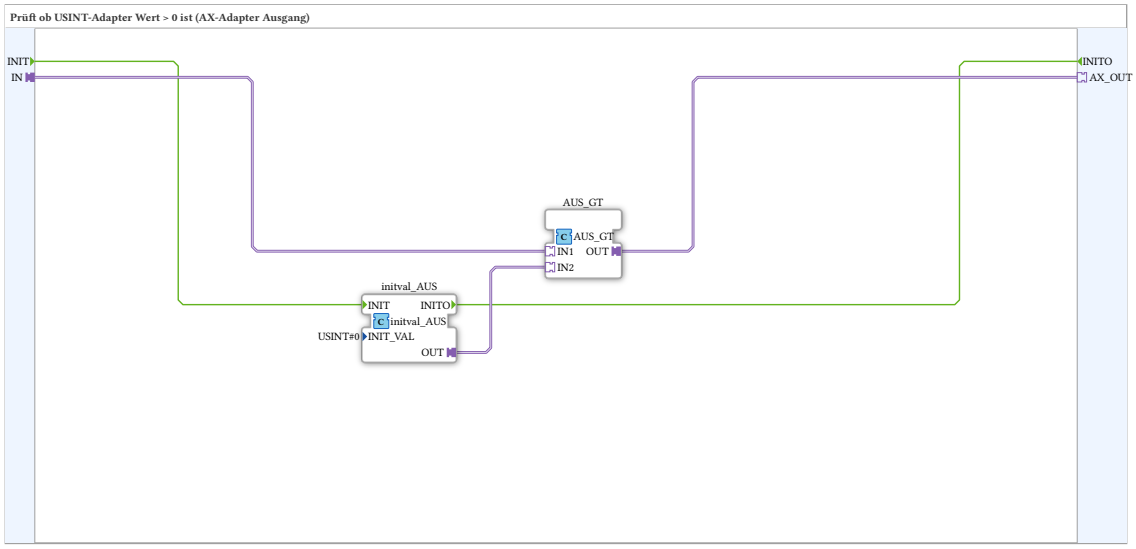
Function Blocks (FBs) Used

- **SCALE_1**: `logiBUS::signalprocessing::fieldbus::AUS_FIELDBUS_USINT_TO_SIGNAL_SCALED`
  - Parameters: `SCALE=1.0`, `OFFSET=0`

Program Flow and Connections

- `IN` ⟶ `SCALE_1.IN`
- `SCALE_1.OUT` ⟶ `OUT`

The `VALID` plug of the inner block is not exposed.

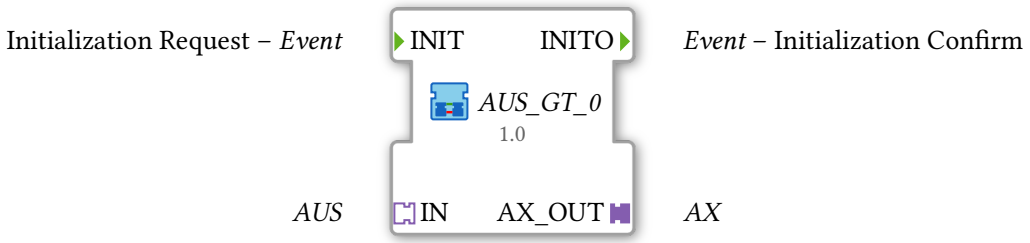


Application Scenarios

- Taking over TECU values (`USINT`) as a filtered, unscaled `AR` value

Summary

`AUS_FIELDBUS_USINT_TO_AR` is a small wrapper SubApp that provides `AUS_FIELDBUS_USINT_TO_SIGNAL_SCALED` with the fixed parameters `SCALE=1.0`/`OFFSET=0`.



AUS_GT_0

• – ○ • – ○ • – ○ •

Introduction

`AUS_GT_0` checks whether a USINT adapter value is greater than 0 and outputs the result as a boolean AX adapter signal. A typical input is an unsigned 8-bit value. The block is built identically for every numeric type (`AS`, `AI`, `ADI`, `ALI`, `AUS`, `AUI`, `AUDI`, `AULI`, `AR`, `ALR`).

Interface

- **Event input**: `INIT` (initialization)
- **Event output**: `INITO` (initialization finished, comes from the internal `initval_AUS`)
- **Socket**: `IN` (`AUS`) — the value compared against 0
- **Plug**: `AX_OUT` (`AX`) — TRUE when `IN > 0`

Function Blocks (FBs) Used

Sub-blocks: AUS_GT_0

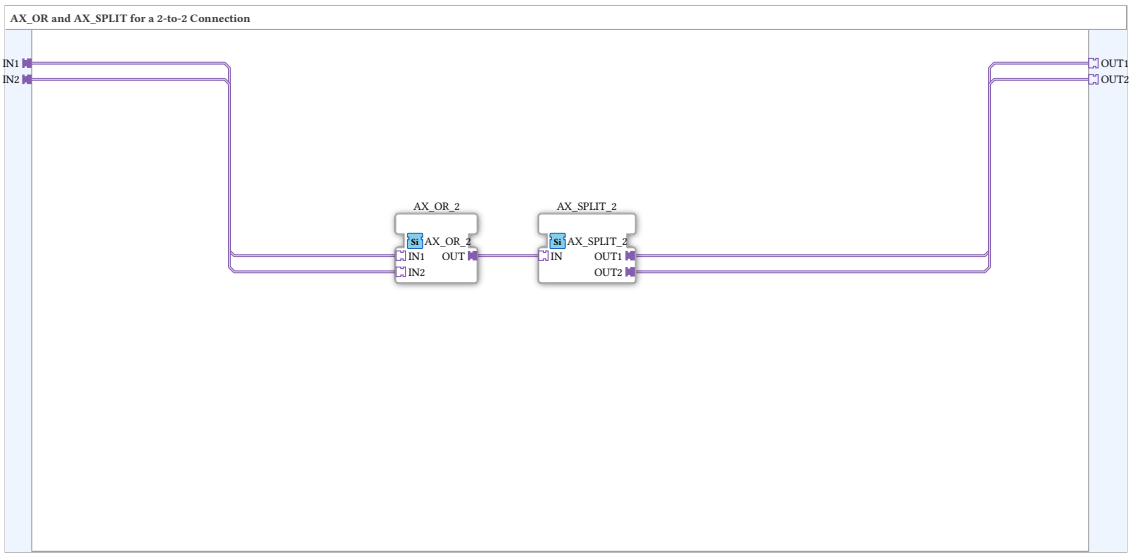
- **Type**: SubAppType
- **Internal FBs used**:
  - **initval_AUS**: `adapter::types::unidirectional::AUS::initval::initval_AUS` — supplies the fixed comparison constant `USINT#0` as an adapter value (`INIT_VAL=USINT#0`). An adapter socket cannot take the constant as a parameter, so it is fed in through this block.
  - **AUS_GT**: `adapter::iec61131::comparison::AUS_GT` — adapter-native comparison `IN1 > IN2`.
- **Functionality**: `IN` ⟶ `AUS_GT.IN1`; constant 0 ⟶ `AUS_GT.IN2`; result ⟶ `AX_OUT`.

Program Flow and Connections

1. `INIT` ⟶ `initval_AUS.INIT`; `initval_AUS.INITO` ⟶ `INITO`.
2. `IN` (adapter) ⟶ `AUS_GT.IN1`.
3. `initval_AUS.OUT` (constant `USINT#0`) ⟶ `AUS_GT.IN2`.
4. `AUS_GT.OUT` ⟶ `AX_OUT` (adapter).

Application Scenarios

- Converting an unsigned 8-bit value into a simple boolean adapter signal for VT status displays or enable logic.

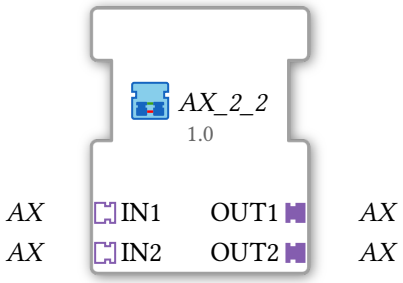


Summary

`AUS_GT_0` is a compact wrapper around the adapter-native comparison `AUS_GT` — converts “USINT > 0” directly into an AX adapter signal, so the caller does not have to create and wire the zero constant itself.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



AX_2_2

• – ○ • – ○ • – ○ •

Introduction

`AX_2_2` ORs two AX adapter inputs (`IN1`, `IN2`) and distributes the result to two AX adapter outputs (`OUT1`, `OUT2`) — a "2-to-2" wiring block for cases where two independent boolean sources must be combined and the result forwarded to two independent destinations.

Function Blocks (FBs) Used

Sub-blocks: AX_2_2

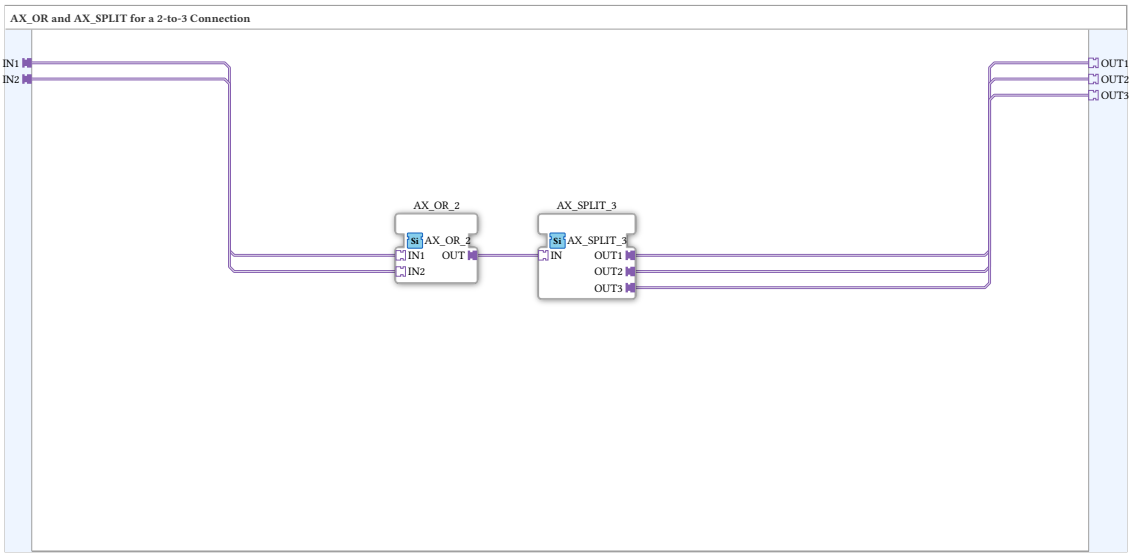
- **Type**: SubAppType
- **Internal FBs used**:
  - **AX_OR_2**: `adapter::booleanOperators::AX_OR_2` — ORs two adapter inputs.
  - **AX_SPLIT_2**: `adapter::events::unidirectional::AX_SPLIT_2` — splits the OR result into two outputs.
- **Functionality**: `IN1 OR IN2` ⟶ `OUT1` and `OUT2` simultaneously.

Program Flow and Connections

1. `IN1` ⟶ `AX_OR_2.IN1`, `IN2` ⟶ `AX_OR_2.IN2`.
2. `AX_OR_2.OUT` ⟶ `AX_SPLIT_2.IN`.
3. `AX_SPLIT_2.OUT1` ⟶ `OUT1`, `AX_SPLIT_2.OUT2` ⟶ `OUT2`.

Application Scenarios

- Anywhere two independent boolean adapter sources need to be ORed and the combined result forwarded to two independent consumers (e.g. two VT status displays) without wiring a duplicate adapter connection.

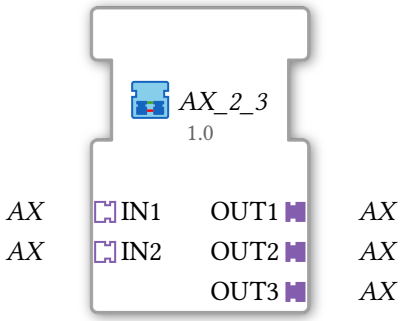


Summary

`AX_2_2` is a minimal block for "OR two sources, distribute to two destinations" — pure adapter wiring with no state logic of its own.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



AX_2_3

• – ◦ • – ◦ • – ◦ •

Introduction

AX_2_3 combines AX_OR_2 and AX_SPLIT_3 into a single, complete module: Two AX sources (IN1, IN2) are ORed together to form a single signal and then distributed to three destinations (OUT1, OUT2, OUT3).

Function Blocks (FBs) Used

Sub-Blocks: AX_2_3

- **Type**: SubAppType
- **Internal FBs Used**:
  - **AX_OR_2**: adapter::booleanOperators::AX_OR_2 — ORs IN1 and IN2.
  - **AX_SPLIT_3**: adapter::events::unidirectional::AX_SPLIT_3 — distributes the OR result to three outputs.
- **How it works**: IN1/IN2 ⟶ AX_OR_2.OUT ⟶ AX_SPLIT_3.IN ⟶ OUT1/OUT2/OUT3.

Program Flow and Connections

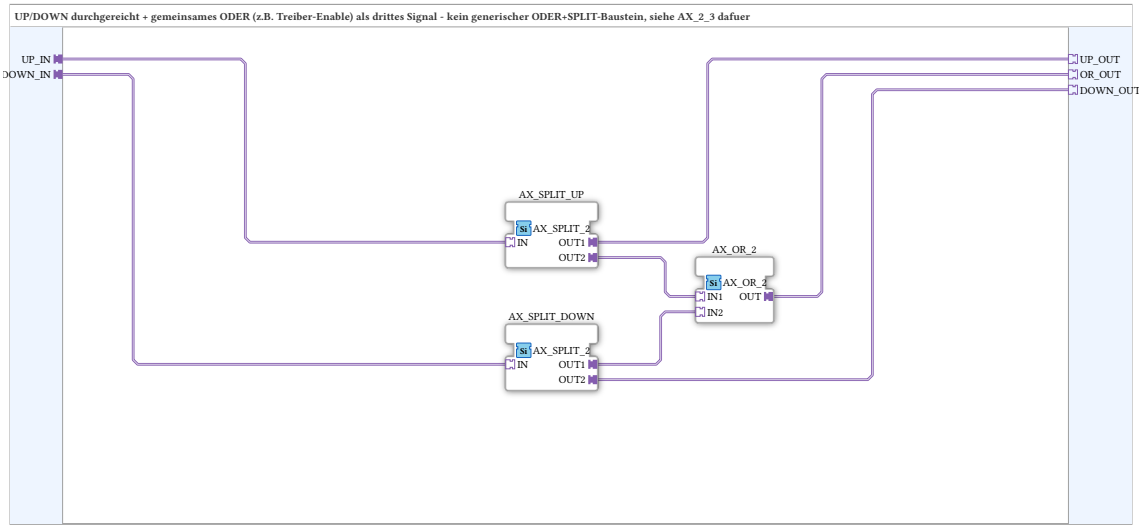
1. IN1 ⟶ AX_OR_2.IN1; IN2 ⟶ AX_OR_2.IN2.
2. AX_OR_2.OUT ⟶ AX_SPLIT_3.IN.
3. AX_SPLIT_3.OUT1 ⟶ OUT1; AX_SPLIT_3.OUT2 ⟶ OUT2; AX_SPLIT_3.OUT3 ⟶ OUT3.

Application Scenarios

- Merging two AX sources (e.g., two command paths) whose combined output must be distributed to three independent destinations (e.g., hardware, VT display, OPC UA publishing).

Comparison with Similar Components

For other source/destination counts: `AX_3_2` (3⟶2), `AX_3_3` (3⟶3). Not to be confused with `AX_2_TO_3`: this one passes UP/DOWN through individually and only provides the OR as a third additional signal, instead of generically combining OR+SPLIT.

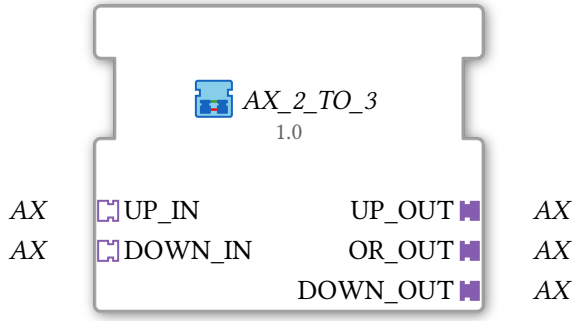


Summary

`AX_2_3` is purely a wiring aid that combines two `AX` sources via OR and distributes them to three destinations—without its own state logic.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & Color Reference on ms-muc-docs.de



AX_2_TO_3

• – ○ • – ○ • – ○ •

Introduction

`AX_2_TO_3` takes two independent AX adapter signals (`UP_IN`, `DOWN_IN`) and provides three outputs: the two inputs passed through unchanged (`UP_OUT`, `DOWN_OUT`) plus their OR combination as a third signal (`OR_OUT`) — typically for "up"/"down" buttons where a combined "either direction active" signal is also needed.

Function Blocks (FBs) Used

Sub-blocks: AX_2_TO_3

- **Type**: SubAppType
- **Internal FBs used**:
  - **AX_SPLIT_UP** / **AX_SPLIT_DOWN**: each `adapter::events::unidirectional::AX_SPLIT_2` — split `UP_IN`/`DOWN_IN` each into a direct pass-through and a branch feeding the OR.
  - **AX_OR_2**: `adapter::booleanOperators::AX_OR_2` — combines both branches into `OR_OUT`.

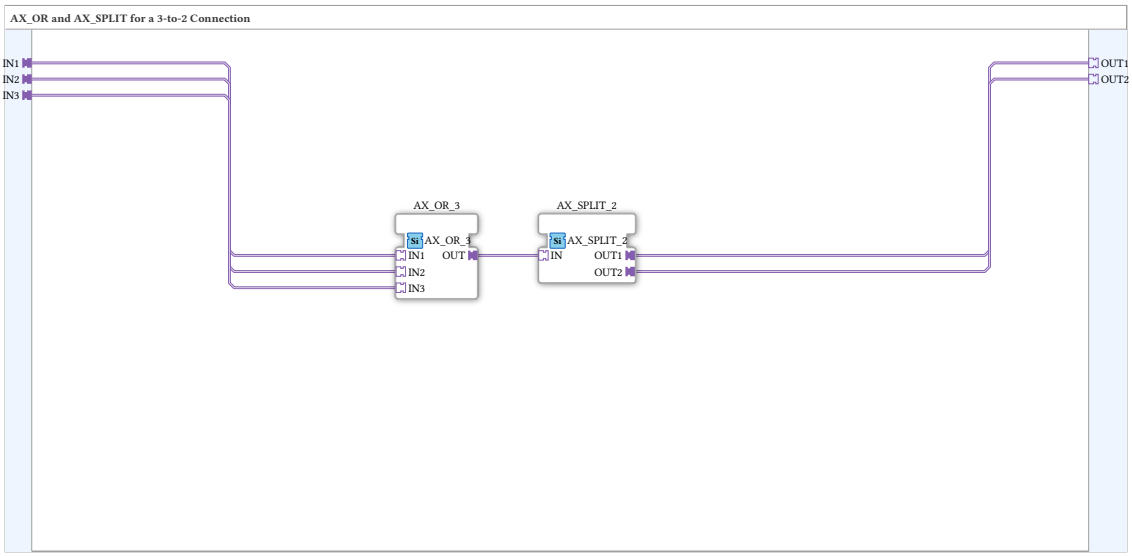
- **Functionality**: `UP_IN` ⟶ `UP_OUT` (direct) and into `AX_OR_2`; `DOWN_IN` ⟶ `DOWN_OUT` (direct) and into `AX_OR_2`; `AX_OR_2.OUT` ⟶ `OR_OUT`.

Program Flow and Connections

1. `UP_IN` ⟶ `AX_SPLIT_UP.IN` ⟶ `AX_SPLIT_UP.OUT1` ⟶ `UP_OUT`, `AX_SPLIT_UP.OUT2` ⟶ `AX_OR_2.IN1`.
2. `DOWN_IN` ⟶ `AX_SPLIT_DOWN.IN` ⟶ `AX_SPLIT_DOWN.OUT2` ⟶ `DOWN_OUT`, `AX_SPLIT_DOWN.OUT1` ⟶ `AX_OR_2.IN2`.
3. `AX_OR_2.OUT` ⟶ `OR_OUT`.

Application Scenarios

- Ramp/ramp-button wiring (e.g. “up”/“down”) where, besides the individual direction signals, a combined “either button active” signal is also needed (e.g. to light up a status indicator only while actively operated).



Summary

`AX_2_TO_3` passes two adapter signals through unchanged and adds their OR combination as a third signal — a pure wiring helper with no state logic of its own.

AX_3_2

• – ○ • – ○ • – ○ •

Introduction

`AX_3_2` combines `AX_OR_3` and `AX_SPLIT_2` into a single, complete module: Three `AX` sources (`IN1`, `IN2`, `IN3`) are ORed together to form a single signal and then distributed to two destinations (`OUT1`, `OUT2`).

Function Blocks (FBs) Used

Sub-Blocks: AX_3_2

- **Type**: SubAppType
- **Internal FBs Used**:
  - **AX_OR_3**: `adapter::booleanOperators::AX_OR_3` — ORs `IN1`/`IN2`/`IN3`.
  - **AX_SPLIT_2**: `adapter::events::unidirectional::AX_SPLIT_2` — splits the OR result to two outputs.
- **How it works**: `IN1`/`IN2`/`IN3` ⟶ `AX_OR_3.OUT` ⟶ `AX_SPLIT_2.IN` ⟶ `OUT1`/`OUT2`.

Program Flow and Connections

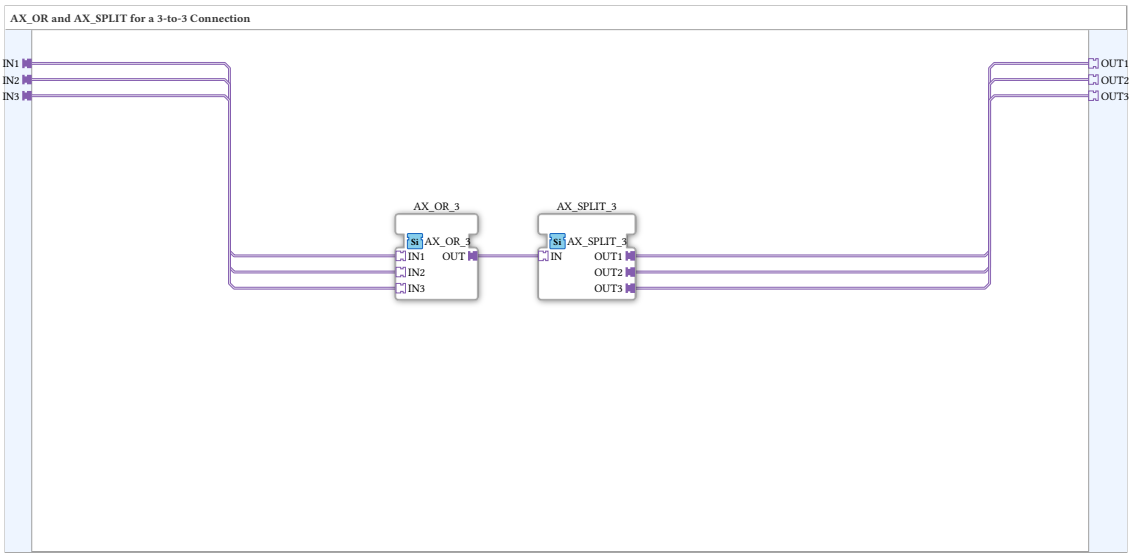
1. `IN1` ⟶ `AX_OR_3.IN1`; `IN2` ⟶ `AX_OR_3.IN2`; `IN3` ⟶ `AX_OR_3.IN3`.
2. `AX_OR_3.OUT` ⟶ `AX_SPLIT_2.IN`.
3. `AX_SPLIT_2.OUT1` ⟶ `OUT1`; `AX_SPLIT_2.OUT2` ⟶ `OUT2`.

Application Scenarios

- Merging three `AX` sources (e.g., three command paths) whose combined output must be distributed to two independent destinations.

Comparison with Similar Building Blocks

For other source/destination counts: `AX_2_3` (2⟶3), `AX_3_3` (3⟶3).



Summary

`AX_3_2` is a simple wiring aid that combines three `AX` sources using an OR operation and distributes them to two destinations—without its own state logic.

AX_3_3

• – ○ • – ○ • – ○ •

Introduction

`AX_3_3` combines `AX_OR_3` and `AX_SPLIT_3` into a single, complete module: Three `AX` sources (`IN1`, `IN2`, `IN3`) are ORed together to form a single signal and then distributed to three destinations (`OUT1`, `OUT2`, `OUT3`).

Function Blocks (FBs) Used

Sub-Blocks: AX_3_3

- **Type**: SubAppType
- **Internal FBs Used**:
  - **AX_OR_3**: `adapter::booleanOperators::AX_OR_3` — ORs `IN1`/`IN2`/`IN3`.
  - **AX_SPLIT_3**: `adapter::events::unidirectional::AX_SPLIT_3` — distributes the OR result to three outputs.
- **How it works**: `IN1`/`IN2`/`IN3` ⟶ `AX_OR_3.OUT` ⟶ `AX_SPLIT_3.IN` ⟶ `OUT1`/`OUT2`/`OUT3`.

Program Flow and Connections

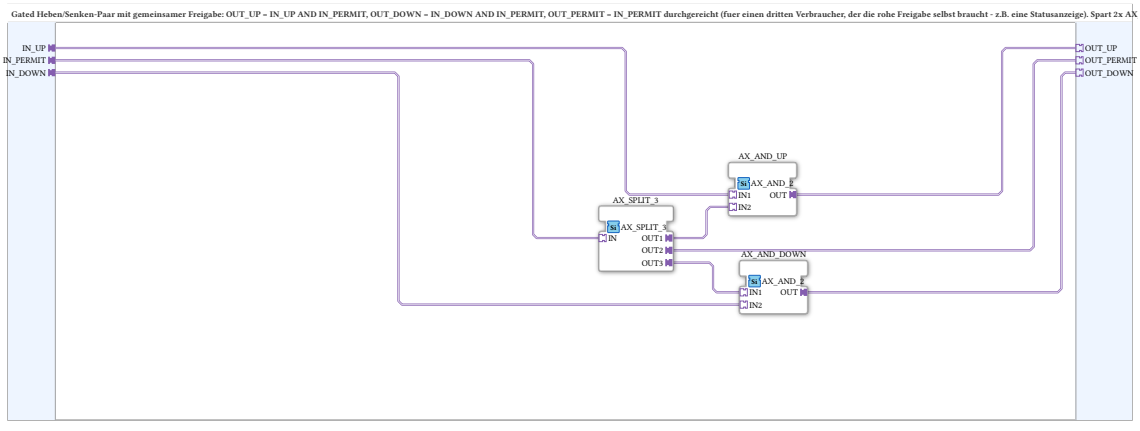
1. `IN1` ⟶ `AX_OR_3.IN1`; `IN2` ⟶ `AX_OR_3.IN2`; `IN3` ⟶ `AX_OR_3.IN3`.
2. `AX_OR_3.OUT` ⟶ `AX_SPLIT_3.IN`.
3. `AX_SPLIT_3.OUT1` ⟶ `OUT1`; `AX_SPLIT_3.OUT2` ⟶ `OUT2`; `AX_SPLIT_3.OUT3` ⟶ `OUT3`.

Application Scenarios

- Merging three `AX` sources (e.g., three command paths) whose combined output must be distributed to three independent destinations.

Comparison with Similar Building Blocks

For other source/destination counts: `AX_2_3` (2⟶3), `AX_3_2` (3⟶2).



Summary

`AX_3_3` is a simple wiring aid that combines three `AX` sources using an OR operation and distributes them to three destinations—without its own state logic.

AX_AND_2_DUAL

• – ○ • – ○ • – ○ •

Introduction

`AX_AND_2_DUAL` is a gated raise/lower pair with a common permit: `OUT_UP = IN_UP AND IN_PERMIT` and `OUT_DOWN = IN_DOWN AND IN_PERMIT`. In addition, `IN_PERMIT` is passed through unchanged as `OUT_PERMIT`, e.g. for a third consumer such as a status display. The SubApp replaces two `AX_AND_2` plus one `AX_SPLIT_3` as individual blocks.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

All adapters are of type `adapter::types::unidirectional::AX`.

- **IN_UP** (socket): raw raise signal, gated with `IN_PERMIT`
- **IN_PERMIT** (socket): common permit for `IN_UP`/`IN_DOWN`, additionally passed through unchanged to `OUT_PERMIT`
- **IN_DOWN** (socket): raw lower signal, gated with `IN_PERMIT`
- **OUT_UP** (plug): `IN_UP AND IN_PERMIT`
- **OUT_PERMIT** (plug): `IN_PERMIT` unchanged (for a third consumer, e.g. a status display)
- **OUT_DOWN** (plug): `IN_DOWN AND IN_PERMIT`

Function Blocks (FBs) Used

- **`AX_SPLIT_3`** (`adapter::events::unidirectional::AX_SPLIT_3`): distributes `IN_PERMIT` to three targets
- **`AX_AND_UP`**, **`AX_AND_DOWN`** (each `adapter::booleanOperators::AX_AND_2`): AND combination

Functionality

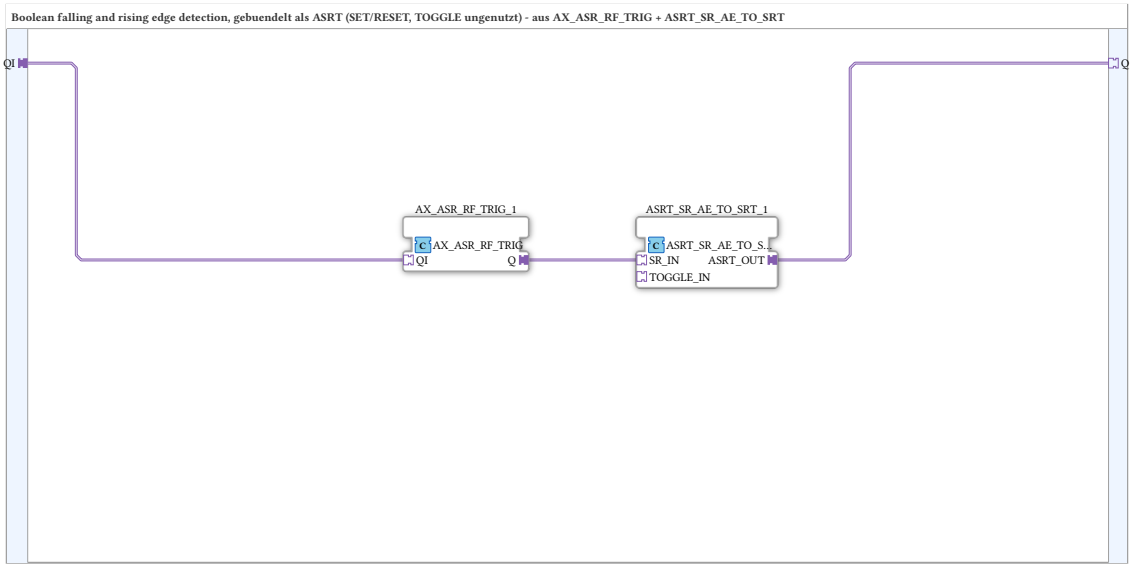
- `IN_PERMIT` ⟶ `AX_SPLIT_3.IN`
- `AX_SPLIT_3.OUT1` ⟶ `AX_AND_UP.IN2`; `IN_UP` ⟶ `AX_AND_UP.IN1`; `AX_AND_UP.OUT` ⟶ `OUT_UP`
- `AX_SPLIT_3.OUT3` ⟶ `AX_AND_DOWN.IN1`; `IN_DOWN` ⟶ `AX_AND_DOWN.IN2`; `AX_AND_DOWN.OUT` ⟶ `OUT_DOWN`
- `AX_SPLIT_3.OUT2` ⟶ `OUT_PERMIT`

Technical Details

- Since an adapter must not branch to several targets, `AX_SPLIT_3` distributes the permit to both AND elements and the pass-through output
- No logic of its own beyond the standard blocks used

Application Scenarios

- Any raise/lower signal pair that needs the same permit (e.g. an interlock), where the permit should additionally be available for a display



Summary

`AX_AND_2_DUAL` gates a raise/lower pair with a common permit and additionally passes the permit through.

AX_ASRT_RF_TRIG

• – ○ • – ○ • – ○ •

Introduction

`AX_ASRT_RF_TRIG` detects rising and falling edges of an `AX` signal and combines them as an `ASRT` adapter (Set/Reset, Toggle remains unused). Instead of a new low-level `FBType`, the function block is constructed as a composite of the existing `AX_ASR_RF_TRIG` (which returns an `ASR` from an edge) and `ASRT_SR_AE_TO_SRT` (which combines an `ASR` with an optional AE toggle event to create an `ASRT`).

value to check for a rising or falling edge – *AX*

ASRT – Set/Reset Output (Toggle wird nie gefeuert)

Function Blocks (FBs) Used

Sub-Blocks: AX_ASRT_RF_TRIG

- **Type**: SubAppType
- **Internal FBs Used**:
- **AX_ASR_RF_TRIG_1**: `adapter::events::unidirectional::AX_ASR_RF_TRIG` — rising edge at `QI` ⟶ SET, falling edge ⟶ RESET, bundled as `ASR`.
- **ASRT_SR_AE_TO_SRT_1**: `adapter::conversion::unidirectional::ASRT_SR_AE_TO_SRT` — takes `ASR` as `SR_IN` and bundles it to `ASRT_OUT`; The second socket (`TOGGLE_IN`, a single AE event) remains unwired and never fires, as a pure edge signal does not allow for the derivation of an independent third event.
- **Functionality**: `AX_ASR_RF_TRIG_1` generates a `ASR` from the edge of `QI`. This `SR_IN` is directly fed into `ASRT_SR_AE_TO_SRT_1`, whose `ASRT_OUT` then serves the plug `Q`.

Program Flow and Connections

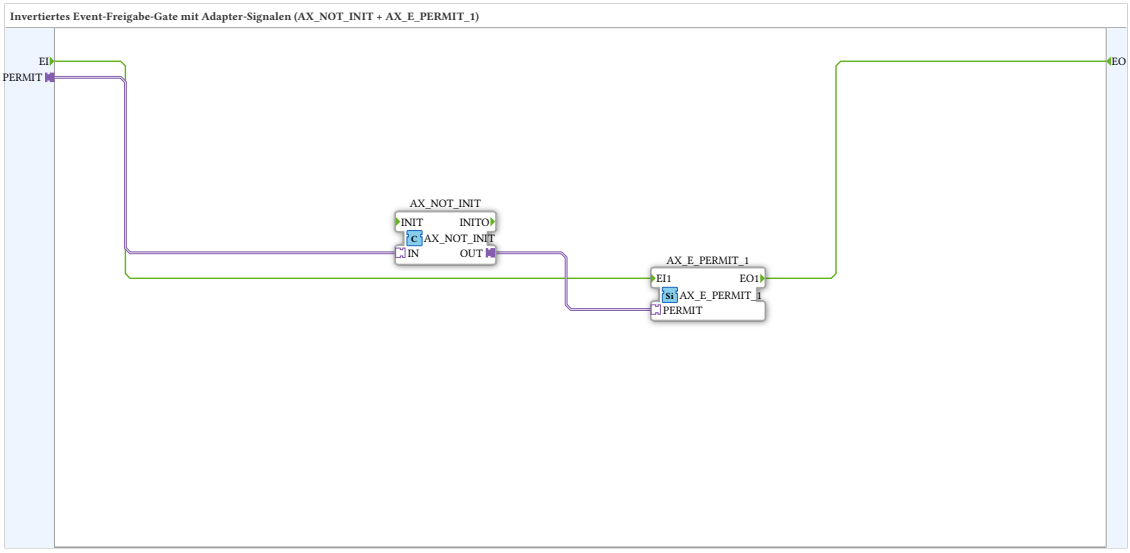
1. `QI` (Socket) ⟶ `AX_ASR_RF_TRIG_1.QI`.
2. `AX_ASR_RF_TRIG_1.Q` ⟶ `ASRT_SR_AE_TO_SRT_1.SR_IN`.
3. `ASRT_SR_AE_TO_SRT_1.ASRT_OUT` ⟶ `Q` (Plug).

Technical Features

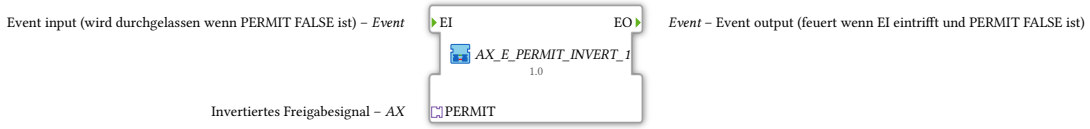
- **Composite instead of a new low-level component**: Reuses two existing components instead of implementing a new `FBType`.
- **TOGGLE socket remains unused**: `ASRT_SR_AE_TO_SRT_1.TOGGLE_IN` is never wired and therefore never fires—the component only provides SET/RESET, never a true toggle event.

Application Scenarios

- As one of several `ASRT` sources for a `ASRT_MERGE_2`, e.g., in `Uebung_232_AX`.



Summary



`AX_ASRT_RF_TRIG` delivers a `ASRT` adapter signal (Set/Reset only, Toggle unused) from a single edge detection and can therefore be directly connected to devices that expect a `ASRT` socket.

AX_E_PERMIT_INVERT_1

• – ○ • – ○ • – ○ •

Introduction

AX_E_PERMIT_INVERT_1 is a composite subapplication that implements an inverted event-permission gate. It combines the adapter-based blocks `AX_NOT_INIT` and `AX_E_PERMIT_1` to allow an event to pass from the event input `EI` to the event output `EO` only when the adapter signal `PERMIT` is **FALSE**.

This subapp is useful when an external permission condition is expressed through a unidirectional adapter and the desired logic is “pass the event when the permission is not active”.

Interface Structure

Event Inputs

Name	Type	Description
`EI`	Event	Event input. The event is forwarded to `EO` only when the `PERMIT` adapter value is FALSE.

Event Outputs

Name	Type	Description
EO	Event	Event output. Fires when an event arrives on EI and PERMIT is FALSE.

Data Inputs

There are no data inputs.

Data Outputs

There are no data outputs.

Adapters

Name	Type	Direction	Description
PERMIT	adapter::types::unidirectional::AX	Socket	Adapter signal used as the gate condition. Events are allowed to pass when this signal is FALSE.

Functionality

The internal network consists of two connected adapter-based function blocks:

1. AX_NOT_INIT
   Receives the PERMIT adapter signal and produces its logical inversion on OUT.
2. AX_E_PERMIT_1
   Receives the inverted signal on its PERMIT adapter input. It forwards events from its event input EI1 to its event output EO1 when the inverted signal is TRUE.

The event flow is:

- An event at EI is connected to AX_E_PERMIT_1.EI1.
- If the external PERMIT signal is FALSE, AX_NOT_INIT outputs TRUE.
- AX_E_PERMIT_1 therefore opens the gate and propagates the event to EO.
- If the external PERMIT signal is TRUE, the gate remains closed and the incoming event is not forwarded.

In other words, the subapp behaves as an event gate with inverted permission logic:

External PERMIT	Event EI	Event EO
FALSE	arrives	fires
TRUE	arrives	does not fire

Technical Features

- IEC 61499-2 compliant subapplication type.
- No data inputs or data outputs.
- One unidirectional adapter socket PERMIT.
- One event input and one event output.
- Internally composed of two reusable adapter-based function blocks.
- The event path and the adapter condition path are strictly separated.
- The inversion of the adapter signal is encapsulated inside the subapp, simplifying the external interface.

State Overview

The subapp does not expose an internal state machine. Its behavior is event-driven and depends on the current value of the PERMIT adapter at the moment an event arrives on EI.

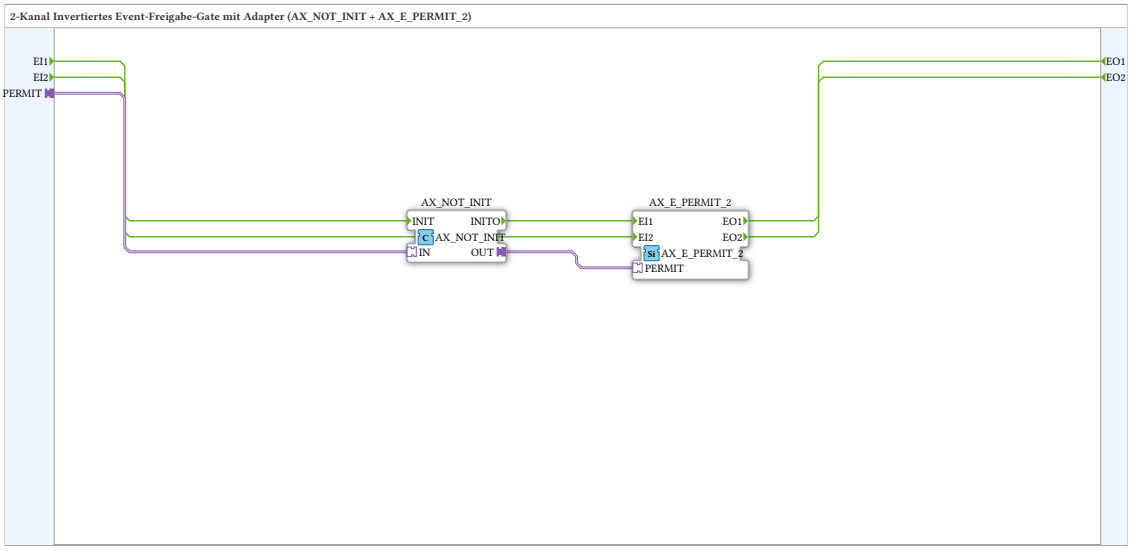
There is no latching or retention of events. If the gate is closed when EI occurs, that event is discarded. If PERMIT changes afterward, the next event on EI is evaluated using the new adapter value.

Application Scenarios

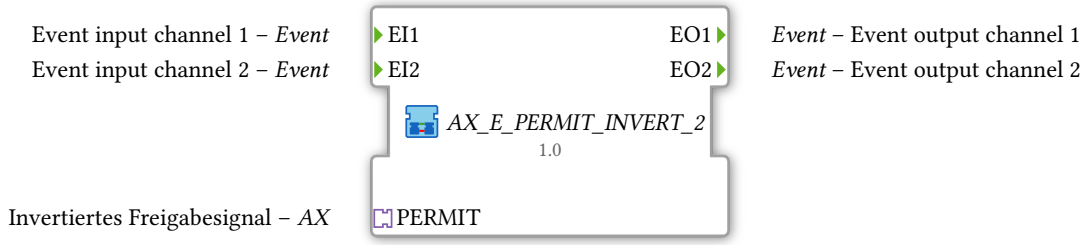
- **Active-low permission logic**
  Useful when a system should process an event only while a permission signal is not active.

- **Adapter-based event filtering**
  Can be placed in an event chain to suppress events when an adapter condition is TRUE.
- **Polarity conversion in larger subapplications**
  Allows standard `AX_E_PERMIT_1` logic to be reused with an inverted enable signal without additional external wiring.
- **Safety and interlock patterns**
  Suitable for cases where an event must only be forwarded when a certain release condition is absent, such as “not in manual mode” or “no suppression active”.

Comparison with Similar Blocks



Block / Subapp	Gate Condition	Behavior
`AX_E_PERMIT_1`	Adapter signal TRUE	Forwards event when the adapter signal is TRUE.
`AX_E_PERMIT_INVERT_1`	External adapter signal FALSE	Forwards event when the external adapter signal is FALSE.
`E_PERMIT` (classic)	BOOL data input TRUE	Forwards event when the BOOL permission input is TRUE.



The main difference is that `AX_E_PERMIT_INVERT_1` encapsulates the inversion of an adapter signal. This makes it directly usable in adapter-based architectures where the permission condition is already provided as a unidirectional `AX` adapter.

Conclusion

AX_E_PERMIT_INVERT_1 provides a clean, reusable way to implement an inverted event-permission gate. By combining `AX_NOT_INIT` and `AX_E_PERMIT_1`, it converts a permit adapter signal into a blocking condition and only passes events when the permit is FALSE. This makes it a useful building block for adapter-oriented IEC 61499 applications that require active-low event gating.

AX_E_PERMIT_INVERT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The **AX_E_PERMIT_INVERT_2** is a composite subapplication that provides a two-channel inverted event gating mechanism. It combines a boolean NOT operator (`AX_NOT_INIT`) with a two-channel event permit gate (`AX_E_PERMIT_2`) to create an event pass-through logic where events are only forwarded when the externally supplied permit signal is **inactive** (i.e., `FALSE`). This is particularly useful in safety-oriented control systems where events must be suppressed unless an explicit release condition is met.

Interface Structure

The subapplication exposes two event inputs, two event outputs, and one adapter socket. It contains no data inputs or data outputs.

Event Inputs

Name	Type	Description
`EI1`	Event	Event input channel 1
`EI2`	Event	Event input channel 2

Event Outputs

Name	Type	Description
`EO1`	Event	Event output channel 1
`EO2`	Event	Event output channel 2

Data Inputs

None.

Data Outputs

None.

Adapters

Name	Type	Description
`PERMIT`	`adapter::types::unidirectional::AX`	Inverted enable signal (socket)

Functionality

The subapplication implements a two-stage processing pipeline:

1. **Signal Inversion Stage**: The incoming `PERMIT` adapter signal is routed to the `AX_NOT_INIT` function block, which performs a logical NOT operation on the boolean value carried by the adapter.
2. **Event Gating Stage**: The inverted boolean result is forwarded to the `PERMIT` input of the `AX_E_PERMIT_2` function block. This block acts as an event gate that conditionally forwards incoming events based on the state of its permit input.

The event flow is straightforward:

- `EI1` ⟶ `AX_E_PERMIT_2.EI1` ⟶ `EO1`
- `EI2` ⟶ `AX_E_PERMIT_2.EI2` ⟶ `EO2`

Gating Behavior:

- When the external `PERMIT` signal is `FALSE`, the inverted signal becomes `TRUE`. The events arriving at `EI1`/`EI2` are passed through to `EO1`/`EO2`.
- When the external `PERMIT` signal is `TRUE`, the inverted signal becomes `FALSE`. The events arriving at `EI1`/`EI2` are **blocked** and not propagated to the outputs.

This inverted behavior distinguishes the block from a standard permit gate: events are allowed **by default** and are only suppressed when an explicit inhibit signal is asserted.

Technical Features

- **Two Identical Channels**: Both channels operate independently and identically, allowing simultaneous event processing on two separate paths.
- **Adapter-based Signal Interface**: The permit signal is exchanged via a unidirectional adapter type (`AX`), enabling seamless integration with other 4diac IDE components using the same adapter type.
- **Composite Design**: The subapplication is built from standard, reusable function blocks, making its internal logic transparent and maintainable.
- **No Internal State**: The absence of internal state variables makes the block deterministic and stateless with respect to event processing.
- **Eclipse Public License 2.0**: The implementation is distributed under EPL-2.0, allowing free use and modification.

State Overview

The subapplication does not maintain any internal state machine. Its behavior is purely combinational in the signal domain:

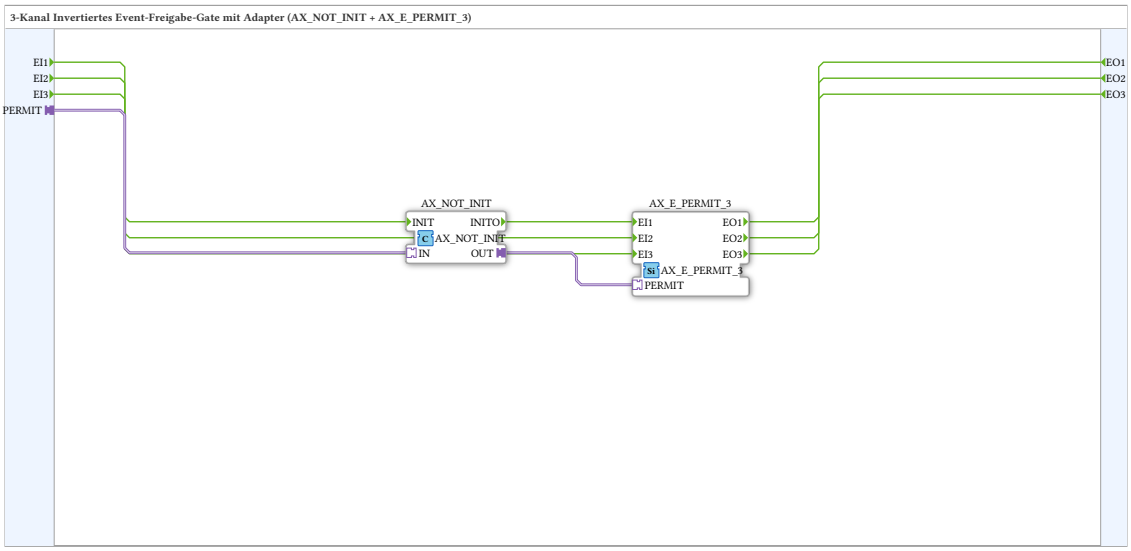
- The boolean inversion stage is static and immediate.
- The permit gate, `AX_E_PERMIT_2`, may maintain its own internal permit state, which is entirely determined by the inverted adapter signal.

Consequently, there are no distinct operational states to enumerate. The block behaves identically at all times, reacting to the current values of the permit signal and incoming events.

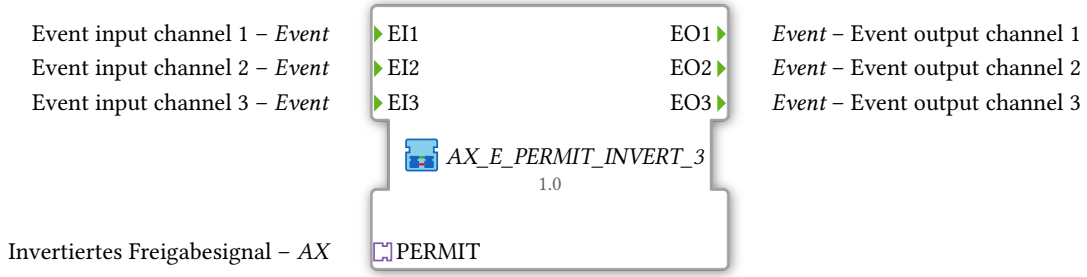
Application Scenarios

- **Safety Interlocks**: Suppress process events when a safety condition (e.g., emergency stop or guard open) is active, thereby preventing unintended operations.
- **Maintenance Mode**: Block event-triggered actions during maintenance windows by asserting the permit signal, while allowing normal operation when the signal is deasserted.
- **Inverted Permission Logic**: Implement logic where the absence of an explicit deny signal permits event processing, simplifying default-open policies.
- **Supervisory Control**: In multi-channel control systems, gate two independent event streams with a single shared inhibit signal.

Comparison with Similar Blocks



Feature	`AX_E_PERMIT_2`	`AX_E_PERMIT_INVERT_2`
Permit semantics	Events pass when permit is `TRUE`	Events pass when permit is `FALSE`
Number of channels	2	2
Inversion stage	None (direct permit)	Built-in `AX_NOT_INIT` inversion
Use case	Enable-based gating	Inhibit-based gating
Complexity	Lower	Slightly higher (added NOT operator)



The inverted variant is functionally equivalent to inserting a NOT gate between the permit source and a standard permit block, but encapsulates this logic into a single reusable component.

Conclusion

The **AX_E_PERMIT_INVERT_2** subapplication provides a clean and reusable solution for two-channel event gating with inverted permit semantics. By integrating a boolean inversion stage with a standard event permit gate, it enables applications where events flow freely until an explicit inhibit signal is applied. Its adapter-based interface ensures compatibility with the broader 4diac ecosystem, while the composite structure keeps the logic transparent and easily maintainable. This block is particularly well suited for safety, maintenance, and supervisory control applications requiring default-open event behavior.

AX_E_PERMIT_INVERT_3

• – ○ • – ○ • – ○ •

Introduction

AX_E_PERMIT_INVERT_3 is a composite subapplication for 3-channel event gating with an inverted adapter-based enable signal. It combines an adapter inverter AX_NOT_INIT and a 3-channel event permit gate AX_E_PERMIT_3. The subapplication forwards events only when the external PERMIT signal is FALSE; when PERMIT is TRUE, all event channels are blocked.

Interface Structure

Event Inputs

Name	Type	Description
EI1	Event	Event input channel 1
EI2	Event	Event input channel 2
EI3	Event	Event input channel 3

Event Outputs

Name	Type	Description
EO1	Event	Event output channel 1
EO2	Event	Event output channel 2
EO3	Event	Event output channel 3

Data Inputs

This subapplication has no explicit data inputs.

Data Outputs

This subapplication has no explicit data outputs.

Adapters

Name	Type	Direction	Description
PERMIT	adapter::types::unidirectional::AX	Socket	Active-low permit signal. The boolean value carried by this adapter is inverted internally; events are passed only when this value is FALSE.

Functionality

The function is achieved by two internal components:

1. `AX_NOT_INIT` acts as a logical NOT operator on the adapter-based boolean signal connected to `PERMIT`.
2. `AX_E_PERMIT_3` is a three-channel event gate. It receives events from `EI1` … `EI3` and forwards them to `EO1` … `EO3` only when its own `PERMIT` input is active.

The external `PERMIT` adapter is connected to `AX_NOT_INIT.IN`. The inverted result is sent from `AX_NOT_INIT.OUT` to `AX_E_PERMIT_3.PERMIT`. Thus, the effective gate condition is the opposite of the external signal:

External PERMIT	Signal seen by gate	Event behavior
FALSE	TRUE	Events are forwarded
TRUE	FALSE	Events are blocked

Each event channel is independent: `EI1` is routed through the gate to `EO1`, `EI2` to `EO2`, and `EI3` to `EO3`. The same inverted permit value applies to all three channels.

Technical Features

- Three independent event input/output channels.
- Inverted enable behavior using an adapter-based boolean inverter.
- No explicit data inputs or outputs; the permission state is transported through the `PERMIT` adapter.
- One unidirectional adapter socket of type `adapter::types::unidirectional::AX`.
- Internal composition consists of `AX_NOT_INIT` and `AX_E_PERMIT_3`.
- The subapplication has no ECC or state machine; it is a purely event-routing composition.

State Overview

This subapplication does not define internal persisting states. The behavior is determined solely by the current boolean value carried by the `PERMIT` adapter. From an external perspective, the gate is either open or closed:

- **Open**: External `PERMIT` is `FALSE`, the gate receives an active permit, and arriving events are released on the matching event output.
- **Closed**: External `PERMIT` is `TRUE`, the gate receives an inactive permit, and arriving events are suppressed.

Because there is no internal state memory, the behavior is deterministic and independent of previous event occurrences.

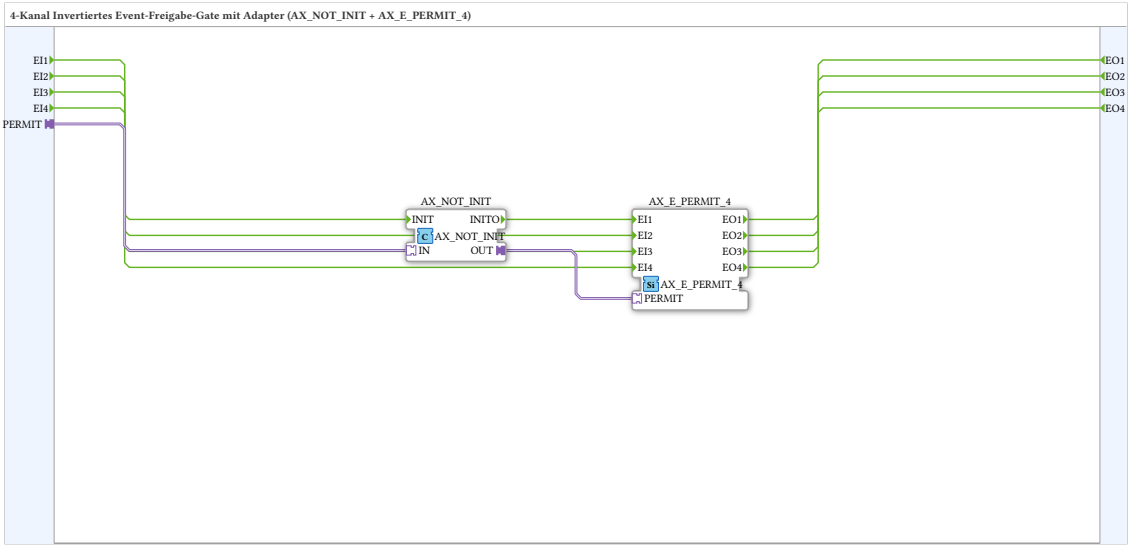
Application Scenarios

Typical use cases include:

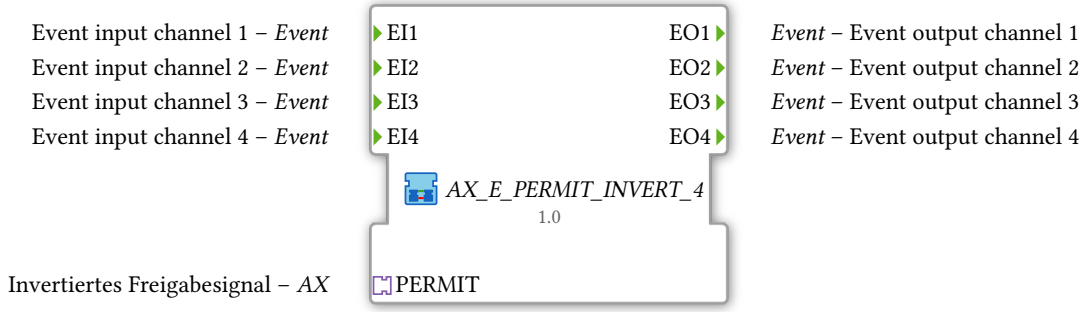
- **Active-low enable signals**: An application that should run while an enable signal is de-asserted.
- **Safety/inhibit gating**: A machine control event may be allowed only while an inhibit flag is `FALSE`.
- **Multi-channel event distribution**: Three related event paths, such as preparation, execution, and completion, can be opened or closed together using one common inverted permission signal.
- **Adapter-based software architectures**: Used in IEC 61499 systems where boolean status information is exchanged via unidirectional adapters rather than separate data connections.

Comparison with Similar Blocks

AX_E_PERMIT_3 is the direct non-inverted counterpart. It forwards events when its PERMIT adapter value is TRUE. AX_E_PERMIT_INVERT_3 inserts AX_NOT_INIT before the same gate, so the permission condition becomes inverted. In systems where the available inhibit signal is active-high, this avoids manually inverting the signal outside the subapplication.



Block	Permits events when external PERMIT is
AX_E_PERMIT_3	TRUE
AX_E_PERMIT_INVERT_3	FALSE



This makes the block suitable for applications that need an event gate with active-low enable logic while retaining the same channel structure as the standard AX_E_PERMIT_3.

Conclusion

AX_E_PERMIT_INVERT_3 is a compact, reusable subapplication for event gating with inverted adapter-based permission. By combining an adapter inverter with a 3-channel event gate, it provides a clean solution for applications that must pass events only while the permit signal is FALSE. Its simple internal structure and absence of data pins make it easy to integrate in event-driven IEC 61499 systems.

AX_E_PERMIT_INVERT_4

• – ○ • – ○ • – ○ •

Introduction

The **AX_E_PERMIT_INVERT_4** is a 4-channel inverted event permit gate implemented as a subapplication type. It combines the adapter logic block **AX_NOT_INIT** with the 4-channel event gate **AX_E_PERMIT_4**.

The subapplication receives four independent event inputs and forwards them to four event outputs only when the external adapter-based permit signal is inactive. The incoming PERMIT adapter is inverted

first, so the internal event gate sees the negated permission value. This provides a simple and reusable way to suppress or enable event streams using an active-low adapter signal.

Interface Structure

Event Inputs

Name	Type	Description
EI1	Event	Event input channel 1
EI2	Event	Event input channel 2
EI3	Event	Event input channel 3
EI4	Event	Event input channel 4

Event Outputs

Name	Type	Description
EO1	Event	Event output channel 1
EO2	Event	Event output channel 2
EO3	Event	Event output channel 3
EO4	Event	Event output channel 4

Data Inputs

None.

Data Outputs

None.

Adapters

Name	Type	Description
`PERMIT`	`adapter::types::unidirectional::AX`	Inverted enable signal for all event channels

Functionality

The subapplication uses two internal function blocks:

- **AX_NOT_INIT** inverts the adapter signal connected to its input.
- **AX_E_PERMIT_4** passes or blocks event inputs depending on the permit signal at its adapter socket.

The external `PERMIT` adapter is connected to `AX_NOT_INIT.IN`. The inverted adapter output `AX_NOT_INIT.OUT` is then connected to `AX_E_PERMIT_4.PERMIT`.

Each event input is directly wired to the corresponding event input of `AX_E_PERMIT_4`, and each internal event output is connected to the corresponding external event output:

- `EI1` ⟶ `AX_E_PERMIT_4.EI1` ⟶ `EO1`
- `EI2` ⟶ `AX_E_PERMIT_4.EI2` ⟶ `EO2`
- `EI3` ⟶ `AX_E_PERMIT_4.EI3` ⟶ `EO3`
- `EI4` ⟶ `AX_E_PERMIT_4.EI4` ⟶ `EO4`

As a result:

- If the external `PERMIT` signal is **false**, the internal permit becomes **true**, and incoming events are forwarded to the outputs.
- If the external `PERMIT` signal is **true**, the internal permit becomes **false**, and incoming events are blocked.

Technical Features

- Four independent event channels.

- Single common adapter socket for centralized event gating.
- Active-low permit behavior due to internal signal inversion.
- Implemented as a subapplication network using `AX_NOT_INIT` and `AX_E_PERMIT_4`.
- No data inputs or outputs are required.
- Designed for use in IEC 61499-compliant systems with unidirectional adapter types.
- Easy to reuse and integrate into larger 4diac applications.

State Overview

The subapplication itself does not contain an explicit state machine. Its behavior is determined by the combined logic of the internal function blocks.

The effective state depends on the current value of the `PERMIT` adapter signal:

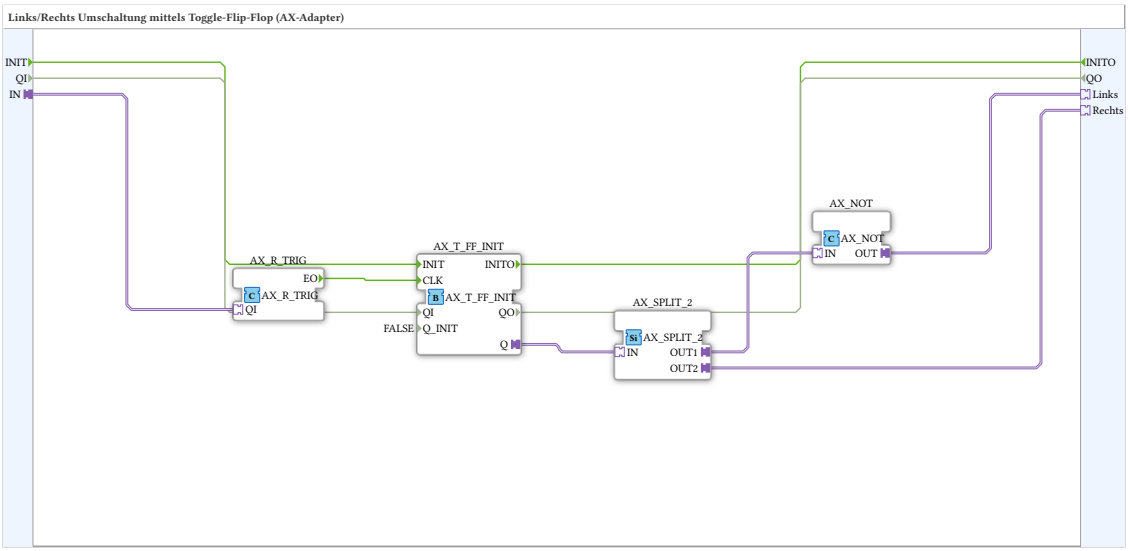
External `PERMIT`	Internal permit	Event forwarding
`false`	`true`	Enabled
`true`	`false`	Disabled

The internal `AX_E_PERMIT_4` gate handles the actual per-channel event passing based on this internal permit state.

Application Scenarios

- **Active-low event enabling**: When the permit signal is used as a disable or inhibit flag, events are passed only while the flag is inactive.
- **Central gating of multiple event streams**: A single adapter signal can control four independent event paths at once.
- **Conditional event propagation**: Events can be forwarded or suppressed depending on external system states such as ready signals, safety conditions, or operating modes.
- **Composite subapplication design**: Useful as a reusable building block inside larger 4diac applications that require inverted permit logic.

Comparison with Similar Blocks

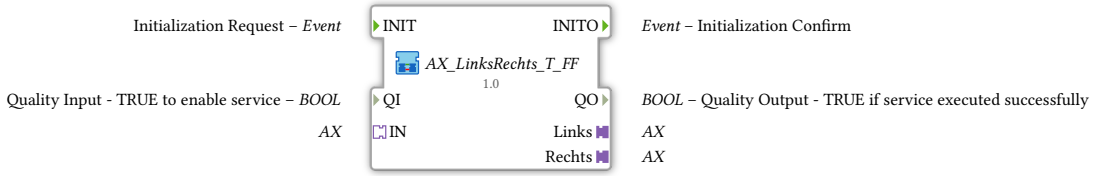


Block	Behavior
`AX_E_PERMIT_4`	Passes events while the permit adapter signal is true.
`AX_E_PERMIT_INVERT_4`	Passes events while the permit adapter signal is false.
`AX_NOT_INIT`	Inverts an adapter signal and is used here to negate the permit input before the event gate.

The main difference to the standard `AX_E_PERMIT_4` is the integrated inversion. This removes the need to manually insert an inverter block in the application network when an active-low permission is required.

Conclusion

The **AX_E_PERMIT_INVERT_4** subapplication provides a compact and reusable solution for 4-channel event gating with an inverted adapter-based permit signal. By combining `AX_NOT_INIT` and `AX_E_PERMIT_4`, it offers a clear, structured way to block or forward multiple event streams using a single active-low control signal. It is especially useful in IEC 61499 applications where conditional event propagation and centralized gating are required.



AX_LinksRechts_T_FF

• – ○ • – ○ • – ○ •

Introduction

`AX_LinksRechts_T_FF` ("left/right toggle flip-flop") converts a single button press (`IN`) via a toggle flip-flop into two complementary adapter outputs `Links`/`Rechts` (left/right) — each button press switches between "left active" and "right active".

Interface Structure

- **Event inputs**: `INIT` (initialization request)
- **Event outputs**: `INITO` (initialization confirm)
- **Data inputs**: `QI` (`BOOL`, default `TRUE`) — quality input
- **Data outputs**: `QO` (`BOOL`) — quality output
- **Adapters**: socket `IN`, plugs `Links` and `Rechts` (each `adapter::types::unidirectional::AX`)

Function Blocks (FBs) Used

Sub-blocks: AX_LinksRechts_T_FF

- **Type**: SubAppType
- **Internal FBs used**:
  - **AX_R_TRIG**: `adapter::events::unidirectional::AX_R_TRIG` — detects the button's rising edge.
  - **AX_T_FF_INIT**: `adapter::events::unidirectional::AX_T_FF_INIT` — toggle flip-flop with a defined initial state (`Q_INIT=FALSE`; `QI` comes from the wrapper input `QI`).
  - **AX_SPLIT_2**: `adapter::events::unidirectional::AX_SPLIT_2` — splits the flip-flop state.
  - **AX_NOT**: `adapter::booleanOperators::AX_NOT` — negates one of the two branches to produce the complementary signal.
- **Functionality**: Every rising edge on `IN` toggles `AX_T_FF_INIT.Q`. The direct state feeds `Rechts` (right), the negated state feeds `Links` (left) — so `Links` and `Rechts` are always exactly complementary (per the source comment: "AX_T_FF_INIT switches the Active output to FALSE, so LEFT is then TRUE").

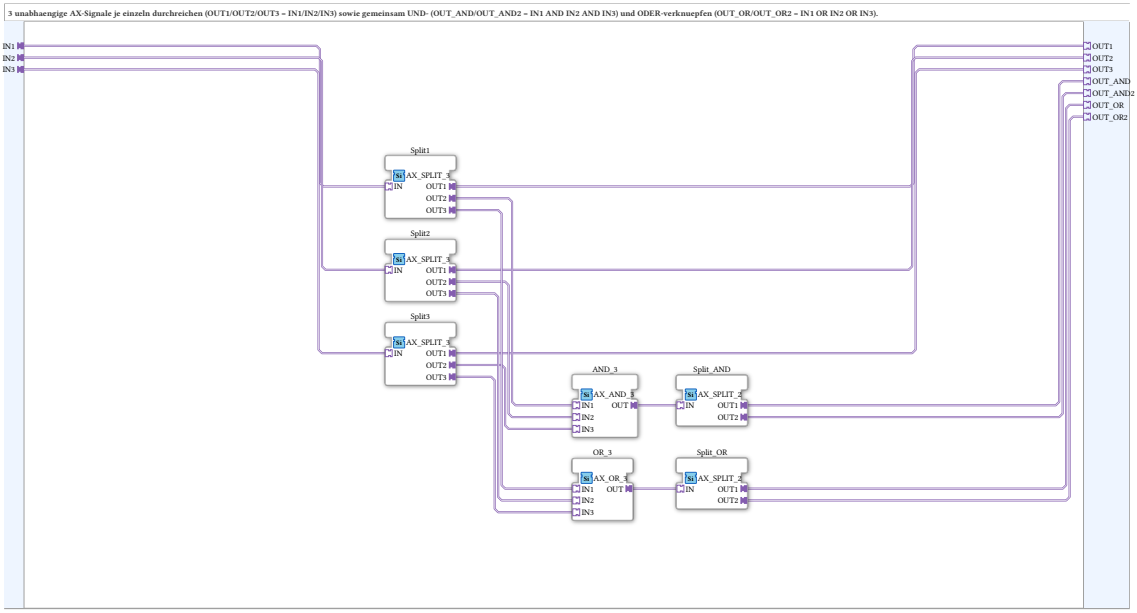
Program Flow and Connections

1. `IN` ⟶ `AX_R_TRIG.QI`; `AX_R_TRIG.EO` ⟶ `AX_T_FF_INIT.CLK` (toggles on every rising edge).
2. `AX_T_FF_INIT.Q` ⟶ `AX_SPLIT_2.IN`.
3. `AX_SPLIT_2.OUT1` ⟶ `AX_NOT.IN` ⟶ `AX_NOT.OUT` ⟶ `Links`.

4. `AX_SPLIT_2.OUT2` ⟶ `Rechts`.
5. `INIT` ⟶ `AX_T_FF_INIT.INIT`; `AX_T_FF_INIT.INITO` ⟶ `INITO`.
6. `QI` ⟶ `AX_T_FF_INIT.QI`; `AX_T_FF_INIT.QO` ⟶ `QO`.

Application Scenarios

- Single-button switching between two mutually exclusive states (e.g. direction of travel, display toggling) without needing two separate buttons.



Summary

`AX_LinksRechts_T_FF` implements a classic single-button toggle between two complementary states, using a toggle flip-flop with a defined initial state and a negation for the opposite signal.

AX_OR_AND_3_SPLIT

• – ○ • – ○ • – ○ •

Introduction

`AX_OR_AND_3_SPLIT` passes **three independent AX signals** through individually (`OUT1`/`OUT2`/`OUT3` = `IN1`/`IN2`/`IN3`) and additionally combines them jointly with **AND** (`OUT_AND`/`OUT_AND2` = `IN1 AND IN2 AND IN3`) and **OR** (`OUT_OR`/`OUT_OR2` = `IN1 OR IN2 OR IN3`). The combined outputs are each provided twice (branch 1/branch 2).

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

All adapters are unidirectional of type `adapter::types::unidirectional::AX`.

- **IN1**, **IN2**, **IN3** (sockets): input signals 1 to 3
- **OUT1**, **OUT2**, **OUT3** (plugs): passed-through input signals 1 to 3
- **OUT_AND**, **OUT_AND2** (plugs): `IN1 AND IN2 AND IN3` - collective status "all active" (branch 1/ branch 2)
- **OUT_OR**, **OUT_OR2** (plugs): `IN1 OR IN2 OR IN3` - collective status "at least one active" (branch 1/ branch 2)

Function Blocks (FBs) Used

- **Split1**, **Split2**, **Split3**: each `adapter::events::unidirectional::AX_SPLIT_3` (branches each input signal onto three targets)
- **AND_3**: `adapter::booleanOperators::AX_AND_3`
- **OR_3**: `adapter::booleanOperators::AX_OR_3`
- **Split_AND**, **Split_OR**: each `adapter::events::unidirectional::AX_SPLIT_2` (duplicate the respective collective output)

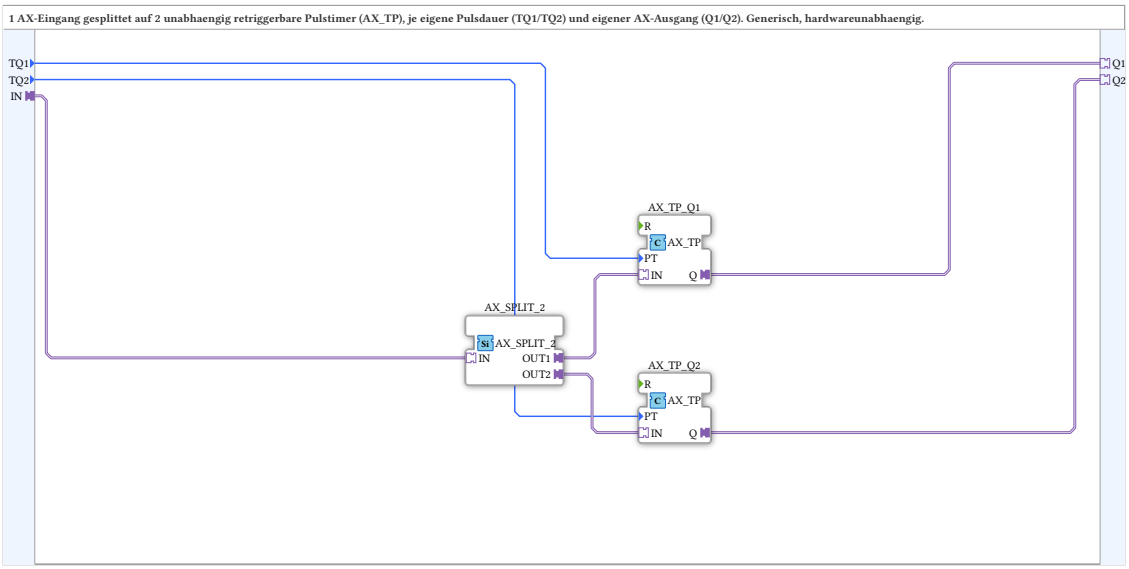
Program Flow and Connections

- `INx` ⟶ `Splitx.IN`
- `Splitx.OUT1` ⟶ `OUTx` (pass-through)
- `Splitx.OUT2` ⟶ `AND_3.INx`
- `Splitx.OUT3` ⟶ `OR_3.INx`
- `AND_3.OUT` ⟶ `Split_AND.IN`; `Split_AND.OUT1` ⟶ `OUT_AND`, `Split_AND.OUT2` ⟶ `OUT_AND2`
- `OR_3.OUT` ⟶ `Split_OR.IN`; `Split_OR.OUT1` ⟶ `OUT_OR`, `Split_OR.OUT2` ⟶ `OUT_OR2`

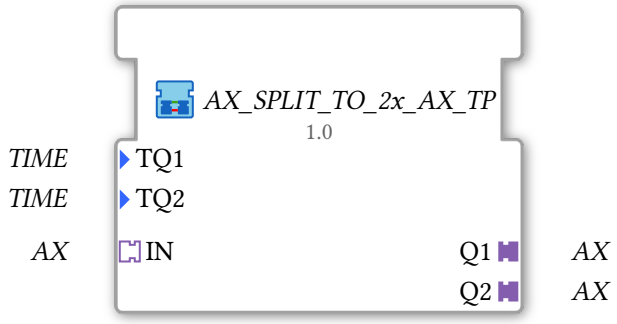
(with x = 1, 2, 3)

Technical Details

- The AND and OR collective outputs are doubled (`AX_SPLIT_2`) so that two consumers each can be supplied.



Application Scenarios



- Using several status signals (e.g. belts) individually and additionally forming a common status "all active" or "at least one active"

Summary

`AX_OR_AND_3_SPLIT` bundles pass-through, AND and OR combination of three AX signals in one SubApp.

AX_SPLIT_TO_2x_AX_TP

• – ○ • – ○ • – ○ •

Introduction

This subapplication provides a generic solution for splitting a single AX (axis) event input into two independent retriggerable pulse timers. Each timer has its own adjustable pulse duration and produces a separate AX output. The subapp is hardware-independent and can be reused in various control scenarios.

Interface Structure

Event Inputs

There are no direct event inputs. However, the adapter `IN` acts as an event-triggering input; events received on this adapter are processed internally.

Event Outputs

There are no direct event outputs. The generated pulse events are exposed via the adapter outputs `Q1` and `Q2`.

Data Inputs

Name	Type	Description
`TQ1`	`TIME`	Pulse duration for the first output (Q1).
`TQ2`	`TIME`	Pulse duration for the second output (Q2).

Data Outputs

None.

Adapters

Name	Type	Direction	Description
IN	adapter::types::unidirectional::AX	Input (Socket)	Receives the incoming AX event.
Q1	adapter::types::unidirectional::AX	Output (Plug)	Emits the pulse event for the first channel.
Q2	adapter::types::unidirectional::AX	Output (Plug)	Emits the pulse event for the second channel.

Functionality

The subapp uses an internal AX_SPLIT_2 instance to split the incoming AX event into two identical AX events. These events are then forwarded to two separate AX_TP timer instances (AX_TP_Q1 and AX_TP_Q2). Each timer is retriggerable: every new incoming event restarts the timing period. The pulse duration is independently set by TQ1 and TQ2. When a timing period elapses, the corresponding timer outputs an AX event on its Q adapter, which is then relayed to the respective subapp output (Q1 or Q2).

The split operation is transparent, meaning both channels receive the same trigger event. The timers operate independently, allowing different pulse widths and asynchronous behavior.

Technical Features

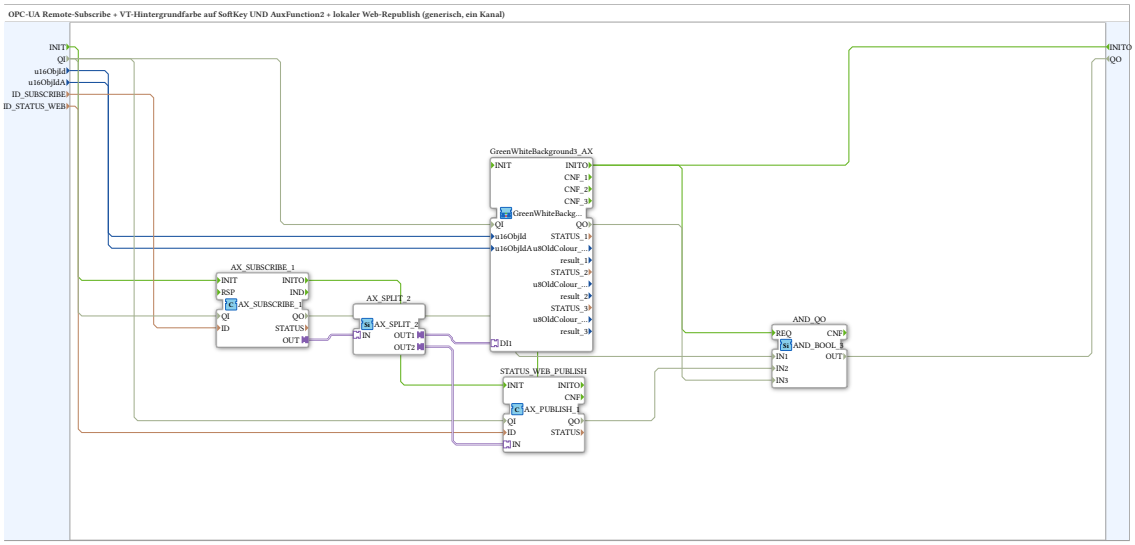
- **Generic and hardware-independent**: The subapp does not rely on any specific hardware platform.
- **Two independent retriggerable timers**: Each channel has its own timer and pulse duration.
- **Split of input event**: Uses the AX_SPLIT_2 block to duplicate the incoming event.
- **Easy configuration**: Pulse durations are set via data inputs.
- **Standard 61499 compliance**: Uses standard adapter types (unidirectional AX) and timers.

State Overview

The subapp does not maintain an explicit state machine; its behavior is determined by the internal AX_TP timers. The timers operate in a retriggerable manner: upon receiving an input event, they start (or restart) their timing cycle. When the timing period elapses, they emit an output event. While the timer is active, further input events reset the timing.

Application Scenarios

- **Control of two independent actuators** based on a single trigger signal.
- **Generation of two different pulse widths** for testing or calibration purposes.
- **Staggered pulse outputs** where each channel has its own response delay or duration.
- **Event distribution in automation systems** where a single sensor event must trigger multiple devices with different on-times.

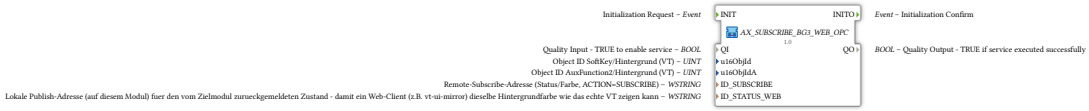


Comparison with Similar Blocks

Unlike a fixed pulse generator or a single retriggerable timer, this subapp provides dual-channel capability with independent timing settings. It can be seen as a combination of an event splitter and two pulse timers, offering flexibility not found in single-timer blocks. Compared to using two separate AX_TP instances manually, this subapp encapsulates the split and timer logic, reducing wiring complexity and improving readability.

Conclusion

AX_SPLIT_TO_2x_AX_TP is a compact, reusable component for scenarios requiring an AX trigger to be duplicated and delayed with independent pulse durations. Its clear interface, generic design, and straightforward configuration make it a valuable addition to any 4diac-based automation project.



AX_SUBSCRIBE_BG3_WEB_OPC

• – ○ • – ○ • – ○ •

Introduction

`AX_SUBSCRIBE_BG3_WEB_OPC` is the status half of `Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC`, extracted as an independent component: a remote subscribe value is displayed as a background color on both a SoftKey AND an AuxFunction2 (`GreenWhiteBackground3_AX`) and is also republished locally via OPC UA so that a web client (e.g., vt-ui-mirror) on the same module can read the same status without needing its own connection to the target module.

Interface

- **Event input**: `INIT` (`EInit`, Initialization Request)
- **Event output**: `INITO` (`EInit`, Initialization Confirm)
- **Data inputs**: `QI` (`BOOL`, initial value `TRUE`, Quality Input), `u16ObjId`, `u16ObjIdA`, `ID_SUBSCRIBE`, `ID_STATUS_WEB`
- **Data output**: `QO` (`BOOL`, Quality Output)

Function Blocks (FBs) Used

Sub-Blocks: AX_SUBSCRIBE_BG3_WEB_OPC

- **Type**: SubAppType
- **Internal FBs Used**:
- **AX_SUBSCRIBE_1**: `adapter::net::AX_SUBSCRIBE_1` (`QI` from the block input `QI`) — Remote subscription of the status/color (`ID_SUBSCRIBE`).
- **AX_SPLIT_2**: `adapter::events::unidirectional::AX_SPLIT_2` — Branches the received signal to the VT display and the local web republish.
- **GreenWhiteBackground3_AX** (SubApp, `MyLib::sys`): Synchronously colors both a SoftKey (`u16ObjId`) and an AuxFunction2 (`u16ObjIdA`); it has its own `INIT`/`INITO` and `QI`/`QO`.
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_3` — ANDs the `QO` outputs of `AX_SUBSCRIBE_1`, `STATUS_WEB_PUBLISH` and `GreenWhiteBackground3_AX` into the block output `QO`.
- **STATUS_WEB_PUBLISH**: `adapter::net::AX_PUBLISH_1` (`QI` from the block input `QI`) — Republishes the received state to this module's local OPC UA server (`ID_STATUS_WEB`).
- **How it works**: The state received via remote subscribe is simultaneously passed to the VT background color and the local web republish server via `AX_SPLIT_2`.

Program Flow and Connections

1. u16ObjId → GreenWhiteBackground3_AX.u16ObjId; u16ObjIdA → GreenWhiteBackground3_AX.u16ObjIdA; ID_SUBSCRIBE → AX_SUBSCRIBE_1.ID; ID_STATUS_WEB → STATUS_WEB_PUBLISH.ID (Data connections, hidden).
2. AX_SUBSCRIBE_1.OUT → AX_SPLIT_2.IN → AX_SPLIT_2.OUT1 → GreenWhiteBackground3_AX.DI1 (VT display), AX_SPLIT_2.OUT2 → STATUS_WEB_PUBLISH.IN (Web Republish).
3. Initialization chain: INIT → AX_SUBSCRIBE_1.INIT, AX_SUBSCRIBE_1.INIT0 → STATUS_WEB_PUBLISH.INIT, STATUS_WEB_PUBLISH.INIT0 → GreenWhiteBackground3_AX.INIT, GreenWhiteBackground3_AX.INIT0 → INIT0; additionally GreenWhiteBackground3_AX.INIT0 → AND_Q0.REQ.
4. QI → AX_SUBSCRIBE_1.QI, STATUS_WEB_PUBLISH.QI and GreenWhiteBackground3_AX.QI.
5. AX_SUBSCRIBE_1.Q0 → AND_Q0.IN1, STATUS_WEB_PUBLISH.Q0 → AND_Q0.IN2, GreenWhiteBackground3_AX.Q0 → AND_Q0.IN3; AND_Q0.OUT → Q0.

Technical Features

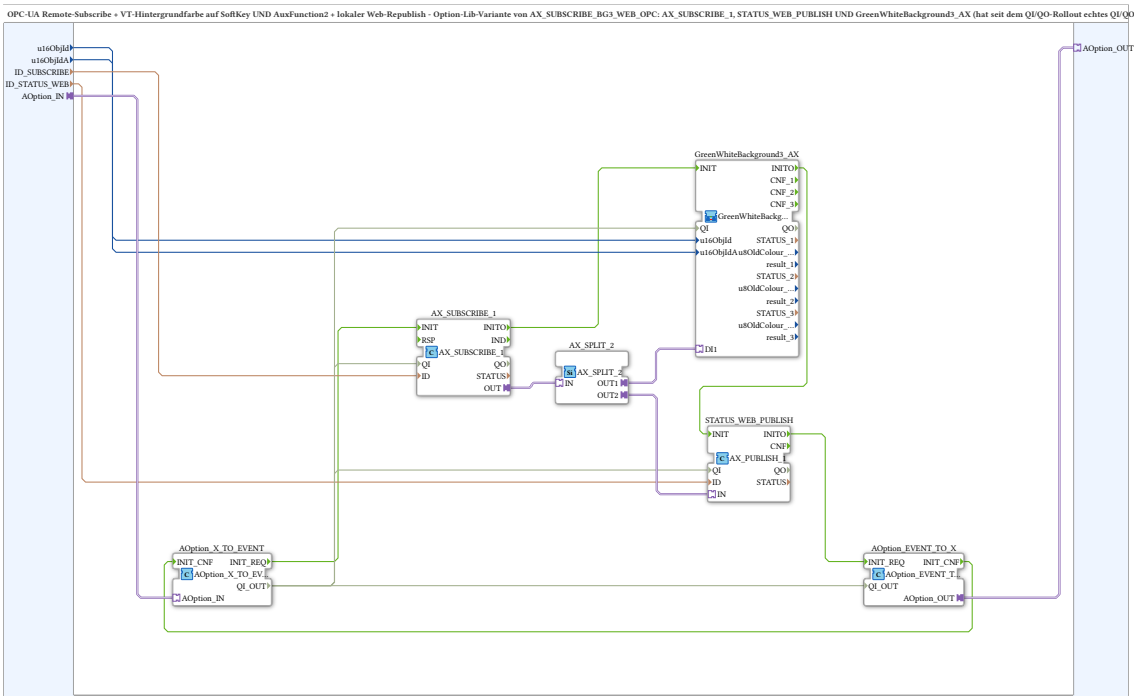
- **Extension of AX_SUBSCRIBE_BG_OPC**: Compared to the simpler version (only Subscribe + background color), two things are added: GreenWhiteBackground3_AX instead of GreenWhiteBackground1_AX (colors SoftKey and Aux together) and local Web Republish via AX_SPLIT_2/STATUS_WEB_PUBLISH.
- **Decoupling from the target module**: A web client connected only to this module does not need to establish its own connection to the target module to see the same status as the actual VT.

Application Scenarios

- Status display for functions that need to be displayed synchronously on both a SoftKey and an AuxFunction2 (joystick assignment), plus web mirroring.
- For a SoftKey without an Aux, use AX_SUBSCRIBE_BG_OPC instead (no web republish).

Comparison with similar modules

For the complete, pre-wired combination with the command-line interface (SoftKey/Aux read + remote write), continue to use Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC, which includes this module as a status sub-module.



Summary

AX_SUBSCRIBE_BG3_WEB_OPC encapsulates the status page of a remote channel: reception, synchronous softkey/aux background color, and local web republish in a self-contained, reusable building block.

AX_SUBSCRIBE_BG3_WEB_Option_OPC

• — ○ • — ○ • — ○ •

Introduction

`AX_SUBSCRIBE_BG3_WEB_Option_OPC` is the option-lib variant of `AX_SUBSCRIBE_BG3_WEB_OPC`: OPC-UA remote subscribe with VT background colour on SoftKey AND AuxFunction2 plus local web republish. `AX_SUBSCRIBE_1`, `STATUS_WEB_PUBLISH` and `GreenWhiteBackground3_AX` (which has had a real `QI`/`QO` since the QI/QO rollout) are initialized and gated here by the adapter socket `Option::AOption`: all three sequentially in the order `AX_SUBSCRIBE_1` -> `GreenWhiteBackground3_AX` -> `STATUS_WEB_PUBLISH`. The plug `AOption_OUT` passes the activation on to a downstream group (daisy chain).

Interface Structure

Event Inputs

None (initialization runs via the adapter `AOption_IN`).

Event Outputs

None.

Data Inputs

Variable	Type	Default	Comment
`u16ObjId`	UINT	`ID_NULL`	Object ID SoftKey/background (VT).
`u16ObjIdA`	UINT	`ID_NULL`	Object ID AuxFunction2/background (VT).
`ID_SUBSCRIBE`	WSTRING		Remote subscribe address (status/colour, `ACTION=SUBSCRIBE`).
`ID_STATUS_WEB`	WSTRING		Local publish address for the state reported back by the target module, so that a web client (e.g. `vt-ui-mirror`) can show the same background colour as the real VT.

Data Outputs

None.

Adapters

Adapter	Type	Direction	Comment
AOption_IN	Option::AOption	Socket	Drives INIT/QI of AX_SUBSCRIBE_1, STATUS_WEB_PUBLISH and GreenWhiteBackground3_AX; typically fed by the AOption_OUT of Softkey_Aux_IXA_TO_Remote_WRITE_Option.
AOption_OUT	Option::AOption	Plug	Passes the activation on to a downstream group (daisy chain); leave unused if nothing follows.

Function Blocks (FBs) Used

Sub-blocks: AX_SUBSCRIBE_BG3_WEB_Option_OPC

- **Type**: SubAppType
- **Internal FBs used**:
  - **AOption_X_TO_EVENT** (Option::conversion::AOption_X_TO_EVENT): converts the socket AOption_IN into INIT_REQ/QI_OUT, see AOption_X_TO_EVENT.
  - **AX_SUBSCRIBE_1** (adapter::net::AX_SUBSCRIBE_1): OPC-UA subscribe on ID_SUBSCRIBE.
  - **AX_SPLIT_2** (adapter::events::unidirectional::AX_SPLIT_2): distributes the subscribe value to two branches.
  - **GreenWhiteBackground3_AX** (SubApp MyLib::sys::GreenWhiteBackground3_AX): sets the background colour on SoftKey and AuxFunction2; initialized and gated by the option socket sequentially, after AX_SUBSCRIBE_1 and before STATUS_WEB_PUBLISH.
  - **STATUS_WEB_PUBLISH** (adapter::net::AX_PUBLISH_1): local publish of the status on ID_STATUS_WEB.
  - **AOption_EVENT_TO_X** (Option::conversion::AOption_EVENT_TO_X): passes the activation on to AOption_OUT.

Program Flow and Connections

1. Option chain: AOption_X_TO_EVENT.INIT_REQ -> AX_SUBSCRIBE_1.INIT; AX_SUBSCRIBE_1.INITO -> GreenWhiteBackground3_AX.INIT; GreenWhiteBackground3_AX.INITO -> STATUS_WEB_PUBLISH.INIT; STATUS_WEB_PUBLISH.INITO -> AOption_EVENT_TO_X.INIT_REQ; AOption_EVENT_TO_X.INIT_CNF -> AOption_X_TO_EVENT.INIT_CNF.
2. AOption_X_TO_EVENT.QI_OUT -> AX_SUBSCRIBE_1.QI, STATUS_WEB_PUBLISH.QI, GreenWhiteBackground3_AX.QI and AOption_EVENT_TO_X.QI_OUT.
3. Adapters: AOption_IN -> AOption_X_TO_EVENT.AOption_IN; AOption_EVENT_TO_X.AOption_OUT -> AOption_OUT.
4. Data: AX_SUBSCRIBE_1.OUT -> AX_SPLIT_2.IN; AX_SPLIT_2.OUT1 -> GreenWhiteBackground3_AX.DI1; AX_SPLIT_2.OUT2 -> STATUS_WEB_PUBLISH.IN.
5. Parameters: ID_SUBSCRIBE -> AX_SUBSCRIBE_1.ID; ID_STATUS_WEB -> STATUS_WEB_PUBLISH.ID; u16ObjId/u16ObjIdA -> GreenWhiteBackground3_AX.u16ObjId/u16ObjIdA.
6. The block has no event and no QI/QO interface; activation and acknowledgment run exclusively via the adapters AOption_IN/AOption_OUT.

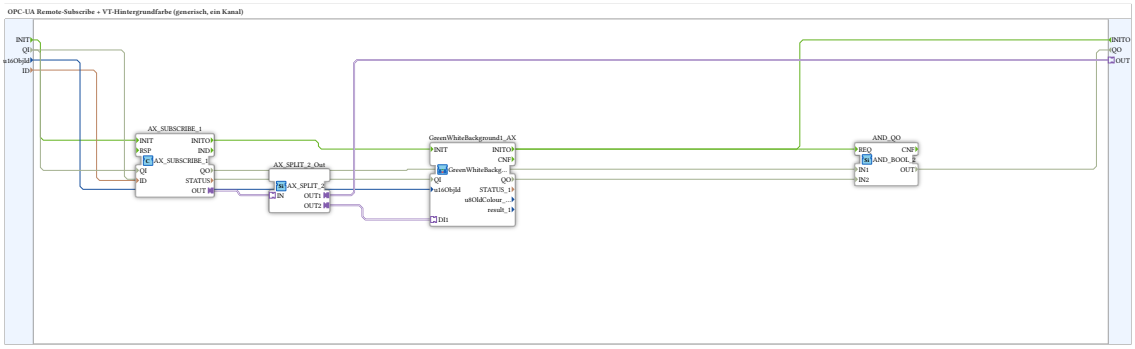
Technical Features

- **All three blocks gated:** AX_SUBSCRIBE_1, STATUS_WEB_PUBLISH and GreenWhiteBackground3_AX hang on the option socket (version 1.1; GreenWhiteBackground3_AX has had a real QI/QO since the QI/QO rollout, the earlier assumption of no gating was outdated).
- **Sequential initialization:** The option chain initializes AX_SUBSCRIBE_1, GreenWhiteBackground3_AX and STATUS_WEB_PUBLISH one after the other; only after STATUS_WEB_PUBLISH.INITO does AOption_EVENT_TO_X.INIT_REQ fire.
- **Option initialization instead of INIT/QI:** The block has no INIT/INITO/QI/QO connections of its own; initialization runs via the INIT_REQ/INIT_CNF handshake of the option chain, and the acknowledgment returns via AOption_EVENT_TO_X.INIT_CNF to AOption_X_TO_EVENT.

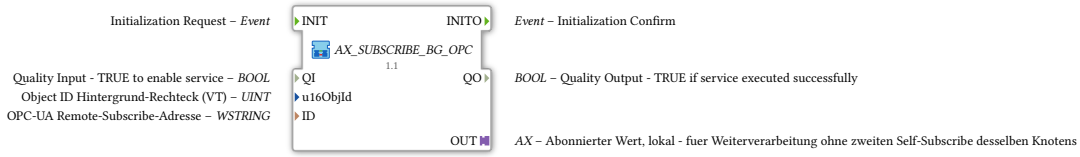
- **Daisy chain:** `AOption_OUT` allows further instances or groups to be attached to the same option.
- The counterpart without option is `AX_SUBSCRIBE_BG3_WEB_OPC`.

Application Scenarios

- Status half of `Softkey_Aux_IXA_TO_Remote_WRITE_BG_Option_OPC`: background colour on SoftKey and Aux from a remote subscribe, active only when the option is selected.



Summary



`AX_SUBSCRIBE_BG3_WEB_Option_OPC` combines remote subscribe, background colour on SoftKey and Aux and local web republish, and gates subscribe, publish and background colour via an `AOption` socket with forwarding through `AOption_OUT`.

🌐 Related topic subpages on ms-muc-docs.de

AX_SUBSCRIBE_BG_OPC

• — ○ • — ○ • — ○ •

Introduction

The **AX_SUBSCRIBE_BG_OPC** subapplication is a generic, single-channel solution that combines an OPC-UA remote subscription with a visualization (VT) background color change mechanism. It is designed for industrial HMI scenarios where a background rectangle of a VT screen needs to be dynamically recolored based on data received from an OPC-UA server. The subapp encapsulates the subscription logic and the background-color transformation into a single reusable component, hiding the internal complexity from the application engineer.

Interface Structure

The subapplication exposes the event input `INIT`, the event output `INITO`, the data inputs `QI`, `u16ObjId` and `ID`, and the data output `QO`. It has no adapter sockets at its external boundary. All internal communication is handled within the encapsulated network.

Event Inputs

- **INIT** (`EInit`): initialization request; starts the initialization chain `AX_SUBSCRIBE_1` → `GreenWhiteBackground1_AX`.

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `GreenWhiteBackground1_AX.INITO`.

Data Inputs

Name	Data Type	Description
QI	BOOL	Quality input, service enable (initial value TRUE).
u16ObjId	UINT	Object ID of the VT background rectangle. Default value is ID_NULL.
ID	WSTRING	OPC-UA remote-subscribe address (the server node or subscription identifier).

Data Outputs

Name	Data Type	Description
QO	BOOL	Quality output, AND of the QO outputs of AX_SUBSCRIBE_1 and GreenWhiteBackground1_AX.

The actual result is realized through the internal adapter connection to the background-color subapplication.

Adapters

No external adapters are exposed. Internally, the OPC-UA subscription function block AX_SUBSCRIBE_1 uses an adapter-type output (OUT) which is connected to the DI1 adapter socket of the embedded GreenWhiteBackground1_AX subapplication.

Functionality

The subapplication performs the following operations:

1. **Subscription Setup** – The internal function block AX_SUBSCRIBE_1 (type adapter::net::AX_SUBSCRIBE_1) is enabled through the subapplication input QI (wired to AX_SUBSCRIBE_1.QI; it is no longer a fixed QI=TRUE parameter) and is initialized via INIT → AX_SUBSCRIBE_1.INIT.
2. **Address Provision** – The external ID input (the OPC-UA subscribe address) is forwarded to the ID input of the AX_SUBSCRIBE_1 function block.
3. **Object Identification** – The external u16ObjId input is passed to the u16ObjId input of the embedded GreenWhiteBackground1_AX subapplication, identifying which VT background rectangle is to be affected.
4. **Color Change Propagation** – The adapter connection from AX_SUBSCRIBE_1.OUT to GreenWhiteBackground1_AX.DI1 transports the subscription result (e.g., a numeric value or status) to the background-color logic, which then alters the fill color of the specified VT rectangle accordingly.
5. **Initialization and Quality** – AX_SUBSCRIBE_1.INITO → GreenWhiteBackground1_AX.INIT; GreenWhiteBackground1_AX.INITO → INITO and → AND_QO.REQ. QI is also passed to GreenWhiteBackground1_AX.QI. AX_SUBSCRIBE_1.QO → AND_QO.IN1 and GreenWhiteBackground1_AX.QO → AND_QO.IN2; the instance AND_QO (iec61131::booleanOperators::AND_BOOL_2) drives QO.

The two data connections (ID → AX_SUBSCRIBE_1.ID and u16ObjId → GreenWhiteBackground1_AX.u16ObjId) are marked as invisible (Visible = false) in the diagram, reducing visual clutter in the engineering environment.

Technical Features

- **Generic Single-Channel Design** – The subapp is parameterized through its data inputs u16ObjId and ID (plus the enable QI), making it reusable for any OPC-UA node address and any VT rectangle object ID.
- **Embedded Subscription Logic** – The OPC-UA subscription FB is internally instantiated; its enable comes from QI and its initialization is sequenced by the subapp's own INIT/INITO chain.
- **Adapter-Based Coupling** – Communication between the subscription FB and the background-color FB is performed via an adapter connection (OUT to DI1), enabling type-safe links between the internal components.

- **Hidden Internal Wiring** – All internal connections are marked invisible to keep the subapp representation clean in the overall application diagram.
- **Default Object ID** – The `u16ObjId` input defaults to `ID_NULL`, allowing the subapp to be instantiated before a concrete object ID is assigned.

State Overview

Since `AX_SUBSCRIBE_BG_OPC` is a composite subapplication rather than a stateful function block, it does not define its own explicit state machine. However, the internal `AX_SUBSCRIBE_1` FB is expected to implement the standard OPC-UA subscription states:

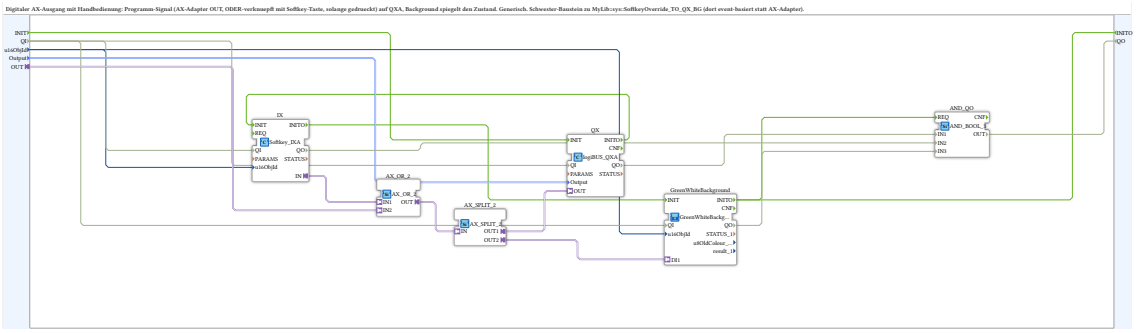
- **Initialization** – With `QI = TRUE` and after `INIT`, the FB begins establishing the subscription to the given OPC-UA address.
- **Subscribed** – The subscription is active and data updates are propagated through the adapter output.
- **Error / Disconnected** – If the server is unreachable or the subscription fails, the FB signals an error condition (internally handled, not exposed externally).

The `GreenWhiteBackground1_AX` subapplication receives the subscription value via `DI1` and updates the background color based on the received data, typically switching between green (active/OK) and white (inactive/fault).

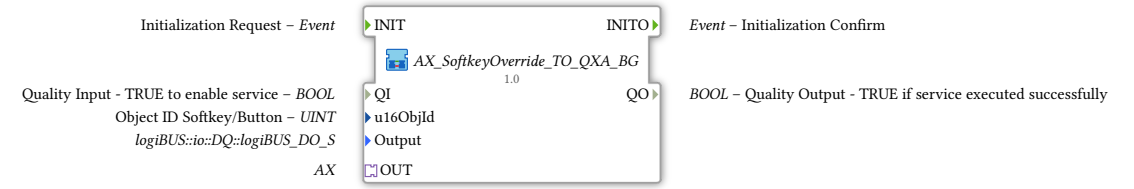
Application Scenarios

Typical use cases for this subapplication include:

- **Machine Status Indication** – In a machine HMI, a background rectangle is colored green when the OPC-UA node reports the machine as running, and white when it is stopped or in an error state.
- **Remote Variable Monitoring** – Monitoring a single OPC-UA variable (e.g., a production counter threshold) and visually reflecting its state on a VT screen.
- **Generic HMI Building Blocks** – Reuse in larger applications where multiple instances of the subapp are placed, each bound to a different OPC-UA address and a different VT rectangle, allowing rapid assembly of status displays.
- **SCADA-Style Dashboards** – Simple visual alarming where the background color of a label or area changes based on values read from a remote automation controller.



Comparison with Similar Blocks



Feature	AX_SUBSCRIBE_BG_OPC	Direct FB Pairing (AX_SUBSCRIBE + GreenWhiteBackground)
Integration Effort	Low – only two inputs need configuring	Higher – requires manual wiring of adapter connections and parameters
Reusability	High – encapsulated as a self-contained unit	Medium – each instance must be reconnected individually
Interface Complexity	Small (`INIT`/`INITO`, `QI`/`QO`, 2 data inputs)	Multiple connections and event wiring
Error Handling	Handled internally by the subscribe FB	Depends on the immediate FB configuration
Visual Clarity	Clean – internal wiring hidden	Cluttered – all connections visible
Flexibility	Limited to one channel per instance	More flexible when individual FBs are used in complex networks

Conclusion

The **AX_SUBSCRIBE_BG_OPC** subapplication provides a compact, ready-to-use building block for OPC-UA-driven background color changes in visualization screens. By encapsulating the subscription logic and the color-change logic behind a simple interface (`INIT`/`INITO`, `QI`/`QO` and two data inputs), it significantly reduces engineering effort and improves the readability of application diagrams. Its generic design makes it suitable for a wide range of single-channel monitoring and status indication scenarios in industrial automation HMI environments.

AX_SoftkeyOverride_TO_QXA_BG

• – ○ • – ○ • – ○ •

Introduction

The **AX_SoftkeyOverride_TO_QXA_BG** is a generic subapplication that combines a program signal (via an AX adapter) with a manual softkey input to control a digital output (QXA). The effective output state is also mirrored to a background indicator for visual feedback. It is a sister block to `MyLib::sys::SoftkeyOverride_TO_QX_BG` but uses an adapter-based signal instead of an event-based trigger.

Interface Structure

Event Inputs

- `INIT` (EInit): initialization request; starts the init chain at `QX.INIT`.

Event Outputs

- `INITO` (EInit): initialization confirmation; comes from `GreenWhiteBackground.INITO`, the end of the init chain.

Data Inputs

- `QI` (BOOL) – Quality input, enables the service (initial value: `TRUE`); passed on to `QX.QI`, `IX.QI` and `GreenWhiteBackground.QI`.
- `u16ObjId` (UINT) – Object ID of the softkey used for manual override. Default value: `ID_NULL`.
- `Output` (`logiBUS::io::DQ::logiBUS_DO_S`) – Desired output value sent to the QXA block. Initial value: `logiBUS_DO::Invalid`.

Data Outputs

- `QO` (BOOL) – Quality output, AND combination (`AND_QO`, `AND_BOOL_3`) of the `QO` outputs of `QX`, `IX` and `GreenWhiteBackground`.

Adapters

- `OUT` (adapter::types::unidirectional::AX) – Receives the program signal that is logically OR-ed with the softkey state.

Functionality

The subapplication continuously processes the AX program signal from the `OUT` adapter and the softkey state from the internal `Softkey_IXA` block (identified by `u16ObjId`). These two signals are combined using an AX_OR_2 logic gate. The resulting boolean value is split via an AX_SPLIT_2 adapter:

- One branch (OUT1) is sent to the `QX` block (`logiBUS_QXA`) which drives the actual digital output.

- The second branch (OUT2) is connected to the `GreenWhiteBackground1_AX` subapplication to display the current output state.

Initialization and quality: `INIT` → `QX.INIT`, `QX.INITO` → `IX.INIT`, `IX.INITO` → `GreenWhiteBackground.INIT`, `GreenWhiteBackground.INITO` → `INITO` and `AND_QO.REQ`. `QI` is passed on to `QX`, `IX` and `GreenWhiteBackground`; `QX.QO`, `IX.QO` and `GreenWhiteBackground.QO` are combined in `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`) into the output `QO`.

The `Output` data input provides the value to be used by the QX block when the output is active.

Technical Features

- Integrates `Softkey_IXA` for reading the softkey state.
- Uses `AX_OR_2` to perform the logical OR operation between the program signal and the manual override.
- Employs `AX_SPLIT_2` to fan out the combined signal.
- Contains `GreenWhiteBackground1_AX` for visual state indication.
- Uses `logiBUS_QXA` as the digital output driver; its quality input `QI` (like those of `Softkey_IXA` and the background) comes from the block input `QI` instead of being fixed to `TRUE`.
- The init chain (`INIT` → `QX` → `IX` → `GreenWhiteBackground` → `INITO`) and the AND combination of the quality outputs (`QI`/`QO`) follow the standard interface pattern of the wrapper subapps.

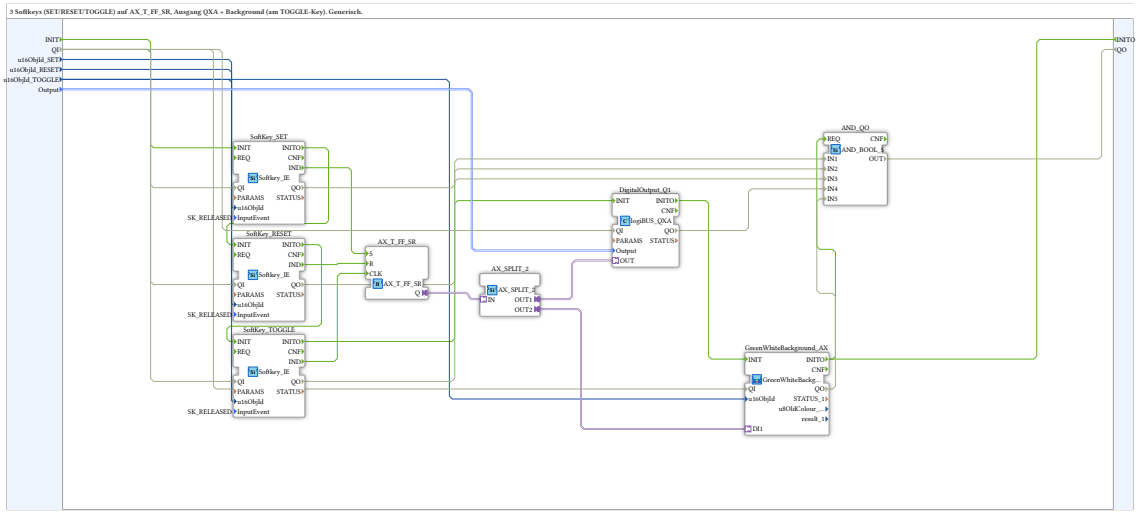
State Overview

Program Signal (AX)	Softkey Pressed	Output (QXA)	Background
0	0	OFF	OFF
1	0	ON	ON
0	1	ON	ON
1	1	ON	ON

The output is ON whenever either the program signal or the manual softkey is active.

Application Scenarios

This subapplication is ideal for control systems requiring a manual override capability, e.g., a machine operator can force a digital output (like a valve, motor, or lamp) on or off using a softkey while automatic control is active. The background display helps operators quickly identify the current output state even in complex HMI environments.



Comparison with Similar Blocks

- **SoftkeyOverride_TO_QX_BG**: This sister block achieves the same logical function but uses an event-based mechanism to trigger the override. It does not require an AX adapter and instead relies on event inputs and outputs.
- **AX_SoftkeyOverride_TO_QXA_BG**: The present block is adapter-centric, making it easier to integrate into systems where signals are communicated via unidirectional AX connections.

Conclusion

AX_SoftkeyOverride_TO_QXA_BG provides a clean, reusable solution for combining an automatic control signal with a manual softkey override to drive a digital output and its corresponding visual indicator. Its adapter-based interface simplifies integration into larger control networks and ensures consistent behavior across different applications.

AX_SoftkeySR_TO_QXA_BG

• — ○ • — ○ • — ○ •

Introduction

`AX_SoftkeySR_TO_QXA_BG` is a reusable 4diac subapplication that combines three softkeys with a SET/RESET/TOGGLE flip-flop function and a digital QXA output. It also integrates a green/white background indication that follows the same state, making it suitable for HMI or machine control applications where visual feedback is required.

The subapplication is generic: the softkey object IDs and the output selector are provided as configuration inputs. This allows the same subapplication to be reused in different ISOBUS or logiBUS-based control layouts without internal changes.

Interface Structure

The subapplication exposes the initialization events `INIT`/`INITO`, the quality ports `QI`/`QO` and the configuration data inputs. There are no adapter sockets/plugs at the subapplication boundary.

Event Inputs

- **INIT** (`EInit`): initialization request; starts the initialization chain of the inner blocks.

Event Outputs

- **INITO** (`EInit`): initialization confirm; comes from `GreenWhiteBackground_AX.INITO`, the last link of the chain.

Data Inputs

Name	Type	Initial Value	Comment
`QI`	`BOOL`	`TRUE`	Quality input - TRUE enables the service; distributed to all inner blocks
`u16ObjId_SET`	`UINT`	`ID_NULL`	Object ID of the SET softkey
`u16ObjId_RESET`	`UINT`	`ID_NULL`	Object ID of the RESET softkey

u16ObjId_TOGGLE	UINT	ID_NULL	Object ID of the TOGGLE softkey, also used for the green/white background
Output	logiBUS::io::DQ::logiBUS_DQ_8	logiBUS_DO::Invalid	Identifies the output, Output_Q1..Q8

Data Outputs

- **QO** (BOOL): quality output - TRUE if the service was executed successfully (AND of the QO of all five inner instances).

Adapters

No adapter interface is exposed by the subapplication. All adapter connections are internal.

Functionality

The subapplication contains three Softkey_IE instances named SoftKey_SET, SoftKey_RESET, and SoftKey_TOGGLE. Each is configured with InputEvent = SK_RELEASED (its QI comes from the subapplication input QI), so a softkey action is triggered when the assigned softkey is released.

The internal event flow is:

- SoftKey_SET.IND is connected to AX_T_FF_SR.S
- SoftKey_RESET.IND is connected to AX_T_FF_SR.R
- SoftKey_TOGGLE.IND is connected to AX_T_FF_SR.CLK

This means:

- Pressing the configured SET softkey sets the flip-flop output Q to TRUE.
- Pressing the configured RESET softkey resets the flip-flop output Q to FALSE.
- Pressing the configured TOGGLE softkey toggles the flip-flop output Q.

The flip-flop output Q is then passed to AX_SPLIT_2, which duplicates the signal to two destinations:

1. DigitalOutput_Q1.OUT, a logiBUS_QXA digital output.
2. GreenWhiteBackground_AX.DI1, a subapplication of type MyLib::sys::GreenWhiteBackground1_AX.

The same u16ObjId_TOGGLE value is also connected to the background subapplication. Therefore, the TOGGLE softkey is used both to toggle the QXA output and to provide the associated visual background feedback.

Initialization and quality: INIT → SoftKey_SET.INIT, SoftKey_SET.INITO → SoftKey_RESET.INIT, SoftKey_RESET.INITO → SoftKey_TOGGLE.INIT, SoftKey_TOGGLE.INITO → DigitalOutput_Q1.INIT, DigitalOutput_Q1.INITO → GreenWhiteBackground_AX.INIT and GreenWhiteBackground_AX.INITO → INITO. QI is passed to SoftKey_SET, SoftKey_RESET, SoftKey_TOGGLE, DigitalOutput_Q1 and GreenWhiteBackground_AX. QO is the output of the instance AND_QO (iec61131::booleanOperators::AND_BOOL_5), which combines the QO of these five instances; its REQ is triggered by GreenWhiteBackground_AX.INITO.

The internal wiring is fully encapsulated. From the outside, the application only requires the three softkey object IDs and the desired QXA output selector.

Technical Features

- Encapsulates three softkey input FBs, one SET/RESET/TOGGLE flip-flop, one signal splitter, one QXA digital output, and one background feedback subapplication.
- Uses SK_RELEASED as the softkey activation behaviour.
- Generic object IDs are used with default value ID_NULL, so they can be assigned per integration.
- Generic output selector is used with default value logiBUS_DO::Invalid.
- QI is no longer hard-wired to TRUE inside; it is passed from the subapplication input QI (default TRUE) to all inner blocks, so the subapplication is ready to operate when integrated.
- Initialization runs sequentially through the chain from INIT to INITO; operation is otherwise controlled through softkey events internally mapped to the flip-flop logic.
- The same state is propagated to both the QXA digital output and the green/white background subapplication.

State Overview

The central state logic is performed by `AX_T_FF_SR`.

Condition	`Q` State	Effect
SET softkey released	`TRUE`	QXA output and background become active
RESET softkey released	`FALSE`	QXA output and background become inactive
TOGGLE softkey released	Toggles	QXA output and background change to the opposite state

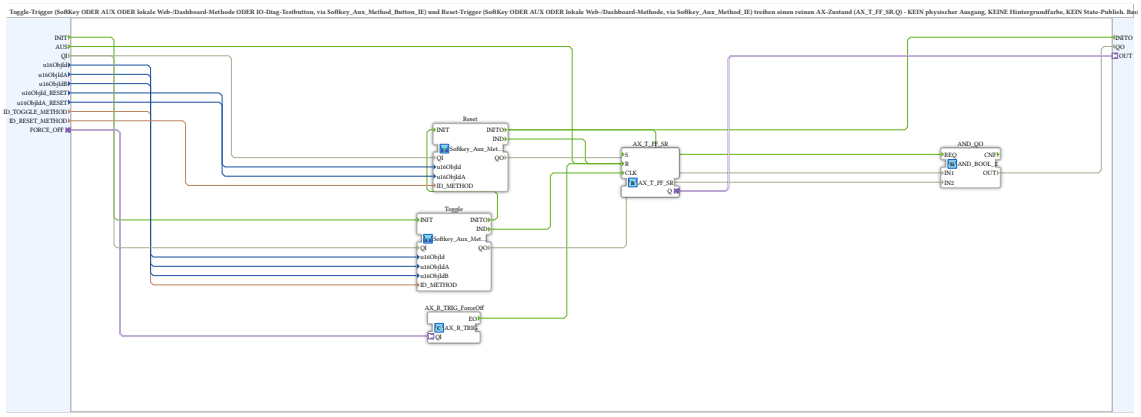
All state changes occur on softkey release events, which prevents unintended multiple triggers during a single physical press.

Application Scenarios

- Machine HMI panels where three softkeys are assigned to SET, RESET, and TOGGLE functions.
- ISOBUS/logiBUS control tasks requiring a simple boolean QXA output.
- Applications where a green/white background indication should follow the state of the output.
- Reusable subapplication in larger control programs where multiple softkey-controlled outputs are needed.
- Generic integration into different machine layouts by configuring object IDs and output selectors externally.

Comparison with Similar Blocks

Compared to a manually wired network of `Softkey_IE` FBs and a flip-flop, this subapplication provides a clean and reusable interface. The internal event and adapter connections are already defined, which reduces integration effort.

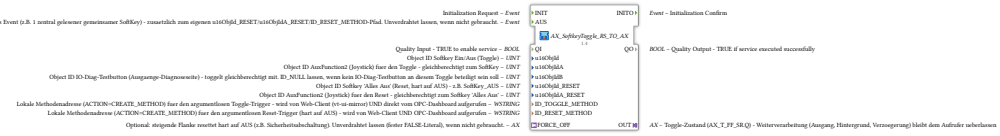


Compared to a simple SR flip-flop without a toggle function, `AX_SoftkeySR_TO_QXA_BG` adds a dedicated TOGGLE softkey input and therefore supports cyclic output switching from a single key.

Compared to fixed softkey implementations, this subapplication is generic. The object IDs and the QXA output can be configured, making it suitable for different HMI layouts without changing the internal logic.

Conclusion

`AX_SoftkeySR_TO_QXA_BG` is a compact, reusable subapplication for softkey-based SET/RESET/TOGGLE control of a QXA digital output. It combines the input handling, flip-flop state logic, output selection, and background feedback in a single encapsulated component. Its generic data interface makes it flexible for various machine control and HMI applications.



AX_SoftkeyToggle_RS_TO_AX

• – ○ • – ○ • – ○ •

Introduction

`AX_SoftkeyToggle_RS_TO_AX` generates a pure AX state from a toggle trigger and a reset trigger. The toggle trigger comes from SoftKey, AUX, a local web/dashboard method or an IO diagnostics test button (via `Softkey_Aux_Method_Button_IE`), the reset trigger from SoftKey, AUX or a local method (via `Softkey_Aux_Method_IE`). Both drive an `AX_T_FF_SR` whose state is present at the plug `OUT`. There is **no** physical output, **no** background colour and **no** state publish; these are left to the caller.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialisation request
- **AUS**: hard-resets the state to OFF from outside as an event (e.g. a centrally read common SoftKey 'All off'); in addition to the block's own reset path via `u16ObjId_RESET`/`u16ObjIdA_RESET`/`ID_RESET_METHOD`. Leave unwired if not needed.

Event Outputs

- **INITO** (`EInit`): initialisation confirmation

Data Inputs

- **QI** (BOOL): Quality Input, TRUE enables the service (default `TRUE`)
- **u16ObjId** (UINT): object ID of the SoftKey on/off (toggle), default `ID_NULL`
- **u16ObjIdA** (UINT): object ID of the AuxFunction2 (joystick) for the toggle, equal in rank to the SoftKey
- **u16ObjIdB** (UINT): object ID of the IO diagnostics test button (outputs diagnostics page), toggles with equal rank; leave `ID_NULL` if no such button is involved
- **u16ObjId_RESET** (UINT): object ID of the SoftKey 'All off' (reset, hard to OFF)
- **u16ObjIdA_RESET** (UINT): object ID of the AuxFunction2 (joystick) for the reset, equal in rank to the SoftKey 'All off'
- **ID_TOGGLE_METHOD** (WSTRING): local method address (`ACTION=CREATE_METHOD`) for the argument-less toggle trigger; called by the web client (vt-ui-mirror) and directly by the OPC dashboard
- **ID_RESET_METHOD** (WSTRING): local method address (`ACTION=CREATE_METHOD`) for the argument-less reset trigger (hard to OFF); called by the web client and the OPC dashboard

Data Outputs

- **QO** (BOOL): Quality Output, AND of `Toggle.QO` and `Reset.QO`

Adapters

- **OUT** (plug, `adapter::types::unidirectional::AX`): toggle state (`AX_T_FF_SR.Q`); further processing (output, background, delay) is left to the caller
- **FORCE_OFF** (socket, `adapter::types::unidirectional::AX`): optional; a rising edge hard-resets to OFF (e.g. safety shutdown). Leave unwired or at a fixed FALSE if not needed

Functionality

The network contains five parts:

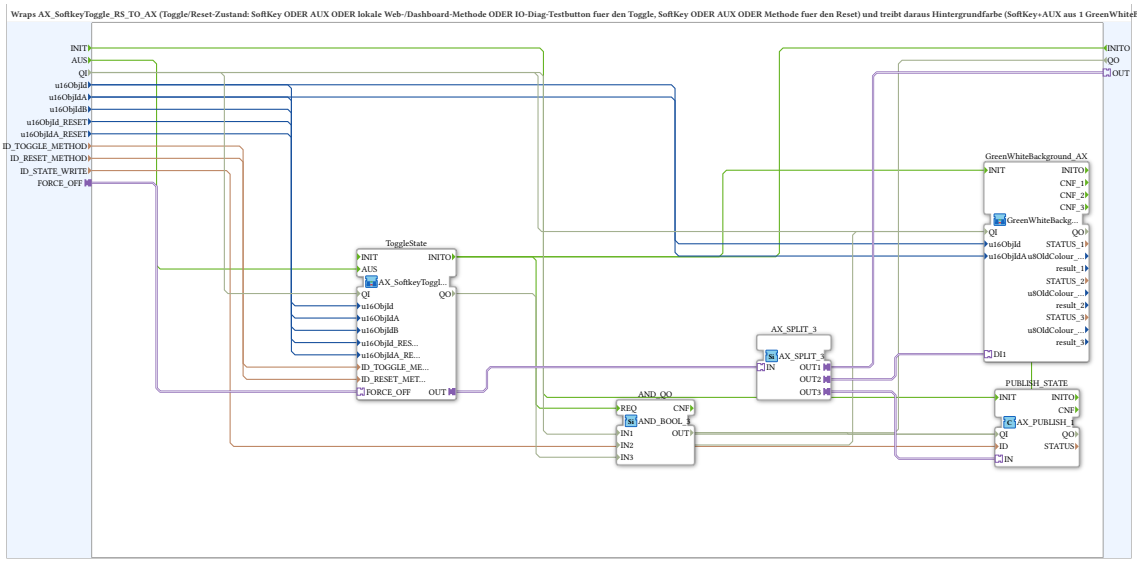
- `Toggle` (`MyLib::sys::Softkey_Aux_Method_Button_IE`): reads `u16ObjId`, `u16ObjIdA`, `u16ObjIdB` and `ID_TOGGLE_METHOD` (to `Toggle.ID_METHOD`); its `IND` goes to `AX_T_FF_SR.CLK` and toggles the state.
- `Reset` (`MyLib::sys::Softkey_Aux_Method_IE`): reads `u16ObjId_RESET` (to `Reset.u16ObjId`), `u16ObjIdA_RESET` (to `Reset.u16ObjIdA`) and `ID_RESET_METHOD`; its `IND` goes to `AX_T_FF_SR.R`.
- `AX_T_FF_SR` (`adapter::events::unidirectional::AX_T_FF_SR`): toggle flip-flop with set/reset; `AX_T_FF_SR.Q` ⟶ `OUT`.
- `AX_R_TRIG_ForceOff` (`adapter::events::unidirectional::AX_R_TRIG`): detects the rising edge on `FORCE_OFF` (`FORCE_OFF` ⟶ `AX_R_TRIG_ForceOff.QI`); its `EO` also goes to `AX_T_FF_SR.R`.
- `AND_QO` (`iec61131::booleanOperators::AND_BOOL_2`): combines `Toggle.QO` (`IN1`) and `Reset.QO` (`IN2`) into the `QO` of the SubApp.

The event `AUS` is a third, additive path to `AX_T_FF_SR.R`.

Initialisation and quality: `INIT` ⟶ `Toggle.INIT`; `Toggle.INITO` ⟶ `Reset.INIT`; `Reset.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`). `QI` is distributed to `Toggle.QI` and `Reset.QI`.

Technical Details

- Base block: for **one** output there is `MyLib::sys::AX_SoftkeyToggle_RS_TO_QXA_BG`, which wraps this block. For several time-staggered outputs (e.g. belt sequencing) this block is used directly and the `OUT` state is processed per channel with `AX_TON`/`AX_TOF`
- Three equal reset paths (VT/AUX/method, event `AUS`, edge on `FORCE_OFF`) all end at `AX_T_FF_SR.R`
- The reset input is called `AUS`, matching the central 'All off' softkey that several toggle instances distribute together

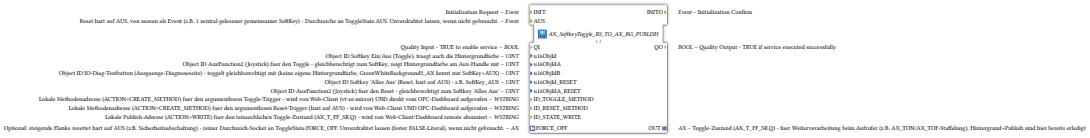


Application Scenarios

- On/off switch for drives operated equally by SoftKey, joystick assignment, web/dashboard and diagnostics button
- Central 'All off' for several toggle instances via the event `AUS`
- Safety shutdown via `FORCE_OFF` (e.g. PTO monitoring)

Conclusion

`AX_SoftkeyToggle_RS_TO_AX` supplies the pure toggle state with several equal operating and reset paths and leaves output, background colour and publish to the caller.



AX_SoftkeyToggle_RS_TO_AX_BG_PUBLISH

• — ○ • — ○ • — ○ •

Introduction

`AX_SoftkeyToggle_RS_TO_AX_BG_PUBLISH` wraps `AX_SoftkeyToggle_RS_TO_AX` (toggle/reset state) and drives the background colour and a local state publish from it, **without** a physical output. The toggle is triggered by SoftKey, AUX, local web/dashboard method or IO-diag test button; the reset by SoftKey, AUX or method. The background colour (SoftKey and AUX) comes from one shared `GreenWhiteBackground3_AX`. The block is the counterpart of `AX_SoftkeyToggle_RS_TO_QXA_BG`, which additionally drives a `logiBUS_QXA`. It is meant for cases in which the caller processes the toggle state further before it goes to one or more physical outputs (e.g. conveyor sequencing: key 5 toggles, only then `AX_TON`/`AX_TOF` per channel). The toggle state remains available as plug `OUT`.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request (chain: `PUBLISH_STATE` ⟶ `GreenWhiteBackground_AX` ⟶ `ToggleState`)
- **AUS**: hard reset to OFF, from outside as an event (e.g. one centrally read shared SoftKey). Pass-through to `ToggleState.AUS`. Leave unwired if not needed.

Event Outputs

- **INITO** (`EInit`): initialization confirm (from `ToggleState.INITO`)

Data Inputs

- **QI** (`BOOL`): quality input, TRUE enables the service (default `TRUE`)
- **u16ObjId** (`UINT`): object ID of the on/off softkey (toggle), also carries the background colour (default `ID_NULL`)
- **u16ObjIdA** (`UINT`): object ID of the AuxFunction2 (joystick) for the toggle, equal in rank to the SoftKey, also shows the background colour on the aux handle (default `ID_NULL`)
- **u16ObjIdB** (`UINT`): object ID of the IO-diag test button (outputs diagnostic page), toggles with equal rank; no background colour of its own because `GreenWhiteBackground3_AX` only knows SoftKey and AUX (default `ID_NULL`)
- **u16ObjId_RESET** (`UINT`): object ID of the "all off" softkey (reset, hard to OFF), e.g. `SoftKey_AUS` (default `ID_NULL`)
- **u16ObjIdA_RESET** (`UINT`): object ID of the AuxFunction2 (joystick) for the reset, equal in rank to the "all off" softkey (default `ID_NULL`)
- **ID_TOGGLE_METHOD** (`WSTRING`): local method address (`ACTION=CREATE_METHOD`) for the argument-less toggle trigger, called by the web client (vt-ui-mirror) and directly by the OPC dashboard
- **ID_RESET_METHOD** (`WSTRING`): local method address (`ACTION=CREATE_METHOD`) for the argument-less reset trigger (hard to OFF), called by the web client and the OPC dashboard
- **ID_STATE_WRITE** (`WSTRING`): local publish address (`ACTION=WRITE`) for the actual toggle state (`AX_T_FF_SR.Q`), subscribed remotely by web client/dashboard

Data Outputs

- **QO** (`BOOL`): quality output, AND combination (`AND_QO`) of the `QO` outputs of `PUBLISH_STATE`, `GreenWhiteBackground_AX` and `ToggleState`

Adapters

- **FORCE_OFF** (socket, `adapter::types::unidirectional::AX`): optional; a rising edge hard-resets to OFF (e.g. safety shutdown). Pure pass-through socket to `ToggleState.FORCE_OFF`. Leave unwired (fixed FALSE literal) if not needed.
- **OUT** (plug, `adapter::types::unidirectional::AX`): toggle state (`AX_T_FF_SR.Q`) for further processing by the caller; background and publish are already handled here

Function Blocks (FBs) Used

- **`ToggleState`** (SubApp `MyLib::sys::AX_SoftkeyToggle_RS_TO_AX`): generates the toggle/reset state
- **`AX_SPLIT_3`** (`adapter::events::unidirectional::AX_SPLIT_3`): distributes the state to three targets
- **`GreenWhiteBackground_AX`** (SubApp `MyLib::sys::GreenWhiteBackground3_AX`): green/white background colour
- **`PUBLISH_STATE`** (`adapter::net::AX_PUBLISH_1`): publishes the state (`QI` comes from the wrapper input `QI`)
- **`AND_QO`** (`iec61131::booleanOperators::AND_BOOL_3`): combines the `QO` outputs of the three inner blocks into `QO`

Functionality

- `AUS` ⟶ `ToggleState.AUS`; `FORCE_OFF` ⟶ `ToggleState.FORCE_OFF`
- `u16ObjId`, `u16ObjIdA`, `u16ObjIdB`, `u16ObjId_RESET`, `u16ObjIdA_RESET`, `ID_TOGGLE_METHOD`, `ID_RESET_METHOD` ⟶ the like-named inputs of `ToggleState`
- `ToggleState.OUT` ⟶ `AX_SPLIT_3.IN`
- `AX_SPLIT_3.OUT1` ⟶ `OUT`

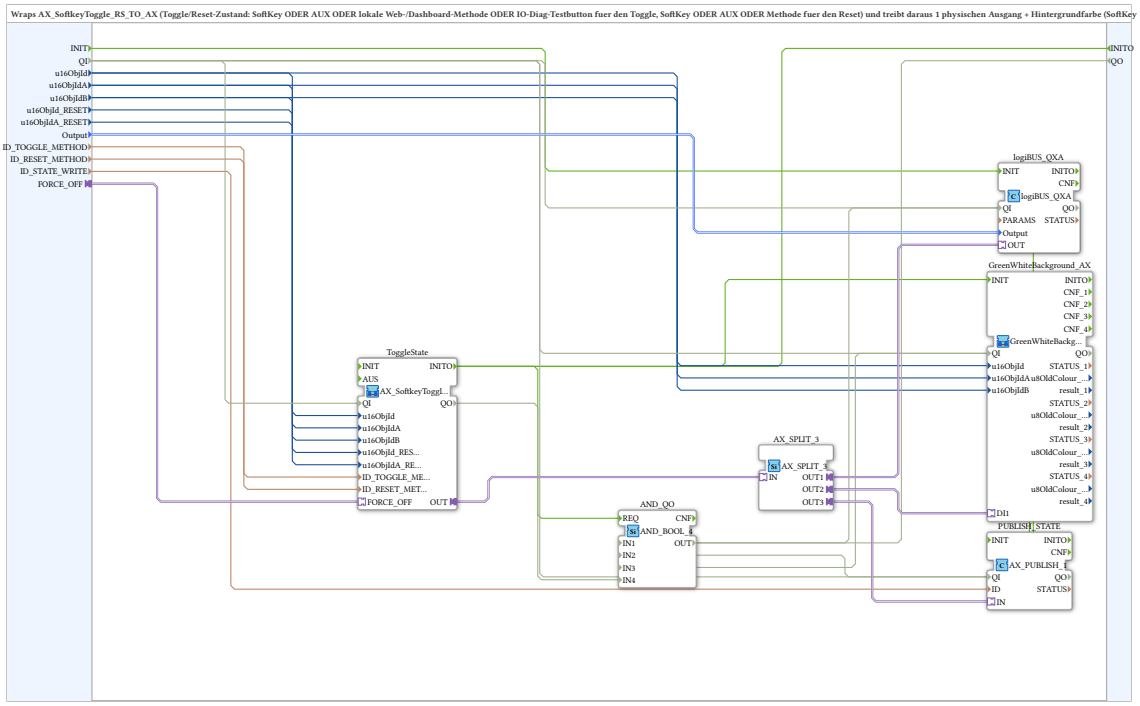
- AX_SPLIT_3.OUT2 ⟶ GreenWhiteBackground_AX.DI1; u16ObjId, u16ObjIdA ⟶ GreenWhiteBackground_AX
- AX_SPLIT_3.OUT3 ⟶ PUBLISH_STATE.IN; ID_STATE_WRITE ⟶ PUBLISH_STATE.ID
- Initialization: INIT ⟶ PUBLISH_STATE.INIT; PUBLISH_STATE.INITO ⟶ GreenWhiteBackground_AX.INIT; GreenWhiteBackground_AX.INITO ⟶ ToggleState.INIT; ToggleState.INITO ⟶ INITO and ⟶ AND_QO.REQ
- Quality: QI ⟶ PUBLISH_STATE.QI, GreenWhiteBackground_AX.QI, ToggleState.QI; PUBLISH_STATE.QO ⟶ AND_QO.IN1, GreenWhiteBackground_AX.QO ⟶ AND_QO.IN2, ToggleState.QO ⟶ AND_QO.IN3; AND_QO.OUT ⟶ QO

Technical Details

- Extracted from Baender_EinAus (ToggleState/AX_SPLIT_3 part for background and publish, GreenWhiteBackground_AX, PUBLISH_STATE). The time-staggered outputs (TOF_IgelElevator/TON_Querband staggering) stay with the caller.
- Version history: FORCE_OFF (v1.1, for a higher-level safety shutdown), RESET pass-through (v1.2), input RESET renamed to AUS (v1.3).
- Imports isobus::UT::Q::const::IDs::ID_NULL as default for the object IDs.

Application Scenarios

- On/off toggle with colour indication and web publish whose state is processed further before the physical output (e.g. staggered conveyors)



Summary

AX_SoftkeyToggle_RS_TO_AX_BG_PUBLISH provides a toggle/reset state with background colour and state publish and outputs the state as an AX plug for further processing.

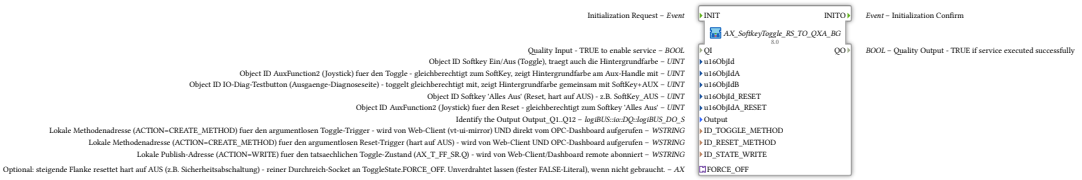
AX_SoftkeyToggle_RS_TO_QXA_BG



• – ○ • – ○ • – ○ •

Introduction

`AX_SoftkeyToggle_RS_TO_QXA_BG` wraps `AX_SoftkeyToggle_RS_TO_AX` (toggle/reset state) and uses it to drive **one physical output**, the **background colour** and a **local state publish**:

- Toggle: SoftKey **or** AUX **or** local web/dashboard method **or** IO-diag test button
- Reset: SoftKey **or** AUX **or** method
- Background colour: SoftKey, AUX handle and IO-diag test button together from one `GreenWhiteBackground4_AX`
- Publish: state for the web client/OPC dashboard background colour

Generic for any on/off output that must also be reset by a global “all off” key (e.g. saw blade drive).

Function Blocks (FBs) Used

Sub-blocks: AX_SoftkeyToggle_RS_TO_QXA_BG

- **Type**: SubAppType
- **Internal blocks used**:
  - **ToggleState**: SubApp `MyLib::sys::AX_SoftkeyToggle_RS_TO_AX` - toggle/reset state (incl. `FORCE_OFF`)
  - **AX_SPLIT_3**: `adapter::events::unidirectional::AX_SPLIT_3` - distributes the state to three consumers
  - **logiBUS_QXA**: `logiBUS::io::DQ::logiBUS_QXA` (`QI` from the block input `QI`) - physical output
  - **GreenWhiteBackground_AX**: SubApp `MyLib::sys::GreenWhiteBackground4_AX` - background colour for SoftKey, AUX and test button
  - **PUBLISH_STATE**: `adapter::net::AX_PUBLISH_1` (`QI` from the block input `QI`) - local state publish
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_4` - ANDs the `QO` outputs of `logiBUS_QXA`, `PUBLISH_STATE`, `GreenWhiteBackground_AX` and `ToggleState` into the block output `QO`
- **Imports**: `ID_NULL`, `logiBUS_DO`, `logiBUS_DO_S`

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization Request

Event Outputs

- **INITO** (`EInit`): Initialization Confirm

The signal processing (toggle/reset) still travels via the adapters.

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE to enable the service
- **u16ObjId** (`UINT`, default `ID_NULL`): Object ID of the on/off softkey (toggle), also carries the background colour
- **u16ObjIdA** (`UINT`, default `ID_NULL`): Object ID of the `AuxFunction2` (joystick) for the toggle - equal to the SoftKey, also shows the background colour on the aux handle
- **u16ObjIdB** (`UINT`, default `ID_NULL`): Object ID of the IO-diag test button (outputs diagnostic page) - toggles equally, shows the background colour together with SoftKey and AUX
- **u16ObjId_RESET** (`UINT`, default `ID_NULL`): Object ID of the “all off” softkey (reset, hard to OFF), e.g. `SoftKey_AUS`
- **u16ObjIdA_RESET** (`UINT`, default `ID_NULL`): Object ID of the `AuxFunction2` (joystick) for the reset - equal to the “all off” softkey
- **Output** (`logiBUS::io::DQ::logiBUS_DO_S`, default `logiBUS_DO::Invalid`): Output `Output_Q1..Q12`
- **ID_TOGGLE_METHOD** (`WSTRING`): Local method address (`ACTION=CREATE_METHOD`) for the argument-less toggle trigger - called by the web client (`vt-ui-mirror`) and directly by the OPC dashboard

- **ID_RESET_METHOD** (WSTRING): Local method address (ACTION=CREATE_METHOD) for the argument-less reset trigger (hard to OFF) - called by the web client and OPC dashboard
- **ID_STATE_WRITE** (WSTRING): Local publish address (ACTION=WRITE) for the actual toggle state (AX_T_FF_SR.Q) - subscribed remotely by the web client/dashboard

Data Outputs

- **QO** (BOOL): Quality Output - TRUE if the service executed successfully (AND of the QO of the inner blocks)

Adapters

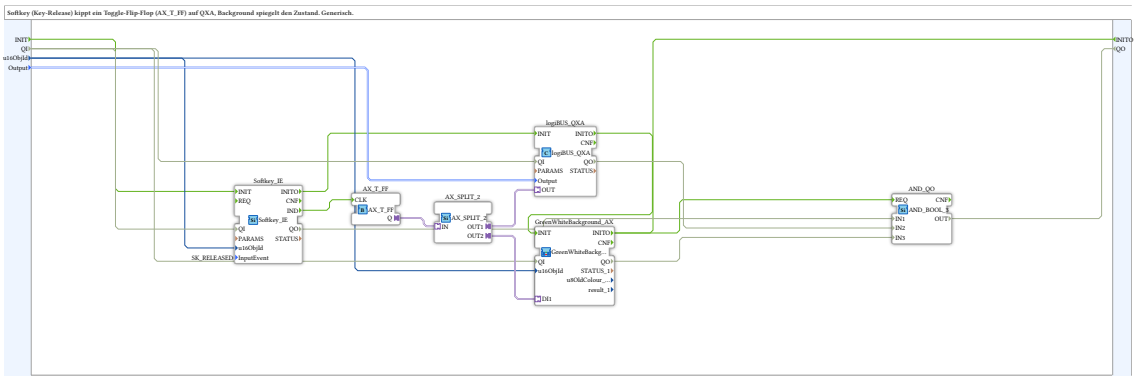
- **FORCE_OFF** (socket, adapter::types::unidirectional::AX): Optional: a rising edge hard-resets to OFF (e.g. safety shutdown) - pure passthrough socket to ToggleState.FORCE_OFF. Leave unwired (fixed FALSE literal) if not needed.

Program Flow and Connections

- u16ObjId, u16ObjIdA, u16ObjIdB, u16ObjId_RESET, u16ObjIdA_RESET, ID_TOGGLE_METHOD, ID_RESET_METHOD → like-named inputs of ToggleState
- FORCE_OFF → ToggleState.FORCE_OFF
- ToggleState.OUT → AX_SPLIT_3.IN
- AX_SPLIT_3.OUT1 → logiBUS_QXA.OUT (Output → logiBUS_QXA.Output)
- AX_SPLIT_3.OUT2 → GreenWhiteBackground_AX.DI1 (u16ObjId, u16ObjIdA, u16ObjIdB → like-named inputs)
- AX_SPLIT_3.OUT3 → PUBLISH_STATE.IN (ID_STATE_WRITE → PUBLISH_STATE.ID)
- Initialization chain: INIT → logiBUS_QXA.INIT, logiBUS_QXA.INITO → PUBLISH_STATE.INIT, PUBLISH_STATE.INITO → GreenWhiteBackground_AX.INIT, GreenWhiteBackground_AX.INITO → ToggleState.INIT, ToggleState.INITO → INITO; additionally ToggleState.INITO → AND_QO.REQ
- QI → logiBUS_QXA.QI, PUBLISH_STATE.QI, GreenWhiteBackground_AX.QI and ToggleState.QI
- logiBUS_QXA.QO → AND_QO.IN1, PUBLISH_STATE.QO → AND_QO.IN2, GreenWhiteBackground_AX.QO → AND_QO.IN3, ToggleState.QO → AND_QO.IN4; AND_QO.OUT → QO

Technical Details

- Since version 7.0 only a wrapper: toggle, reset and AX_T_FF_SR live in AX_SoftkeyToggle_RS_TO_AX, which is also used for multi-channel sequencing (several time-shifted outputs)
- Since version 6.0: one GreenWhiteBackground4_AX instead of two GreenWhiteBackground1_AX, so the joystick handle also receives feedback
- Version 8.0 (2026-09-15): FORCE_OFF socket added (purely additive; existing instances must wire it, e.g. to a fixed FALSE literal)
- History: 1.0 reset-set-toggle variant of AX_SoftkeyToggle_TO_QXA_BG; 2.0 IO-diag test button, two local RPC methods and state publish; 3.0 AUX added; 4.0/5.0 factored out into Softkey_Aux_Method_IE and Softkey_Aux_Method_Button_IE



Application Scenarios

- On/off output operated via SoftKey, joystick, IO-diag test button and web/dashboard plus a global “all off” key (e.g. saw blade drive)

Summary

AX_SoftkeyToggle_RS_TO_QXA_BG connects the toggle/reset state from AX_SoftkeyToggle_RS_TO_AX with a physical output, background colour and local state publish.

AX_SoftkeyToggle_TO_QXA_BG

• – ○ • – ○ • – ○ •

Introduction

`AX_SoftkeyToggle_TO_QXA_BG` is a composite 4diac subapplication that implements a softkey release toggle for a QXA output and synchronizes an HMI background with the toggled state. It is generic: the softkey object ID and the QXA output channel are supplied as data inputs.

The internal network combines:

- `Softkey_IE` for detecting a configured softkey release event,
- `AX_T_FF` as a toggle flip-flop,
- `AX_SPLIT_2` to distribute the toggle state,
- `logiBUS_QXA` to drive the selected output,
- `GreenWhiteBackground_AX` to visualize the state in the background.

Interface Structure

The subapplication exposes the event input `INIT`, the event output `INITO`, the data inputs `QI`, `u16ObjId` and `Output`, and the data output `QO`. It has no public adapter endpoints.

Event Inputs

- **INIT** (`EInit`): initialization request; starts the chain `Softkey_IE` → `logiBUS_QXA` → `GreenWhiteBackground_AX`.

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `GreenWhiteBackground_AX.INITO`.

Data Inputs

Name	Type	Initial Value	Comment
`QI`	`BOOL`	`TRUE`	Quality input, service enable; passed on to `Softkey_IE`, `logiBUS_QXA` and `GreenWhiteBackground_AX`.
`u16ObjId`	`UINT`	`ID_NULL`	Object ID of the softkey to be used.
`Output`	`logiBUS::io::DQ::logiBUS_DO_S`	`logiBUS_DO::Invalid`	Identifies the QXA output channel (`Output_Q1` … `Output_Q8`).

Data Outputs

Name	Type	Comment
QO	BOOL	Quality output, AND of the QO outputs of Softkey_IE, logiBUS_QXA and GreenWhiteBackground_AX (via AND_QO).

Adapters

The subapplication does not expose any adapter sockets or plugs. Internally, unidirectional adapters are used for the toggle state flow:

- AX_T_FF.Q ⟶ AX_SPLIT_2.IN
- AX_SPLIT_2.OUT1 ⟶ logiBUS_QXA.OUT
- AX_SPLIT_2.OUT2 ⟶ GreenWhiteBackground_AX.DI1

Functionality

The subapplication is triggered by a softkey release. Softkey_IE is configured with InputEvent = SK_RELEASED (its QI comes from the subapplication input QI); it monitors the object ID given by u16ObjId. When the configured softkey is released, Softkey_IE emits the IND event. This event clocks the AX_T_FF toggle flip-flop. Each clock pulse changes the state of the toggle. The current toggle state is output on the adapter Q.

AX_SPLIT_2 forwards the same toggle state to two consumers:

1. logiBUS_QXA.OUT, which writes the state to the selected QXA output channel (Output).
2. GreenWhiteBackground_AX.DI1, which updates the background visualization according to the state.

Thus, a single key release toggles the actual output and keeps the HMI background in sync.

Initialization and quality: INIT ⟶ Softkey_IE.INIT, Softkey_IE.INITO ⟶ logiBUS_QXA.INIT, logiBUS_QXA.INITO ⟶ GreenWhiteBackground_AX.INIT, GreenWhiteBackground_AX.INITO ⟶ INITO and ⟶ AND_QO.REQ. QI goes to Softkey_IE.QI, logiBUS_QXA.QI and GreenWhiteBackground_AX.QI; their QO outputs are combined via AND_QO (iec61131::booleanOperators::AND_BOOL_3) into QO.

Technical Features

- Composite SubAppType reusable as a library element.
- Generic softkey identification via u16ObjId.
- Generic QXA output selection via Output.
- Internal event handling: the only external events are INIT/INITO; the clock events are handled internally.
- QI is no longer hard-coded to TRUE on Softkey_IE; it is passed through from the subapplication input QI (initial value TRUE).
- Key-release detection using SK_RELEASED, so the toggle reacts on release, not on press.
- AX_T_FF provides the bistable toggle memory.
- AX_SPLIT_2 provides a clean one-to-two adapter state distribution.
- logiBUS_QXA is enabled by the passed-through QI and drives the selected output.
- GreenWhiteBackground_AX receives the same state to show the HMI background.
- Internal data connections are marked invisible in the 4diac diagram for readability.

State Overview

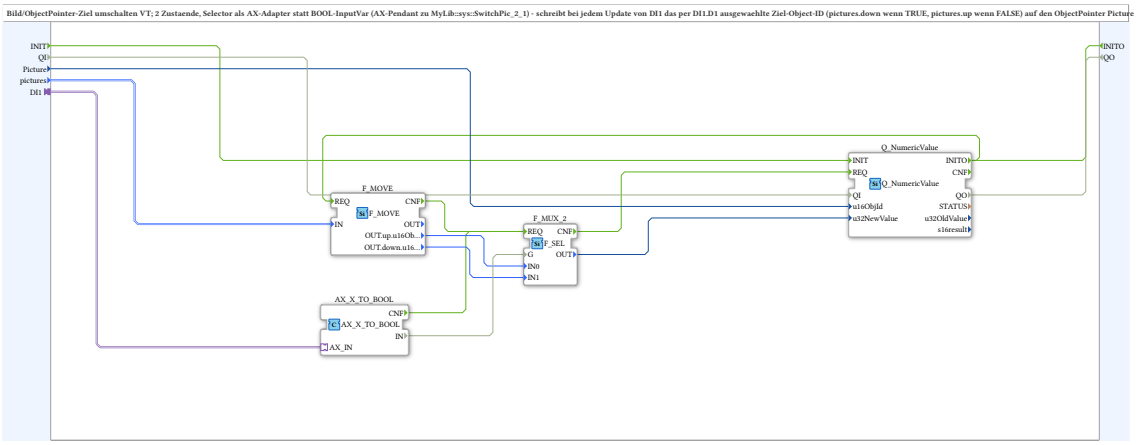
The main state is the internal toggle state of AX_T_FF.

Condition	Event Path	Result
No softkey release	—	Toggle state remains unchanged.
Configured softkey released	Softkey_IE.IND ⟶ AX_T_FF.CLK	Toggle state changes from 0 to 1 or from 1 to 0.
Toggle state updated	AX_T_FF.Q ⟶ AX_SPLIT_2.IN	Both QXA output and background receive the new state.

Apart from INIT, the subapplication does not define an explicit reset input or initial state in the XML; the startup behavior depends on the default/reset behavior of AX_T_FF.

Application Scenarios

- Machine control panels where a softkey toggles a latching output.
- Operator buttons on HMI screens that must show the current state as a colored background.
- Generic output toggling for QXA modules, with flexible configuration of softkey and output channel.
- Reusable library subapplication for projects using `isobus` softkey handling and `logiBUS` digital outputs.



Comparison with Similar Blocks

- **Compared with a direct `Softkey_IE` → `logiBUS_QXA` connection:** The direct connection only follows the momentary softkey state. `AX_SoftkeyToggle_TO_QXA_BG` adds a toggle flip-flop, so the output remains latched after each release.
- **Compared with the same toggle without background:** This subapplication additionally drives `GreenWhiteBackground_AX`, so visualization and output always show the same state.
- **Compared with a fixed-softkey implementation:** The use of `u16ObjId` and `Output` makes the subapplication generic; no modification is needed when a different softkey or QXA channel is used.

Conclusion

`AX_SoftkeyToggle_TO_QXA_BG` is a compact and reusable 4diac subapplication that combines softkey release detection, a toggle flip-flop, QXA output control, and background visualization in one generic component. It reduces wiring effort and improves consistency between the physical/logical output state and the HMI background display.

AX_SwitchPic_2_1

• – ○ • – ○ • – ○ •

Introduction

`AX_SwitchPic_2_1` switches the target of a VT **ObjectPointer** (picture) between two states. The selector arrives as an **AX adapter** instead of a `BOOL` input variable (AX counterpart of `MyLib::sys::SwitchPic_2_1`): on every update of `DI1`, the target object ID selected via `DI1.D1` (`pictures.down` if `TRUE`, `pictures.up` if `FALSE`) is written to the ObjectPointer `Picture`. No external trigger is needed, since `DI1`'s own `E1/D1` feeds it directly. Initialization runs via `INIT/INITO` of the inner `Q_NumericValue` (quality pattern with `QI/QO`).

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request - to `Q_NumericValue.INIT`; further events arrive via the adapter socket

Event Outputs

- **INITO** (`EInit`): initialization confirmation - from `Q_NumericValue.INITO`

Data Inputs

- **QI** (BOOL, default TRUE): Quality Input - TRUE to enable the service (to Q_NumericValue.QI)
- **Picture** (UINT): Object ID of the ObjectPointer to write into
- **pictures** (isobus::UT::Q::types::s2x1ObjectIDs): The two target object IDs (up, down); default: both ID_NULL

Data Outputs

- **QO** (BOOL): Quality Output - TRUE if the service was executed successfully (from Q_NumericValue.QO)

Adapters

- **DI1** (socket): Unidirectional adapter of type adapter::types::unidirectional::AX - selector: down (pictures.down) if TRUE, up (pictures.up) if FALSE. Every update writes immediately.

Function Blocks (FBs) Used

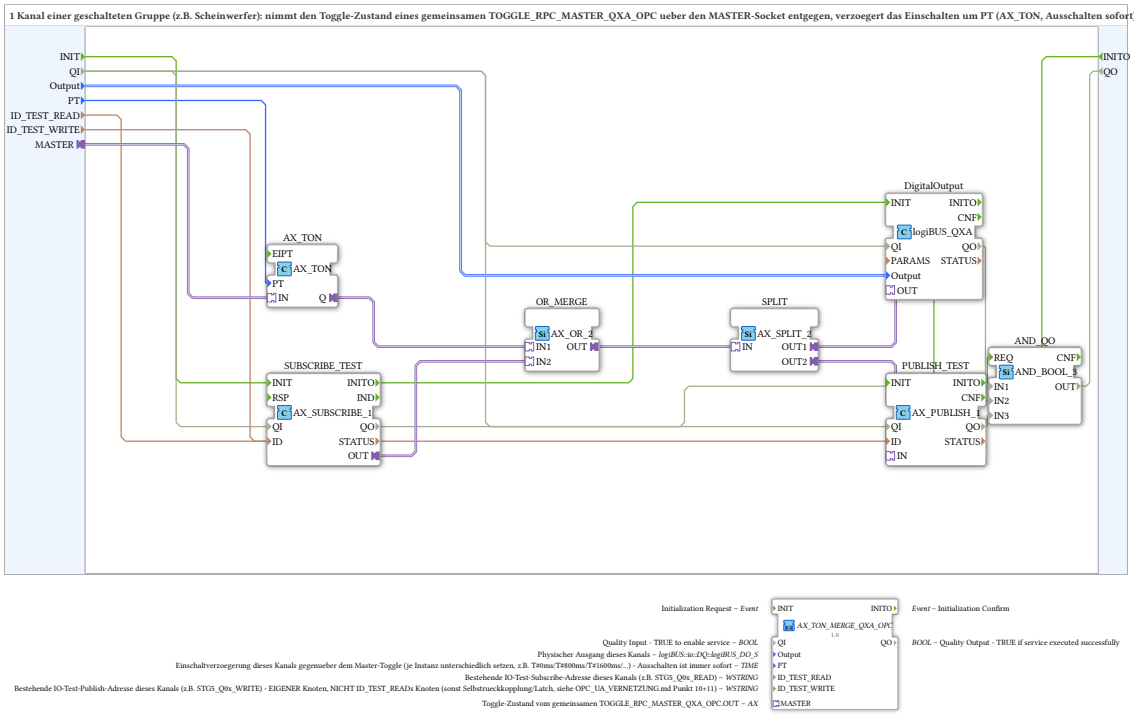
- **F_MOVE**: iec61131::selection::F_MOVE (DataType=isobus::UT::Q::types::s2x1ObjectIDs) - copies pictures to OUT.up.u16ObjId/OUT.down.u16ObjId
- **AX_X_TO_BOOL**: adapter::conversion::unidirectional::AX_X_TO_BOOL - converts the AX selector into event CNF and value IN (BOOL)
- **F_MUX_2**: iec61131::selection::F_SEL - selects IN0 (up) for G=FALSE, IN1 (down) for G=TRUE
- **Q_NumericValue**: isobus::UT::Q::Q_NumericValue - writes the selected value (u32NewValue) to the VT object u16ObjId

Program Flow and Connections

1. INIT → Q_NumericValue.INIT; Q_NumericValue.INITO → INITO and → F_MOVE.REQ; F_MOVE.CNF → F_MUX_2.REQ (initialization of the target object IDs).
2. DI1 → AX_X_TO_BOOL.AX_IN; AX_X_TO_BOOL.CNF → F_MUX_2.REQ, AX_X_TO_BOOL.IN → F_MUX_2.G.
3. F_MOVE.OUT.up.u16ObjId → F_MUX_2.IN0; F_MOVE.OUT.down.u16ObjId → F_MUX_2.IN1.
4. F_MUX_2.CNF → Q_NumericValue.REQ; F_MUX_2.OUT → Q_NumericValue.u32NewValue; Picture → Q_NumericValue.u16ObjId.
5. QI → Q_NumericValue.QI; Q_NumericValue.QO → QO.

Technical Details

- Unlike SwitchPic_2_1 (there DI1: BOOL plus an external EI event), the AX variant needs no external trigger.
- The target ID_NULL can be used, for example, to switch an ObjectPointer "empty".



Application Scenarios

- Switching an ObjectPointer between e.g. Rectangle_Aktiv and ID_NULL depending on the operating state (e.g. display for elevator belt, hedgehog belt, filling belt)

Summary

AX_SwitchPic_2_1 writes one of two configurable object IDs to a VT ObjectPointer on every update of an AX selector.

AX_TON_MERGE_QXA_OPC

• — ○ • — ○ • — ○ •

Introduction

The `AX_TON_MERGE_QXA_OPC` function block (subapplication) implements a single channel of a switched group (e.g., a spotlight bank). It receives the toggle state from a common master via an adapter, delays the switch-on by a configurable time, and merges the result with the existing IO-test command for that channel. The combined signal drives the physical output and optionally publishes the state back for diagnostics. This design distributes capacitive inrush currents over time when multiple channels are switched together.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; starts the init chain at `SUBSCRIBE_TEST.INIT`.

The actual signal processing remains purely data- and adapter-driven.

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `PUBLISH_TEST.INITO`, the end of the init chain.

Data Inputs

Name	Type	Description
`QI`	`BOOL`	Quality input, enables the service; initial value `TRUE`; passed on to `SUBSCRIBE_TEST`, `DigitalOutput` and `PUBLISH_TEST`.
`Output`	`logiBUS::io::DQ::logiBUS_DO_S`	Physical output for this channel (initial value: `logiBUS_DO::Invalid`).
`PT`	`TIME`	Switch-on delay relative to the master toggle. Set per instance (e.g., `T#0ms`, `T#800ms`, `T#1600ms`). Switch-off is always immediate.

ID_TEST_READ	WSTRING	Existing IO-test subscribe address for this channel (e.g., STG5_Q0x_READ).
ID_TEST_WRITE	WSTRING	Existing IO-test publish address for this channel (e.g., STG5_Q0x_WRITE). **Must be on its own OPC UA node** (not the same as ID_TEST_READ) to avoid feedback/latching issues.

Data Outputs

Name	Type	Description
QO	BOOL	Quality output, AND combination (AND_QO, AND_BOOL_3) of the QO outputs of SUBSCRIBE_TEST, DigitalOutput and PUBLISH_TEST.

Adapters

Socket	Type	Description
MASTER	adapter::types::unidirectional::AX	Receives the toggle state from a shared TOGGLE_RPC_MASTER_QXA_OPC block.

Functionality

1. The MASTER adapter supplies a toggle state (typically a boolean).
2. An internal AX_TON timer delays only the *activation* of this state by the configured PT. Deactivation (switch-off) propagates immediately.
3. The delayed signal is combined with the IO-test command via an AX_OR_2 gate. The IO-test command is obtained by subscribing to the OPC UA address ID_TEST_READ.
4. The merged output is then split (AX_SPLIT_2) into two paths:
   - **Path 1** drives the physical output via logiBUS_QXA.
   - **Path 2** publishes the state back to the OPC UA address ID_TEST_WRITE for monitoring or test feedback.

Initialization and quality: INIT → SUBSCRIBE_TEST.INIT, SUBSCRIBE_TEST.INITO → DigitalOutput.INIT, DigitalOutput.INITO → PUBLISH_TEST.INIT, PUBLISH_TEST.INITO → INITO and AND_QO.REQ. QI is passed on to SUBSCRIBE_TEST.QI, DigitalOutput.QI and PUBLISH_TEST.QI; their QO outputs are combined in AND_QO (iec61131::booleanOperators::AND_BOOL_3, IN1 to IN3) into the output QO.

The complete signal flow is internal and appears as a single logical unit to the application.

Technical Features

- **Configurable switch-on delay**: Each instance can have a distinct PT value, allowing a staggered startup of multiple channels.
- **Immediate switch-off**: No delay is applied to the falling edge, ensuring rapid deactivation.
- **Integration with existing IO-test infrastructure**: Reuses subscribe/publish addresses to merge manual test commands with the master toggle.
- **Decoupled OPC UA nodes**: Separate read and write addresses prevent self-feedback and unintended latching.
- **Physical output handling**: The block maps directly to a logiBUS_QXA digital output, abstracting low-level hardware access.

State Overview

This subapplication does not define an explicit state machine; its behavior is deterministic and solely based on the input data and the internal timer logic. The AX_TON component internally manages the delay timing, but no user-visible states are exposed.

Application Scenarios

Staggered activation of a spotlight bank

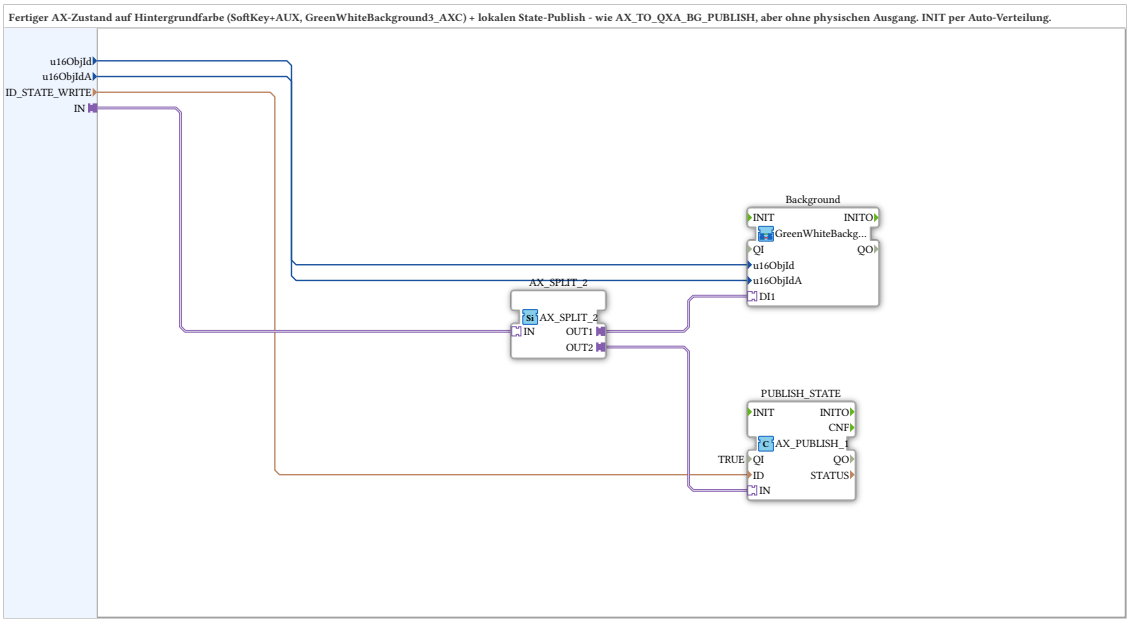
Consider a bank of six LED channels, each connected to the same master toggle via a shared

TOGGLE_RPC_MASTER_QXA_OPC. By assigning increasing PT values (e.g., 0 ms, 800 ms, 1600 ms, ...), the capacitive inrush currents of the LED drivers are spread over time instead of being switched simultaneously. This prevents overloads and reduces electrical stress.

Merging IO-test commands

When the IO-test system issues a command for a channel (via ID_TEST_READ), the AX_OR_2 gate combines it with the master-derived toggle. The physical output is driven by either source, and the resulting state is published back on ID_TEST_WRITE for verification.

Comparison with Similar Blocks

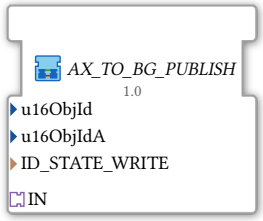


- **AX_TON_MERGE_QXA_OPC** (this block) – for channels that share a common master toggle and require a staggered switch-on. It adds a delay and merges with the IO-test input.
- **TOGGLE_RPC_MERGE_QXA_OPC** – for completely independent channels with their own soft-key, no shared master.
- **MERGE_SWITCH_1_QXA_OPC** – a simpler variant without the delayed-on feature, suitable when inrush spreading is not required.

Choose AX_TON_MERGE_QXA_OPC when you need to synchronize multiple channels from one master while avoiding simultaneous switching peaks.

Conclusion

AX_TON_MERGE_QXA_OPC provides a clean, reusable solution for controlling a switched group with controlled switch-on timing. Its integration with existing IO-test mechanisms and support for per-channel delays make it ideal for applications with capacitive loads and multiple outputs. The block encapsulates the required logic, simplifying application design and maintenance.



AX_TO_BG_PUBLISH

• – ○ • – ○ • – ○ •

Introduction

AX_TO_BG_PUBLISH brings a finished AX state to the background colour (SoftKey and AUX, GreenWhiteBackground3_AXC) and to a local state publish. It corresponds to AX_TO_QXA_BG_PUBLISH, but without a physical output. Initialization is done by automatic distribution (no event connections of its own). The block was extracted from Baender_EinAus.SUB (Background_Alle/AX_PUBLISH_Alle) as a reusable block.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

Variable	Type	Default	Comment
`u16ObjId`	UINT	`ID_NULL`	Object ID SoftKey; carries the background colour.
`u16ObjIdA`	UINT	`ID_NULL`	Object ID AuxFunction2 (joystick); also shows the background colour on the Aux handle.
`ID_STATE_WRITE`	WSTRING		Local publish address (`ACTION=WRITE`) for the state; subscribed remotely.

Data Outputs

None.

Adapters

Adapter	Type	Direction	Comment
`IN`	`adapter::types::unidirectional::AX`	Socket	Finished AX state; distributed to background and publish.

Function Blocks (FBs) Used

- **AX_SPLIT_2** (`adapter::events::unidirectional::AX_SPLIT_2`): adapter fan-out (strictly 1:1)
- **Background** (SubApp `MyLib::sys::GreenWhiteBackground3_AXC`): sets the background colour of SoftKey and Aux; see `GreenWhiteBackground3_AXC`
- **PUBLISH_STATE** (`adapter::net::AX_PUBLISH_1`, `QI = TRUE`): local state publish

Program Flow and Connections

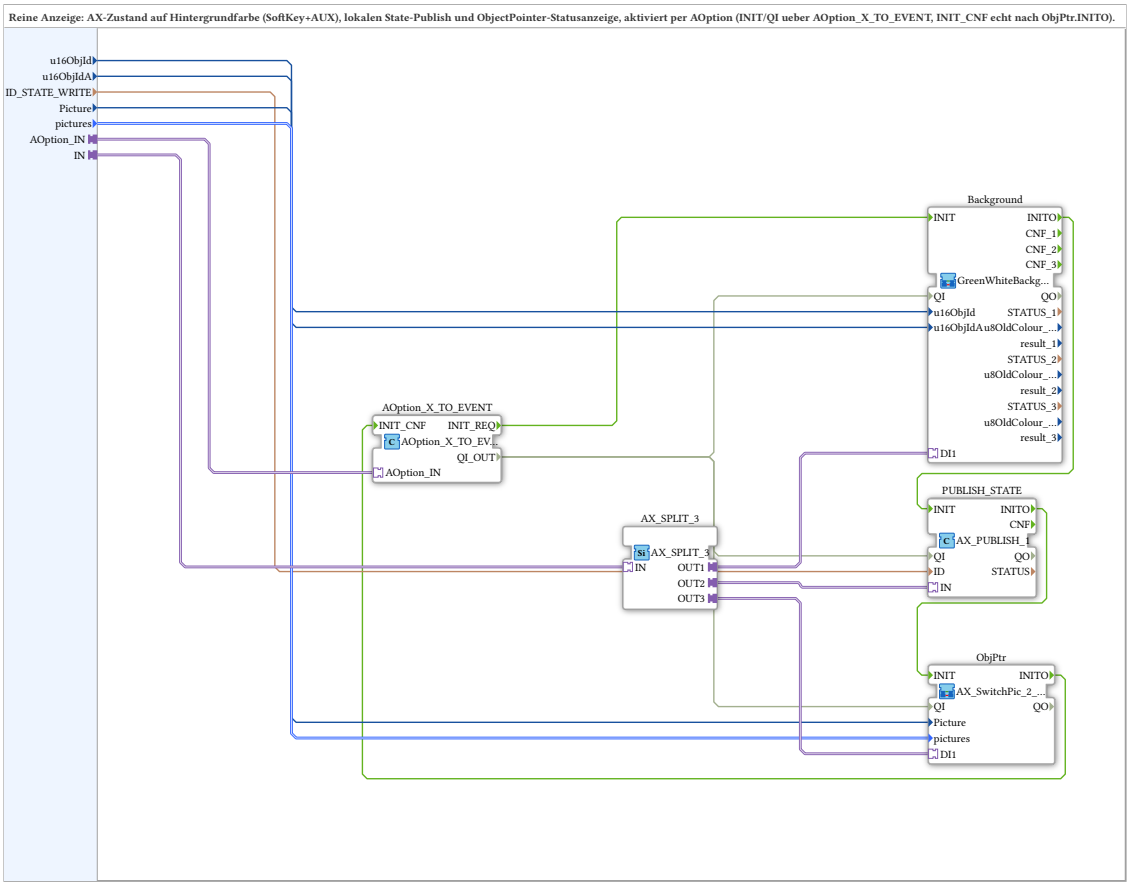
1. `IN` -> `AX_SPLIT_2.IN`.
2. `AX_SPLIT_2.OUT1` -> `Background.DI1`; `AX_SPLIT_2.OUT2` -> `PUBLISH_STATE.IN`.
3. `u16ObjId` -> `Background.u16ObjId`; `u16ObjIdA` -> `Background.u16ObjIdA`; `ID_STATE_WRITE` -> `PUBLISH_STATE.ID`.
4. The block has no event and no `QI`/`QO` connections; `PUBLISH_STATE.QI` is fixed to `TRUE` via parameter.

Technical Features

- The `AX_SPLIT_2` is needed because the adapter fan-out is strictly 1:1.
- Initialization runs by automatic distribution instead of via a dedicated `INIT` input.
- Compared with `AX_TO_QXA_BG_PUBLISH` the physical output (`Output`) as well as `QI`/`QO` and `INIT`/`INITO` are missing.

Application Scenarios

- Pure display and publish channels without a hardware output of their own, e.g. identically structured channels with background colour on the SoftKey and Aux handle plus state publishing.



Summary

`AX_TO_BG_PUBLISH` distributes a finished AX state to the background colour of SoftKey and Aux and to a local state publish, without a physical output.

AX_TO_BG_PUBLISH_SWITCHPIC_Option

• – ○ • – ○ • – ○ •

Introduction

`AX_TO_BG_PUBLISH_SWITCHPIC_Option` is a pure display: it brings a finished AX state to the background colour (SoftKey and AUX), a local state publish and the ObjectPointer status display (`AX_SwitchPic_2_1`). It is activated via `AOption`: `INIT` and `QI` come through `AOption_X_TO_EVENT`, and `INIT_CNF` is returned for real after `ObjPtr.INITO`. It is the display part of `AX_TO_QXA_BG_PUBLISH_SWITCHPIC_OPT` as a block of its own and corresponds to `AX_TO_QXA_BG_PUBLISH_SWITCHPIC` without the physical output.

Object ID Softkey - traegt die Hintergrundfarbe – *UINT*
Object ID AuxFunction2 (Joystick) - zeigt Hintergrundfarbe am Aux-Handle mit – *UINT*
Lokale Publish-Adresse (ACTION=WRITE) fuer den Zustand - wird remote abonniert – *WSTRING*
Object ID des ObjectPointer, der den Status-Kaestchen-Inhalt traegt – *UINT*
die beiden Ziel-Object-IDs (up=aus, down=an) – *isobus::UT::Q::types::s2x1ObjectIDs*

Aktiviert/deaktiviert die Anzeige – *AOption*
Fertiger AX-Zustand fuer Hintergrund, Publish und ObjectPointer – *AX*

Interface Structure

Event Inputs
None.

Event Outputs
None.

Data Inputs

Variable	Type	Default	Comment
u16ObjId	UINT	ID_NULL	Object ID SoftKey; carries the background colour.
u16ObjIdA	UINT	ID_NULL	Object ID AuxFunction2 (joystick); also shows the background colour on the Aux handle.
ID_STATE_WRITE	WSTRING		Local publish address (ACTION=WRITE) for the state; subscribed remotely.
Picture	UINT		Object ID of the ObjectPointer carrying the status box content.
pictureIDs	isobus::UT::Q::types::s2x1ObjectIDs	(up := (u16ObjId := ID_NULL), down := (u16ObjId := ID_NULL))	The two target object IDs (up = off, down = on).

Data Outputs
None.

Adapters

Adapter	Type	Direction	Comment
AOption_IN	Option::AOption	Socket	Enables/disables the display.
IN	adapter::types::unidirectional::AX	Socket	Finished AX state for background, publish and ObjectPointer.

Function Blocks (FBs) Used
- **AOption_X_TO_EVENT** (Option::conversion::AOption_X_TO_EVENT): converts the option into INIT_REQ/QI_OUT and accepts INIT_CNF
- **AX_SPLIT_3** (adapter::events::unidirectional::AX_SPLIT_3): adapter fan-out (strictly 1:1)
- **Background** (SubApp MyLib::sys::GreenWhiteBackground3_AX): background colour of SoftKey and Aux; see GreenWhiteBackground3_AX
- **PUBLISH_STATE** (adapter::net::AX_PUBLISH_1): local state publish
- **ObjPtr** (SubApp MyLib::sys::AX_SwitchPic_2_1): ObjectPointer status display; see AX_SwitchPic_2_1

Program Flow and Connections
1. Initialization chain: AOption_X_TO_EVENT.INIT_REQ -> Background.INIT; Background.INITO -> PUBLISH_STATE.INIT; PUBLISH_STATE.INITO -> ObjPtr.INIT; ObjPtr.INITO -> AOption_X_TO_EVENT.INIT_CNF.
2. Qualifier: AOption_X_TO_EVENT.QI_OUT -> Background.QI, PUBLISH_STATE.QI and ObjPtr.QI.
3. Option: AOption_IN -> AOption_X_TO_EVENT.AOption_IN.

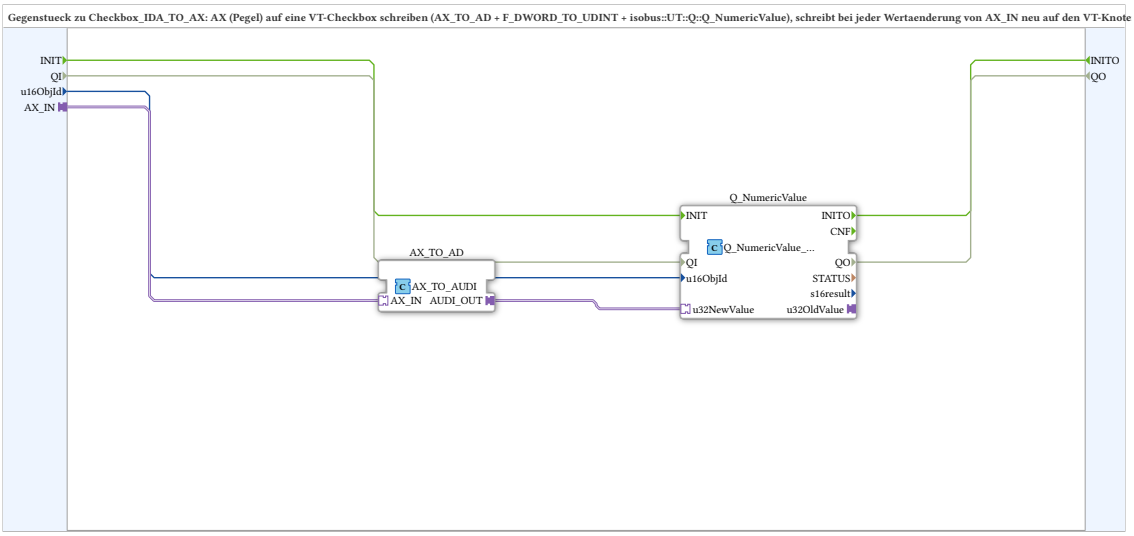
4. AX state: `IN -> AX_SPLIT_3.IN`; `OUT1 -> Background.DI1`; `OUT2 -> PUBLISH_STATE.IN`; `OUT3 -> ObjPtr.DI1`.
5. Data: `u16ObjId -> Background.u16ObjId`; `u16ObjIdA -> Background.u16ObjIdA`; `ID_STATE_WRITE -> PUBLISH_STATE.ID`; `Picture -> ObjPtr.Picture`; `pictures -> ObjPtr.pictures`.
6. The block has no event or `QI`/`QO` connections of its own and no plug; activation and acknowledgment run via `AOption_IN`.

Technical Features

- The `AX_SPLIT_3` is needed because the adapter fan-out is strictly 1:1.
- `INIT_CNF` comes for real from the end of the chain (`ObjPtr.INITO`), not from a short-circuit connection.
- There is no `AOption_OUT` plug; the block therefore cannot be daisy-chained.

Application Scenarios

- Pure display side of a channel (background colour, state publish, status picture) that is active only when the option is selected, e.g. on an `AOption_OR_2` combination of several variants.



Summary

`AX_TO_BG_PUBLISH_SWITCHPIC_Option` shows a finished AX state as background colour, state publish and status picture and is activated via `AOption`.

AX_TO_Checkbox

• – ○ • – ○ • – ○ •

Introduction

`AX_TO_Checkbox` is the counterpart of `Checkbox_IDA_TO_AX`: it writes a level (`AX_IN`, 0/1) to a VT checkbox (ECU → VT instead of VT → ECU). Internally, `AX_TO_AD` (`adapter::conversion::unidirectional::AX_TO_AUDI`) converts the level into a UDINT value, which `Q_NumericValue` (`isobus::UT::Q::Q_NumericValue_AUDI`) sends to the VT via `u32NewValue`.

Interface

Event ports

- **Input `INIT`** (`EInit`): initialization request - to `Q_NumericValue.INIT`.
- **Output `INITO`** (`EInit`): initialization confirmation - from `Q_NumericValue.INITO`.

Input variables

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable the service (to `Q_NumericValue.QI`).
- `u16ObjId` (UINT, default `ID_NULL`): ObjectID of the VT NumberVariable behind the checkbox.

Output variables

- `QO` (BOOL): Quality Output - TRUE if the service was executed successfully (from `Q_NumericValue.QO`).

Adapters

- **Socket `AX_IN`** (`adapter::types::unidirectional::AX`): level to be written (0/1).

Apart from `INIT`/`INITO`, the block has no event ports of its own; writing is triggered by the adapter `AX_IN`.

How it works

1. `AX_IN` is converted into a UDINT value via `AX_TO_AD`.
2. `Q_NumericValue` writes this value to the VT node under `u16ObjId`. According to the source comment, it is rewritten on every value change of `AX_IN`.
3. `INIT` ⟶ `Q_NumericValue.INIT`, `Q_NumericValue.INITO` ⟶ `INITO`, `QI` ⟶ `Q_NumericValue.QI`, `Q_NumericValue.QO` ⟶ `QO`.

Technical notes

- `u16ObjId` is the ObjectID of the **CNumberVariable** that the checkbox references as its value store - **not** the ObjectID of the checkbox (`CInputBoolean`) itself. The VT expects value changes under the NumberVariable ID (analogous to `Checkbox_IDA_TO_AX`).
- Instance uniqueness: `Q_NumericValue` allows only one instance per target ObjectID in the entire project.

Summary

Writes an AX level to a VT checkbox via its associated NumberVariable.

AX_TO_QXA_BG_PUBLISH

• — ○ • — ○ • — ○ •

Introduction

`AX_TO_QXA_BG_PUBLISH` drives, from an already finished AX state (e.g. merged by OR of several sources such as a staggered group signal, single toggle or IO diagnostics test button), **one** physical output, the background colour (SoftKey and AUX) and a local state publish for web client and OPC dashboard. It is the counterpart to `MyLib::sys::AX_SoftkeyToggle_RS_TO_QXA_BG`, which still generates the toggle/reset itself; here the AX state is already available.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialisation; passed on to `DigitalOutput.INIT` instead of automatic distribution

Event Outputs

- **INITO** (`EInit`): initialisation completed; real confirm from `PUBLISH_STATE.INITO` at the end of the chain `DigitalOutput` ⟶ `GreenWhiteBackground_AX` ⟶ `PUBLISH_STATE`

Data Inputs

- **QI** (BOOL): qualifier; goes to `DigitalOutput`, `GreenWhiteBackground_AX` and `PUBLISH_STATE`, FALSE keeps this instance completely inactive (default `TRUE`)
- **u16ObjId** (UINT): object ID of the SoftKey, carries the background colour (default `ID_NULL`)

- **u16ObjIdA** (UINT): object ID of the AuxFunction2 (joystick), also shows the background colour at the aux handle (default `ID_NULL`)
- **Output** (`logiBUS::io::DQ::logiBUS_DO_S`): selection of the output `Output_Q1`..`Output_Q12` (default `logiBUS_DO::Invalid`)
- **ID_STATE_WRITE** (WSTRING): local publish address (`ACTION=WRITE`) for the actual state; subscribed remotely by web client/dashboard

Data Outputs

- **QO** (BOOL): quality output - TRUE if the service was executed successfully (AND of `DigitalOutput`, `GreenWhiteBackground_AX` and `PUBLISH_STATE`)

Adapters

- **IN** (socket, `adapter::types::unidirectional::AX`): finished, already merged AX state; distributed to output, background and publish

Functionality

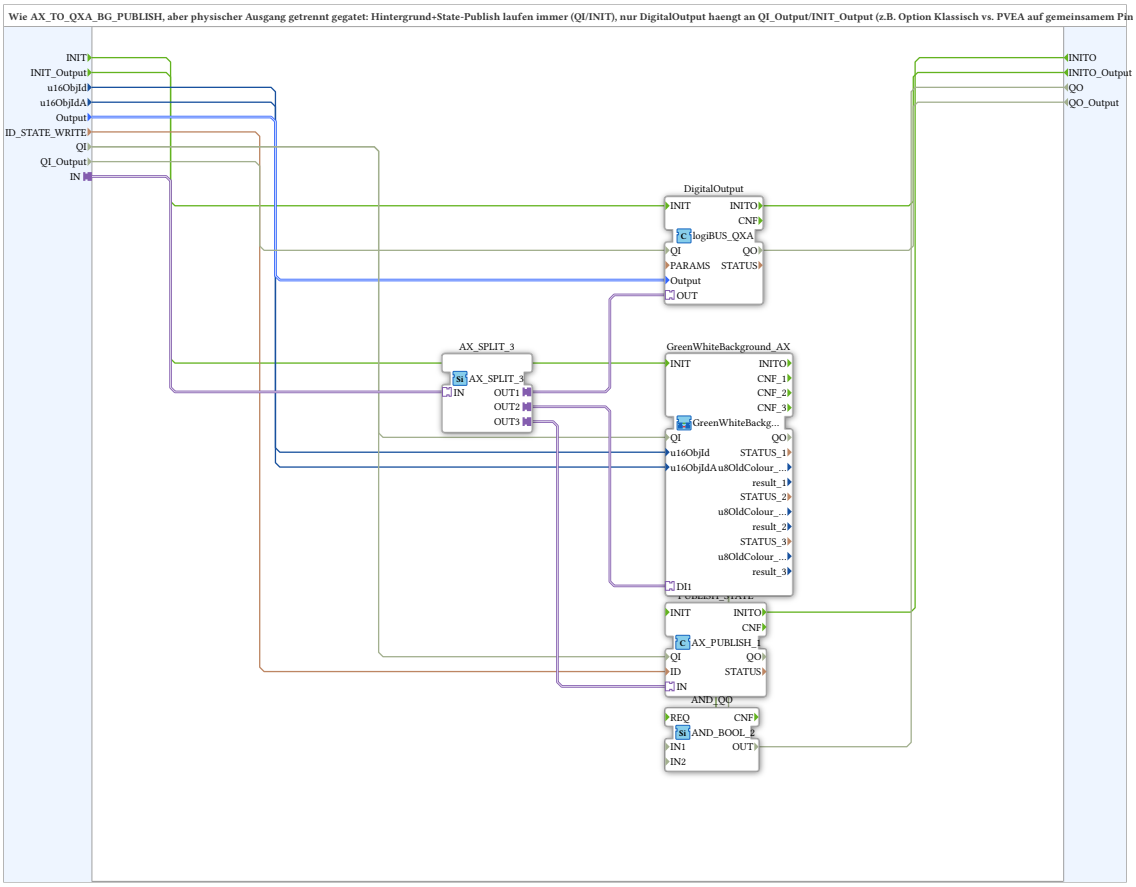
`IN` is routed to an `AX_SPLIT_3` (`adapter::events::unidirectional::AX_SPLIT_3`), which distributes the state to three destinations:

- `AX_SPLIT_3.OUT1` ⟶ `DigitalOutput.OUT`: `DigitalOutput` (`logiBUS::io::DQ::logiBUS_QXA`) switches the physical output; `Output` ⟶ `DigitalOutput.Output`, `QI` ⟶ `DigitalOutput.QI` and the event `INIT` ⟶ `DigitalOutput.INIT`.
- `AX_SPLIT_3.OUT2` ⟶ `GreenWhiteBackground_AX.DI1`: `GreenWhiteBackground_AX` (`MyLib::sys::GreenWhiteBackground3_AX`) colours the background green (TRUE) or white (FALSE); `u16ObjId` and `u16ObjIdA` go to its inputs of the same name, `QI` to `GreenWhiteBackground_AX.QI`.
- `AX_SPLIT_3.OUT3` ⟶ `PUBLISH_STATE.IN`: `PUBLISH_STATE` (`adapter::net::AX_PUBLISH_1`, `QI` from outside) publishes the state to the address `ID_STATE_WRITE` (`ID_STATE_WRITE` ⟶ `PUBLISH_STATE.ID`).

Initialisation and quality: `INIT` ⟶ `DigitalOutput.INIT`, `DigitalOutput.INITO` ⟶ `GreenWhiteBackground_AX.INIT`, `GreenWhiteBackground_AX.INITO` ⟶ `PUBLISH_STATE.INIT`, `PUBLISH_STATE.INITO` ⟶ `INITO`. `QO` is the output of the instance `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`) with `DigitalOutput.QO`, `GreenWhiteBackground_AX.QO` and `PUBLISH_STATE.QO` at `IN1`..`IN3`; its `REQ` is triggered by `PUBLISH_STATE.INITO`.

Technical Details

- Extracted from `Baender_EinAus` (wired three times identically there for hedgehog belt, elevator and cross belt)
- `ID_STATE_WRITE` is new because the web mirror needs its own state publish for the individual belt softkeys
- Version 1.1: `QI` and `INIT` are passed on to `DigitalOutput` (instead of a hard `TRUE` and automatic distribution), so that e.g. classic-vs-PVEA variants sharing pins can keep an instance inactive and the initialisation can be sequenced by the caller
- Version 1.2: new event output `INITO` (initialisation completed) and data output `QO` (AND of the inner `QO`); initialisation runs as a chain `DigitalOutput` ⟶ `GreenWhiteBackground_AX` ⟶ `PUBLISH_STATE`, `QI` is distributed to all three instances
- There are no own event or data ports for the state; everything runs via the AX adapter `IN`

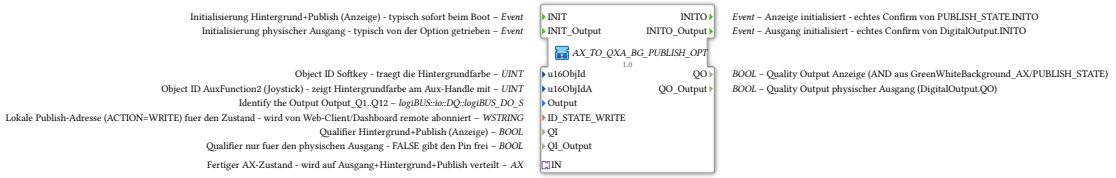


Application Scenarios

- Group signal or OR-merged state that is to switch an output, show the softkey colour and be published for the web
- Several time-staggered channels, each supplying its own state

Conclusion

`AX_TO_QXA_BG_PUBLISH` distributes a finished AX state to the physical output, background colour and state publish.



AX_TO_QXA_BG_PUBLISH_OPT

• — ○ • — ○ • — ○ •

Introduction

`AX_TO_QXA_BG_PUBLISH_OPT` corresponds to `AX_TO_QXA_BG_PUBLISH`, but gates the physical output separately: background and state publish always run via `QI/INIT`, only the `DigitalOutput` depends on `QI_Output/INIT_Output` (e.g. option “classic” versus “PVEA” on a shared pin). The block is a copy of `AX_TO_QXA_BG_PUBLISH` v1.2; the reason was that with the PVEA variant the SoftKey background and state publish stayed inactive together with the output.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization of background and publish (display); typically right at boot
- **INIT_Output** (`EInit`): initialization of the physical output; typically driven by the option

Event Outputs

- **INITO** (`EInit`): display initialized; real confirm from `PUBLISH_STATE.INITO`
- **INITO_Output** (`EInit`): output initialized; real confirm from `DigitalOutput.INITO`

Data Inputs

Variable	Type	Default	Comment

u16ObjId	UINT	ID_NULL	Object ID SoftKey; carries the background colour.
u16ObjIdA	UINT	ID_NULL	Object ID AuxFunction2 (joystick); also shows the background colour on the Aux handle.
Output	logiBUS::io::DQ::logiBUS_DO_1	logiBUS_DO::Invalid	Selection of the output Output_Q1..Output_Q12.
ID_STATE_WRITE	WSTRING		Local publish address (ACTION=WRITE) for the state; subscribed remotely by web client/dashboard.
QI	BOOL	TRUE	Qualifier for background and publish (display).
QI_Output	BOOL	TRUE	Qualifier for the physical output only; FALSE releases the pin.

Data Outputs

Variable	Type	Default	Comment
QO	BOOL		Quality output display (AND of GreenWhiteBackground_AX.QO and PUBLISH_STATE.QO).
QO_Output	BOOL		Quality output physical output (DigitalOutput.QO).

Adapters

Adapter	Type	Direction	Comment
IN	adapter::types::unidirectional::AX	Socket	Finished AX state; distributed to output, background and publish.

Function Blocks (FBs) Used

- **AX_SPLIT_3** (adapter::events::unidirectional::AX_SPLIT_3): adapter fan-out (strictly 1:1)
- **DigitalOutput** (logiBUS::io::DQ::logiBUS_QXA): physical output
- **GreenWhiteBackground_AX** (SubApp MyLib::sys::GreenWhiteBackground3_AX): background colour of SoftKey and Aux; see GreenWhiteBackground3_AX
- **PUBLISH_STATE** (adapter::net::AX_PUBLISH_1): local state publish
- **AND_QO** (iec61131::booleanOperators::AND_BOOL_2): combines the QO of the display

Program Flow and Connections

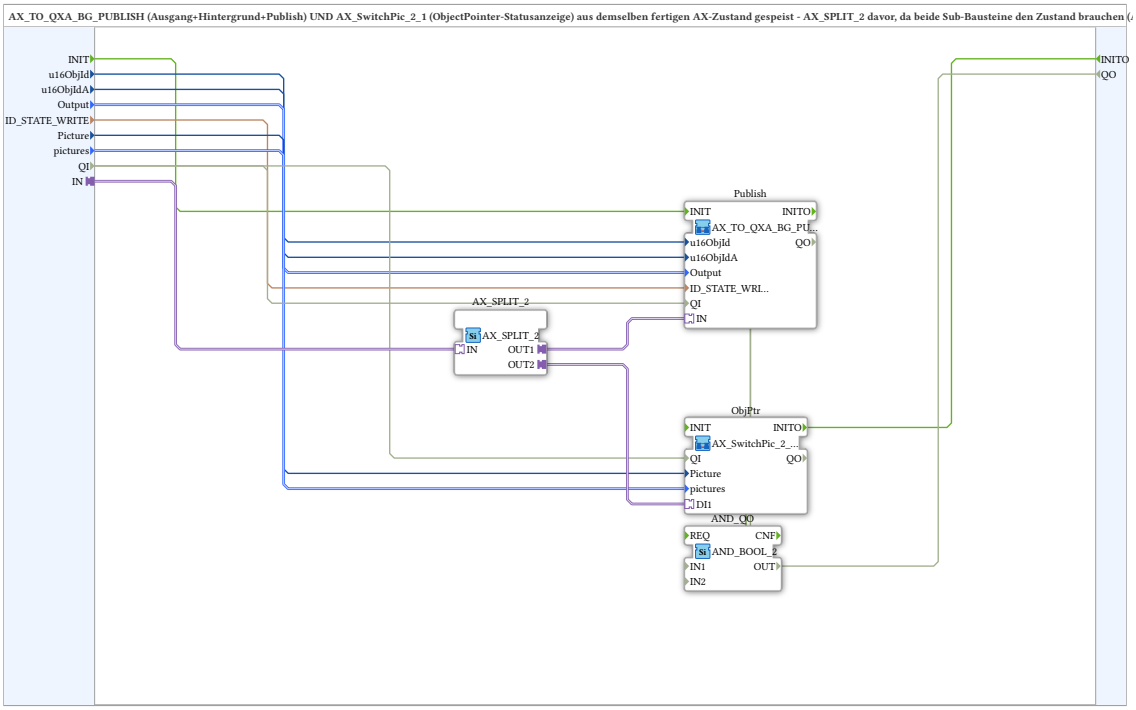
1. AX state: IN -> AX_SPLIT_3.IN; OUT1 -> DigitalOutput.OUT; OUT2 -> GreenWhiteBackground_AX.DI1; OUT3 -> PUBLISH_STATE.IN.
2. Output initialization: INIT_Output -> DigitalOutput.INIT; DigitalOutput.INITO -> INITO_Output.
3. Display initialization: INIT -> GreenWhiteBackground_AX.INIT; GreenWhiteBackground_AX.INITO -> PUBLISH_STATE.INIT; PUBLISH_STATE.INITO -> INITO and -> AND_QO.REQ.
4. Qualifier: QI -> GreenWhiteBackground_AX.QI and PUBLISH_STATE.QI; QI_Output -> DigitalOutput.QI.
5. Quality: GreenWhiteBackground_AX.QO -> AND_QO.IN1; PUBLISH_STATE.QO -> AND_QO.IN2; AND_QO.OUT -> QO; DigitalOutput.QO -> QO_Output.
6. Data: u16ObjId, u16ObjIdA -> GreenWhiteBackground_AX; Output -> DigitalOutput.Output; ID_STATE_WRITE -> PUBLISH_STATE.ID.

Technical Features

- `QI`/`INIT` now apply only to background and publish; `QI_Output`/`INIT_Output`/`INITO_Output`/`QO_Output` belong exclusively to the `DigitalOutput`.
- The `AX_SPLIT_3` is needed because the adapter fan-out is strictly 1:1.

Application Scenarios

- Channels where the physical output can be switched off via an option (e.g. classic versus PVEA on a shared pin), while SoftKey background and state publish should always run.



Summary

`AX_TO_QXA_BG_PUBLISH_OPT` distributes a finished AX state to output, background and publish, with the physical output enabled and initialized separately.

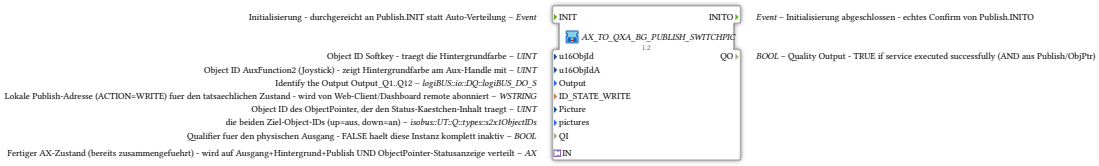
- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



AX_TO_QXA_BG_PUBLISH_SWITCHPIC

• — ○ • — ○ • — ○ •

Introduction

`AX_TO_QXA_BG_PUBLISH_SWITCHPIC` feeds `AX_TO_QXA_BG_PUBLISH` (output + background + publish) **and** `AX_SwitchPic_2_1` (ObjectPointer status display) from the same finished AX state. An `AX_SPLIT_2` in front is required because both sub-blocks need the state (adapter fan-out rule). Extracted from `Baender_EinAus`, where this combination existed three times identically (Igel, Elevator, Querband).

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialisation; passed on to `Publish.INIT` instead of automatic distribution

Event Outputs

- **INITO** (`EInit`): initialisation completed; real confirm from `ObjPtr.INITO` (end of the chain `Publish` → `ObjPtr`)

Data Inputs

- **QI** (`BOOL`): qualifier for the physical output; FALSE keeps this instance completely inactive (default `TRUE`)
- **u16ObjId** (`UINT`): object ID of the SoftKey, carries the background colour (default `ID_NULL`)
- **u16ObjIdA** (`UINT`): object ID of the AuxFunction2 (joystick), also shows the background colour on the aux handle (default `ID_NULL`)
- **Output** (`logiBUS::io::DQ::logiBUS_DO_S`): selection of the output `Output_Q1`..`Output_Q12` (default `logiBUS_DO::Invalid`)
- **ID_STATE_WRITE** (`WSTRING`): local publish address (`ACTION=WRITE`) for the actual state, subscribed remotely by web client/dashboard
- **Picture** (`UINT`): object ID of the ObjectPointer that carries the status box content
- **pictures** (`isobus::UT::Q::types::s2x1ObjectIDs`): the two target object IDs (`up` = off, `down` = on); default both `ID_NULL`

Data Outputs

- **QO** (`BOOL`): Quality Output, AND of `Publish.QO` and `ObjPtr.QO`

Adapters

- **IN** (socket, `adapter::types::unidirectional::AX`): finished, already merged AX state, distributed to output + background + publish and to the ObjectPointer status display

Function Blocks (FBs) Used

- **`AX_SPLIT_2`** (`adapter::events::unidirectional::AX_SPLIT_2`)
- **`Publish`** (SubApp `MyLib::sys::AX_TO_QXA_BG_PUBLISH`)
- **`ObjPtr`** (SubApp `MyLib::sys::AX_SwitchPic_2_1`)
- **`AND_QO`** (`iec61131::booleanOperators::AND_BOOL_2`)

Functionality

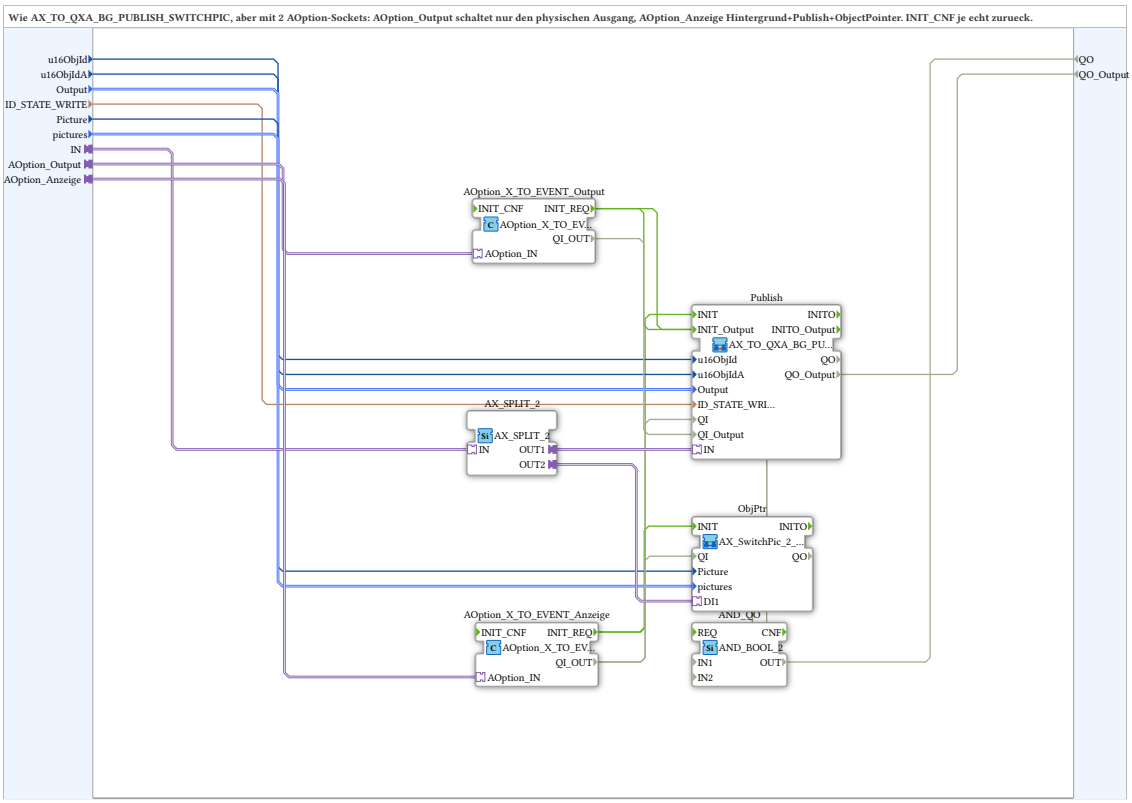
- `IN` → `AX_SPLIT_2.IN`
- `AX_SPLIT_2.OUT1` → `Publish.IN`; `u16ObjId`, `u16ObjIdA`, `Output`, `ID_STATE_WRITE`, `QI` → the like-named inputs of `Publish`
- `INIT` → `Publish.INIT`; `Publish.INITO` → `ObjPtr.INIT`; `ObjPtr.INITO` → `INITO` (and → `AND_QO.REQ`)
- `QI` → `ObjPtr.QI` (in addition to `Publish.QI`)
- `Publish.QO` → `AND_QO.IN1`; `ObjPtr.QO` → `AND_QO.IN2`; `AND_QO.OUT` → `QO`
- `AX_SPLIT_2.OUT2` → `ObjPtr.DI1`; `Picture` → `ObjPtr.Picture`, `pictures` → `ObjPtr.pictures`

Technical Details

- The `AX_SPLIT_2` is necessary because an adapter must not branch to two sub-blocks
- No logic of its own, just a combination of two existing SubApps
- Version 1.1: `QI` and `INIT` are passed on to `Publish` (`AX_TO_QXA_BG_PUBLISH` v1.1) (QI gate classic-vs-PVEA, initialisation sequenced by the caller)
- Version 1.2: new event output `INITO`, passed on from `Publish.INITO` via `ObjPtr`; additionally `QO` as AND of `Publish.QO` and `ObjPtr.QO`

Application Scenarios

- Several identically structured channels (e.g. conveyor belts) that each switch an output, show the softkey colour, publish, and additionally switch a status picture



Summary

`AX_TO_QXA_BG_PUBLISH_SWITCHPIC` distributes a finished AX state to output/background/publish and an ObjectPointer status display.

AX_TO_QXA_BG_PUBLISH_SWITCHPIC_OPT

• – ○ • – ○ • – ○ •

Introduction

`AX_TO_QXA_BG_PUBLISH_SWITCHPIC_OPT` corresponds to `AX_TO_QXA_BG_PUBLISH_SWITCHPIC`, but has two `AOption` sockets instead of `QI`/`INIT`: `AOption_Output` switches only the physical output, `AOption_Anzeige` switches background, publish and ObjectPointer. `INIT_CNF` is returned for real in each case. The block is a copy of `AX_TO_QXA_BG_PUBLISH_SWITCHPIC` v1.2; the reason was that with the PVEA variant the SoftKey background, ObjectPointer and state publish stayed inactive. The output part is also available on its own as `AX_TO_QXA_Option`, the display part as `AX_TO_BG_PUBLISH_SWITCHPIC_Option`.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

Variable	Type	Default	Comment
u16ObjId	UINT	ID_NULL	Object ID SoftKey; carries the background colour.
u16ObjIdA	UINT	ID_NULL	Object ID AuxFunction2 (joystick); also shows the background colour on the Aux handle.
Output	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Selection of the output Output_Q1..Output_Q12.
ID_STATE_WRITE	WSTRING		Local publish address (ACTION=WRITE) for the state; subscribed remotely by web client/ dashboard.
Picture	UINT		Object ID of the ObjectPointer carrying the status box content.
pictureIDs	isobus::UT::Q::types::s2x1ObjectIDs	(up := (u16ObjId := ID_NULL), down := (u16ObjId := ID_NULL))	The two target object IDs (up = off, down = on).

Data Outputs

Variable	Type	Default	Comment
QO	BOOL		Quality output display (AND of Publish.QO and ObjPtr.QO).
QO_Output	BOOL		Quality output physical output (Publish.QO_Output).

Adapters

Adapter	Type	Direction	Comment
IN	adapter::types::unidirectional::AX	Socket	Finished AX state; distributed to output, background, publish and ObjectPointer status display.
AOption_Output	Option::AOption	Socket	Enables only the physical output (e.g. DEMUX branch classic).
AOption_Anzeige	Option::AOption	Socket	Enables background, publish and ObjectPointer (e.g. AOption_OR_2 of classic and PVEA).

Function Blocks (FBs) Used

- **AX_SPLIT_2** (adapter::events::unidirectional::AX_SPLIT_2): adapter fan-out (strictly 1:1)
- **AOption_X_TO_EVENT_Output** (Option::conversion::AOption_X_TO_EVENT): option for the physical output
- **AOption_X_TO_EVENT_Anzeige** (Option::conversion::AOption_X_TO_EVENT): option for the display
- **Publish** (SubApp MyLib::sys::AX_TO_QXA_BG_PUBLISH_OPT): output, background and state publish; see AX_TO_QXA_BG_PUBLISH_OPT
- **ObjPtr** (SubApp MyLib::sys::AX_SwitchPic_2_1): ObjectPointer status display; see AX_SwitchPic_2_1
- **AND_QO** (iec61131::booleanOperators::AND_BOOL_2): combines the QO of the display

Program Flow and Connections

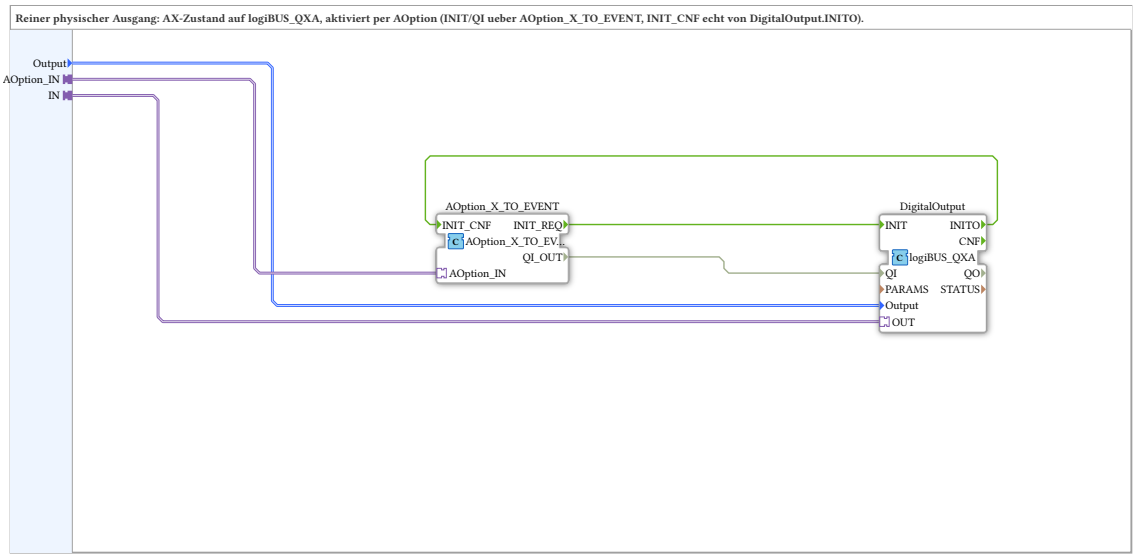
1. AX state: `IN` -> `AX_SPLIT_2.IN`; `OUT1` -> `Publish.IN`; `OUT2` -> `ObjPtr.DI1`.
2. Options: `AOption_Output` -> `AOption_X_TO_EVENT_Output.AOption_IN`; `AOption_Anzeige` -> `AOption_X_TO_EVENT_Anzeige.AOption_IN`.
3. Display initialization: `AOption_X_TO_EVENT_Anzeige.INIT_REQ` -> `Publish.INIT`; `Publish.INITO` -> `ObjPtr.INIT`; `ObjPtr.INITO` -> `AOption_X_TO_EVENT_Anzeige.INIT_CNF` and -> `AND_QO.REQ`.
4. Output initialization: `AOption_X_TO_EVENT_Output.INIT_REQ` -> `Publish.INIT_Output`; `Publish.INITO_Output` -> `AOption_X_TO_EVENT_Output.INIT_CNF`.
5. Qualifier: `AOption_X_TO_EVENT_Anzeige.QI_OUT` -> `Publish.QI` and `ObjPtr.QI`; `AOption_X_TO_EVENT_Output.QI_OUT` -> `Publish.QI_Output`.
6. Quality: `Publish.QO` -> `AND_QO.IN1`; `ObjPtr.QO` -> `AND_QO.IN2`; `AND_QO.OUT` -> `QO`; `Publish.QO_Output` -> `QO_Output`.
7. Data: `u16ObjId`, `u16ObjIdA`, `Output`, `ID_STATE_WRITE` -> inputs of `Publish` with the same name; `Picture` -> `ObjPtr.Picture`; `pictures` -> `ObjPtr.pictures`.

Technical Features

- The block has no event inputs/outputs of its own; initialization runs via the two `AOption` sockets.
- Output and display can be enabled independently of each other.
- The `AX_SPLIT_2` is needed because the adapter fan-out is strictly 1:1.

Application Scenarios

- Several identically structured channels (e.g. conveyor belts) with output, SoftKey colour, publish and status picture, where the output should be active for one option only (e.g. classic), but the display for several options (e.g. classic and PVEA).



Summary

`AX_TO_QXA_BG_PUBLISH_SWITCHPIC_OPT` distributes a finished AX state to output, background, publish and ObjectPointer status display and enables output and display via two separate `AOption` sockets.

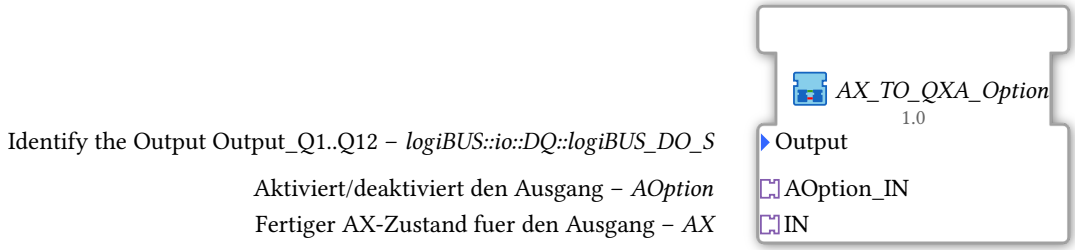
AX_TO_QXA_Option



• – ○ • – ○ • – ○ •

Introduction

`AX_TO_QXA_Option` is a pure physical output: it brings a finished AX state to `logiBUS_QXA`. It is activated via `AOption` (`INIT/QI` through `AOption_X_TO_EVENT`, `INIT_CNF` for real from `DigitalOutput.INITO`). It is

the output part of AX_TO_QXA_BG_PUBLISH_SWITCHPIC_OPT as a block of its own, following the pattern of OptionalGroup_001.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

Variable	Type	Default	Comment
Output	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Selection of the output Output_Q1..Output_Q12.

Data Outputs

None.

Adapters

Adapter	Type	Direction	Comment
AOption_IN	Option::AOption	Socket	Enables/disables the output.
IN	adapter::types::unidirectional::AX	Socket	Finished AX state for the output.

Function Blocks (FBs) Used

- **AOption_X_TO_EVENT** (Option::conversion::AOption_X_TO_EVENT): converts the option into INIT_REQ/QI_OUT and accepts INIT_CNF
- **DigitalOutput** (logiBUS::io::DQ::logiBUS_QXA): physical output

Program Flow and Connections

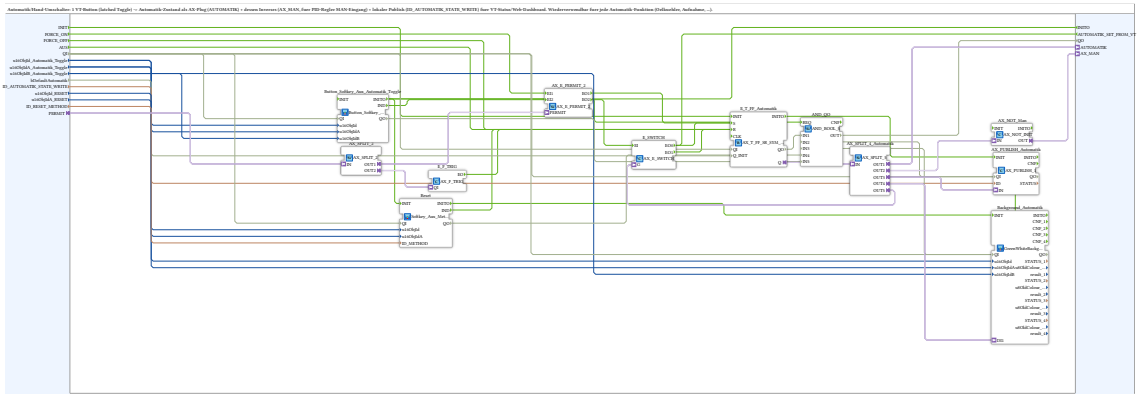
1. Option: AOption_IN -> AOption_X_TO_EVENT.AOption_IN.
2. Initialization: AOption_X_TO_EVENT.INIT_REQ -> DigitalOutput.INIT; DigitalOutput.INITO -> AOption_X_TO_EVENT.INIT_CNF.
3. Qualifier: AOption_X_TO_EVENT.QI_OUT -> DigitalOutput.QI.
4. AX state: IN -> DigitalOutput.OUT.
5. Data: Output -> DigitalOutput.Output.
6. The block has no event or QI/QO connections of its own and no plug.

Technical Features

- No logic of its own: only the option connection and logiBUS_QXA.
- INIT_CNF comes for real from DigitalOutput.INITO.
- There is no AOption_OUT plug; the block therefore cannot be daisy-chained.

Application Scenarios

- Physical output that is to be switched only when the option (e.g. classic) is selected, separate from display and publish.



Summary

`AX_TO_QXA_Option` drives a physical output from a finished AX state and is activated via `AOption`.

Automatik_Toggle_Button

• – ○ • – ○ • – ○ •

Introduction

`Automatik_Toggle_Button` is an **automatic/manual toggle**: a VT button (or softkey or AUX function) toggles the automatic state. The state is output as an AX plug (`AUTOMATIK`), as its inverse (`AX_MAN`, e.g. for the `MAN` input of a PID controller) and as a local publish (`ID_AUTOMATIK_STATE_WRITE`) for the VT status and web dashboard. The SubApp is reusable for any automatic function (oil cooler, pickup, ...) and was extracted from `Aufnahme_Automatik.SUB`.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request
- **FORCE_ON**: Switches the automatic hard ON (e.g. from a superordinate automatic or a method call). Runs via `AX_E_PERMIT_2` and is therefore `PERMIT`-filtered. Leave unconnected if not needed.
- **FORCE_OFF**: Switches the automatic hard OFF (e.g. by a collision protection). Leave unconnected if not needed.
- **AUS**: Hard reset to manual/OFF from outside as an event (e.g. a centrally read common softkey), in addition to the block's own `u16ObjId_RESET`/`u16ObjIdA_RESET`/`ID_RESET_METHOD` path. Leave unconnected if not needed.

Event Outputs

- **INITO** (`EInit`): initialization confirm
- **AUTOMATIK_SET_FROM_VT**: Fires only on a click (button/softkey/aux, `PERMIT`-filtered) that switches the automatic from OFF to ON. A click that switches the automatic off does not fire this event. It is a genuine display click event, not a state level or republish.

Data Inputs

- **QI** (`BOOL`, default `TRUE`): quality input, TRUE enables the service
- **u16ObjId_Automatik_Toggle** (`UINT`, default `ID_NULL`): Object ID of the VT softkey (automatic/manual toggle)
- **u16ObjIdA_Automatik_Toggle** (`UINT`, default `ID_NULL`): Object ID of the AuxFunction2 (joystick), equivalent to the VT button; optional

- **u16ObjIdB_Automatik_Toggle** (UINT): Object ID of the VT button (automatic/manual toggle)
- **bDefaultAutomatik** (BOOL, default FALSE): Automatic state at start
- **ID_AUTOMATIK_STATE_WRITE** (WSTRING): Local publish address (BOOL, ACTION=WRITE) for the automatic on/off state (status text on the VT, web client/dashboard)
- **u16ObjId_RESET** (UINT, default ID_NULL): Object ID of the softkey "All off" (reset, hard to manual/OFF), e.g. SoftKey_AUS
- **u16ObjIdA_RESET** (UINT, default ID_NULL): Object ID of the AuxFunction2 (joystick) for the reset
- **ID_RESET_METHOD** (WSTRING): Local method address (ACTION=CREATE_METHOD) for the argument-less reset trigger; called by the web client and the OPC dashboard

Data Outputs

- **QO** (BOOL): quality output, AND combination (AND_QO) of the QO outputs of E_T_FF_Automatik, AX_PUBLISH_Automatik, Background_Automatik, Reset and Button_Softkey_Aux_Automatik_Toggle

Adapters

- **PERMIT** (socket, adapter::types::unidirectional::AX): Enable. Gates the entire on/off; on the transition 1⟶0 a one-time RESET is triggered.
- **AUTOMATIK** (plug, AX): Automatic active (raw, e.g. for an enable AND combination)
- **AX_MAN** (plug, AX): NOT automatic active (for the MAN input of a PID controller)

Function Blocks (FBs) Used

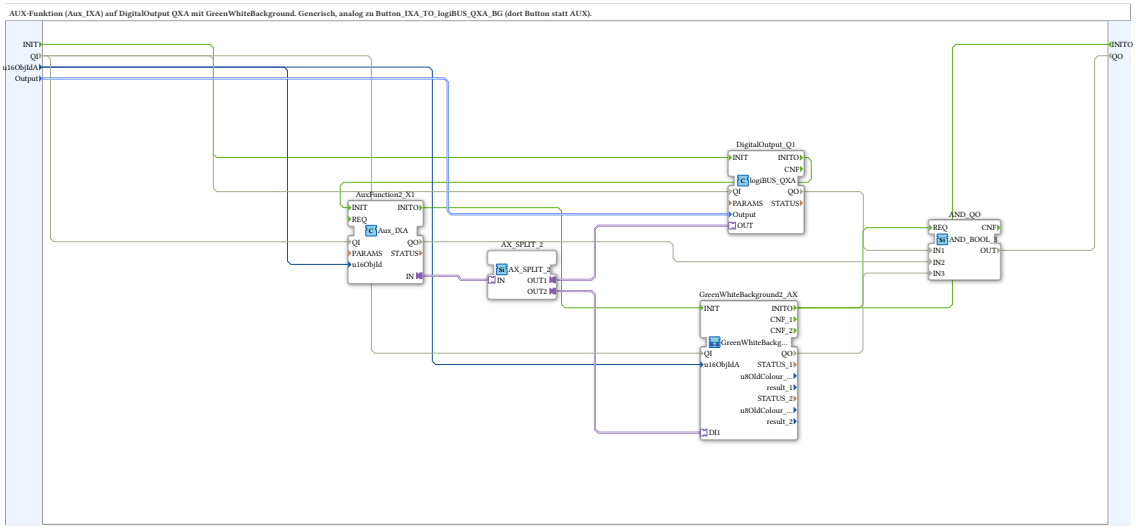
- **Button_Softkey_Aux_Automatik_Toggle**: SubApp MyLib::sys::Button_Softkey_Aux_IE - merges button, softkey and aux into one IND
- **Reset**: SubApp MyLib::sys::Softkey_Aux_Method_IE - reset via softkey, aux or method call
- **E_T_FF_Automatik**: AX_T_FF_SR_SYM_INIT (QI from the wrapper input) - stores the automatic state, start value bDefaultAutomatik
- **AX_E_PERMIT_2**: AX_E_PERMIT_2 - lets FORCE_ON and the click through only when PERMIT=TRUE
- **AX_SPLIT_2**: distributes PERMIT to AX_E_PERMIT_2 and E_F_TRIG
- **E_F_TRIG**: AX_F_TRIG - falling edge on PERMIT
- **E_SWITCH**: AX_E_SWITCH - filters the click by the state before the click
- **AX_SPLIT_4_Automatik**: AX_SPLIT_5 - distributes the state to five targets
- **AX_NOT_Man**: AX_NOT_INIT - inverse for AX_MAN
- **AX_PUBLISH_Automatik**: AX_PUBLISH_1 (QI from the wrapper input) - publishes the state under ID_AUTOMATIK_STATE_WRITE
- **Background_Automatik**: GreenWhiteBackground4_AX - colors button and AUX green/white
- **AND_QO**: iec61131::booleanOperators::AND_BOOL_5 - combines the QO outputs of the five blocks E_T_FF_Automatik, AX_PUBLISH_Automatik, Background_Automatik, Reset and Button_Softkey_Aux_Automatik_Toggle into QO

Program Flow and Connections

1. Button_Softkey_Aux_Automatik_Toggle.IND ⟶ AX_E_PERMIT_2.EI2; FORCE_ON ⟶ AX_E_PERMIT_2.EI1.
2. AX_E_PERMIT_2.EO1 ⟶ E_T_FF_Automatik.S (switch-on via FORCE_ON).
3. AX_E_PERMIT_2.EO2 ⟶ E_SWITCH.EI; E_SWITCH.G receives the state Q before the click (AX_SPLIT_4_Automatik.OUT5).
   - E_SWITCH.EO0 (OFF ⟶ ON) ⟶ AUTOMATIK_SET_FROM_VT and E_T_FF_Automatik.S
   - E_SWITCH.EO1 (ON ⟶ OFF) ⟶ E_T_FF_Automatik.R
4. Reset.IND, AUS, FORCE_OFF and E_F_TRIG.EO ⟶ E_T_FF_Automatik.R.
5. PERMIT ⟶ AX_SPLIT_2 ⟶ AX_E_PERMIT_2.PERMIT and E_F_TRIG.QI.
6. E_T_FF_Automatik.Q ⟶ AX_SPLIT_4_Automatik: OUT1 ⟶ AUTOMATIK, OUT2 ⟶ AX_NOT_Man ⟶ AX_MAN, OUT3 ⟶ AX_PUBLISH_Automatik, OUT4 ⟶ Background_Automatik.DI1, OUT5 ⟶ E_SWITCH.G.
7. Initialization chain: INIT ⟶ E_T_FF_Automatik.INIT ⟶ AX_PUBLISH_Automatik.INIT ⟶ Background_Automatik.INIT ⟶ Reset.INIT ⟶ Button_Softkey_Aux_Automatik_Toggle.INIT; Button_Softkey_Aux_Automatik_Toggle.INITO ⟶ INITO and ⟶ AND_QO.REQ.
8. Quality: QI ⟶ .QI of E_T_FF_Automatik, AX_PUBLISH_Automatik, Background_Automatik, Reset and Button_Softkey_Aux_Automatik_Toggle; their QO ⟶ AND_QO.IN1 to AND_QO.IN5 (in that order); AND_QO.OUT ⟶ QO.

Technical Details

- **Button instead of softkey**: The VT button must be non-latching (`Latchable=0`); the feedback of the automatic display is provided by `Background_Automatik`.
- **PERMIT** gates the entire on/off and resets once on the transition 1⟶0 - it thereby acts like an `AX_PERMIT`.
- `FORCE_ON`/`FORCE_OFF`/`AUS` are genuine events; callers with level-based sources must provide the edge detection themselves.
- `AUTOMATIK_SET_FROM_VT` reacts only to the display click OFF ⟶ ON, not to `FORCE_ON` echoes.



Application Scenarios

- Automatic/manual switching with status display for automatic functions (oil cooler, pickup, bunker harvest, ...)
- Manual mode signal for PID controllers (`AX_MAN`)

Summary

`Automatik_Toggle_Button` encapsulates operation, state storage, enable, reset and status output of an automatic function in one reusable SubApp.

AuxIXA_TO_logiBUS_QXA_BG

• – ○ • – ○ • – ○ •

Introduction

The `AuxIXA_TO_logiBUS_QXA_BG` subapplication is a generic, reusable composite function block that connects an AUX (auxiliary) input event from the ISOBUS UT system to a digital output on a logiBUS QXA module. It also incorporates a green/white background color control for visual indication. The subapp is designed to be instantiated wherever an AUX input needs to drive a digital output with color feedback, following the same pattern as the `Button_IXA_TO_logiBUS_QXA_BG` but using an AUX function block instead of a button.

Interface Structure

The subapplication exposes the initialization events `INIT`/`INITO`, the status pair `QI`/`QO` and data inputs; no adapters are visible at its boundary.

Event Inputs

- **INIT** (`EInit`): Initialization Request - starts the initialization chain of the internal blocks.

Event Outputs

- **INITO** (EInit): Initialization Confirm - emitted after the initialization chain has completed.

Data Inputs

Name	Type	Initial Value	Comment
QI	BOOL	TRUE	Quality Input - TRUE to enable the service
u16ObjIdA	UINT	ID_NULL	Object ID of the AUX input
Output	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Selects the physical output (Q1..Q8)

Data Outputs

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if the service executed successfully

QO is the AND (AND_QO, type iec61131::booleanOperators::AND_BOOL_3) of the QO outputs of DigitalOutput_Q1, AuxFunction2_X1 and GreenWhiteBackground2_AX.

Adapters

The subapplication does not expose any adapters; all internal adapter connections are encapsulated.

Functionality

The subapplication receives an AUX object ID (u16ObjIdA) and an output selection (Output). Internally, it performs the following steps:

1. The AuxFunction2_X1 block (type isobus::UT::io::Auxiliary::IN::Aux_IXA) receives QI from the subapplication's QI input and processes the AUX input based on the provided object ID. It generates an event on its IN adapter when the AUX input is activated.
2. The AX_SPLIT_2 block (type adapter::events::unidirectional::AX_SPLIT_2) splits the incoming event into two parallel event connections.
3. One event output (OUT1) goes to the DigitalOutput_Q1 block (type logiBUS::io::DQ::logiBUS_QXA), which drives the selected logiBUS digital output (based on the Output data input).
4. The other event output (OUT2) goes to the GreenWhiteBackground2_AX subapplication, which presumably handles the green/white background color logic for the display.
5. The u16ObjIdA is also connected to GreenWhiteBackground2_AX to keep the color logic synchronized with the AUX object.

Initialization and status: INIT → DigitalOutput_Q1.INIT, DigitalOutput_Q1.INITO → AuxFunction2_X1.INIT, AuxFunction2_X1.INITO → GreenWhiteBackground2_AX.INIT, GreenWhiteBackground2_AX.INITO → INITO (and additionally → AND_QO.REQ). QI is forwarded to DigitalOutput_Q1, AuxFunction2_X1 and GreenWhiteBackground2_AX; their QO outputs go to AND_QO.IN1..IN3, and AND_QO.OUT → QO.

The subapp thus provides a complete mapping from an AUX input to a physical digital output with visual feedback on the user interface.

Technical Features

- **Reusability**: The subapp is generic and can be used multiple times in a project, only needing the object ID and output selector to be configured.
- **Event-driven**: Uses adapter-based event propagation for efficient and clear signal flow.
- **Separation of concerns**: The AUX input handling, event splitting, and color logic are modular and can be replaced or extended individually.
- **Compatibility**: Internally uses standard ISOBUS and logiBUS function blocks, ensuring interoperability.

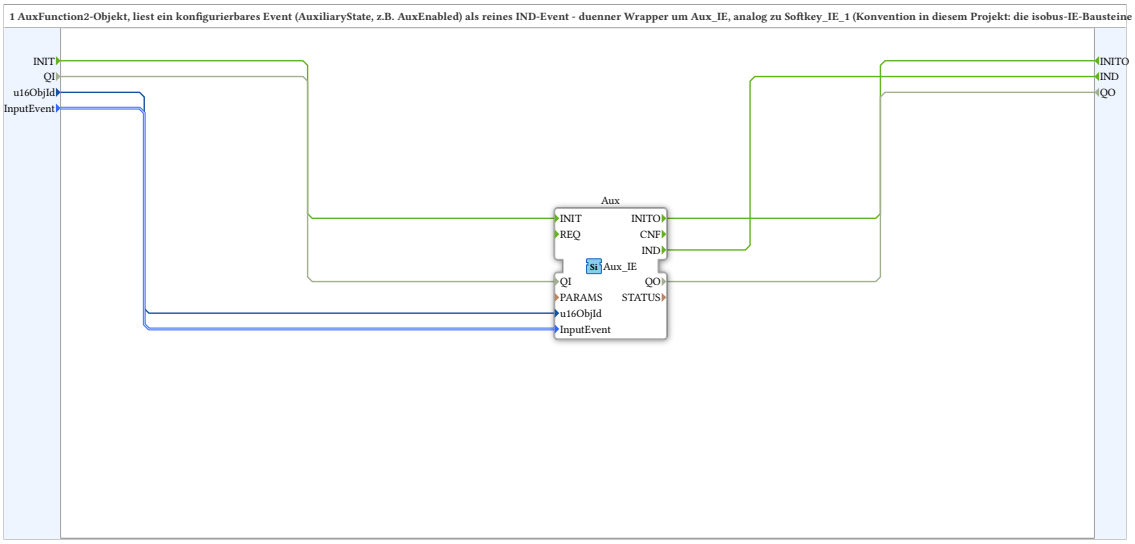
State Overview

Although the subapp does not define an explicit state machine, the internal blocks may have their own states. The AUX function block likely includes filtering and debouncing mechanisms, while the digital

output block handles energizing/de-energizing of the physical output. The background color subapplication manages visual states (green/white) based on the AUX activity.

Application Scenarios

- **Agricultural machinery**: Mapping AUX buttons to digital outputs (e.g., valve control, lighting) with simultaneous color indication on the in-cab display.
- **Generic ISOBUS UT implementations**: Wherever a simple AUX-to-output conversion with green/white feedback is required.
- **Rapid prototyping**: The subapp can be dropped into a network and configured without needing to redesign the logic.

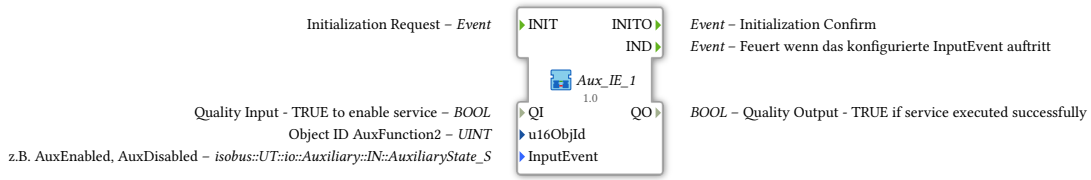


Comparison with Similar Blocks

- **Button_IXA_TO_logiBUS_QXA_BG**: Similar structure but uses a button input instead of an AUX object. This subapp replaces the button block with `Aux_IXA`.
- **Direct connection to logiBUS_DO**: A simpler approach would directly connect an event to the logiBUS output, but without color feedback and without the flexibility of an object ID mapping.

Conclusion

The `AuxIXA_TO_logiBUS_QXA_BG` subapplication provides a clean, reusable solution for integrating AUX inputs with digital outputs and visual feedback in ISOBUS-based systems. Its modular architecture makes it easy to maintain and adapt for various use cases, ensuring consistent behavior across different machines.



Aux_IE_1

• – ○ • – ○ • – ○ •

Introduction

`Aux_IE_1` reads an AuxFunction2 object and outputs a configurable event (`AuxiliaryState`, e.g. `AuxEnabled`) as a pure `IND` event. The block is a thin wrapper around `isobus::UT::io::Auxiliary::IN::Aux_IE`, analogous to `Softkey_IE_1` and `Button_IE_1`. Convention in this project: the isobus IE blocks are never used raw inline but always wrapped.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; passed on to `Aux.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `Aux.INITO`
- **IND**: fires when the configured `InputEvent` occurs

Data Inputs

- **QI** (BOOL): quality input, service enable (initial value `TRUE`), passed on to `Aux.QI`
- **u16ObjId** (UINT): object ID of the AuxFunction2 (default `ID_NULL`)
- **InputEvent** (`isobus::UT::io::Auxiliary::IN::AuxiliaryState_S`): e.g. `AuxEnabled`, `AuxDisabled` (default `Invalid`)

Data Outputs

- **QO** (BOOL): quality output, comes from `Aux.QO`

Adapters

No adapters are used.

Functionality

The network contains exactly one instance `Aux` of type `isobus::UT::io::Auxiliary::IN::Aux_IE`. `u16ObjId` and `InputEvent` are routed unchanged to the like-named inputs of the instance, and its event `IND` is output directly as the `IND` of the SubApp. In addition, `INIT` ⟶ `Aux.INIT`, `Aux.INITO` ⟶ `INITO`, `QI` ⟶ `Aux.QI` and `Aux.QO` ⟶ `QO` are passed through.

Technical Details

- Pure pass-through without logic or state of its own
- `QI` is no longer hard-wired to TRUE; it is passed through together with `INIT`/`INITO` and `QO` (the initial value of `QI` is `TRUE`)
- Because `InputEvent` is a parameter, the same SubApp can be used for different kinds of events (e.g. pressing or releasing)

Application Scenarios

- Reading a single VT operation as an event without using the raw IE block directly in the network

⚖️ Comparison with Similar Blocks

Equivalent wrappers are `Button_IE_1` and `Softkey_IE_1` they differ only in the VT object type and in the enumeration type of `InputEvent`.

Conclusion

`Aux_IE_1` is a minimal wrapper that provides a configurable AuxFunction2 event as `IND`.

Background Color Blocks: Shared Pattern

• – ◦ • – ◦ • – ◦ •

Introduction

`MyLib::sys` contains, in both training systems (`test_AX` and `test_B`), a large family of nearly identical blocks that **switch the VT background color of one or more objects based on a single boolean signal** — e.g. `GreenWhiteBackground1_AX`, `GreenRedBackground4_AXS`, `RedWhiteBackground2_AXC`. This page explains the shared pattern once in full; the individual block pages link back here and only state the concrete differences (color pair, object count, variant).

Naming Scheme

`<Color1><Color2>Background<N>[_aux][_AX][S][C]`

Component	Meaning

Color pair (`GreenWhite`, `GreenRed`, `GreenBlue`, `RedGreen`, `RedWhite`)	`TRUE` → first color, `FALSE` → second color (e.g. `GreenWhiteBackground`: TRUE→green, FALSE→white)
N (1–4)	Number of VT objects colored **simultaneously from the same selector bit** (not: number of independent channels)
`_aux` (N=1 only)	Uses `Q_BackgroundColourAux` instead of `Q_BackgroundColour` — targets an ISOBUS **Auxiliary Function** object instead of a regular softkey/button/data-mask object. For N≥2 variants, this role may already be baked into one specific position (see the individual page).
`_AX` (test_AX only)	The selector signal arrives via an `AX` adapter socket (`DI1`), not as a plain data input. In test_B this suffix is absent — there, `DI1` is a plain `BOOL` data input.
`S`	Object ID(s) are passed via the structured type `isobus::UT::Q::types::s1ObjectID` (`u16ObjIds`, unpacked internally via `F_MOVE`) instead of individual `UINT u16ObjId` inputs — a later unification of object-ID passing in the library.
`C` ("Compact")	A thin wrapper that just instantiates the base variant (`_AX` or `_AXS`) and doesn't expose the `CNF` event outputs/intermediate values (`STATUS_n`, `u8OldColour_n`, `result_n`) — for the common case where those diagnostic values aren't needed.

Examples: `GreenWhiteBackground1_AX` (base, 1 object, adapter), `GreenWhiteBackground1_AXC` (compact wrapper of it), `GreenWhiteBackground1_AXS` (with struct object ID), `GreenWhiteBackground1_AXSC` (struct ID + compact), `GreenWhiteBackground1_aux_AX` (like base, but for an AUX-function object).

Functionality (base variant, N=1)

1. The selector signal (`DI1` adapter for `_AX`, otherwise `DI1` data value) goes to `AX_SEL`/`F_SEL` (binary selection), parameterized with the two color constants (`IN0`=second color, `IN1`=first color, e.g. `IN0=COLOR_WHITE`, `IN1=COLOR_GREEN`).
2. `AX_SEL.CNF` triggers `Q_BackgroundColour.REQ` (or `Q_BackgroundColourAux.REQ` for `_aux`).
3. `Q_BackgroundColour` sets the background color of the VT object identified by `u16ObjId` and reports back `CNF` with `STATUS`, `u8OldColour` (previous color), and `s16result` (error code).

Functionality (N≥2)

With multiple objects (`GreenRedBackground4_AX` and similar), there is still **only one** selector (`DI1`/`AX_SEL`), whose output is distributed in parallel to several `Q_BackgroundColour_n` instances (numbered `_1`..`_N`) — each with its own `u16ObjId`/`u16ObjIdA`/`u16ObjIdB` (different object IDs, sometimes for different object roles like softkey/AUX/button) and its own `STATUS_n`/`u8OldColour_n`/`result_n`/`CNF_n` outputs. **Which position uses `Q_BackgroundColourAux` instead of `Q_BackgroundColour` varies per block** (not always the same position) — each block's individual page states the concrete mapping.

Technical Details

- **One selector, multiple destinations**: the point of N>1 is to apply the same boolean condition (e.g. "channel active") simultaneously to several VT representations of the same logical state (e.g. softkey background AND auxiliary-function background AND button background for the same function).
- **`_aux`/`Q_BackgroundColourAux`**: ISOBUS auxiliary function objects (controls freely assignable by the driver) require their own Q-block, since they use a different object ID range/VT message than regular softkeys/buttons.

- **`S` variant as a later unification**: identifiable by the later `VersionInfo` dates (2026 vs. 2022) — the `S` variants are a follow-up refactor that aligns object-ID passing with a later-established standard (`s1ObjectID`), without replacing the older base variants.

Family Overview

Color pair	test_AX (base/_aux, each also with S/SC/C)	test_B (base/_aux, each also with S/SC/C)
Green/White	1, 2, 3, 4	1, 2, 3, 4
Green/Red	1, 2, 3, 4	1, 2, 3, 4
Green/Blue	1	1
Red/Green	1, 4	1, 4
Red/White	1, 2, 3, 4	1, 2, 3, 4

In test_AX every combination additionally carries the `_AX` suffix; in test_B it's absent (selector is a `BOOL` data input instead of an adapter socket) — see MyLib (test_B) → sys.

Summary

The background color blocks are a single recurring idea (boolean signal → color selection → `Q_BackgroundColour`) offered in many small variants for different color pairs, object counts, and object-ID conventions. Understand one variant and you understand them all — the individual pages only state the concrete parameters.

Background Color Blocks: Common Pattern

• – ◦ • – ◦ • – ◦ •

Introduction

In both training systems (`test_AX` and `test_B`), `MyLib::sys` contains a large family of nearly identical blocks that **toggle the VT background color of one or more objects based on a single Boolean signal** — e.g., `GreenWhiteBackground1_AX`, `GreenRedBackground4_AXS`, `RedWhiteBackground2_AXC`. This page explains the common pattern in full; the individual block pages refer back to this page and only mention the specific differences (color pair, number of objects, variant).

Naming Scheme

`<Farbe1><Farbe2>Background<N>[_aux][_AX][S][C]`

Component	Meaning
Color Pair (`GreenWhite`, `GreenRed`, `GreenBlue`, `RedGreen`, `RedWhite`)	`TRUE` → first color, `FALSE` → second color (e.g., `GreenWhiteBackground`: TRUE→Green, FALSE→White)
N (1–4)	Number of VT objects that are **simultaneously colored from the same selector bit** (not: number of independent channels)
`_aux` (only for N=1)	Uses `Q_BackgroundColourAux` instead of `Q_BackgroundColour` — targets an ISOBUS **Auxiliary Function** object instead of a normal softkey/button/data mask object. For N≥2 variants, this role may already be permanently integrated into one of the positions (see individual page).
`_AX` (only for test_AX)	The selector signal arrives via a `AX` adapter socket (`DI1`), not as a pure data input. This suffix is miss-

	ing in test_B — there, `DI1` is a simple `BOOL` data input.
`S`	Object ID(s) are passed via the structured type `isobus::UT::Q::types::s1ObjectID` (`u16ObjIds`, internally unpacked via `F_MOVE`) instead of via individual `UINT u16ObjId` inputs — a later standardization of object ID passing in the library.
`C` ("Compact")	A thin wrapper that instantiates only the base variant (`_AX` or `_AXS`) and does not expose the `CNF` event outputs/intermediate values (`STATUS_n`, `u8OldColour_n`, `result_n`) – for the typical case where these diagnostic values are not needed.

Examples: `GreenWhiteBackground1_AX` (Basic, 1 object, adapter), `GreenWhiteBackground1_AXC` (Compact wrapper of this), `GreenWhiteBackground1_AXS` (with struct object ID), `GreenWhiteBackground1_AXSC` (struct ID + compact), `GreenWhiteBackground1_aux_AX` (like Basic, but with an AUX function object).

Functionality (Basic Variant, N=1)

1. The selector signal (`DI1` adapter for `_AX`, otherwise `DI1` data value) goes to `AX_SEL`/`F_SEL` (binary selection), parameterized with the two color constants (`IN0` = second color, `IN1` = first color, e.g., `IN0=COLOR_WHITE`, `IN1=COLOR_GREEN`).
2. `AX_SEL.CNF`/`F_SEL.CNF` triggers `Q_BackgroundColour.REQ` (or `Q_BackgroundColourAux.REQ` for `_aux`).
3. `Q_BackgroundColour` sets the background color of the VT object identified by `u16ObjId` and returns `CNF` with `STATUS`, `u8OldColour` (previous color), and `s16result` (error code).

Functionality (N≥2)

For multiple objects (`GreenRedBackground4_AX` etc.), there is still only **one** selector (`DI1`/`AX_SEL`/`F_SEL`), whose output is distributed in parallel to multiple `Q_BackgroundColour_n` instances (numbered `_1`..`_N`) — each with its own `u16ObjId`/`u16ObjIdA`/`u16ObjIdB` (different object IDs, sometimes for different object roles such as softkey/AUX/button) and its own `STATUS_n`/`u8OldColour_n`/`result_n`/`CNF_n` outputs. **Which position uses `Q_BackgroundColourAux` instead of `Q_BackgroundColour` varies per block** (not always the same position) — the individual page for each block specifies the exact assignment.

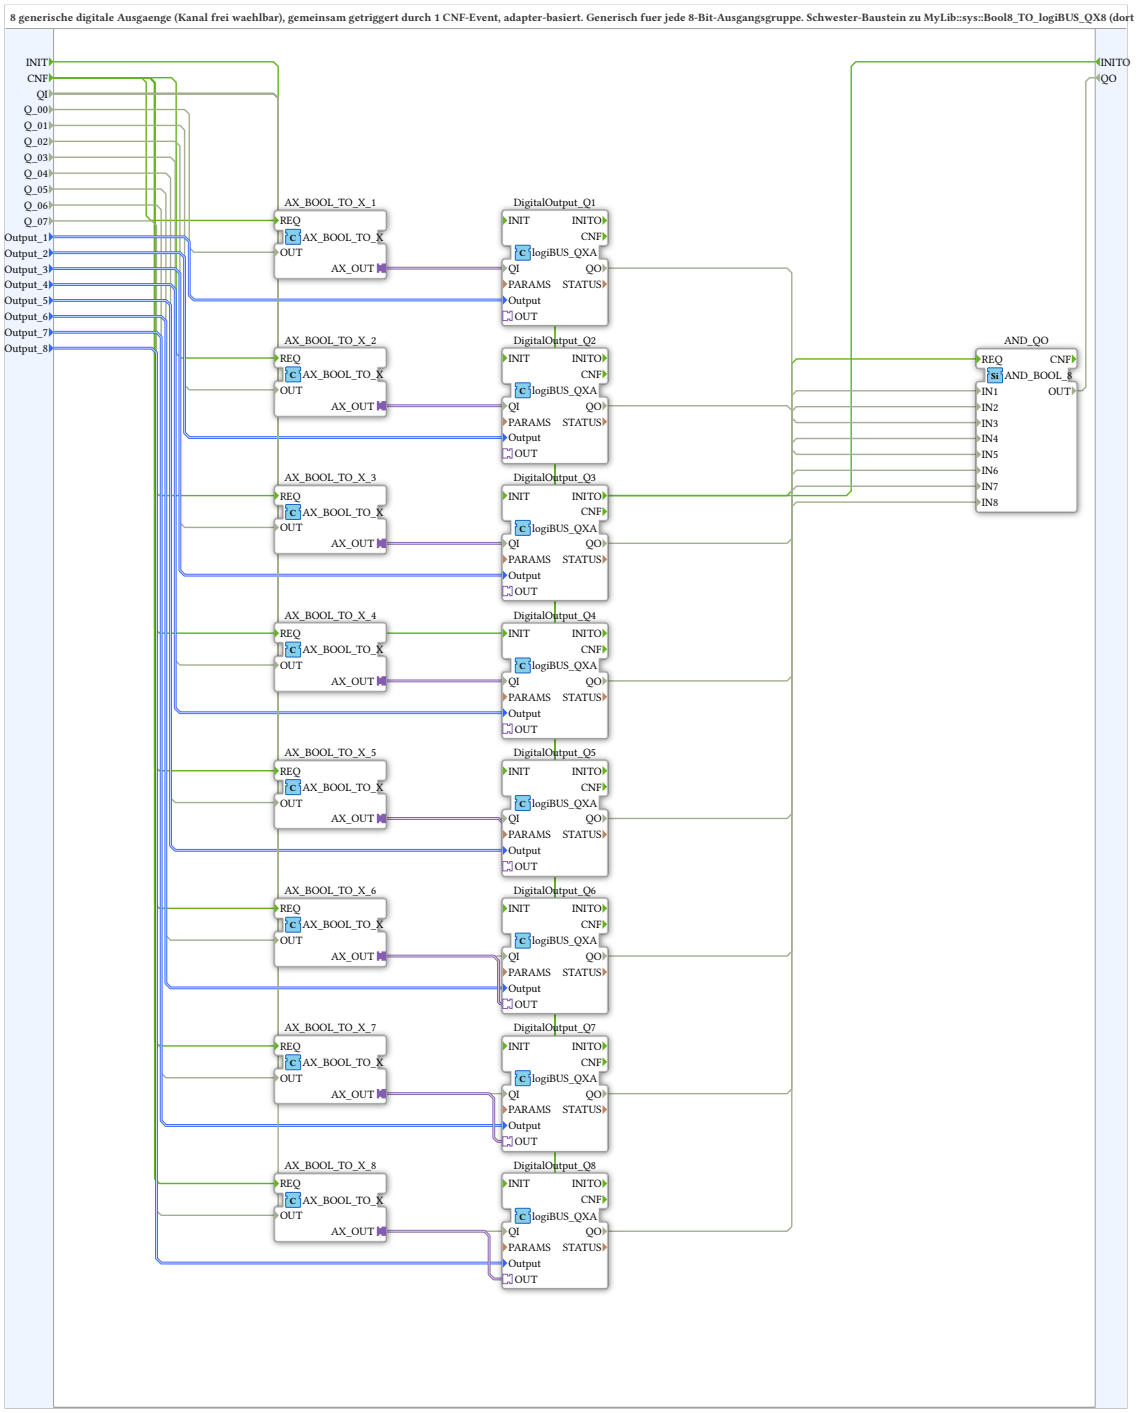
Technical Features

- **One selector, multiple Objectives**: The purpose of N>1 is to apply the same Boolean condition (e.g., "Channel active") simultaneously to multiple VT representations of the same logical state (e.g., softkey background AND auxiliary function background AND button background of the same function).
- **`_aux`/`Q_BackgroundColourAux`**: ISOBUS auxiliary function objects (controls that can be freely assigned to the driver) require their own Q block because they use a different ObjectID range/VT message than normal softkeys/buttons.
- **`S` variant as a later unification**: Recognizable by the later `VersionInfo` dates (2026 vs. 2022) — the `S` variants are a follow-up refactoring that aligns object ID passing with a later-established standard (`s1ObjectID`), without replacing the older base variants.

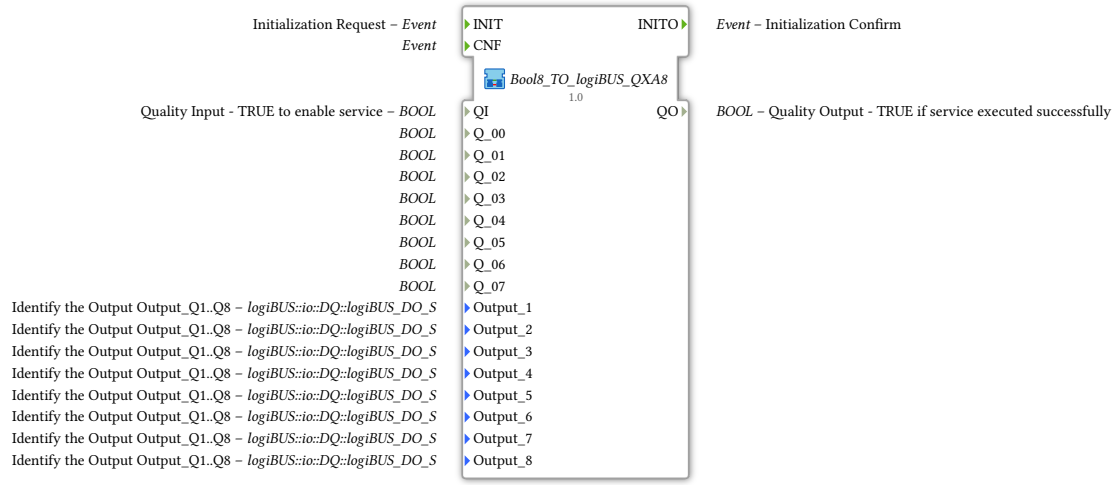
Family Overview

Color Pair	test_AX (Base/_aux, also S/SC/C)	test_B (Base/_aux, also S/SC/C)
Green/White	1, 2, 3, 4	1, 2, 3, 4
Green/Red	1, 2, 3, 4	1, 2, 3, 4
Green/Blue	1	1
Red/Green	1, 4	1, 4
Red/White	1, 2, 3, 4	1, 2, 3, 4

In test_AX, each combination also carries the suffix `_AX`; in test_B, this suffix is omitted (selector as `BOOL` data input instead of adapter socket) — see MyLib (test_B) → sys.



Summary



The background color blocks are based on a single, recurring concept (Boolean signal → color selection → `Q_BackgroundColour`) with many minor variations for different color pairs, object counts, and object ID conventions. Understanding one variation makes them all understandable—the individual pages simply list the specific parameters.

Bool8_TO_logiBUS_QXA8

• – ○ • – ○ • – ○ •

Introduction

The `Bool8_TO_logiBUS_QXA8` is a generic composite function block (subapplication) designed to convert eight Boolean input signals into eight digital output channels of a logiBUS system. It provides a flexible, adapter-based solution where each output channel can be freely assigned to any of the eight Boolean inputs via configuration parameters. All outputs are triggered simultaneously by a single event, ensuring synchronized updates across the entire group.

The block is particularly useful in control applications that require multiple digital outputs (e.g., relays, LEDs, solenoid valves) to be driven from a central logic controller, with the ability to remap outputs without changing the block's internal structure.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; starts the init chain at `DigitalOutput_Q4.INIT`.
- **CNF** (Event): Common trigger event. When this event arrives, all eight Boolean inputs are read and their corresponding digital outputs are updated in the same processing cycle.

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `DigitalOutput_Q3.INITO`, the end of the init chain.

Data Inputs

- **QI** (BOOL, initial value `TRUE`): quality input, enables the service; passed on to all eight `DigitalOutput_Qx.QI`.
- **Q_00** … **Q_07** (BOOL): These eight Boolean inputs carry the logic values that are to be written to the selected output channels.
- **Output_1** … **Output_8** (logiBUS::io::DQ::logiBUS_DO_S): Channel selectors. Each parameter identifies the physical output channel (e.g., "Output_Q1" … "Output_Q8") to which the associated Boolean input (Q_00 ⟶ Output_1, Q_01 ⟶ Output_2, …) is routed. The value must be a valid logiBUS output identifier; setting it to `logiBUS_DO::Invalid` disables that output.

Data Outputs

- **QO** (BOOL): quality output, AND combination (`AND_QO`, `AND_BOOL_8`) of the `QO` outputs of all eight `DigitalOutput_Qx`.

Adapters

- None exposed at the interface level. Adapter connections are internal to the subapplication, linking the Boolean conversion blocks to the output driver blocks.

Functionality

The subapplication internally instantiates eight pairs of function blocks:

- **AX_BOOL_TO_X_1** ... **AX_BOOL_TO_X_8** (type: adapter::conversion::unidirectional::AX_BOOL_TO_X): These convert each Boolean input into an adapter-compatible signal (unidirectional data plug).
- **DigitalOutput_Q1** ... **DigitalOutput_Q8** (type: logiBUS::io::DQ::logiBUS_QXA): These are the actual digital output driver blocks that communicate with the logiBUS hardware.

On each `CNF` event, all eight conversion blocks receive the event and simultaneously fetch their corresponding Boolean input values. Each converted value is then passed via an adapter connection to its associated digital output block. The digital output block uses the `Output_n` parameter to determine which physical channel to write to (or to ignore the value if the output is disabled).

Initialization and quality: `INIT` is chained through all eight `logiBUS_QXA` instances (`INIT` → `DigitalOutput_Q4` → `DigitalOutput_Q7` → `DigitalOutput_Q1` → `DigitalOutput_Q5` → `DigitalOutput_Q2` → `DigitalOutput_Q6` → `DigitalOutput_Q8` → `DigitalOutput_Q3`, each `INITO` → next `INIT`); `DigitalOutput_Q3.INITO` leads to `INITO` and `AND_QO.REQ`. `QI` is distributed to all eight `DigitalOutput_Qx.QI`; their `QO` outputs go to `AND_QO.IN1` to `AND_QO.IN8` (`iec61131::booleanOperators::AND_BOOL_8`), whose `OUT` forms the output `QO`.

Since all conversion blocks are triggered by the same event, the entire group of outputs is updated in a single, atomic operation, ensuring temporal consistency among the eight channels.

Technical Features

- **8-channel design**: Supports eight independent digital outputs.
- **Free channel mapping**: Each Boolean input can be routed to any available output channel using the `Output_n` parameters, allowing flexible reconfiguration without changing wiring.
- **Single-event triggering**: A common `CNF` event triggers all outputs simultaneously, simplifying synchronization and reducing event overhead.
- **Adapter-based conversion**: Utilizes unidirectional adapter conversions, promoting modularity and compatibility with various logiBUS output types.
- **Generic and reusable**: The block is designed generically for any 8-bit output group; it can be instantiated multiple times for different hardware configurations.

State Overview

This subapplication is combinational in nature; it does not maintain any internal state. Each activation of the `CNF` event directly maps the current Boolean inputs to the configured physical outputs. There is no feedback or memory function, and the block's behavior is completely deterministic based on the input values and channel selection parameters.

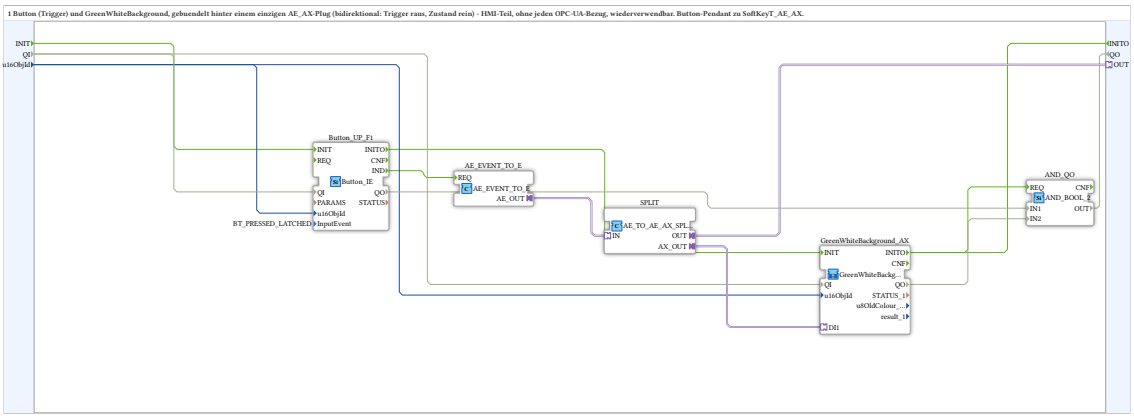
Application Scenarios

Typical use cases include:

- **Industrial control panels**: Driving eight relays or contactors from a PLC's logic, with the ability to assign each Boolean signal to a specific relay.
- **Lighting or LED groups**: Controlling multiple lamps individually via a central control system, where each lamp can be remapped to a different Boolean input as needed.
- **Factory automation**: Setting up quick-change output configurations for different manufacturing cells without modifying the underlying control logic.
- **Prototyping and testing**: Allowing developers to experiment with different output assignments in a simulation environment before deployment.

Comparison with Similar Blocks

The `Bool8_TO_logiBUS_QXA8` is the sister block of `MyLib::sys::Bool8_TO_logiBUS_QX8`. The main difference lies in the type of digital output driver used:

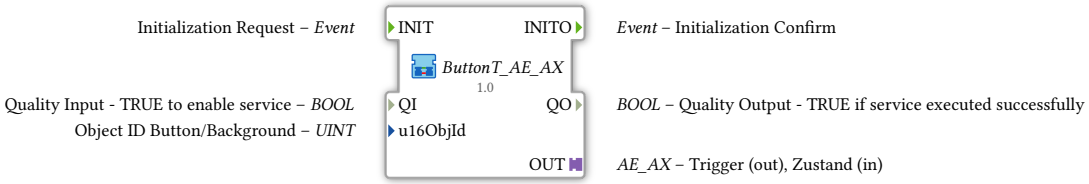


- **Bool8_TO_logiBUS_QX8** uses the `logiBUS_QX` block, which directly interfaces with logiBUS output modules without an adapter layer.
- **Bool8_TO_logiBUS_QXA8** uses the `logiBUS_QXA` block, which includes an adapter interface. This makes it more flexible when the hardware requires a specific adapter connection or when additional signal conditioning is needed.

Compared to other generic 8-output blocks, this subapplication offers the distinct advantage of per-output channel selection combined with a common trigger, whereas many simpler blocks either fix the output mapping or require separate events for each channel.

Conclusion

The `Bool8_TO_logiBUS_QXA8` subapplication provides a robust and flexible solution for driving eight digital outputs over a logiBUS network. Its design emphasizes modularity, ease of reconfiguration, and synchronized updates. By leveraging adapter-based conversions and a single trigger event, it simplifies complex output management tasks and can be seamlessly integrated into a wide range of industrial and automation projects. Its sister relationship with the `QXA`-free variant ensures that developers can choose the appropriate level of abstraction for their specific hardware requirements.



ButtonT_AE_AX

• – ○ • – ○ • – ○ •

Introduction

`ButtonT_AE_AX` bundles **one button (trigger)** and a `GreenWhiteBackground` behind a single bidirectional `AE_AX` plug (trigger out, state in). It is the pure HMI part without any OPC-UA reference and is reusable. The block is the button counterpart of `SoftKeyT_AE_AX`: `Softkey_IE` was replaced by `Button_IE`, `SK_RELEASED` by `BT_PRESSED_LATCHED`.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; goes to `Button_UP_F1.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirm; comes from `GreenWhiteBackground_AX.INITO`

Data Inputs

- **QI** (`BOOL`): quality input - TRUE enables the service (default `TRUE`); goes to `Button_UP_F1.QI` and `GreenWhiteBackground_AX.QI`
- **u16ObjId** (`UINT`): object ID of button/background (default `ID_NULL`)

Data Outputs

- **QO** (`BOOL`): quality output - TRUE if the service was executed successfully (AND of `Button_UP_F1.QO` and `GreenWhiteBackground_AX.QO`)

Adapters

- **OUT** (plug, `adapter::types::bidirectional::AE_AX`): trigger (out), state (in)

Function Blocks (FBs) Used

- **`Button_UP_F1`** (`isobus::UT::io::Button::Button_IE`): parameter `InputEvent` = `BT_PRESSED_LATCHED` (`QI` comes from outside)
- **`AE_EVENT_TO_E`** (`adapter::conversion::unidirectional::AE_EVENT_TO_E`): converts the button event into an `AE` adapter
- **`SPLIT`** (`adapter::events::bidirectional::AE_TO_AE_AX_SPLIT`): separates the bidirectional `AE_AX` plug into trigger direction and state direction
- **`GreenWhiteBackground_AX`** (SubApp `MyLib::sys::GreenWhiteBackground1_AX`): green/white background colour
- **`AND_QO`** (`iec61131::booleanOperators::AND_BOOL_2`): combines the `QO` of `Button_UP_F1` and `GreenWhiteBackground_AX`

Functionality

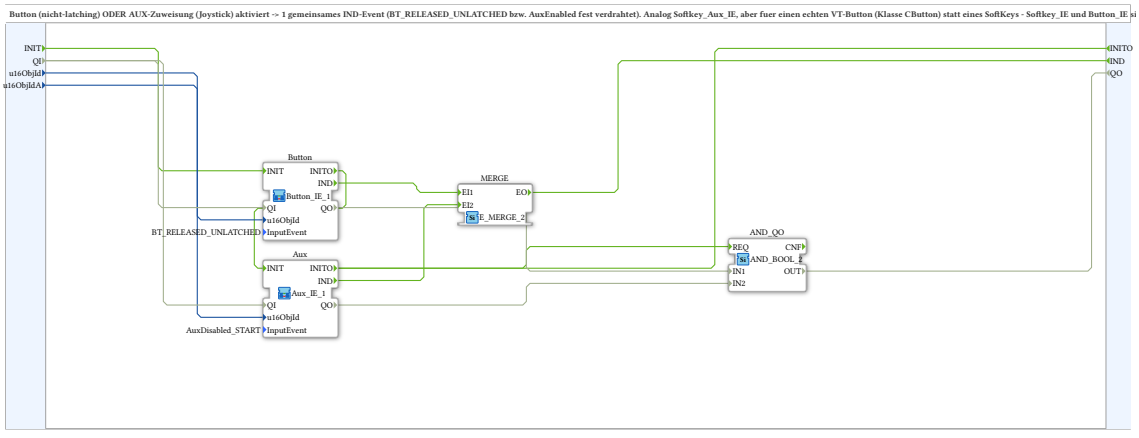
- `Button_UP_F1.IND` ⟶ `AE_EVENT_TO_E.REQ`
- `AE_EVENT_TO_E.AE_OUT` ⟶ `SPLIT.IN`
- `SPLIT.OUT` ⟶ `OUT` (trigger to the outside, state from the outside)
- `SPLIT.AX_OUT` ⟶ `GreenWhiteBackground_AX.DI1` (the state colours the background)
- `u16ObjId` ⟶ `Button_UP_F1.u16ObjId` and `GreenWhiteBackground_AX.u16ObjId`
- Initialization: `INIT` ⟶ `Button_UP_F1.INIT`, `Button_UP_F1.INITO` ⟶ `GreenWhiteBackground_AX.INIT`, `GreenWhiteBackground_AX.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`
- Quality: `QI` ⟶ `Button_UP_F1.QI` and `GreenWhiteBackground_AX.QI`; `Button_UP_F1.QO` ⟶ `AND_QO.IN1`, `GreenWhiteBackground_AX.QO` ⟶ `AND_QO.IN2`, `AND_QO.OUT` ⟶ `QO`

Technical Details

- The same object ID serves the button and the background colour
- `BT_PRESSED_LATCHED` instead of `SK_RELEASED` of the softkey counterpart
- No OPC-UA reference, so reusable in any scenario

Application Scenarios

- A button in the VT as a trigger whose state (e.g. from a toggle) is fed back as background colour, through a single `AE_AX` connection



Summary

`ButtonT_AE_AX` bundles button trigger and state colour behind one `AE_AX` plug.

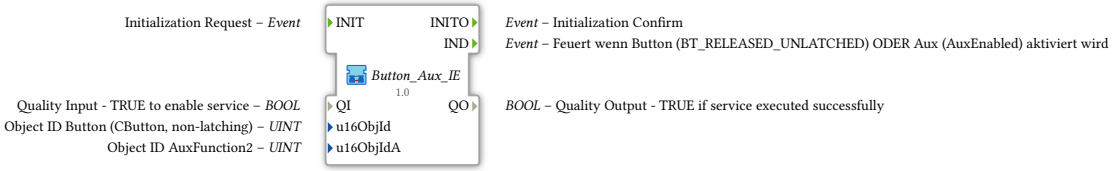
Button_Aux_IE



• — ○ • — ○ • — ○ •

Introduction

`Button_Aux_IE` combines a non-latching VT button **or** an AUX assignment (joystick) into one common `IND` event. The activation type is hard-wired (`BT_RELEASED_UNLATCHED` and `AuxEnabled` respectively). The block corresponds to `Softkey_Aux_IE`, but for a real VT button (class `CButton`) instead of a SoftKey: `Softkey_IE` and `Button_IE` are two separate FORTE service interface blocks for different VT activation messages; a button never delivers an `SK_PRESSED`.

The button **must** be non-latching (`Latchable=0` in the pool). A latching button can sensibly be read only via `Button_IXA` (continuous state/level), not via this event/`InputEvent` pattern.

Function Blocks (FBs) Used

Sub-blocks: Button_Aux_IE

- **Type**: SubAppType
- **Internal blocks used**:
  - **Button**: SubApp `Button_IE_1` with `InputEvent=BT_RELEASED_UNLATCHED`
  - **Aux**: SubApp `Aux_IE_1` with `InputEvent=AuxDisabled_START`
  - **MERGE**: `iec61499::events::E_MERGE_2` - merges both `IND` events
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` - combines `Button.QO` and `Aux.QO` into `QO`
- **Imports**: `BT_RELEASED_UNLATCHED` (`ButtonActivationCode`), `AuxDisabled_START` (`AuxiliaryState`)

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialisation request

Event Outputs

- **INITO** (`EInit`): initialisation confirmation
- **IND**: Fires when the button (`BT_RELEASED_UNLATCHED`) or the aux assignment (`AuxEnabled`) is activated

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service
- **u16ObjId** (`UINT`): Object ID of the button (`CButton`, non-latching)
- **u16ObjIdA** (`UINT`): Object ID of the `AuxFunction2`

Data Outputs

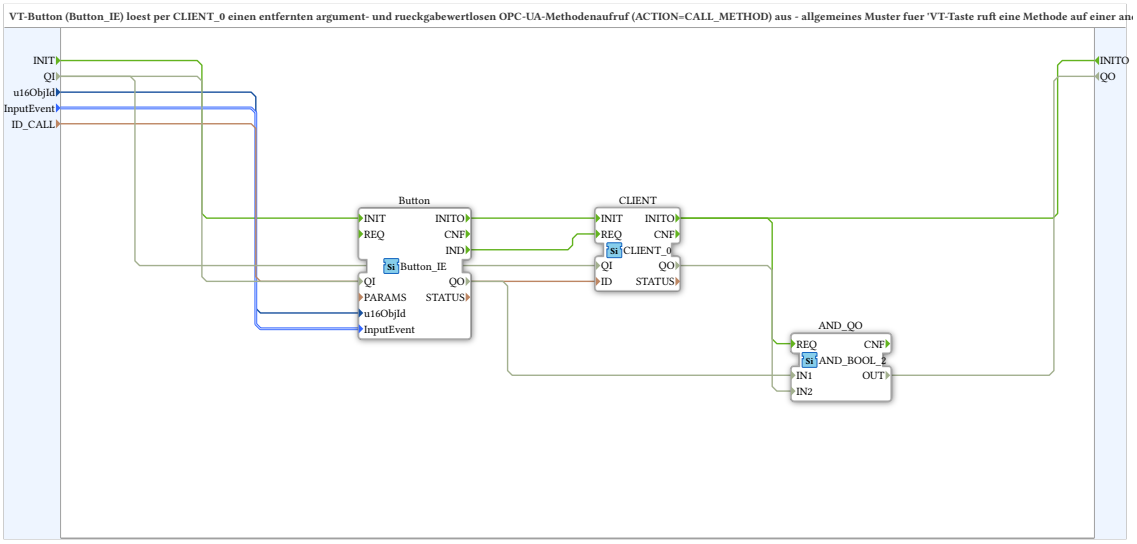
- **QO** (`BOOL`): Quality Output - AND of `Button.QO` and `Aux.QO`

Program Flow and Connections

- `u16ObjId` ⟶ `Button.u16ObjId`
- `u16ObjIdA` ⟶ `Aux.u16ObjId`
- `Button.IND` ⟶ `MERGE.EI1`
- `Aux.IND` ⟶ `MERGE.EI2`
- `MERGE.EO` ⟶ `IND`
- `INIT` ⟶ `Button.INIT`; `Button.INITO` ⟶ `Aux.INIT`; `Aux.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`)
- `QI` ⟶ `Button.QI` and `QI` ⟶ `Aux.QI`
- `Button.QO` ⟶ `AND_QO.IN1`; `Aux.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`

Technical Details

- Bugfix for `Automatik_Toggle_Button`: it previously used `Softkey_Aux_IE` with a button object ID, but `Softkey_IE` receives no button activation message (confirmed by the author of the FORTE implementation)
- The `E_MERGE_2` forwards the event whichever of the two sources fires
- Version 1.0 (2026-09-20)

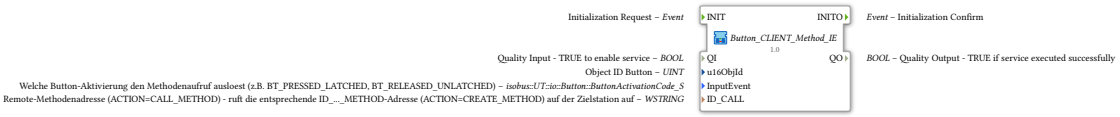


Application Scenarios

- A control element that is to be triggered either via a VT button or an AUX joystick input
- Toggle logic (e.g. `Automatik_Toggle_Button`) with two equivalent triggers

Summary

`Button_Aux_IE` combines `Button_IE_1` and `Aux_IE_1` via an `E_MERGE_2` into a single `IND` event for button and AUX.



Button_CLIENT_Method_IE

• — ○ • — ○ • — ○ •

Introduction

`Button_CLIENT_Method_IE` uses a VT button (`Button_IE`) to trigger, via `CLIENT_0`, a remote **OPC-UA method call** without arguments and return value (`ACTION=CALL_METHOD`). It is the general pattern "VT key calls a method on another station" and was extracted from `logiBUS_AI_Calibrated_Subscribe_VT_OPC`, where it occurred twice identically. Unlike `Button_Method_IE` (button OR local method → common `IND`), this is the reverse "caller" case: button → remote method.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirm

Data Inputs

- **QI** (`BOOL`, default `TRUE`): quality input, TRUE enables the service
- **u16ObjId** (`UINT`): Object ID of the button
- **InputEvent** (`isobus::UT::io::Button::ButtonActivationCode_S`): Which button activation triggers the method call (e.g. `BT_PRESSED_LATCHED`, `BT_RELEASED_UNLATCHED`)
- **ID_CALL** (`WSTRING`): Remote method address (`ACTION=CALL_METHOD`); calls the corresponding `ID_..._METHOD` address (`ACTION=CREATE_METHOD`) on the target station

Data Outputs

- **QO** (`BOOL`): quality output, AND combination (`AND_QO`) of the `QO` outputs of `Button` and `CLIENT`

Adapters

This function block uses no adapters.

Function Blocks (FBs) Used

- **Button**: `isobus::UT::io::Button::Button_IE` (`QI` from the wrapper input)
- **CLIENT**: `iec61499::net::CLIENT_0` (`QI` from the wrapper input)
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` - combines `Button.QO` and `CLIENT.QO` into `QO`

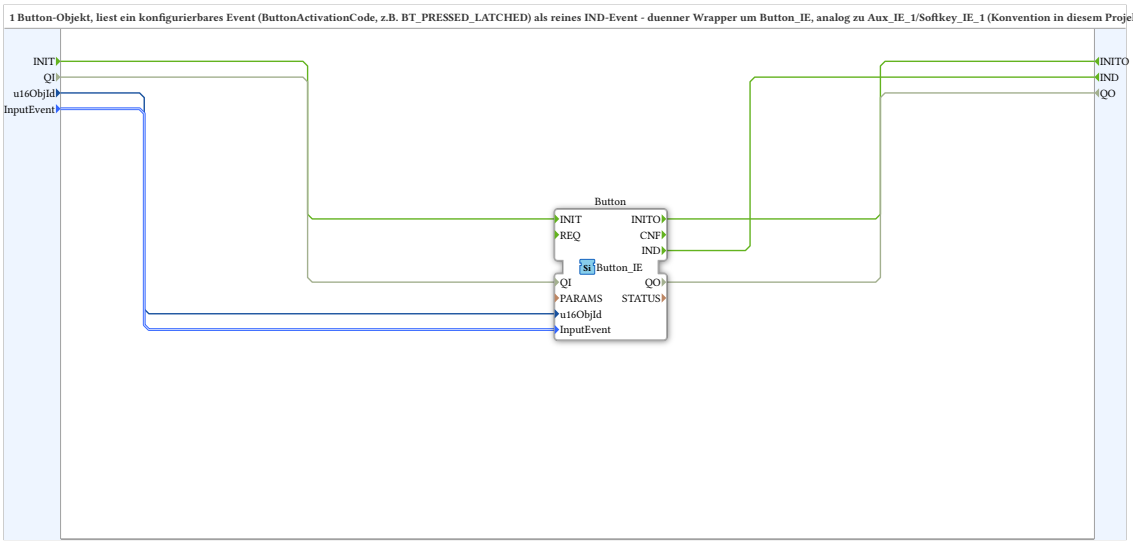
Program Flow and Connections

- `u16ObjId` ⟶ `Button.u16ObjId`; `InputEvent` ⟶ `Button.InputEvent`
- `Button.IND` ⟶ `CLIENT.REQ`
- `ID_CALL` ⟶ `CLIENT.ID`
- Initialization: `INIT` ⟶ `Button.INIT`; `Button.INITO` ⟶ `CLIENT.INIT`; `CLIENT.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`
- Quality: `QI` ⟶ `Button.QI` and `CLIENT.QI`; `Button.QO` ⟶ `AND_QO.IN1`; `CLIENT.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`

On every button activation matching `InputEvent`, the method call `CLIENT_0` is thus triggered.

Technical Details

- `InputEvent` is a parameter and not hard-coded to `BT_PRESSED_LATCHED`, so that other activation types (e.g. release) are reusable as well.
- The confirmation (`CNF`) of `CLIENT_0` is not exposed.

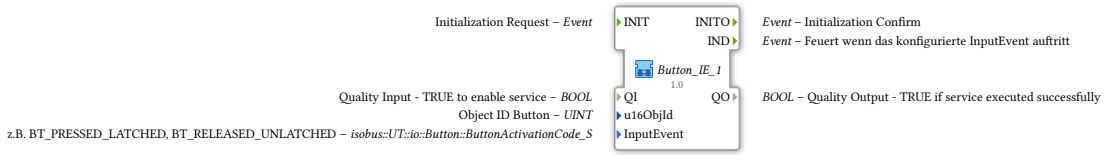


Application Scenarios

- VT key that calls a method on another station (e.g. calibration via OPC-UA)

Summary

`Button_CLIENT_Method_IE` is a small, generic pattern for calling a remote OPC-UA method via a VT key.



Button_IE_1

• – ◦ • – ◦ • – ◦ •

Introduction

`Button_IE_1` reads a button object and outputs a configurable event (`ButtonActivationCode`, e.g. `BT_PRESSED_LATCHED`) as a pure `IND` event. The block is a thin wrapper around `isobus::UT::io::Button::Button_IE`, analogous to `Aux_IE_1` and `Softkey_IE_1`. Convention in this project: the isobus IE blocks are never used raw inline but always wrapped.

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization Request

Event Outputs

- **INITO** (`EInit`): Initialization Confirm
- **IND**: fires when the configured `InputEvent` occurs

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE to enable the service
- **u16ObjId** (UINT): object ID of the button (default `ID_NULL`)
- **InputEvent** (`isobus::UT::io::Button::ButtonActivationCode_S`): e.g. `BT_PRESSED_LATCHED`, `BT_RELEASED_UNLATCHED` (default `Invalid`)

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service executed successfully (passed through from `Button.QO`)

Adapters

No adapters are used.

Functionality

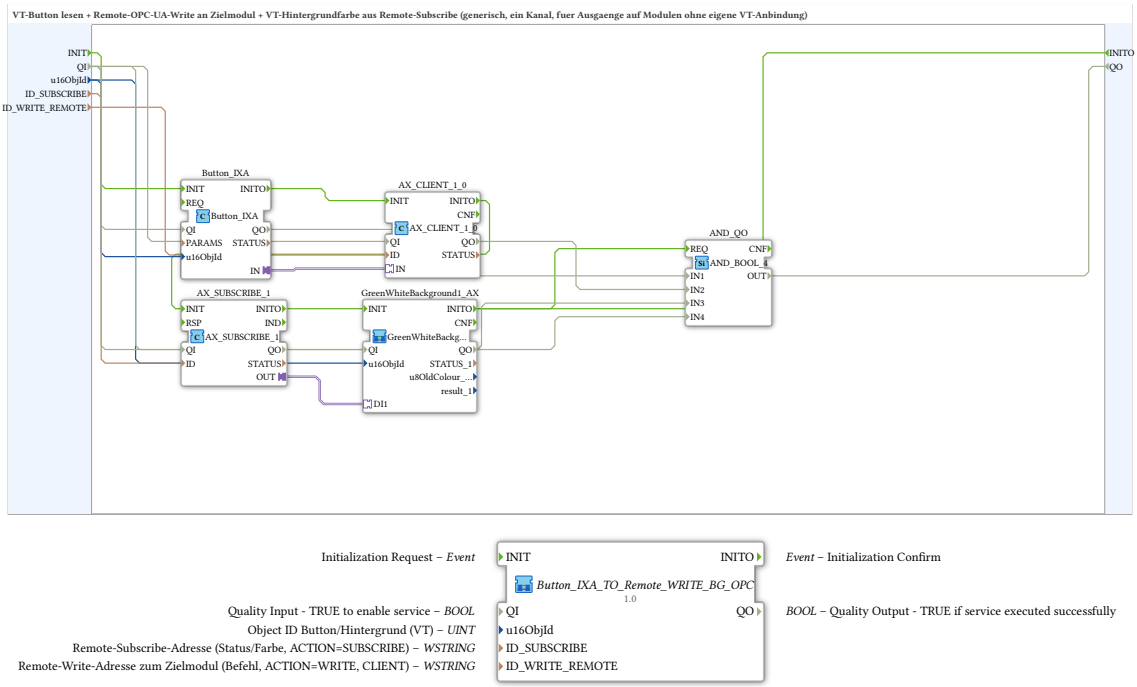
The network contains exactly one instance `Button` of type `isobus::UT::io::Button::Button_IE`. `u16ObjId`, `InputEvent` and `QI` are routed unchanged to the like-named inputs of the instance, `INIT` → `Button.INIT`; its events `IND` and `INITO` and its output `QO` are output directly as `IND`, `INITO` and `QO` of the SubApp.

Technical Details

- Pure pass-through without logic or state of its own
- `QI` is passed through from outside to the inner block (default `TRUE`)
- Because `InputEvent` is a parameter, the same SubApp can be used for different kinds of events (e.g. pressing or releasing)

Application Scenarios

- Reading a single VT operation as an event without using the raw IE block directly in the network



⚖️ Comparison with Similar Blocks

Equivalent wrappers are `Aux_IE_1` and `Softkey_IE_1` they differ only in the VT object type and in the enumeration type of `InputEvent`.

Conclusion

`Button_IE_1` is a minimal wrapper that provides a configurable button event as `IND`.

Button_IXA_TO_Remote_WRITE_BG_OPC

• – ○ • – ○ • – ○ •

Introduction

The **Button_IXA_TO_Remote_WRITE_BG_OPC** subapplication is a generic single-channel solution that combines three core functions:

- Reading a visual terminal (VT) button state via the `isobus::UT::io::Button::Button_IXA` function block.
- Writing the button state to a remote target module using an OPC-UA client adapter (`adapter::net::AX_CLIENT_1_0`).
- Updating a VT background colour based on a remote subscription (`adapter::net::AX_SUBSCRIBE_1`) that feeds a background-processing subapplication (`GreenWhiteBackground1_AX`).

It is intended for outputs on modules that do not have their own VT connection, allowing the VT button to both send commands and reflect remote status.

Interface Structure

The subapplication exposes the event input `INIT`, the event output `INITO`, the data inputs `QI`, `u16ObjId`, `ID_SUBSCRIBE` and `ID_WRITE_REMOTE`, and the data output `QO`; it has no external adapters. All internal communication is handled through data and adapter connections inside the subapplication.

Event Inputs

- `INIT` (EInit): initialization request; starts the chain `Button_IXA` ⟶ `AX_CLIENT_1_0` ⟶ `AX_SUBSCRIBE_1` ⟶ `GreenWhiteBackground1_AX`

Event Outputs

- `INITO` (EInit): initialization confirmation; comes from `GreenWhiteBackground1_AX.INITO`

Data Inputs

Name	Type	Initial Value	Comment
`QI`	BOOL	`TRUE`	Quality input, service enable
`u16ObjId`	UINT	`ID_NULL`	Object ID of the button and background (VT)

ID_SUBSCRIBE	WSTRING	–	Remote-subscribe address for status/colour (ACTION=SUBSCRIBE)
ID_WRITE_REMOTE	WSTRING	–	Remote-write address to the target module (ACTION=WRITE, CLIENT)

Data Outputs

Name	Type	Comment
QO	BOOL	Quality output, AND of the QO outputs of Button_IXA, AX_CLIENT_1_0, AX_SUBSCRIBE_1 and GreenWhiteBackground1_AX (via AND_QO)

Adapters

None at the subapplication interface level. Adapters are used internally for OPC-UA communication and subscription handling.

Functionality

The subapplication works as follows:

1. **Button Reading** – The Button_IXA block reads the state of a VT-associated button identified by u16ObjId. Its output is connected through an adapter to the OPC-UA client block.
2. **Remote Write** – The AX_CLIENT_1_0 block acts as an OPC-UA client. It receives the button state via an adapter connection from Button_IXA.IN and writes it to the remote address specified by ID_WRITE_REMOTE. This enables the button to control an output on a module without a direct VT link.
3. **Remote Subscribe** – The AX_SUBSCRIBE_1 block subscribes to a remote status/colour signal using the address given in ID_SUBSCRIBE. The subscribed data is passed via an adapter connection to the GreenWhiteBackground1_AX subapplication, which determines the appropriate VT background colour.
4. **Background Update** – The GreenWhiteBackground1_AX subapplication uses the received status (e.g., on/off, alarm) and the object ID to set the background colour of the same VT object that contains the button.

The data inputs u16ObjId, ID_SUBSCRIBE, ID_WRITE_REMOTE are distributed internally to the respective blocks, ensuring full decoupling between the button input, remote write, and remote subscribe paths.

1. **Initialization and Quality** – INIT → Button_IXA.INIT, Button_IXA.INITO → AX_CLIENT_1_0.INIT, AX_CLIENT_1_0.INITO → AX_SUBSCRIBE_1.INIT, AX_SUBSCRIBE_1.INITO → GreenWhiteBackground1_AX.INIT, GreenWhiteBackground1_AX.INITO → INITO and → AND_QO.REQ. QI goes to Button_IXA.QI, AX_CLIENT_1_0.QI, AX_SUBSCRIBE_1.QI and GreenWhiteBackground1_AX.QI; their four QO outputs feed AND_QO.IN1 to IN4 (iec61131::booleanOperators::AND_BOOL_4), and AND_QO.OUT drives QO.

Technical Features

- **Generic Design** – The subapplication is parameterised by three inputs, making it usable for any VT object, remote write target, and remote subscription source.
- **Integrated OPC-UA Client and Subscriber** – Employs AX_CLIENT_1_0 and AX_SUBSCRIBE_1 adapters, which provide standardised OPC-UA connectivity.
- **Built-in Button Handling** – Uses the Button_IXA block, which encapsulates VT button state detection.
- **Background Colour Logic** – Delegates colour computation to the reusable GreenWhiteBackground1_AX subapplication, promoting modularity.
- **Pass-through enable** – The internal function blocks are no longer fixed to QI = TRUE; they receive the subapplication input QI (initial value TRUE), and QO is the AND of all four internal QO outputs.
- **Input Types** – u16ObjId is a 16-bit unsigned integer, while the two address inputs are wide strings, accommodating full OPC-UA address strings.

State Overview

The subapplication does not maintain its own explicit state machine. Instead, its behaviour is driven by the states of the internal components:

- **Button State** – Determined by the Button_IXA block (pressed/released).

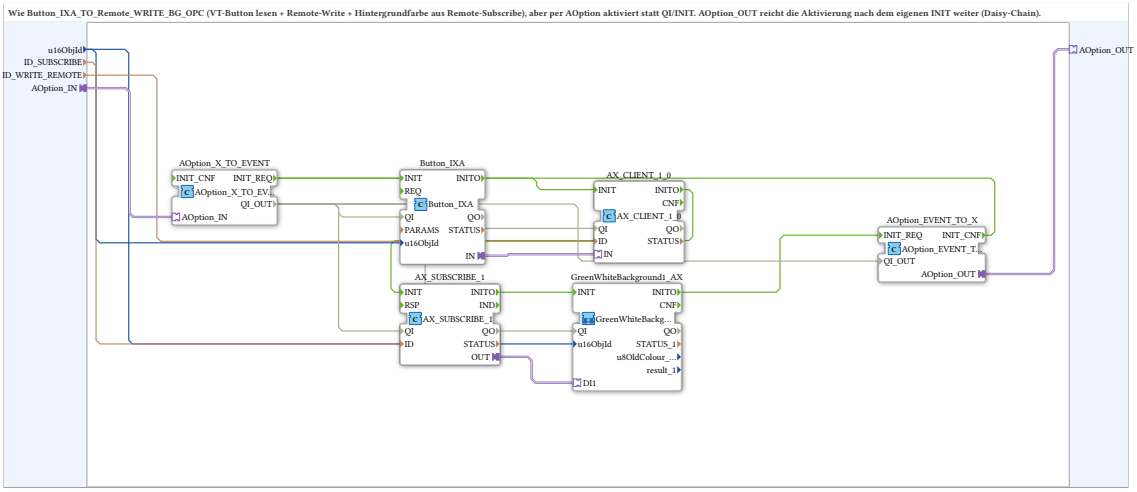
- **Remote Communication State** – The `AX_CLIENT_1_0` and `AX_SUBSCRIBE_1` blocks manage connection establishment, data transfer, and error handling.
- **Background Colour State** – Based on the subscribed value, the `GreenWhiteBackground1_AX` subapplication outputs a colour (e.g., green for running, white for idle, or red for alarm).

Because the logic is entirely distributed, the subapplication can be considered a stateless composition that reacts to its inputs and the current network conditions.

Application Scenarios

- **Remote Output Control without Local VT** – Use a VT pushbutton on a display panel to toggle an output on a remote I/O module that has no visual terminal of its own.
- **Status Indication via Colour** – Simultaneously, the same VT object's background changes colour (e.g., green = active, white = inactive) based on a subscription to the remote output's status.
- **Generic Single-Channel Expansion** – The subapplication can be duplicated for multiple channels, each with its own object ID, write address, and subscribe address, providing a scalable control panel.
- **Legacy Module Integration** – Modules that lack native VT binding can be controlled and monitored through OPC-UA while still being represented on a central VT screen.

Comparison with Similar Blocks



Compared to simpler button-to-remote-write blocks that only send the button state to a remote output, **Button_IXA_TO_Remote_WRITE_BG_OPC** adds the crucial background-colour subscription. This extra capability provides immediate visual feedback on the VT, eliminating the need for separate status polling.

In contrast to blocks that handle local output directly, this subapplication is specifically designed for remote destinations, offering OPC-UA connectivity out of the box. The inclusion of the `GreenWhiteBackground1_AX` subapplication also separates colour logic from communication logic, making the solution more maintainable than a monolithic block with hard-coded colour transitions.

Conclusion

The **Button_IXA_TO_Remote_WRITE_BG_OPC** subapplication provides a compact, reusable, and generic solution for controlling remote outputs via a VT button while visualising their status through a background colour. By combining an OPC-UA client for write operations, an OPC-UA subscriber for status updates, and a dedicated background-colour subapplication, it delivers a complete remote-control and status-indication package. Its simple interface (`INIT`/`INITO`, `QI`/`QO` and three data inputs) and clearly separated internal components make it easy to integrate into larger automation projects.

Button_IXA_TO_Remote_WRITE_BG_Option_OPC

• – ○ • – ○ • – ○ •

Introduction

`Button_IXA_TO_Remote_WRITE_BG_Option_OPC` reads a VT button, writes to a target module via remote OPC-UA write and sets the background colour from a remote subscribe - like `Button_IXA_TO_Remote_WRITE_BG_OPC`, but activated via `AOption` instead of `QI`/`INIT`. `AOption_OUT` passes

the activation on after its own `INIT` (daisy chain like `OptionalGroup_001a`). The block is a copy of `Button_IXA_TO_Remote_WRITE_BG_OPC` in which `INIT/INITO/QI/QO` were replaced by `AOption_IN` and `AOption_OUT`.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

Variable	Type	Default	Comment
`u16ObjId`	UINT	`ID_NULL`	Object ID button/background (VT).
`ID_SUBSCRIBE`	WSTRING		Remote subscribe address (status/colour, `ACTION=SUBSCRIBE`).
`ID_WRITE_REMOTE`	WSTRING		Remote write address to the target module (command, `ACTION=WRITE`, CLIENT).

Data Outputs

None.

Adapters

Adapter	Type	Direction	Comment
`AOption_IN`	`Option::AOption`	Socket	Drives `INIT/QI`; connect to `AOption_AUI_DEMUX_N.OUTx` or the `AOption_OUT` of an upstream instance.
`AOption_OUT`	`Option::AOption`	Plug	Passes the activation on to the next link after its own INIT (daisy chain); must be connected, end of chain e.g. `DummyGroup`.

Function Blocks (FBs) Used

- **AOption_X_TO_EVENT** (`Option::conversion::AOption_X_TO_EVENT`): converts the option into `INIT_REQ/QI_OUT` and accepts `INIT_CNF`
- **Button_IXA** (`isobus::UT::io::Button::Button_IXA`): reads the VT button
- **AX_CLIENT_1_0** (`adapter::net::AX_CLIENT_1_0`): remote write to the target module
- **AX_SUBSCRIBE_1** (`adapter::net::AX_SUBSCRIBE_1`): remote subscribe of status/colour
- **GreenWhiteBackground1_AX** (SubApp `MyLib::sys::GreenWhiteBackground1_AX`): background colour; see `GreenWhiteBackground1_AX`
- **AOption_EVENT_TO_X** (`Option::conversion::AOption_EVENT_TO_X`): passes the activation on to `AOption_OUT`

Program Flow and Connections

1. Initialization chain: `AOption_X_TO_EVENT.INIT_REQ -> Button_IXA.INIT; Button_IXA.INITO -> AX_CLIENT_1_0.INIT; AX_CLIENT_1_0.INITO -> AX_SUBSCRIBE_1.INIT; AX_SUBSCRIBE_1.INITO -> GreenWhiteBackground1_AX.INIT; GreenWhiteBackground1_AX.INITO -> AOption_EVENT_TO_X.INIT_REQ; AOption_EVENT_TO_X.INIT_CNF -> AOption_X_TO_EVENT.INIT_CNF.`
2. Qualifier: `AOption_X_TO_EVENT.QI_OUT -> Button_IXA.QI, AX_CLIENT_1_0.QI, AX_SUBSCRIBE_1.QI, GreenWhiteBackground1_AX.QI` and `AOption_EVENT_TO_X.QI_OUT`.

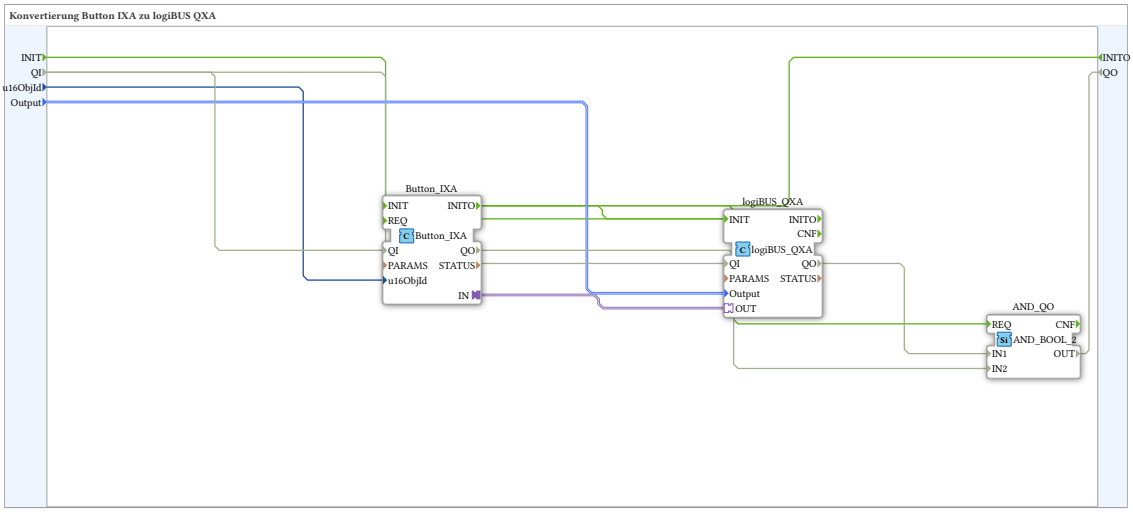
3. Option: `AOption_IN -> AOption_X_TO_EVENT.AOption_IN; AOption_EVENT_TO_X.AOption_OUT -> AOption_OUT`.
4. Command: `Button_IXA.IN -> AX_CLIENT_1_0.IN`.
5. Status: `AX_SUBSCRIBE_1.OUT -> GreenWhiteBackground1_AX.DI1`.
6. Data: `u16ObjId -> Button_IXA.u16ObjId` and `GreenWhiteBackground1_AX.u16ObjId`; `ID_WRITE_REMOTE -> AX_CLIENT_1_0.ID`; `ID_SUBSCRIBE -> AX_SUBSCRIBE_1.ID`.

Technical Features

- The block has no event or `QI`/`QO` connections of its own; activation and acknowledgment run exclusively via `AOption_IN`/`AOption_OUT`.
- `AOption_OUT` must be connected onward (e.g. `DummyGroup` as end of chain), otherwise no `INIT_CNF` is returned.

Application Scenarios

- Optional operator station with a VT button for a remote actuator including coloured status display, active only when the option is selected.
- Several instances sharing the same option, chained via `AOption_OUT`.



Summary

`Button_IXA_TO_Remote_WRITE_BG_Option_OPC` bundles VT button, remote write and background colour from remote subscribe behind an `AOption` socket and passes the activation on via `AOption_OUT`.

Button_IXA_TO_logiBUS_QXA

• — ○ • — ○ • — ○ •

Introduction

`Button_IXA_TO_logiBUS_QXA` connects a VT button (`Button_IXA`) directly to a physical digital output (`logiBUS_QXA`) — the simplest form of a VT-switchable output, with no status display and no OPC-UA. For the variant with a VT status color, see `Button_IXA_TO_logiBUS_QXA_BG`.

Function Blocks (FBs) Used

Sub-blocks: Button_IXA_TO_logiBUS_QXA

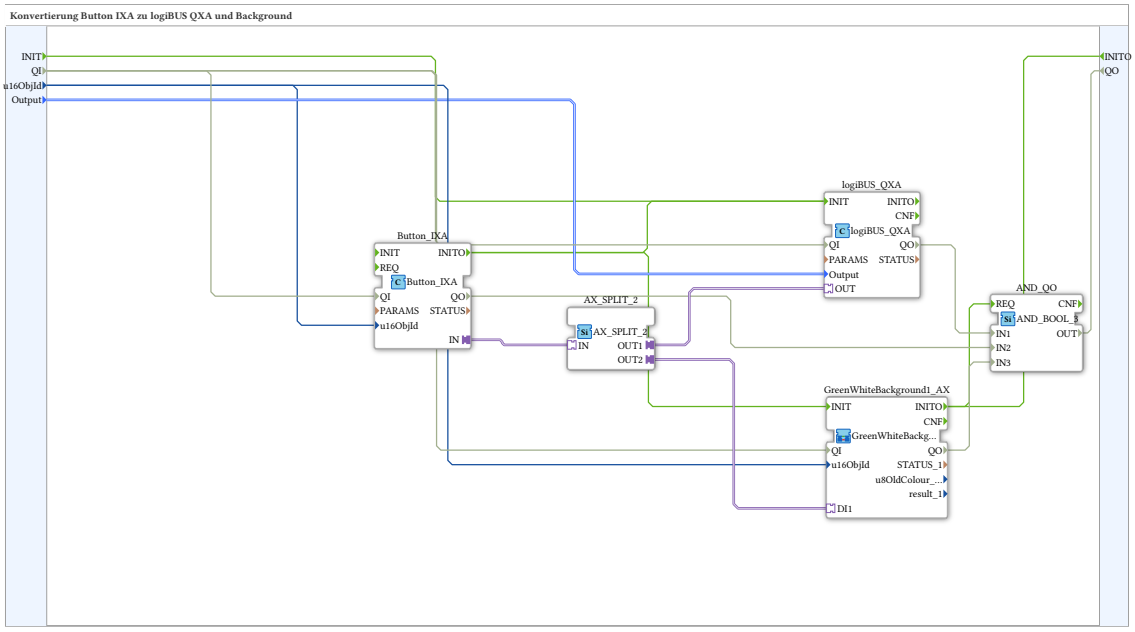
- **Type**: SubAppType
- **Internal FBs used**:
  - **Button_IXA**: `isobus::UT::io::Button::Button_IXA` — VT button adapter, `QI` comes from the input `QI`, `u16ObjId` identifies the VT button.
  - **logiBUS_QXA**: `logiBUS::io::DQ::logiBUS_QXA` — physical digital output, `QI` comes from the input `QI`.
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` — combines `logiBUS_QXA.QO` and `Button_IXA.QO` into the output `QO`.
- **Functionality**: The button's adapter output is wired directly to the physical output's adapter input — no intermediate logic. In addition, the SubApp has the interface `INIT`/`INITO` (events) and `QI`/`QO` (BOOL): `INIT` starts the init chain, `QI` (initial value `TRUE`) is passed on to both FBs, `QO` is the AND combination of their `QO` outputs.

Program Flow and Connections

1. `u16ObjId` ⟶ `Button_IXA.u16ObjId`; `Output` ⟶ `logiBUS_QXA.Output`.
2. `Button_IXA.IN` (adapter) ⟶ `logiBUS_QXA.OUT` (adapter) — direct pass-through.
3. `INIT` ⟶ `logiBUS_QXA.INIT`; `logiBUS_QXA.INITO` ⟶ `Button_IXA.INIT`; `Button_IXA.INITO` ⟶ `INITO` and `AND_QO.REQ`.
4. `QI` ⟶ `logiBUS_QXA.QI` and `Button_IXA.QI`.
5. `logiBUS_QXA.QO` ⟶ `AND_QO.IN1`; `Button_IXA.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.

Application Scenarios

- Minimal VT-button-to-output block for exercises that don't yet need a status display or remote control.



Summary

The simplest block variant in this family: a VT button wired directly to a physical output, with no additional function.

Button_IXA_TO_logiBUS_QXA_BG

• – ○ • – ○ • – ○ •

Introduction

`Button_IXA_TO_logiBUS_QXA_BG` extends `Button_IXA_TO_logiBUS_QXA` with a VT status color: the button state not only switches the physical output but also the button's own background color (green/white). The OPC-UA-capable follow-up is `Button_IXA_TO_logiBUS_QXA_BG_OPC`.

Function Blocks (FBs) Used

Sub-blocks: Button_IXA_TO_logiBUS_QXA_BG

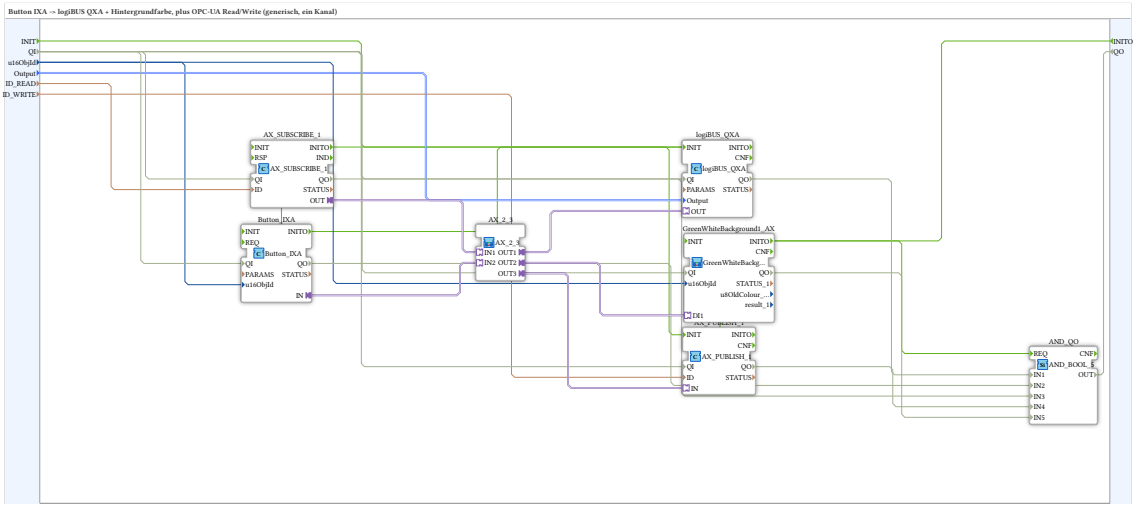
- **Type**: SubAppType
- **Internal FBs used**:
  - **Button_IXA**: `isobus::UT::io::Button::Button_IXA` — VT button adapter.
  - **logiBUS_QXA**: `logiBUS::io::DQ::logiBUS_QXA` — physical digital output.
  - **AX_SPLIT_2**: `adapter::events::unidirectional::AX_SPLIT_2` — splits the button signal.
  - **GreenWhiteBackground1_AX** (SubApp, `MyLib::sys`): sets the VT background color to match the state (see Background Color Blocks).
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_3` — combines the `QO` of `logiBUS_QXA`, `Button_IXA` and `GreenWhiteBackground1_AX`.
- **Functionality**: `Button_IXA.IN` is distributed via `AX_SPLIT_2` to both `logiBUS_QXA.OUT` (physical output) and `GreenWhiteBackground1_AX.DI1` (status color).

Program Flow and Connections

1. `u16ObjId` ⟶ `Button_IXA.u16ObjId` and `GreenWhiteBackground1_AX.u16ObjId`; `Output` ⟶ `logiBUS_QXA.Output`.
2. `Button_IXA.IN` ⟶ `AX_SPLIT_2.IN` ⟶ `AX_SPLIT_2.OUT1` ⟶ `logiBUS_QXA.OUT`, `AX_SPLIT_2.OUT2` ⟶ `GreenWhiteBackground1_AX.DI1`.
3. Initialization: event input `INIT` ⟶ `logiBUS_QXA.INIT`, `logiBUS_QXA.INITO` ⟶ `Button_IXA.INIT`, `Button_IXA.INITO` ⟶ `GreenWhiteBackground1_AX.INIT`, `GreenWhiteBackground1_AX.INITO` ⟶ event output `INITO` and ⟶ `AND_QO.REQ`.
4. Quality: data input `QI` (`BOOL`, default `TRUE`) ⟶ `logiBUS_QXA.QI`, `Button_IXA.QI` and `GreenWhiteBackground1_AX.QI`; `logiBUS_QXA.QO` ⟶ `AND_QO.IN1`, `Button_IXA.QO` ⟶ `AND_QO.IN2`, `GreenWhiteBackground1_AX.QO` ⟶ `AND_QO.IN3`, `AND_QO.OUT` ⟶ data output `QO`.

Application Scenarios

- VT button with direct visual feedback (status color) but no OPC-UA remote control.



Summary

Adds a VT status color to the simple button-to-output wiring — the precursor to the OPC-UA-capable variant.

Button_IXA_TO_logiBUS_QXA_BG_OPC

• – ○ • – ○ • – ○ •

Introduction

`Button_IXA_TO_logiBUS_QXA_BG_OPC` is the reusable block for **a single digital output** that can be switched both via a VT button and via OPC-UA (web client) — including a VT status display. It is instantiated 12 times with different parameters in `InputOutputTesterButton_DIDO_OPC_UA`.

Function Blocks (FBs) Used

Sub-blocks: Button_IXA_TO_logiBUS_QXA_BG_OPC

- **Type**: SubAppType
- **Interface (additional)**: event input `INIT`, event output `INITO` (each `EInit`), data input `QI` (`BOOL`, default `TRUE`), data output `QO` (`BOOL`).
- **Internal FBs used**:
  - **Button_IXA**: `isobus::UT::io::Button::Button_IXA` — VT button, `u16ObjId` identifies the VT button. Since version 1.2 temporarily **non-latching** (momentary level, no click toggle any more).
  - **AX_2_3**: SubApp `AX_2_3` — combines `IN1` (OPC-UA subscribe) and `IN2` (VT button) with `AX_OR_2` into one common level and distributes it with `AX_SPLIT_3` to three destinations (`OUT1`..`OUT3`).
  - **logiBUS_QXA**: `logiBUS::io::DQ::logiBUS_QXA` — physical digital output.
  - **GreenWhiteBackground1_AX** (SubApp, `MyLib::sys`): VT background color matching the output state.
  - **AX_SUBSCRIBE_1** / **AX_PUBLISH_1**: `adapter::net::AX_SUBSCRIBE_1/AX_PUBLISH_1` — OPC-UA read/write access.
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_5` — combines the `QO` outputs of `logiBUS_QXA`, `Button_IXA`, `AX_SUBSCRIBE_1`, `AX_PUBLISH_1` and `GreenWhiteBackground1_AX` into the `QO` of the SubApp.
- **Functionality**: Two independent switching sources (VT button, OPC-UA write) are ORed in `AX_2_3`; the resulting level simultaneously feeds the physical output, the VT status color, and the OPC-UA echo.

Program Flow and Connections

1. **VT button path**: `Button_IXA.IN` (adapter) ⟶ `AX_2_3.IN2`.
2. **OPC-UA path**: `AX_SUBSCRIBE_1.OUT` (adapter, web write) ⟶ `AX_2_3.IN1`.

3. **Shared state**: `AX_2_3.OUT1` ⟶ `logiBUS_QXA.OUT` (physical output), `AX_2_3.OUT2` ⟶ `GreenWhiteBackground1_AX.DI1` (VT status color), `AX_2_3.OUT3` ⟶ `AX_PUBLISH_1.IN` (OPC-UA echo to the web client).
4. **Initialization chain**: `INIT` ⟶ `logiBUS_QXA.INIT` ⟶ `Button_IXA.INIT` ⟶ `AX_SUBSCRIBE_1.INIT`; `AX_SUBSCRIBE_1.INITO` ⟶ `AX_PUBLISH_1.INIT` (hidden connection) — ensures the publish adapter is only initialized after the subscribe adapter is ready; `AX_PUBLISH_1.INITO` ⟶ `GreenWhiteBackground1_AX.INIT`; `GreenWhiteBackground1_AX.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`).
5. **Parameters**: `u16ObjId` ⟶ `Button_IXA.u16ObjId` and `GreenWhiteBackground1_AX.u16ObjId`; `Output` ⟶ `logiBUS_QXA.Output`; `ID_READ` ⟶ `AX_SUBSCRIBE_1.ID`; `ID_WRITE` ⟶ `AX_PUBLISH_1.ID`.
6. **Quality**: `QI` ⟶ `.QI` of `logiBUS_QXA`, `Button_IXA`, `AX_SUBSCRIBE_1`, `AX_PUBLISH_1` and `GreenWhiteBackground1_AX`; their `QO` outputs ⟶ `AND_QO.IN1..IN5`; `AND_QO.OUT` ⟶ `QO`. The instances are no longer hard-wired to `QI=TRUE` but are enabled via the `QI` of the SubApp.

Technical Details

- **Momentary level instead of click toggle**: Since version 1.2 a simple `AX_OR_2` (inside `AX_2_3`) replaces the former SR latch (`AX_ASR_RF_TRIG` × 2 + `ASR_MERGE_2` + `ASR_AX_SR`). VT button **and** remote command are therefore momentary (level); the output follows the OR of both sources. The variant with edge detection and latch is `Button_IXA_TO_logiBUS_QXA_BG_OPC_LATCHING`.
- **Separate OPC-UA keys**: `ID_READ` (subscribe key, writable) and `ID_WRITE` (publish key, readable) are separate parameters; the echo path (`AX_PUBLISH_1`) writes the ORed level, `AX_SUBSCRIBE_1` only reads the web client's write access.
- **`AX_SUBSCRIBE_1`'s `RSP` event is a no-op**: verified in FORTE source (`CCommFB::sendData()`, `commfb.cpp`) — for the *Subscriber* service type, the `RSP` branch is a complete no-op; the `INIT`/`RSP` event pair only exists because `CCommFB` is the shared base class for all "responder"-style service FBs (e.g. `SERVER`, where `RSP` does trigger something real).
- **Boot order**: `AX_SUBSCRIBE_1.INITO` triggers `AX_PUBLISH_1.INIT` to avoid race conditions at deployment (compare the same pattern in the PWM example's `RampLimitFS_TO_logiBUS_QDA_PWM_OPC`).

Application Scenarios

- Any digital output that needs to be switchable in momentary mode both locally (VT button) and remotely (web/OPC-UA), with VT status color and OPC-UA echo.

Comparison with Similar Function Blocks

Compared to its input counterpart `logiBUS_IXA_BG_OPC`, this block adds the second write source (OPC-UA subscribe), which is ORed with the VT button via `AX_2_3`. The latching variant with edge detection and latch is `Button_IXA_TO_logiBUS_QXA_BG_OPC_LATCHING`.

Summary

`Button_IXA_TO_logiBUS_QXA_BG_OPC` connects a digital output bidirectionally with OPC-UA: VT button and web command are ORed in `AX_2_3` and the level is distributed to hardware, VT display, and OPC-UA echo; `INIT`/`INITO` are chained through the services, `QO` is the AND of the services.

Button_IXA_TO_logiBUS_QXA_BG_OPC_LATCHING

• — ○ • — ○ • — ○ •

Introduction

`Button_IXA_TO_logiBUS_QXA_BG_OPC_LATCHING` replaces the simple OR gate (`AX_OR_2`) of `Button_IXA_TO_logiBUS_QXA_BG_OPC` with an edge-detection/merge/latch chain (`AX_ASR_RF_TRIG` × 2, `ASR_MERGE_2`, `ASR_AX_SR`). This is **not** a true click-toggle: `AX_ASR_RF_TRIG` maps the rising edge (press) to `SET` and the falling edge (release) to `RESET`, so with only one source active the block behaves exactly like the momentary `AX_OR_2` variant (ON only while held). The difference only shows up once the VT button and the OPC UA command overlap in time: unlike a true OR gate (which stays ON as long as either source is active), the last edge to arrive always wins here, regardless of which source it came from — e.g. if the OPC UA side sends a release while the VT button is still held, the output switches OFF immediately anyway. The block is retained for use cases that need exactly this last-wins behavior between two sources. Both function blocks share the same interface (`u16ObjId`/`Output`/`ID_READ`/`ID_WRITE`) and are interface-compatible — their switching behavior differs only in this overlap case.

Function Blocks (FBs) Used

Sub-Blocks: Button_IXA_TO_logiBUS_QXA_BG_OPC_LATCHING

- **Type**: SubAppType
- **Interface (additional)**: event input `INIT`, event output `INITO` (each `EInit`), data input `QI` (`BOOL`, default `TRUE`), data output `QO` (`BOOL`).
- **Internal FBs Used**:
- **Button_IXA**: `isobus::UT::io::Button::Button_IXA` (`QI` from the wrapper input) — VT button, `u16ObjId` identifies the VT button.
- **AX_ASR_RF_TRIG_BT** / **AX_ASR_RF_TRIG_OPC**: each `adapter::events::unidirectional::AX_ASR_RF_TRIG` — convert the rising/falling edge of the VT button or the OPC UA subscribe value into a Set/Reset event pair (ASR).
- **ASR_MERGE_2**: `adapter::events::unidirectional::ASR_MERGE_2` — combines the two ASR sources (button, OPC UA).
- **ASR_AX_SR**: `adapter::events::unidirectional::ASR_AX_SR` — Set/Reset latch that creates the latched output state (last wins) from the combined ASR signal.
- **AX_SPLIT_3**: `adapter::events::unidirectional::AX_SPLIT_3` — distributes the latch output to three destinations.
- **logiBUS_QXA**: `logiBUS::io::DQ::logiBUS_QXA` (`QI` from the wrapper input) — Physical digital output.

- **GreenWhiteBackground1_AX** (SubApp, `MyLib::sys`): VT background color matching the output state.
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_5` — combines the `QO` outputs of `logiBUS_QXA`, `Button_IXA`, `AX_SUBSCRIBE_1`, `AX_PUBLISH_1` and `GreenWhiteBackground1_AX` into `QO`.
- **AX_SUBSCRIBE_1** / **AX_PUBLISH_1**: each `adapter::net::AX_SUBSCRIBE_1/AX_PUBLISH_1` (`QI` from the wrapper input) — OPC UA read/write access.

Functionality: Both switching sources (VT button, OPC UA command) are each converted into set/reset events via `AX_ASR_RF_TRIG`, combined via `ASR_MERGE_2`, and latched in `ASR_AX_SR` — the latch state simultaneously powers the hardware, the VT status color, and the OPC UA echo.

Program Flow and Connections

1. `Button_IXA.IN` (adapter) ⟶ `AX_ASR_RF_TRIG_BT.QI` ⟶ `AX_ASR_RF_TRIG_BT.Q` ⟶ `ASR_MERGE_2.IN2`.
2. `AX_SUBSCRIBE_1.OUT` ⟶ `AX_ASR_RF_TRIG_OPC.QI` ⟶ `AX_ASR_RF_TRIG_OPC.Q` ⟶ `ASR_MERGE_2.IN1`
3. `ASR_MERGE_2.OUT` ⟶ `ASR_AX_SR.S_R` (Set/Reset input of the latch).
4. `ASR_AX_SR.Q` ⟶ `AX_SPLIT_3.IN` ⟶ `AX_SPLIT_3.OUT1` ⟶ `logiBUS_QXA.OUT`, `AX_SPLIT_3.OUT2` ⟶ `GreenWhiteBackground1_AX.DI1`, `AX_SPLIT_3.OUT3` ⟶ `AX_PUBLISH_1.IN`.
5. Initialization: `AX_SUBSCRIBE_1.INITO` ⟶ `AX_PUBLISH_1.INIT` (hidden connection). The chain runs in from the outside: `INIT` ⟶ `logiBUS_QXA.INIT`; `logiBUS_QXA.INITO` ⟶ `Button_IXA.INIT`; `Button_IXA.INITO` ⟶ `AX_SUBSCRIBE_1.INIT`; `AX_PUBLISH_1.INITO` ⟶ `GreenWhiteBackground1_AX.INIT`; `GreenWhiteBackground1_AX.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`.
6. Parameters: `u16ObjId` ⟶ `Button_IXA.u16ObjId` and `GreenWhiteBackground1_AX.u16ObjId`; `Output` ⟶ `logiBUS_QXA.Output`; `ID_READ` ⟶ `AX_SUBSCRIBE_1.ID`; `ID_WRITE` ⟶ `AX_PUBLISH_1.ID`.
7. Quality: `QI` ⟶ `.QI` of `logiBUS_QXA`, `Button_IXA`, `AX_SUBSCRIBE_1`, `AX_PUBLISH_1` and `GreenWhiteBackground1_AX`; their `QO` ⟶ `AND_QO.IN1` to `AND_QO.IN5` (in that order); `AND_QO.OUT` ⟶ `QO`.

Technical Features

- **Last-wins via ASR latch, not a real toggle**: Each actuation produces a set (press) or reset (release) event per source; `ASR_AX_SR` latches the combined result. With only one source active, the behavior is purely momentary (ON only while held) — identical to the `AX_OR_2` variant. The difference only shows up once both sources overlap: whichever edge (set or reset, from either source) arrives last determines the state, rather than a continuous OR.
- **Two independent last-wins sources**: The VT button and the OPC UA command each independently deliver set/reset events; `ASR_MERGE_2` combines both into a common latch input without prioritizing either source.
- **Interface-compatible external interface**: The interface is identical to `Button_IXA_TO_logiBUS_QXA_BG_OPC`, so both variants can be instantiated interchangeably. The switching behavior is only identical with a single active source — with overlapping use of both sources it differs (last-wins vs. a true OR gate).

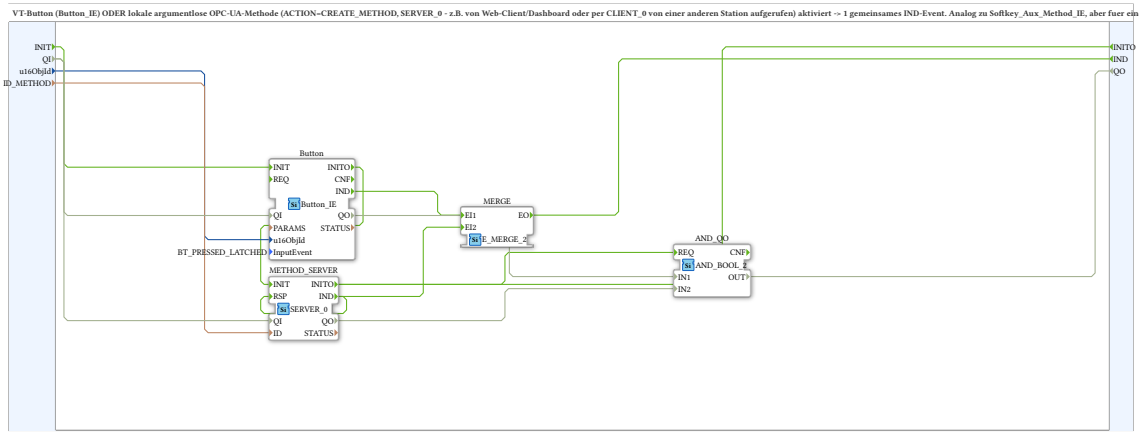
Application Scenarios

- Outputs with two independent switching sources (e.g. a local VT button AND a remote OPC UA command) where whichever action arrives last (press or release, from either source) should win, instead of one permanently active source blocking the other — which is exactly what a true OR gate would do.

Comparison with Similar Modules

Compared to `Button_IXA_TO_logiBUS_QXA_BG_OPC` (currently: tactile `AX_OR_2`), this module replaces the simple OR operation with an edge-detection/merge/latch chain (`AX_ASR_RF_TRIG` × 2, `ASR_MERGE_2`, `ASR_AX_SR`). With only one source active the behavior is identical (momentary); the difference only shows up once both sources overlap (last-wins instead of OR).

Summary



With only one source active, `Button_IXA_TO_logiBUS_QXA_BG_OPC_LATCHING` offers the same momentary basic functionality as `Button_IXA_TO_logiBUS_QXA_BG_OPC` — the difference is last-wins behavior for

overlapping VT/OPC UA commands, not a click-toggle. Both blocks are interface-compatible, but not behaviorally identical in every scenario.

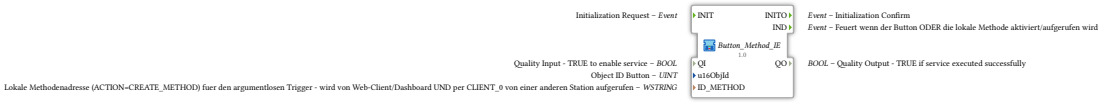
- 🌐 Eclipse 4diac IDE & Color Reference on ms-muc-docs.de



Button_Method_IE

• ─ ○ • ─ ○ • ─ ○ •

Introduction

`Button_Method_IE` raises a common `IND` event when either a **VT button** (`Button_IE`) is activated or a **local argument-less OPC-UA method** (`ACTION=CREATE_METHOD`, `SERVER_0`) is called, e.g. by the web client/dashboard or via `CLIENT_0` from another station. The block is analogous to `Softkey_Aux_Method_IE`, but for a regular VT button instead of SoftKey/AUX. It was extracted from `logiBUS_AI_Calibrate_IDA_OPC`, where the combination (CO/CS) occurred twice identically.

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization Request

Event Outputs

- **INITO** (`EInit`): Initialization Confirm
- **IND**: fires when the button **or** the local method is activated/called

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE to enable the service
- **u16ObjId** (`UINT`): object ID of the button
- **ID_METHOD** (`WSTRING`): local method address (`ACTION=CREATE_METHOD`) for the argument-less trigger; called by the web client/dashboard and via `CLIENT_0` from another station

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service executed successfully (AND of `Button.QO` and `METHOD_SERVER.QO`)

Adapters

None.

Function Blocks (FBs) Used

- **`Button`** (`isobus::UT::io::Button::Button_IE`): parameter `InputEvent = BT_PRESSED_LATCHED`, `QI` from the block input
- **`METHOD_SERVER`** (`iec61499::net::SERVER_0`): `QI` from the block input, provides the local method
- **`MERGE`** (`iec61499::events::E_MERGE_2`): merges both triggers
- **`AND_QO`** (`iec61131::booleanOperators::AND_BOOL_2`): ANDs `Button.QO` and `METHOD_SERVER.QO` into `QO`

Functionality

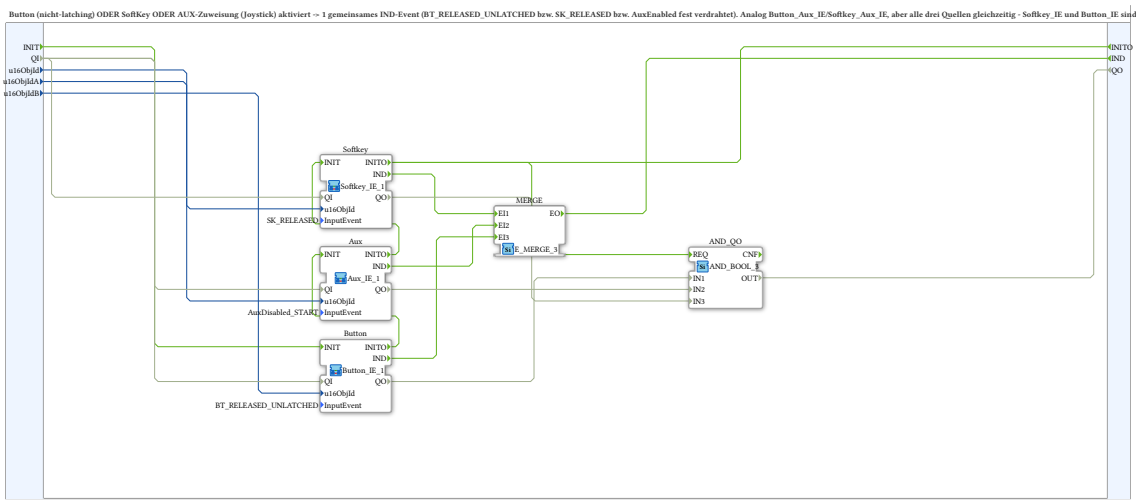
- `u16ObjId` ⟶ `Button.u16ObjId`; `ID_METHOD` ⟶ `METHOD_SERVER.ID`
- `Button.IND` ⟶ `MERGE.EI1`
- `METHOD_SERVER.IND` ⟶ `MERGE.EI2`
- `METHOD_SERVER.IND` ⟶ `METHOD_SERVER.RSP` (immediate response)
- `MERGE.EO` ⟶ `IND`
- Initialization chain: `INIT` ⟶ `Button.INIT`, `Button.INITO` ⟶ `METHOD_SERVER.INIT`, `METHOD_SERVER.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`
- `QI` ⟶ `Button.QI` and `METHOD_SERVER.QI`
- `Button.QO` ⟶ `AND_QO.IN1`, `METHOD_SERVER.QO` ⟶ `AND_QO.IN2`, `AND_QO.OUT` ⟶ `QO`

Technical Details

- **`RSP` must be wired back to `IND`.** The trigger is argument-less and needs no processing. Without the loop-back, FORTE's `onServerMethodCall` blocks the OPC-UA server thread for up to 4 s and meanwhile holds open62541's global `serviceMutex`, which every `AX_PUBLISH_1` on another FORTE thread also needs (see `Ventilsteuerung/OPC_UA_VERNETZUNG.md`, item 12).
- `BT_PRESSED_LATCHED` as the button event (latched press/release)

Application Scenarios

- A button that should additionally be triggered via web client, OPC dashboard or from another station (e.g. a calibration trigger)



Summary

`Button_Method_IE` combines a VT button and a local OPC-UA method into one common `IND` event.

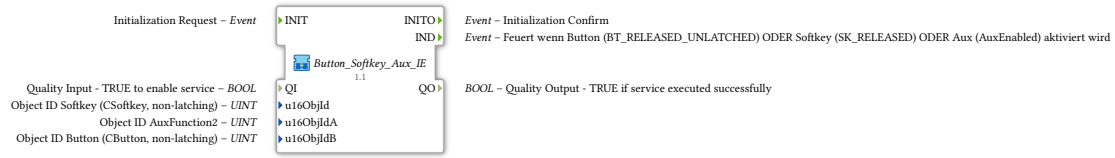
Button_Softkey_Aux_IE



• – ○ • – ○ • – ○ •

Introduction

`Button_Softkey_Aux_IE` combines a non-latching VT button **or** a SoftKey **or** an AUX assignment (joystick) into one common `IND` event. The activation types are hard-wired (`BT_RELEASED_UNLATCHED`, `SK_RELEASED` and `AuxEnabled` respectively). The block corresponds to `Button_Aux_IE` and `Softkey_Aux_IE`, but serves all three sources at once. `Softkey_IE` and `Button_IE` are separate FORTE service interface blocks for different VT activation messages; a button never delivers an `SK_PRESSED`.

The button **must** be non-latching (`Latchable=0` in the pool); a latching button can sensibly be read only via `Button_IXA` (level).

Function Blocks (FBs) Used

Sub-blocks: Button_Softkey_Aux_IE

- **Type**: SubAppType
- **Internal blocks used**:
  - **Button**: SubApp `Button_IE_1` with `InputEvent=BT_RELEASED_UNLATCHED`
  - **Softkey**: SubApp `Softkey_IE_1` with `InputEvent=SK_RELEASED`
  - **Aux**: SubApp `Aux_IE_1` with `InputEvent=AuxDisabled_START`
  - **MERGE**: `iec61499::events::E_MERGE_3` - merges the three `IND` events
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_3` - combines the `QO` outputs of `Button`, `Aux` and `Softkey` into the SubApp output `QO`
- **Imports**: `BT_RELEASED_UNLATCHED`, `AuxDisabled_START`, `SK_RELEASED`

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; starts the chain `Button` ⟶ `Aux` ⟶ `Softkey`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `Softkey.INITO`
- **IND**: Fires when a button (`BT_RELEASED_UNLATCHED`), softkey (`SK_RELEASED`) or aux (`AuxEnabled`) is activated

Data Inputs

- **QI** (`BOOL`): quality input, service enable (initial value `TRUE`); passed on to `Button.QI`, `Aux.QI` and `Softkey.QI`
- **u16ObjId** (`UINT`): Object ID of the softkey (`CSoftkey`, non-latching)
- **u16ObjIdA** (`UINT`): Object ID of the `AuxFunction2`
- **u16ObjIdB** (`UINT`): Object ID of the button (`CButton`, non-latching)

Data Outputs

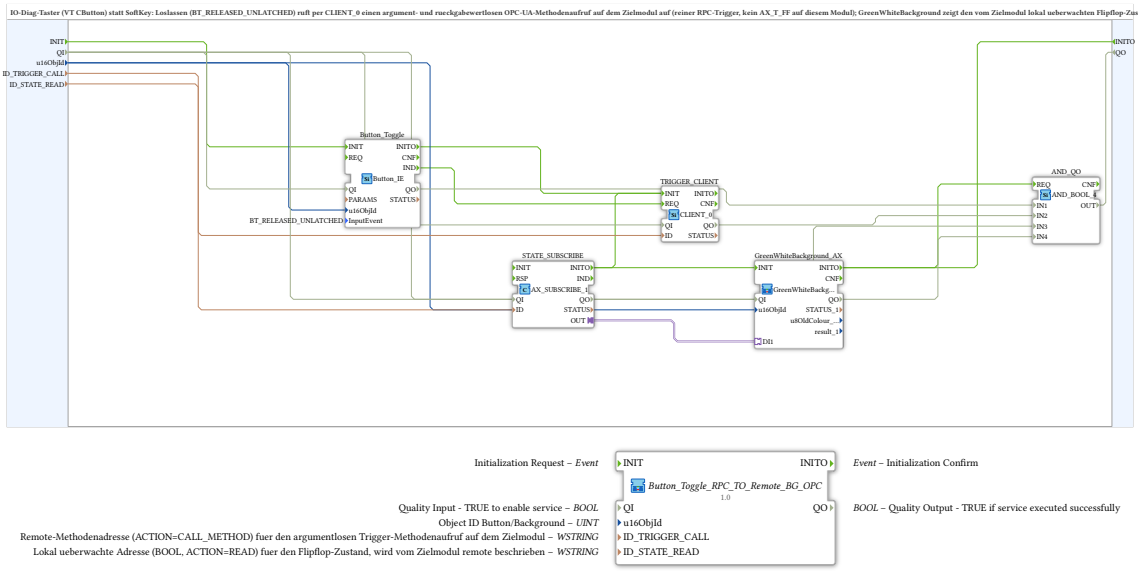
- **QO** (`BOOL`): quality output, `AND` of the `QO` outputs of `Button`, `Aux` and `Softkey` (via `AND_QO`)

Program Flow and Connections

- `u16ObjId` ⟶ `Softkey.u16ObjId`; `Softkey.IND` ⟶ `MERGE.EI1`
- `u16ObjIdA` ⟶ `Aux.u16ObjId`; `Aux.IND` ⟶ `MERGE.EI2`
- `u16ObjIdB` ⟶ `Button.u16ObjId`; `Button.IND` ⟶ `MERGE.EI3`
- `MERGE.EO` ⟶ `IND`
- Initialization: `INIT` ⟶ `Button.INIT`; `Button.INITO` ⟶ `Aux.INIT`; `Aux.INITO` ⟶ `Softkey.INIT`; `Softkey.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`
- Quality: `QI` ⟶ `Button.QI`, `Aux.QI` and `Softkey.QI`; `Button.QO` ⟶ `AND_QO.IN1`, `Aux.QO` ⟶ `AND_QO.IN2`, `Softkey.QO` ⟶ `AND_QO.IN3`; `AND_QO.OUT` ⟶ `QO`

Technical Details

- Version 1.1 (2026-09-29): `packageName` typo fixed (`MyLib_AX::sys` → `MyLib::sys`), instance `Softkey_IE_1` renamed to `Softkey`, comment corrected (it described only 2 of 3 sources)
- Version 1.0 (2026-09-20): bugfix for `Automatik_Toggle_Button`, which previously used `Softkey_Aux_IE` with a button object ID



Application Scenarios

- A control element that can be triggered via a button, a SoftKey or an AUX input

Summary

`Button_Softkey_Aux_IE` bundles `Button_IE_1`, `Softkey_IE_1` and `Aux_IE_1` via an `E_MERGE_3` into a single `IND` event.

Button_Toggle_RPC_TO_Remote_BG_OPC

• — ○ • — ○ • — ○ •

Introduction

The **Button_Toggle_RPC_TO_Remote_BG_OPC** subapplication implements a remote toggle control for IO-Diag buttons on a machine operator panel. When the operator releases the button (activation code `BT_RELEASED_UNLATCHED`), the subapp initiates an argument-less and return-value-less OPC-UA method call on a remote target module via a `CLIENT_0` communication function block. The remote flip-flop state is continuously monitored through a subscription and visually represented by a GreenWhiteBackground indicator. The subapp is designed for IO-Diag DataMask buttons (e.g. VT CButton) and follows the same protocol as its softkey counterpart, differing only in the button input type.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; starts the init chain at `Button_Toggle.INIT`.

The actual event handling is still performed internally by the embedded function blocks.

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `GreenWhiteBackground_AX.INITO`, the end of the init chain.

There are no other event outputs.

Data Inputs

Name	Type	Description

QI	BOOL	Quality input (initial value TRUE), enables the service; passed on to Button_Toggle, TRIGGER_CLIENT, STATE_SUBSCRIBE and GreenWhiteBackground_AX.
u16ObjId	UINT	Object ID for the button and the visual background element. Initial value is ID_NULL.
ID_TRIGGER_CALL	WSTRING	Remote method address (with ACTION=CALL_METHOD) used for the argument-less trigger method invocation on the target module.
ID_STATE_READ	WSTRING	Locally monitored address (BOOL, with ACTION=READ) for the flip-flop state, which is written remotely by the target module.

Data Outputs

- **QO** (BOOL): quality output, AND combination (AND_QO, AND_BOOL_4) of the QO outputs of Button_Toggle, TRIGGER_CLIENT, STATE_SUBSCRIBE and GreenWhiteBackground_AX.

Adapters

None exposed at the subapplication interface. Adapter connections are entirely internal.

Functionality

The subapplication provides a complete remote toggle workflow in a single reusable package:

1. **Button Input Handling** – The embedded Button_IE function block (type isobus::UT::io::Button::Button_IE) is configured with InputEvent=BT_RELEASED_UNLATCHED (its QI comes from the block input QI). It detects the physical button release on the IO-Diag mask and generates an event on its IND output.
2. **Remote Trigger Invocation** – The button release event (Button_Toggle.IND) is connected to the REQ input of the TRIGGER_CLIENT function block (type iec61499::net::CLIENT_0). TRIGGER_CLIENT uses the address provided via ID_TRIGGER_CALL to perform an OPC-UA CALL_METHOD operation on the remote target module. Since the call is argument-less and return-value-less, it acts purely as an RPC trigger – no local flip-flop (AX_T_FF) logic is executed on this module.
3. **State Subscription** – The STATE_SUBSCRIBE function block (type adapter::net::AX_SUBSCRIBE_1) continuously reads the remote boolean state from the address specified by ID_STATE_READ (with ACTION=READ). Its output adapter is connected to the DI1 input of the GreenWhiteBackground_AX subapplication.
4. **Visual Feedback** – The GreenWhiteBackground_AX subapplication (type MyLib::sys::GreenWhiteBackground1_AX) receives the remote flip-flop state and renders it as a green or white background on the associated IO-Diag element, giving the operator immediate visual confirmation of the remote toggle state.
5. **Initialization and Quality** – INIT → Button_Toggle.INIT, Button_Toggle.INITO → TRIGGER_CLIENT.INIT, TRIGGER_CLIENT.INITO → STATE_SUBSCRIBE.INIT, STATE_SUBSCRIBE.INITO → GreenWhiteBackground_AX.INIT, GreenWhiteBackground_AX.INITO → INITO and AND_QO.REQ. QI is passed on to all four blocks; their QO outputs (Button_Toggle, TRIGGER_CLIENT, STATE_SUBSCRIBE, GreenWhiteBackground_AX) go to AND_QO.IN1 to AND_QO.IN4 (iec61131::booleanOperators::AND_BOOL_4), whose OUT forms the output QO.

The u16ObjId input is distributed internally to both the button (Button_Toggle.u16ObjId) and the background (GreenWhiteBackground_AX.u16ObjId), ensuring that both the input element and the visual indicator reference the same object instance.

Technical Features

- **IEC 61499-2 compliant** subapplication type with a cleanly encapsulated networking layer.
- **OPC-UA remote method invocation** via iec61499::net::CLIENT_0 with CALL_METHOD action, supporting argument-less, return-value-less calls (pure RPC trigger).
- **Subscription-based state monitoring** using adapter::net::AX_SUBSCRIBE_1 for continuous polling of the remote boolean state.

- **Activation code configuration** – the button is preconfigured with `BT_RELEASED_UNLATCHED`, meaning the trigger is fired on the release transition (unlatched), preventing repeated triggers while the button is held.
- **Unified object identification** – a single `u16ObjId` parameter links both the button and the background visualization to the same target object.
- **Hidden internal connections** – all internal data connections are marked as non-visible, keeping the subapplication interface clean and focused on the three essential configuration inputs.
- **Standard library components** – uses standard 4diac function blocks and adapters, facilitating maintenance and reuse.

State Overview

The subapplication itself is stateless – it delegates all stateful behavior to its internal blocks. The logical state flow can be described as follows:

Stage	Component	Behavior
Idle	`Button_IE`	Waits for the physical button to be released; no event is generated while the button is pressed or held.
Trigger	`Button_Toggle.IND`	Fires on the release transition (`BT_RELEASED_UNLATCHED`). The event is forwarded to `TRIGGER_CLIENT.REQ`.
Remote Call	`TRIGGER_CLIENT`	Executes the OPC-UA `CALL_METHOD` on the target module using `ID_TRIGGER_CALL`. The remote module toggles its internal flip-flop state.
State Read	`STATE_SUBSCRIBE`	Continuously reads the remote boolean value from `ID_STATE_READ` and forwards it through the adapter to the background visualization.
Visualization	`GreenWhiteBackground_AX`	Displays the current remote state: green when active, white when inactive.

There is no internal state machine in the subapp; the behavior is fully event-driven and data-driven by the remote system.

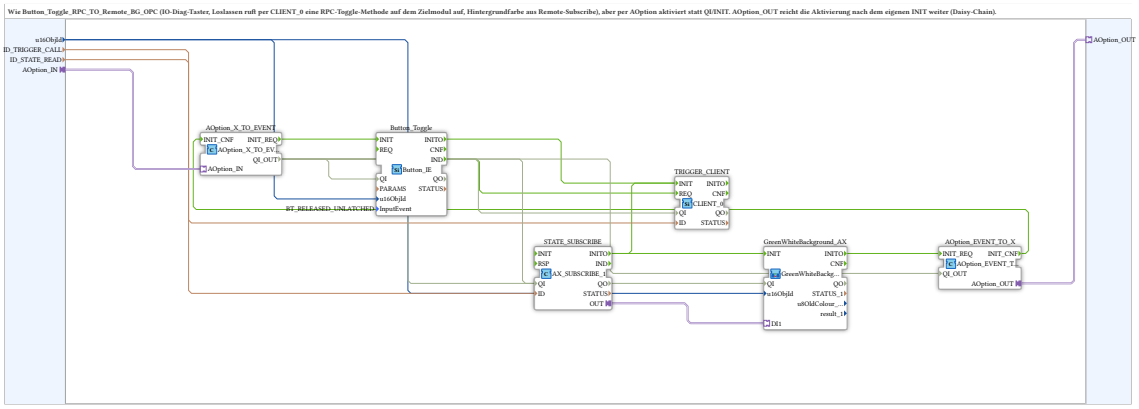
Application Scenarios

- **IO-Diag control panels** – Used on data masks with physical buttons (VT CButton) to toggle remote functions such as record enable/release on camera modules (e.g. Q06/Q08 left/right recording toggle).
- **Remote machine control** – Where operator panel buttons need to trigger actions on distributed PLC or edge modules via OPC-UA without embedding complex logic in the panel itself.
- **Visual state feedback** – Ideal when the operator needs immediate confirmation of a remote toggle state through a colored background indicator (green/white) on the same IO-Diag element.
- **Reusable RPC trigger pattern** – Suitable for any scenario where a button press should issue a remote method call and the result should be visualized locally, following a standard 4diac pattern.

Comparison with Similar Blocks

The main counterpart is the **Softkey_Toggle_RPC_TO_Remote_BG_OPC** subapplication, which follows an identical protocol and internal architecture. The key differences are:

Aspect	Button_Toggle_RPC_TO_Remote_BG_OPC	Softkey_Toggle_RPC_TO_Remote_BG_OPC
Input element	`Button_IE` (IO-Diag button / VT CButton)	Softkey (`Softkey_IE`)
Activation code	`BT_RELEASED_UNLATCHED` (release-triggered)	Softkey-specific activation logic
Use case	Physical buttons on an IO-Diag Data-Mask	Softkeys on a SoftKeyMask
Protocol & RPC	Identical (CLIENT_0, CALL_METHOD)	Identical



State visualization	Identical (GreenWhiteBackground)	Identical

Both variants share the same networking, subscription, and visualization mechanics, making them interchangeable from a protocol perspective – only the input front-end differs.

Conclusion

The **Button_Toggle_RPC_TO_Remote_BG_OPC** subapplication provides a robust, reusable solution for remote toggle control via OPC-UA RPC calls, triggered by physical IO-Diag buttons. It separates the button input handling from the remote communication and visualization logic, keeping the subapplication interface minimal (three configuration inputs plus `QI`) while encapsulating all complex networking inside. Its design follows the IEC 61499 standard and integrates seamlessly with standard 4diac library components, making it suitable for a wide range of industrial operator panel scenarios where a button press must toggle a remote state and provide immediate visual feedback.

Button_Toggle_RPC_TO_Remote_BG_Option_OPC

• – ○ • – ○ • – ○ •

Introduction

`Button_Toggle_RPC_TO_Remote_BG_Option_OPC` is an IO diagnostic button: on release it calls an RPC toggle method on the target module via `CLIENT_0`, and the background colour comes from a remote subscribe. The block corresponds to `Button_Toggle_RPC_TO_Remote_BG_OPC`, but is activated via `AOption` instead of `QI/INIT`. `AOption_OUT` passes the activation on after its own `INIT` (daisy chain like `OptionalGroup_001a`). It is a copy of `Button_Toggle_RPC_TO_Remote_BG_OPC` in which `INIT/INITO/QI/QO` were replaced by `AOption_IN` and `AOption_OUT`.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

Variable	Type	Default	Comment
`u16ObjId`	UINT	`ID_NULL`	Object ID button/background.
`ID_TRIGGER_CALL`	WSTRING		Remote method address (`ACTION=CALL_METHOD`) for the argument-less trigger method call on the target module.

ID_STATE_READ	WSTRING		Locally monitored address (BOOL, ACTION=READ) for the flip-flop state; written remotely by the target module.

Data Outputs

None.

Adapters

Adapter	Type	Direction	Comment
AOption_IN	Option::AOption	Socket	Drives INIT/QI; connect to AOption_AUI_DEMUX_N.OUTx or the AOption_OUT of an upstream instance.
AOption_OUT	Option::AOption	Plug	Passes the activation on to the next link after its own INIT (daisy chain); must be connected, end of chain e.g. DummyGroup.

Function Blocks (FBs) Used

- **AOption_X_TO_EVENT** (Option::conversion::AOption_X_TO_EVENT): converts the option into INIT_REQ/QI_OUT and accepts INIT_CNF
- **Button_Toggle** (isobus::UT::io::Button::Button_IE, InputEvent = BT_RELEASED_UNLATCHED): VT button, event on release
- **TRIGGER_CLIENT** (iec61499::net::CLIENT_0): calls the method on the target module
- **STATE_SUBSCRIBE** (adapter::net::AX_SUBSCRIBE_1): remote subscribe of the state
- **GreenWhiteBackground_AX** (SubApp MyLib::sys::GreenWhiteBackground1_AX): background colour; see GreenWhiteBackground1_AX
- **AOption_EVENT_TO_X** (Option::conversion::AOption_EVENT_TO_X): passes the activation on to AOption_OUT

Program Flow and Connections

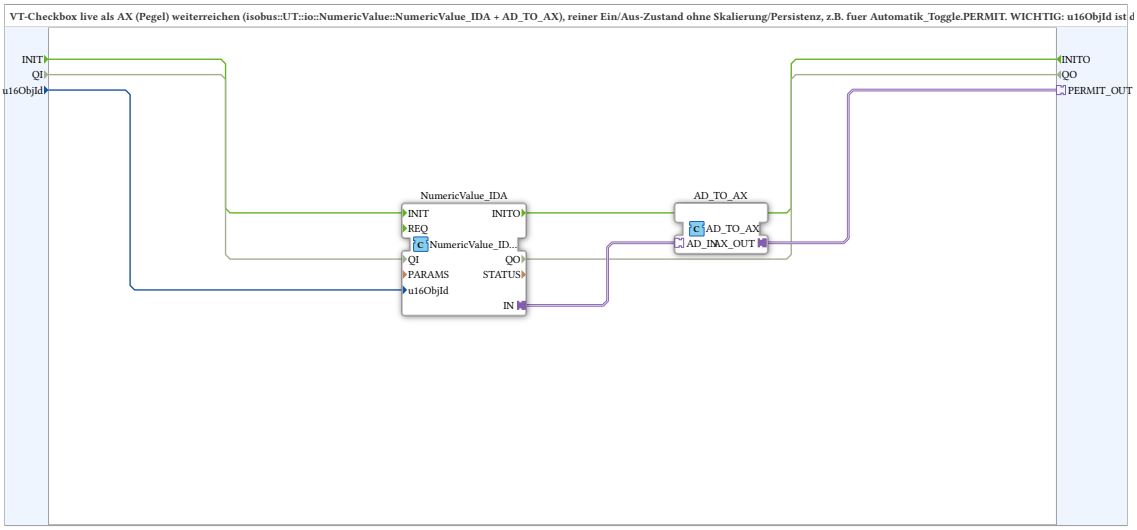
1. Initialization chain: AOption_X_TO_EVENT.INIT_REQ -> Button_Toggle.INIT; Button_Toggle.INITO -> TRIGGER_CLIENT.INIT; TRIGGER_CLIENT.INITO -> STATE_SUBSCRIBE.INIT; STATE_SUBSCRIBE.INITO -> GreenWhiteBackground_AX.INIT; GreenWhiteBackground_AX.INITO -> AOption_EVENT_TO_X.INIT_REQ; AOption_EVENT_TO_X.INIT_CNF -> AOption_X_TO_EVENT.INIT_CNF.
2. Method call: Button_Toggle.IND -> TRIGGER_CLIENT.REQ.
3. Qualifier: AOption_X_TO_EVENT.QI_OUT -> Button_Toggle.QI, TRIGGER_CLIENT.QI, STATE_SUBSCRIBE.QI, GreenWhiteBackground_AX.QI and AOption_EVENT_TO_X.QI_OUT.
4. Option: AOption_IN -> AOption_X_TO_EVENT.AOption_IN; AOption_EVENT_TO_X.AOption_OUT -> AOption_OUT.
5. Status: STATE_SUBSCRIBE.OUT -> GreenWhiteBackground_AX.DI1.
6. Data: u16ObjId -> Button_Toggle.u16ObjId and GreenWhiteBackground_AX.u16ObjId; ID_TRIGGER_CALL -> TRIGGER_CLIENT.ID; ID_STATE_READ -> STATE_SUBSCRIBE.ID.

Technical Features

- The block has no event or QI/QO connections of its own; activation and acknowledgment run exclusively via AOption_IN/AOption_OUT.
- AOption_OUT must be connected onward (e.g. DummyGroup as end of chain), otherwise no INIT_CNF is returned.
- The state is not computed here but delivered remotely by the target module.

Application Scenarios

- Optional diagnostic button that triggers an output toggle on a remote module and shows its state in colour, active only when the option is selected.
- Several instances sharing the same option, chained via AOption_OUT.



Summary

Button_Toggle_RPC_TO_Remote_BG_Option_OPC triggers a remote method call on release, shows the remotely delivered state as background colour and is activated and chained via AOption.

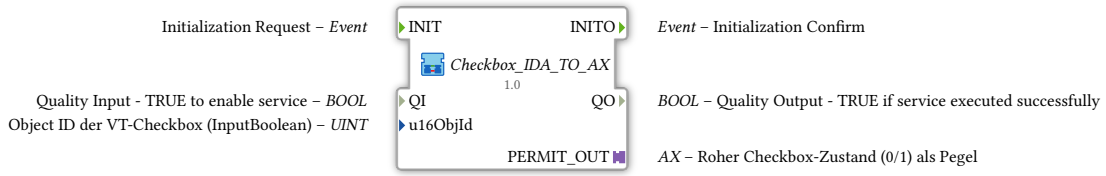
Checkbox_IDA_TO_AX



• — ○ • — ○ • — ○ •

Introduction

`Checkbox_IDA_TO_AX` passes the state of a **VT checkbox on live as an AX level** (`isobus::UT::io::NumericValue::NumericValue_IDA + AD_TO_AX`). It is a pure on/off state without scaling and persistence, e.g. for `Automatik_Toggle.PERMIT`.

Important: `u16ObjId` is the object ID of the **`CNumberVariable`** that the checkbox references as its value store (e.g. `NumberVariable_Bunker_Fuellstand_Hoehe_Automatik`) - **not** the object ID of the checkbox (`CInputBoolean`) itself. The VT reports value changes under the NumberVariable ID (verified live).

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; goes to `NumericValue_IDA.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirm; comes from `NumericValue_IDA.INITO`

Data Inputs

- **QI** (`BOOL`): quality input - TRUE enables the service (default `TRUE`); goes to `NumericValue_IDA.QI`
- **u16ObjId** (`UINT`): object ID of the number variable that the VT checkbox (InputBoolean) uses as its value store (default `ID_NULL`)

Data Outputs

- **QO** (`BOOL`): quality output - TRUE if the service was executed successfully (comes from `NumericValue_IDA.QO`)

Adapters

- **PERMIT_OUT** (plug, `adapter::types::unidirectional::AX`): raw checkbox state (0/1) as a level

Function Blocks (FBs) Used

- **`NumericValue_IDA`** (`isobus::UT::io::NumericValue::NumericValue_IDA`): delivers the value of the number variable as an `AD` adapter
- **`AD_TO_AX`** (`adapter::conversion::unidirectional::AD_TO_AX`): converts the value to an `AX` level

Functionality

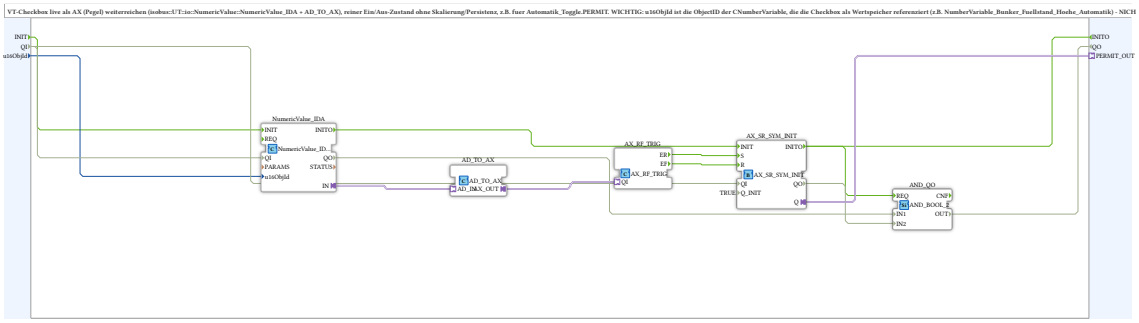
- `u16ObjId` ⟶ `NumericValue_IDA.u16ObjId`
- `NumericValue_IDA.IN` ⟶ `AD_TO_AX.AD_IN`
- `INIT` ⟶ `NumericValue_IDA.INIT`, `NumericValue_IDA.INITO` ⟶ `INITO`
- `QI` ⟶ `NumericValue_IDA.QI`, `NumericValue_IDA.QO` ⟶ `QO`
- `AD_TO_AX.AX_OUT` ⟶ `PERMIT_OUT`

Technical Details

- Level only; no scaling, no persistence
- Variant with initialisation: Checkbox_IDA_TO_AX_INIT_Force1

Application Scenarios

- Permit (`PERMIT`) of an automatic function via a checkbox in the VT, e.g. for `Automatik_Toggle`



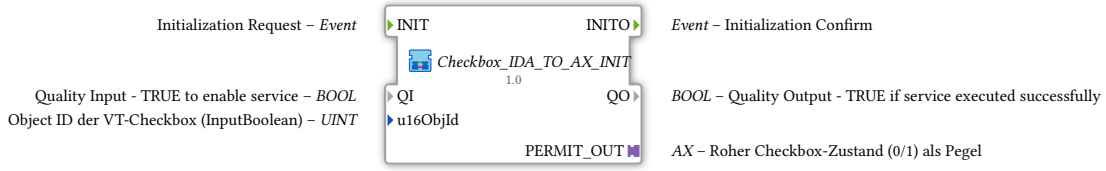
Summary

`Checkbox_IDA_TO_AX` turns a VT checkbox into an `AX` level for further logic.

🌐 Related topic pages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

Checkbox_IDA_TO_AX_INIT



• — ○ • — ○ • — ○ •

Introduction

`Checkbox_IDA_TO_AX_INIT` passes the state of a VT checkbox on live as an `AX` level (`isobus::UT::io::NumericValue::NumericValue_IDA` + `AD_TO_AX`). It is a pure on/off state without scaling or persistence, e.g. for `Automatik_Toggle.PERMIT`. The state is held via an edge detector and an SR flip-flop with a defined initial value (`_INIT`).

Important: `u16ObjId` is the ObjectID of the `CNumberVariable` that the checkbox references as its value store (e.g. `NumberVariable_Bunker_Fuellstand_Hoehe_Automatik`) - **not** the ObjectID of the checkbox (`CInputBoolean`) itself. The VT reports value changes under the NumberVariable ID (verified live).

Function Blocks (FBs) Used

Sub-blocks: Checkbox_IDA_TO_AX_INIT

- **Type**: SubAppType

- **Internal FBs used**:
  - **NumericValue_IDA**: `isobus::UT::io::NumericValue::NumericValue_IDA` - reads the raw value by ObjectID
  - **AD_TO_AX**: `adapter::conversion::unidirectional::AD_TO_AX` - converts the `DWORD` value into an `AX` signal (value <> `0`)
  - **AX_RF_TRIG**: `adapter::events::unidirectional::AX_RF_TRIG` - detects rising (`ER`) and falling (`EF`) edge
  - **AX_SR_SYM_INIT**: `adapter::events::unidirectional::AX_SR_SYM_INIT` (`Q_INIT=TRUE`) - flip-flop with a defined initial value
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` - combines `NumericValue_IDA.QO` and `AX_SR_SYM_INIT.QO` into `QO`
- **Import**: `isobus::UT::Q::const::IDs::ID_NULL` (initial value of `u16ObjId`)

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialisation request

Event Outputs

- **INITO** (`EInit`): initialisation confirmation

The user events still travel via the adapters.

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service
- **u16ObjId** (`UINT`, initial value `ID_NULL`): Object ID of the VT checkbox, i.e. of the NumberVariable it references

Data Outputs

- **QO** (`BOOL`): Quality Output - AND of `NumericValue_IDA.QO` and `AX_SR_SYM_INIT.QO`

Adapters

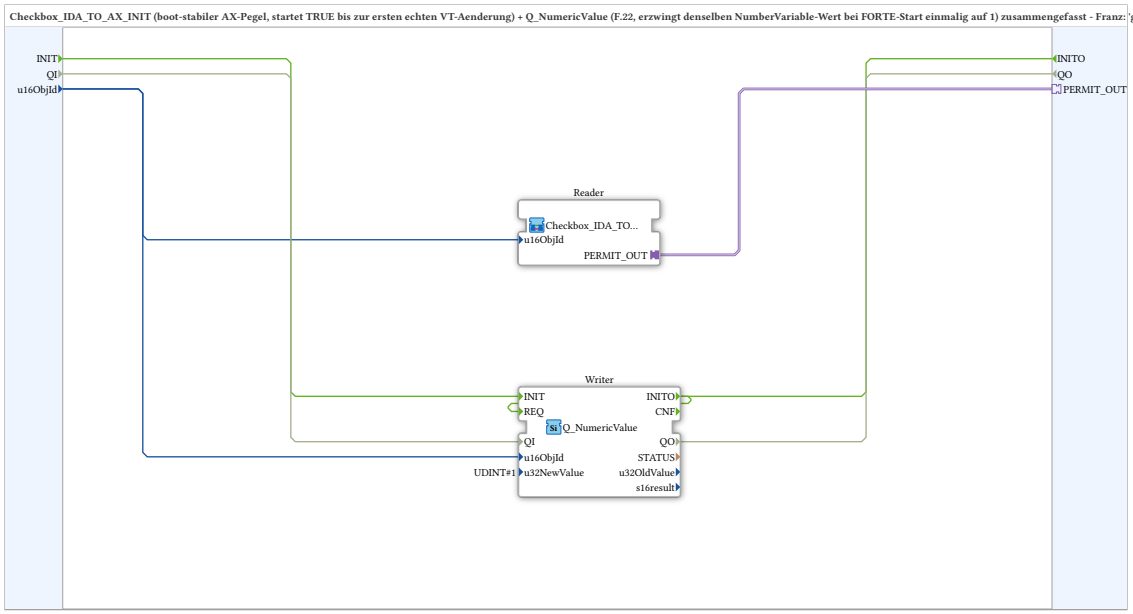
- **PERMIT_OUT** (plug): `adapter::types::unidirectional::AX` - raw checkbox state (0/1) as a level

Program Flow and Connections

- `u16ObjId` ⟶ `NumericValue_IDA.u16ObjId`
- `NumericValue_IDA.IN` ⟶ `AD_TO_AX.AD_IN`
- `AD_TO_AX.AX_OUT` ⟶ `AX_RF_TRIG.QI`
- `AX_RF_TRIG.ER` ⟶ `AX_SR_SYM_INIT.S` (checkbox set)
- `AX_RF_TRIG.EF` ⟶ `AX_SR_SYM_INIT.R` (checkbox cleared)
- `AX_SR_SYM_INIT.Q` ⟶ `PERMIT_OUT`
- `INIT` ⟶ `NumericValue_IDA.INIT`; `NumericValue_IDA.INITO` ⟶ `AX_SR_SYM_INIT.INIT`; `AX_SR_SYM_INIT.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`)
- `QI` ⟶ `NumericValue_IDA.QI` and `QI` ⟶ `AX_SR_SYM_INIT.QI`
- `NumericValue_IDA.QO` ⟶ `AND_QO.IN1`; `AX_SR_SYM_INIT.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`

Technical Details

- Initial value: `AX_SR_SYM_INIT` is parameterised with `Q_INIT=TRUE`
- The checkbox is read raw by ObjectID; there is no scaling and no persistence
- Version 1.0 (2026-09-27): acts like an `AX_PERMIT` to gate the entire on/off of the filling automation



Application Scenarios

- Enabling (`PERMIT`) an automation via a VT checkbox, e.g. `Automatik_Toggle.PERMIT`

Summary

`Checkbox_IDA_TO_AX_INIT` reads a VT checkbox via its NumberVariable and provides the state as an `AX` level with a defined initial value.

Checkbox_IDA_TO_AX_INIT_Force1

• — ○ • — ○ • — ○ •

Introduction

`Checkbox_IDA_TO_AX_INIT_Force1` combines `Checkbox_IDA_TO_AX_INIT` (boot-stable AX level, starts `TRUE` until the first real VT change) and `Q_NumericValue` (forces the value 1 of the associated Number-Variable once at FORTE start). Both blocks read/write the same `u16ObjId`, hence they belong together; the `u16ObjId` is a parameter for reuse. The SubApp was extracted from `Aufnahme_Automatik.SUB` (`Permit_Automatik` plus `Q_NumericValue_Force1_Geschwindigkeitsregelung`).

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request - to `Writer.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirmation - from `Writer.INITO`

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE to enable the service (to `Writer.QI`)
- **u16ObjId** (`UINT`, default `ID_NULL`): Object ID of the VT checkbox NumberVariable (the same object for reading and the Force1 write)

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service was executed successfully (from `Writer.QO`)

Adapters

- **PERMIT_OUT** (plug, `adapter::types::unidirectional::AX`): Boot-stable checkbox state (starts `TRUE`, afterwards follows the real VT checkbox)

Function Blocks (FBs) Used

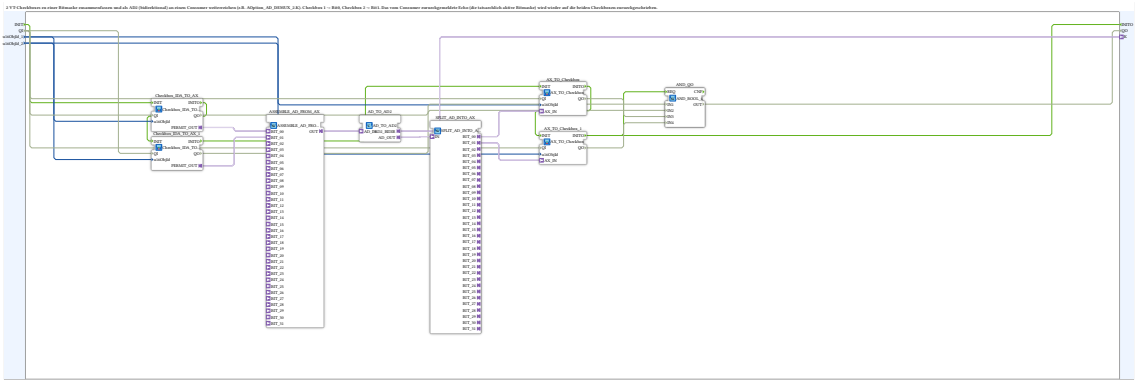
- **Reader**: SubApp `MyLib_AX::sys::Checkbox_IDA_TO_AX_INIT` - provides the boot-stable checkbox state as AX
- **Writer**: `isobus::UT::Q::Q_NumericValue` with `u32NewValue=1` - fixed FB-side one-time writer (not the `InitialValue` property of the VT pool)

Program Flow and Connections

- `u16ObjId` ⟶ `Reader.u16ObjId` and `Writer.u16ObjId`
- `Writer.INITO` ⟶ `Writer.REQ`: the value 1 is written once at start.
- `INIT` ⟶ `Writer.INIT`; `Writer.INITO` ⟶ `INITO`
- `QI` ⟶ `Writer.QI`; `Writer.QO` ⟶ `QO`
- `Reader.PERMIT_OUT` ⟶ `PERMIT_OUT`

Technical Details

- Through the feedback `INITO` ⟶ `REQ`, the writer fires exactly once on initialization; afterwards the checkbox stays under the user's control.

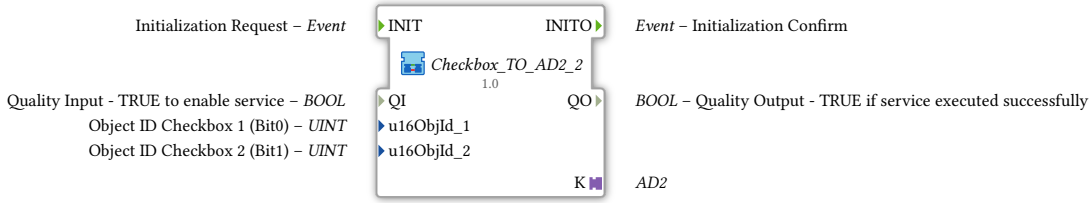


Application Scenarios

- Enable checkbox (e.g. for an automatic) that should be active at start and whose NumberVariable is set consistently to 1 at FORTE start

Summary

`Checkbox_IDA_TO_AX_INIT_Force1` provides a checkbox enable that is active at start and boot-stable as AX, and sets the associated VT object consistently to 1.



Checkbox_TO_AD2_2

• – ○ • – ○ • – ○ •

Introduction

`Checkbox_TO_AD2_2` combines two VT checkboxes into a bitmask and passes it bidirectionally as an AD2 adapter (`K`) to a consumer (e.g. `AOption_AD_DEMUX_2.K`). Checkbox 1 corresponds to bit 0, checkbox 2 to bit 1. The bitmask reported back by the consumer (the actually active one) is written back to the two checkboxes.

Interface

Event inputs

- `INIT` (`EInit`): initialization request.

Event outputs

- `INITO` (`EInit`): initialization confirm.

Input variables

- `QI` (BOOL, default `TRUE`): quality input, TRUE enables the service.

- `u16ObjId_1` (UINT, default `ID_NULL`): ObjectID of checkbox 1 (bit 0).
- `u16ObjId_2` (UINT, default `ID_NULL`): ObjectID of checkbox 2 (bit 1).

Output variables

- `QO` (BOOL): quality output, AND combination (`AND_QO`, `AND_BOOL_4`) of the `QO` outputs of the two `Checkbox_IDA_TO_AX` and the two `AX_TO_Checkbox` instances.

Adapters

- **Plug `K`** (`adapter::types::bidirectional::AD2`): bitmask to the consumer and echo back.

Initialization runs as a chain through the four sub-blocks (see below).

How it works

Forward direction (VT → consumer):

1. Two instances of `Checkbox_IDA_TO_AX` each read one checkbox and deliver an AX level (`PERMIT_OUT`).
2. `ASSEMBLE_AD_FROM_AX` assembles the levels into a DWORD (`BIT_00` and `BIT_01`).
3. `AD_TO_AD2` converts it into the bidirectional AD2 adapter, which is output on `K`.

Reverse direction (consumer → VT):

1. The echo reported back via `K` appears at `AD_TO_AD2.AD_OUT`.
2. `SPLIT_AD_INTO_AX` splits the DWORD into `BIT_00` and `BIT_01`.
3. Two instances of `AX_TO_Checkbox` write the bits to the respective checkbox.

Initialization and quality:

1. `INIT` → `Checkbox_IDA_TO_AX.INIT`; `Checkbox_IDA_TO_AX.INITO` → `Checkbox_IDA_TO_AX_1.INIT`; `Checkbox_IDA_TO_AX_1.INITO` → `AX_TO_Checkbox.INIT`; `AX_TO_Checkbox.INITO` → `AX_TO_Checkbox_1.INIT`; `AX_TO_Checkbox_1.INITO` → `INITO` and → `AND_QO.REQ`.
2. `QI` → `.QI` of all four sub-blocks; their `QO` → `AND_QO.IN1` to `AND_QO.IN4` (`Checkbox_IDA_TO_AX`, `Checkbox_IDA_TO_AX_1`, `AX_TO_Checkbox`, `AX_TO_Checkbox_1`); `AND_QO.OUT` → `QO`.

`u16ObjId_1` and `u16ObjId_2` each go to both the `Checkbox_IDA_TO_AX` and the `AX_TO_Checkbox` instance of the corresponding checkbox.

Technical notes

- Extracted from `Uebung_094b5_AX` for reuse; designed for N=2 bits/checkboxes, analogous to `AOption_AD_DEMUX_2`.
- Does not store anything itself; persistence is the consumer's responsibility.

Summary

Bundles two VT checkboxes as a bitmask onto a bidirectional AD2 plug and mirrors the consumer echo back to the checkboxes.

DO_TOGGLE_RPC_QXA_OPC

• — ○ • — ○ • — ○ •

Introduction

The **DO_TOGGLE_RPC_QXA_OPC** subapplication implements a digital enable output as a click-toggle (flip-flop) that can be triggered by multiple, independent, equal-right callers via an OPC UA RPC method. Typical callers are a local soft-key relay (STG1) and a remote OPC UA dashboard. Every trigger event toggles the internal state; the current state is the single source of truth for both the physical digital output and the remotely published status value. The design deliberately omits any OR-merge logic after the flip-flop, so that the flip-flop output alone determines the physical channel and the published state. This makes the block generic and reusable for any digital toggle output in emergency-operation or street-mode scenarios that require multi-access control.

Interface Structure

The subapplication exposes the initialisation events `INIT`/`INITO`, the input variables and the output `QO`; all other events, adapters, and data processing are encapsulated internally.

Event Inputs

- **INIT** (`EInit`): initialisation; sequenced by the caller instead of automatic distribution, so that `QI` is settled before the physical channel is bound; starts the initialisation chain `DO_TOGGLE_SERVER` ⟶ `AX_T_FF_INIT_DO` ⟶ `DigitalOutput_DO` ⟶ `PUBLISH_STATE_DO`

The toggle events themselves are still generated internally via the embedded OPC UA server (SERVER_0) and the internal event connections.

Event Outputs

- **INITO** (`EInit`): initialisation completed; genuine confirm from `PUBLISH_STATE_DO.INITO` (end of the initialisation chain)

**Data Inputs

Name	Type	Initial Value	Description
`QI`	`BOOL`	`TRUE`	Qualifier for the physical output; FALSE keeps the instance completely inactive (no hardware binding); passed on to `DO_TOGGLE_SERVER.QI`, `AX_T_FF_INIT_DO.QI`, `PUBLISH_STATE_DO.QI` and `DigitalOutput_DO.QI`.
`Output_DO`	`logiBUS::io::DQ::logiBUS_DO`	`logiBUS_DO::Invalid`	Configuration/description of the physical enable output channel. Drives the digital output as a click-toggle with default state **ON**.
`ID_DO_TOGGLE_METHOD`	`WSTRING`	–	OPC UA method node address (ACTION=CREATE_METHOD) for the argumentless toggle trigger. This address is shared by all callers; every caller

			clocks the same flip-flop.
ID_DO_STATE_WRITE	WSTRING	–	OPC UA variable node address (ACTION=WRITE) used to publish the actual enable state (AX_T_FF_INIT.Q). This address is subscribed by remote clients.

Data Outputs

Name	Type	Description
QO	BOOL	Quality Output - TRUE if the service executed successfully; AND (AND_QO, AND_BOOL_4) of the QO of DO_TOGGLE_SERVER, AX_T_FF_INIT_DO, PUBLISH_STATE_DO and DigitalOutput_DO.

Adapters

None exposed at the subapplication interface.

Functionality

The subapplication is built around five internal function blocks plus the AND block AND_QO:

1. **DO_TOGGLE_SERVER** (iec61499::net::SERVER_0) – an OPC UA server endpoint that listens for the method call addressed by ID_DO_TOGGLE_METHOD. The incoming request event (IND) is forwarded directly to the clock input of the toggle flip-flop and – without any processing – immediately back to the server (RSP).
2. **AX_T_FF_INIT_DO** (adapter::events::unidirectional::AX_T_FF_INIT) – a toggle flip-flop. Its parameter Q_INIT=TRUE sets the default enable state to **ON**. Each event arriving at its CLK input flips the state.
3. **SPLIT_DO_STATE** (adapter::events::unidirectional::AX_SPLIT_2) – fans out the flip-flop output to two identical copies.
4. **DigitalOutput_DO** (logiBUS::io::DQ::logiBUS_QXA) – the physical digital output driver; receives OUT1 from the split and applies it to the channel configured by Output_DO; QI comes from the subapplication interface; INIT comes from AX_T_FF_INIT_DO.INITO, and its INITO starts PUBLISH_STATE_DO.INIT.
5. **PUBLISH_STATE_DO** (adapter::net::AX_PUBLISH_1) – publishes OUT2 as the current enable state to the OPC UA variable addressed by ID_DO_STATE_WRITE; INIT comes from DigitalOutput_DO.INITO, and its INITO is output as INITO (last link of the initialisation chain).
6. **AND_QO** (iec61131::booleanOperators::AND_BOOL_4) – ANDs the QO outputs of DO_TOGGLE_SERVER, AX_T_FF_INIT_DO, PUBLISH_STATE_DO and DigitalOutput_DO into the block output QO; triggered by PUBLISH_STATE_DO.INITO (REQ).

Initialisation chain: INIT → DO_TOGGLE_SERVER.INIT, DO_TOGGLE_SERVER.INITO → AX_T_FF_INIT_DO.INIT, AX_T_FF_INIT_DO.INITO → DigitalOutput_DO.INIT, DigitalOutput_DO.INITO → PUBLISH_STATE_DO.INIT, PUBLISH_STATE_DO.INITO → INITO and → AND_QO.REQ.

The event chain for a single toggle request is:

```
DO_TOGGLE_SERVER.IND ──┬─► AX_T_FF_INIT_DO.CLK   (state flips)
                       └─► DO_TOGGLE_SERVER.RSP   (immediate acknowledgement)
```

After the flip, the new state propagates through SPLIT_DO_STATE to both the physical output and the remote publish. Because no intermediate OR logic exists, the flip-flop output is the **sole authoritative state**, and both consumers always see exactly the same value.

Technical Features

- **Single source of truth**: `AX_T_FF_INIT.Q` directly and exclusively drives both the physical output and the published OPC UA variable. There is no merging or arbitration logic on the data path.
- **Multi-caller capability**: Any number of OPC UA clients can invoke the same trigger method; they all clock the same flip-flop, so no data-level synchronization or merge block is required.
- **Argumentless remote trigger**: The RPC method takes no arguments. The server acknowledges immediately without further processing.
- **Race-free RSP handling**: The response event (`RSP`) is wired directly back to the indication event (`IND`) of the server FB. This is mandatory: if the response is not sent, FORTE's `onServerMethodCall` blocks the OPC UA server thread for up to 4 seconds (`scmMethodCallTimeoutInNanoSeconds`). During that time, open62541's global service mutex is held, which is also required by every `AX_PUBLISH_1` running on any other FORTE thread. The consequence would be that the physical output reacts immediately (no lock needed), but every OPC UA status message – not only for this block – would stall for up to 4 seconds.
- **Robust default state**: With `Q_INIT=TRUE`, the output is ON at initialization, which is the safe default for enable-type outputs.
- **Invalid channel protection**: The `Output_DO` input is initialized to `logiBUS_DO::Invalid`; the physical output driver guards against an unconfigured channel.

State Overview

The toggle state machine has two stable states, both reflected simultaneously on the physical output and the published variable:

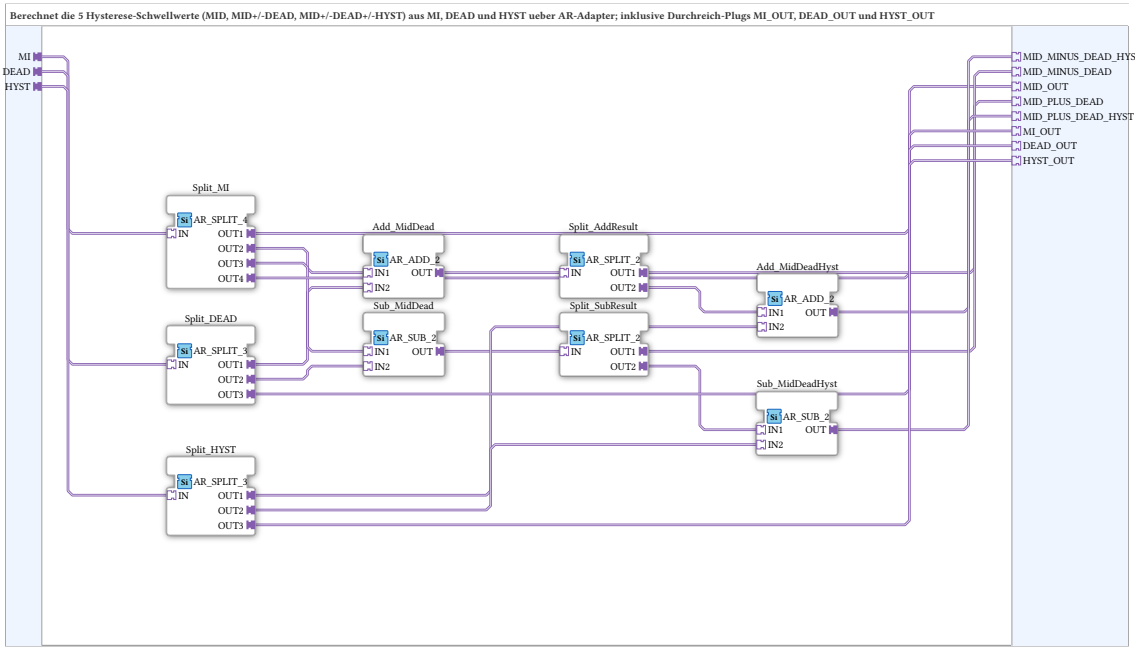
State	Physical Output	Published Variable	Meaning
ON (initial)	Active (1)	TRUE	Enable active / output released
OFF	Inactive (0)	FALSE	Enable inhibited / output blocked

Each valid trigger event on the OPC UA method transitions between these two states. No internal intermediate states exist; the transition is atomic from the perspective of both consumers.

Application Scenarios

- **Emergency-operation enable switches** (Not-Bedienung): A physical soft-key relay on a machine panel and a remote OPC UA dashboard shall both be able to toggle the same safety-related enable output. Every operator action has equal priority; no single side is master.
- **Street-mode or mode-selection toggles**: A digital output that alternates between two operating modes (e.g., manual/semi-automatic, street/workshop) and must be operable from multiple control rooms.
- **Distributed HMI panels**: Multiple HMI clients subscribe to the published state variable, ensuring all screens display the identical, unmodified flip-flop state.
- **Generic reuse**: The block can be instantiated with different `Output_DO` channel configurations and OPC UA address strings for any equipment that requires a remote-toggleable, locally-published digital enable.

Comparison with Similar Blocks

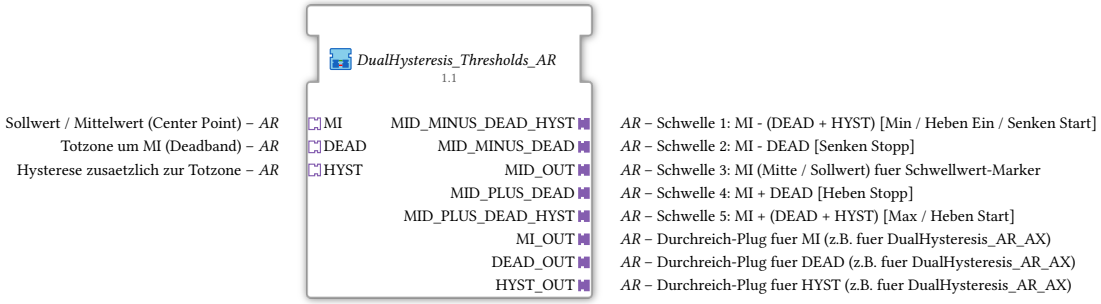


Feature	DO_TOGGLE_RPC_QXA_OPC (this block)	TOGGLE_RPC_MERGE_QXA_OPC (analogous block with merge)
Trigger handling	Single method, multiple callers all clock one flip-flop	Method triggers are merged via an OR gate before the flip-flop
Source of truth	Flip-flop output only	Merged combination of flip-flop output and trigger inputs
Data path after toggle	Straight split to output and publish	Additional OR logic on the data path
Complexity	Lower – fewer blocks, fewer connections	Higher – additional merge FB required
Use case	Truly independent callers, no data arbitration needed	Callers that may drive the output directly without toggling

The absence of the merge block in this subapplication eliminates a potential source of divergence between the physical output and the published state. It is the recommended variant whenever all callers are purely toggle-style (click on / click off) and none shall force an absolute output level.

Conclusion

DO_TOGGLE_RPC_QXA_OPC provides a clean, reliable, and reusable pattern for a remote-toggleable digital enable output that is simultaneously published to OPC UA clients. Its architecture guarantees that the locally measured physical state and the remotely observed state are always identical, because both derive from a single flip-flop with no additional logic in between. The direct RSP-to-IND wiring avoids OPC UA server thread blocking and ensures that remote publications continue to work fluently even under concurrent method calls. With its generic configuration interface (physical channel descriptor and two OPC UA address strings), the block can be dropped into any 4diac application that requires multi-operator click-toggling of a digital output.



DualHysteresis_Thresholds_AR

• – ○ • – ○ • – ○ •

Introduction

`DualHysteresis_Thresholds_AR` calculates, from the set point `MI` (centre value), the dead band `DEAD` and the hysteresis `HYST`, the five thresholds of a two-way hysteresis (e.g. raise/lower) using AR adapters only. In addition, `MI`, `DEAD` and `HYST` are passed on through the pass-through plugs `MI_OUT`, `DEAD_OUT` and `HYST_OUT`.

Interface Structure

Event Inputs

The function block has no direct event inputs.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **MI** (socket, AR): set point / centre value (centre point)
- **DEAD** (socket, AR): dead band around MI
- **HYST** (socket, AR): hysteresis in addition to the dead band
- **MID_MINUS_DEAD_HYST** (plug, AR): threshold 1 = MI - (DEAD + HYST) [min / raise on / lower start]
- **MID_MINUS_DEAD** (plug, AR): threshold 2 = MI - DEAD [lower stop]
- **MID_OUT** (plug, AR): threshold 3 = MI (centre / set point), e.g. for a threshold marker
- **MID_PLUS_DEAD** (plug, AR): threshold 4 = MI + DEAD [raise stop]
- **MID_PLUS_DEAD_HYST** (plug, AR): threshold 5 = MI + (DEAD + HYST) [max / raise start]
- **MI_OUT**, **DEAD_OUT**, **HYST_OUT** (plugs, AR): pass-through plugs for MI, DEAD and HYST (e.g. for DualHysteresis_AR_AX)

Functionality

Each input is first distributed to several consumers by a split block, because an adapter should never be branched without a split:

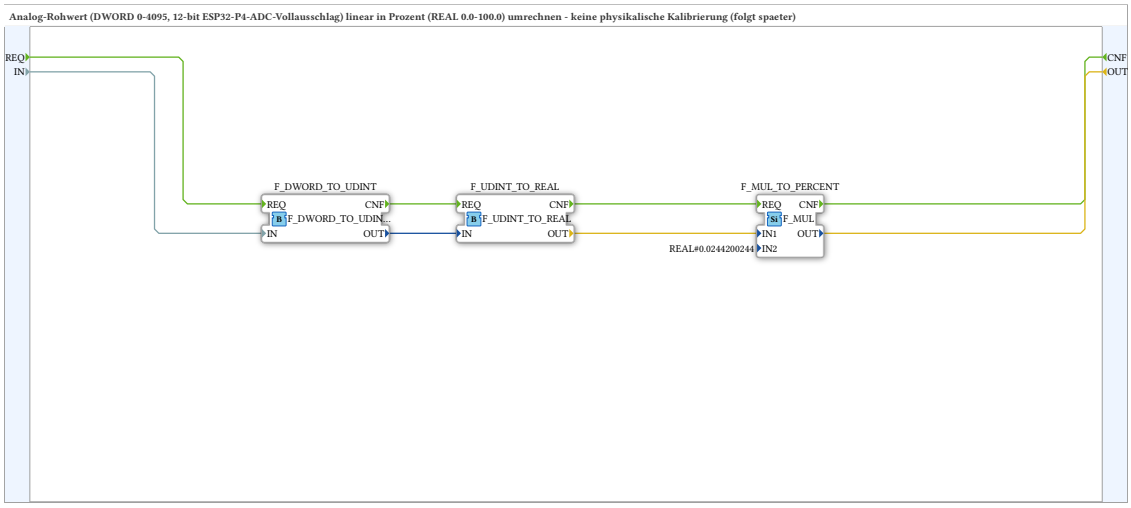
- MI ⟶ Split_MI (AR_SPLIT_4): OUT1 ⟶ MID_OUT, OUT2 ⟶ Add_MidDead.IN1, OUT3 ⟶ Sub_MidDead.IN1, OUT4 ⟶ MI_OUT.
- DEAD ⟶ Split_DEAD (AR_SPLIT_3): OUT1 ⟶ Add_MidDead.IN2, OUT2 ⟶ Sub_MidDead.IN2, OUT3 ⟶ DEAD_OUT.
- HYST ⟶ Split_HYST (AR_SPLIT_3): OUT1 ⟶ Add_MidDeadHyst.IN2, OUT2 ⟶ Sub_MidDeadHyst.IN2, OUT3 ⟶ HYST_OUT.

The calculation chain consists of AR_ADD_2 and AR_SUB_2 (adapter::iec61131::arithmetic):

- Add_MidDead = MI + DEAD ⟶ Split_AddResult (AR_SPLIT_2): OUT1 ⟶ MID_PLUS_DEAD, OUT2 ⟶ Add_MidDeadHyst.IN1.
- Sub_MidDead = MI - DEAD ⟶ Split_SubResult (AR_SPLIT_2): OUT1 ⟶ MID_MINUS_DEAD, OUT2 ⟶ Sub_MidDeadHyst.IN1.
- Add_MidDeadHyst = (MI + DEAD) + HYST ⟶ MID_PLUS_DEAD_HYST.
- Sub_MidDeadHyst = (MI - DEAD) - HYST ⟶ MID_MINUS_DEAD_HYST.

Technical Details

- Pure calculation/wiring block without state of its own; the outputs follow the inputs
- MI_OUT is separate from the threshold MID_OUT (version 1.1: Split_MI extended from AR_SPLIT_3 to AR_SPLIT_4) so that every plug has its own source
- The labels in square brackets (raise/lower) are the intended use of the thresholds in the caller logic

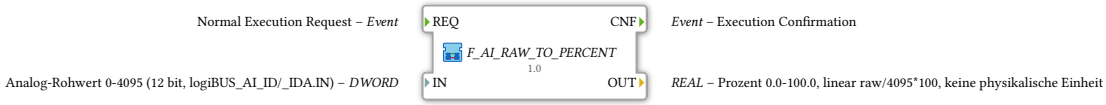


Application Scenarios

- Two-way control (raise/lower) with dead band and hysteresis, e.g. filling belt or slope compensation height control, including threshold markers on the VT

Conclusion

DualHysteresis_Thresholds_AR supplies, from MI, DEAD and HYST, the five thresholds MI ± DEAD and MI ± (DEAD + HYST) as well as MI itself using AR adapter arithmetic and passes the three input quantities on unchanged.



F_AI_RAW_TO_PERCENT

• – ○ • – ○ • – ○ •

Introduction

`F_AI_RAW_TO_PERCENT` converts the raw analog value from `logiBUS_AI_ID`/`logiBUS_AI_IDA` (DWORD, 0-4095, 12-bit ESP32-P4 ADC full scale) **linearly** into percent (REAL 0.0-100.0) — no physical calibration (planned as a later step). Data-based variant; the fully adapter-based alternative is `F_AI_RAW_TO_PERCENT_AD`.

Function Blocks (FBs) Used

Sub-blocks: F_AI_RAW_TO_PERCENT

- **Type**: SubAppType
- **Internal FBs used**:
  - **F_DWORD_TO_UDINT**: `iec61131::conversion::F_DWORD_TO_UDINT` — bit-reinterpretation DWORD⟶UDINT, valid here (same 32-bit unsigned-integer representation).
  - **F_UDINT_TO_REAL**: `iec61131::conversion::F_UDINT_TO_REAL` — a real numeric cast UDINT⟶REAL.
  - **F_MUL_TO_PERCENT**: `iec61131::arithmetic::F_MUL` — multiplication by `REAL#0.0244200244` (= 100/4095).
- **Functionality**: `IN` (raw value 0-4095) ⟶ UDINT ⟶ REAL ⟶ ×(100/4095) = percent.

Program Flow and Connections

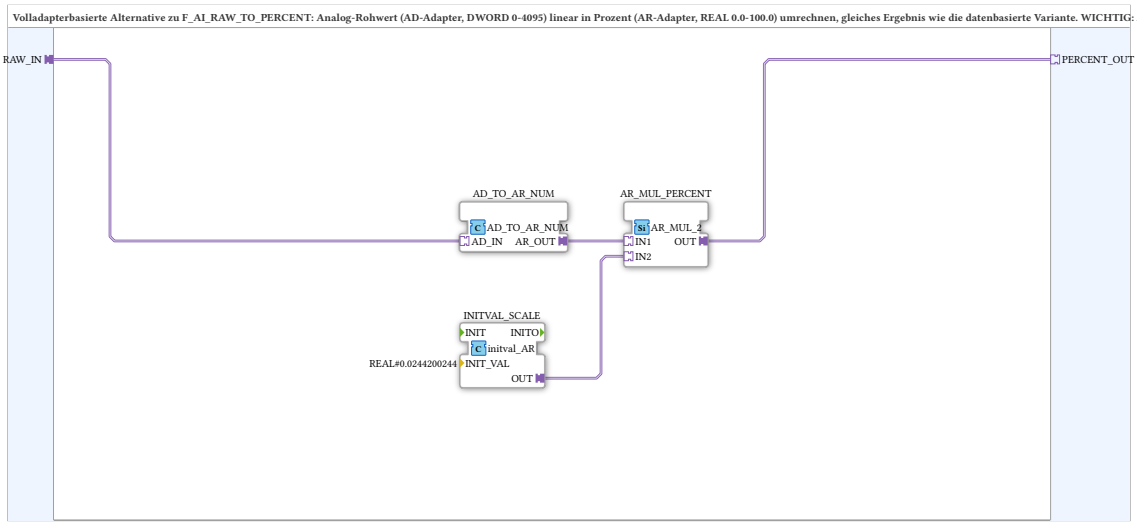
1. `IN` ⟶ `F_DWORD_TO_UDINT.IN` ⟶ `F_UDINT_TO_REAL.IN` ⟶ `F_MUL_TO_PERCENT.IN1`.
2. `F_MUL_TO_PERCENT.IN2 = REAL#0.0244200244` (parameter, = 100/4095).
3. `F_MUL_TO_PERCENT.OUT` ⟶ `OUT` (percent 0.0-100.0).

Technical Details

- **Numerically correct chain**: DWORD⟶UDINT is a valid bit-reinterpretation (see Numeric vs. bitwise), UDINT⟶REAL is a real numeric cast — together they form a correct DWORD⟶REAL conversion, avoiding the bit-reinterpretation trap of `F_DWORD_TO_REAL`.
- **No physical calibration**: The factor 100/4095 only yields the linear percentage of ADC full scale, not a physical unit (volts, bar, etc.) — per the source comment, that's a later extension step.

Application Scenarios

- Displaying/processing a raw analog input value as a percentage, e.g. for an AI training example.



Summary

F_AI_RAW_TO_PERCENT demonstrates the numerically correct DWORD⟶REAL chain (via UDINT) on a concrete analog raw value example — data-based variant; see F_AI_RAW_TO_PERCENT_AD for the adapter-based alternative.

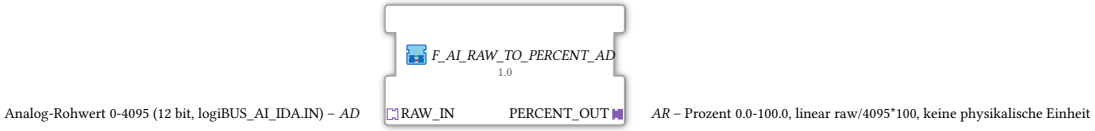
F_AI_RAW_TO_PERCENT_AD



• – ○ • – ○ • – ○ •

Introduction

F_AI_RAW_TO_PERCENT_AD is the fully adapter-based alternative to F_AI_RAW_TO_PERCENT: the same raw analog value (0-4095) is converted linearly to percent via AD/AR adapters instead of regular data connections — identical result, different wiring style.

> ⚠️ **Important note from the block's own comment:** AD_TO_AR/F_DWORD_TO_REAL would be **wrong** here — that's a bit-reinterpretation (IEEE754 cast), not a numeric conversion (see forte_real.cpp, CIEC_REAL::setValue, case e_DWORD: setValueSimple). The correct path is the numeric conversion AD_TO_AR_NUM (DWORD⟶UDINT by bit-reinterpretation, valid here, same bit width/representation; then F_UDINT_TO_REAL, a real numeric conversion). Details in Numeric vs. bitwise: the FORTE conversion trap.

Function Blocks (FBs) Used

Sub-blocks: F_AI_RAW_TO_PERCENT_AD

- **Type**: SubAppType
- **Internal FBs used**:
  - **AD_TO_AR_NUM**: adapter::conversion::unidirectional::AD_TO_AR_NUM — numeric conversion DWORD adapter⟶REAL adapter via UDINT, see AD_TO_AR_NUM.
  - **INITVAL_SCALE**: adapter::types::unidirectional::AR::initval::initval_AR — supplies the constant REAL#0.0244200244 (= 100/4095) as an adapter.

  - **AR_MUL_PERCENT**: `adapter::iec61131::arithmetic::AR_MUL_2` — multiplies two REAL adapters.
- **Functionality**: `RAW_IN` (AD adapter, 0-4095) ⟶ `AD_TO_AR_NUM` ⟶ multiplied by the constant ⟶ `PERCENT_OUT` (AR adapter, 0.0-100.0).

Program Flow and Connections

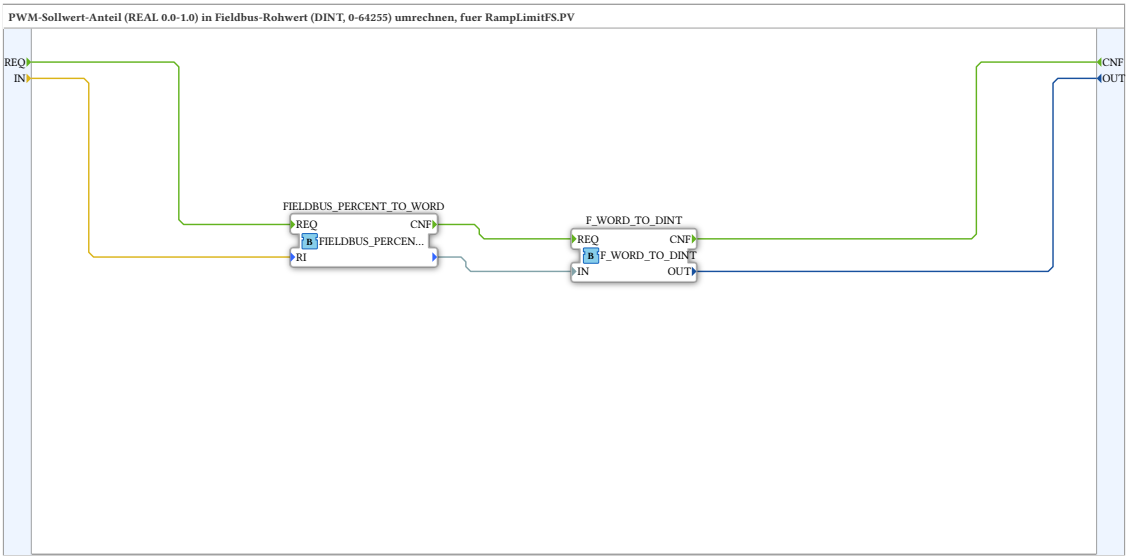
1. `RAW_IN` ⟶ `AD_TO_AR_NUM.AD_IN`; `AD_TO_AR_NUM.AR_OUT` ⟶ `AR_MUL_PERCENT.IN1`.
2. `INITVAL_SCALE.OUT` (constant 0.0244200244) ⟶ `AR_MUL_PERCENT.IN2`.
3. `AR_MUL_PERCENT.OUT` ⟶ `PERCENT_OUT`.

Technical Details

- **Deliberate negative example in the comment**: the block's own comment explicitly documents why `AD_TO_AR` would be wrong here — a rare but valuable "anti-pattern" note right in the source.
- **Adapter constant instead of a parameter**: the scaling constant is supplied via `initval_AR` as an adapter rather than a classic FB parameter — consistent with the block's fully adapter-based design.

Application Scenarios

- Like `F_AI_RAW_TO_PERCENT`, but for SubApp networks built consistently on adapter connections instead of classic data connections.



Summary

`F_AI_RAW_TO_PERCENT_AD` delivers the same numerically correct DWORD⟶REAL percent conversion as `F_AI_RAW_TO_PERCENT`, fully adapter-based — and explicitly documents the bit-reinterpretation trap a naive `AD_TO_AR` wiring would create.

F_PWM_PERCENT_TO_RAW

• — ○ • — ○ • — ○ •

Introduction

`F_PWM_PERCENT_TO_RAW` converts a **PWM setpoint fraction (REAL 0.0–1.0)** into the **fieldbus raw value (DINT, 0–64255)** expected by `RampLimitFS.PV`. Despite its name, the block does not expect a percent value (0–100) but a fraction (0.0–1.0) — the percent-to-fraction conversion is handled upstream by `logiBUS::signalprocessing::fieldbus::F_PERCENT_TO_FRACTION`.

Function Blocks (FBs) Used

Sub-blocks: F_PWM_PERCENT_TO_RAW

- **Type**: SubAppType
- **Internal FBs used**:
  - **FIELDBUS_PERCENT_TO_WORD**: `eclipse4diac::signalprocessing::FIELDBUS_PERCENT_TO_WORD`
    - Data input: `RI` (fraction 0.0-1.0)
    - Event output: `CNF`
  - **F_WORD_TO_DINT**: `iec61131::conversion::F_WORD_TO_DINT`
    - Data input: `IN`, data output: `OUT`
- **Functionality**: The standard 4diac block `FIELDBUS_PERCENT_TO_WORD` already delivers the fieldbus raw value as a `WORD` (16-bit); `F_WORD_TO_DINT` then converts it to `DINT`, since that is the type `RampLimitFS.PV` expects.

Program Flow and Connections

1. `REQ` (SubApp event input) ⟶ `FIELDBUS_PERCENT_TO_WORD.REQ`
2. `IN` (fraction 0.0-1.0) ⟶ `FIELDBUS_PERCENT_TO_WORD.RI`
3. `FIELDBUS_PERCENT_TO_WORD.CNF` ⟶ `F_WORD_TO_DINT.REQ`, its data output ⟶ `F_WORD_TO_DINT.IN`
4. `F_WORD_TO_DINT.OUT` ⟶ `OUT` (fieldbus raw value 0-64255)
5. `F_WORD_TO_DINT.CNF` ⟶ `CNF` (SubApp event output)

Technical Details

- Uses the standard 4diac block `FIELDBUS_PERCENT_TO_WORD` (`eclipse4diac::signalprocessing`) instead of a custom formula — consistent with the SAE J1939/ISO 11783 convention `VALID_SIGNAL_W`.
- Expects a **fraction 0.0-1.0**, not percent 0-100 — easy to confuse with the similarly named `F_PERCENT_TO_FRACTION` (percent ⟶ fraction), which must be placed upstream.

Application Scenarios

- Any exercise that needs to map an analog 0-100 % setpoint onto a `RampLimitFS` or other fieldbus raw-value input (0-64255).

Summary

`F_PWM_PERCENT_TO_RAW` is a thin adapter around the standard block `FIELDBUS_PERCENT_TO_WORD` that brings the fraction-to-fieldbus-raw-value conversion to the `DINT` type expected by `RampLimitFS.PV`.

F_PWM_RAW_TO_PERCENT

• – ○ • – ○ • – ○ •

Introduction

`F_PWM_RAW_TO_PERCENT` is the counterpart to `F_PWM_PERCENT_TO_RAW`: it converts the **fieldbus raw value (DINT, 0–64255)** from `RampLimitFS.OUT` back into a **fraction (REAL 0.0–1.0)**. Despite its name, the block does not produce a percent value — the fraction-to-percent conversion is handled downstream by `logiBUS::signalprocessing::fieldbus::F_FRACTION_TO_PERCENT`.

Function Blocks (FBs) Used

Sub-blocks: F_PWM_RAW_TO_PERCENT

- **Type**: SubAppType
- **Internal FBs used**:
  - **F_DINT_TO_WORD**: `iec61131::conversion::F_DINT_TO_WORD`
    - Data input: `IN`, data output: `OUT`
  - **FIELDBUS_WORD_TO_PERCENT**: `eclipse4diac::signalprocessing::FIELDBUS_WORD_TO_PERCENT`
    - Data input: `WI` (fieldbus raw value as `WORD`)
    - Event output: `CNF`
- **Functionality**: `RampLimitFS.OUT` delivers the raw value as `DINT`; `F_DINT_TO_WORD` converts it back to `WORD`, since the standard 4diac block `FIELDBUS_WORD_TO_PERCENT` expects that type and computes the fraction (0.0-1.0) from it.

Program Flow and Connections

1. `REQ` (SubApp event input) ⟶ `F_DINT_TO_WORD.REQ`
2. `IN` (fieldbus raw value 0-64255, DINT) ⟶ `F_DINT_TO_WORD.IN`
3. `F_DINT_TO_WORD.CNF` ⟶ `FIELDBUS_WORD_TO_PERCENT.REQ`, its data output ⟶ `FIELDBUS_WORD_TO_PERCENT.WI`
4. `FIELDBUS_WORD_TO_PERCENT` (data output) ⟶ `OUT` (fraction 0.0-1.0)
5. `FIELDBUS_WORD_TO_PERCENT.CNF` ⟶ `CNF` (SubApp event output)

Technical Details

- Uses the standard 4diac block `FIELDBUS_WORD_TO_PERCENT` (`eclipse4diac::signalprocessing`) — consistent with the SAE J1939/ISO 11783 convention `VALID_SIGNAL_W`.
- Delivers a **fraction 0.0-1.0**, not percent — for a percent display, the caller must still multiply by 100.0 or place `F_FRACTION_TO_PERCENT` downstream.

Application Scenarios

- Any exercise that needs to convert a `RampLimitFS` or other fieldbus raw value (0-64255) back into an analog 0-100 % setpoint for display or forwarding (e.g. OPC-UA publish).

Summary

`F_PWM_RAW_TO_PERCENT` is a thin adapter around the standard block `FIELDBUS_WORD_TO_PERCENT` that brings the fieldbus-raw-value-to-fraction conversion to the `DINT` type delivered by `RampLimitFS.OUT`.

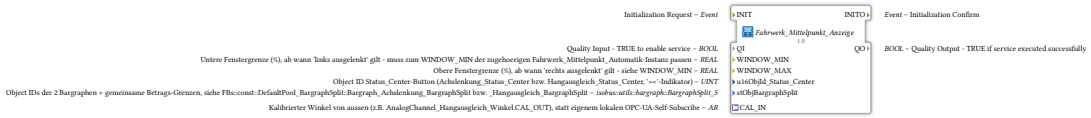
Fahrwerk_Mittelpunkt_Anzeige



• — ○ • — ○ • — ○ •

Introduction

`Fahrwerk_Mittelpunkt_Anzeige` is the **pure display half** of `Fahrwerk_Mittelpunkt_Automatik`: two bar graphs plus a status-centre background colour for an angle sensor with a centre position (axle steering/ slope compensation). It is fed by an `AR` plug that is already available locally (`CAL_IN`) instead of by its own OPC-UA self-subscribe.

It is intended for cases where the actual automation (`AUTO_LINKS/AUTO_RECHTS` control) runs on a different station than the VT (e.g. slope compensation since the move to STG4), but a display is still needed there. No extra forwarding is necessary: the calibration channel consumer (`logiBUS_AI_Calibrated_Subscribe_VT_(3P_)OPC`) already has the value locally as the `CAL_OUT` plug, which is wired on directly here.

Function Blocks (FBs) Used

Sub-blocks: Fahrwerk_Mittelpunkt_Anzeige

- **Type**: SubAppType
- **Internal blocks used**:

- **SPLIT_Y**: `adapter::events::unidirectional::AR_SPLIT_2` - distributes the angle to two consumers
- **CENTER_CMP**: `adapter::Engineering::measurements::AR_DEADBAND_COMPARE` - window comparison
- **LIT_WINDOW_MIN**, **LIT_WINDOW_MAX**: `adapter::types::unidirectional::AR::initval::initval_AR` - convert the parameters `WINDOW_MIN`/`WINDOW_MAX` into `AR` signals
- **SplitBar**: `isobus::UT::Q::BargraphSplitFS_AR` - two bar graphs (left/right of centre)
- **STATUS_CENTER_BG**: SubApp `MyLib::sys::GreenWhiteBackground1_AX` - background colour of the `Status_Center` button

Interface Structure

Event Inputs / Event Outputs

- **INIT** (`EInit`, input): initialization request; passed on to `STATUS_CENTER_BG.INIT`
- **INITO** (`EInit`, output): initialization confirmation; comes from `STATUS_CENTER_BG.INITO`

The runtime events still travel via the adapter.

Data Inputs

- **QI** (`BOOL`, default `TRUE`): quality input, service enable; passed on to `STATUS_CENTER_BG.QI`
- **WINDOW_MIN** (`REAL`, default `-2.0`): Lower window limit (%) from which "deflected left" applies - must match the `WINDOW_MIN` of the associated `Fahrwerk_Mittelpunkt_Automatik` instance
- **WINDOW_MAX** (`REAL`, default `2.0`): Upper window limit (%) from which "deflected right" applies - see `WINDOW_MIN`
- **u16ObjId_Status_Center** (`UINT`): Object ID of the `Status_Center` button (`Achslenkung_Status_Center` or `Hangausgleich_Status_Center`, "><" indicator)
- **stObjBargraphSplit** (`isobus::utils::bargraph::BargraphSplit_S`): Object IDs of the two bar graphs plus common magnitude limits (see `FBs::const::DefaultPool_BargraphSplit::Bargraph_Achslenkung_BargraphSplit` or `_Hangausgleich_BargraphSplit`)

Data Outputs

- **QO** (`BOOL`): quality output, comes from `STATUS_CENTER_BG.QO`

Adapters

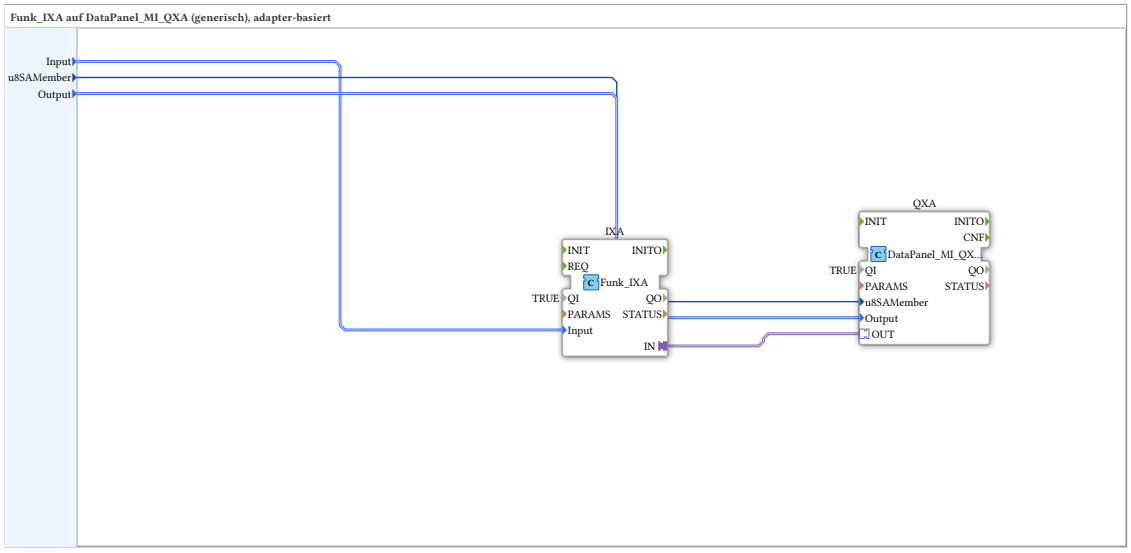
- **CAL_IN** (socket, `adapter::types::unidirectional::AR`): Calibrated angle from outside (e.g. `AnalogChannel_Hangausgleich_Winkel.CAL_OUT`)

Program Flow and Connections

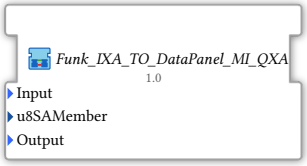
- `CAL_IN` ⟶ `SPLIT_Y.IN`
- `SPLIT_Y.OUT1` ⟶ `CENTER_CMP.Y`; `SPLIT_Y.OUT2` ⟶ `SplitBar.rPhys`
- `WINDOW_MIN` ⟶ `LIT_WINDOW_MIN.INIT_VAL`; `LIT_WINDOW_MIN.OUT` ⟶ `CENTER_CMP.WINDOW_MIN`
- `WINDOW_MAX` ⟶ `LIT_WINDOW_MAX.INIT_VAL`; `LIT_WINDOW_MAX.OUT` ⟶ `CENTER_CMP.WINDOW_MAX`
- `CENTER_CMP.CENTERED` ⟶ `STATUS_CENTER_BG.DI1`
- `u16ObjId_Status_Center` ⟶ `STATUS_CENTER_BG.u16ObjId`
- `stObjBargraphSplit` ⟶ `SplitBar.stObj`
- Initialization: `INIT` ⟶ `STATUS_CENTER_BG.INIT`; `STATUS_CENTER_BG.INITO` ⟶ `INITO`
- Quality: `QI` ⟶ `STATUS_CENTER_BG.QI`; `STATUS_CENTER_BG.QO` ⟶ `QO`

Technical Details

- Factored out of `Fahrwerk_Mittelpunkt_Automatik` (where `SUBSCRIBE_Y`, `SPLIT_Y`, `CENTER_CMP`, `SplitBar` and `STATUS_CENTER_BG` already appeared in exactly the same way)
- The automation itself has run on STG4 (no VT) since v3.0 of the slope compensation (there `u16ObjId_Status_Center` and `stObjBargraphSplit` are deliberately `ID_NULL`); this SubApp runs on STG1 instead, fed by the `CAL_OUT` plug that is available locally anyway - no additional remote round trip
- Version 1.0 (2026-09-26)



Application Scenarios



- Displaying axle steering or slope compensation (two bar graphs plus centre indicator) on a station whose control runs on another station

Summary

`Fahrwerk_Mittelpunkt_Anzeige` displays a calibrated angle as two bar graphs and as a status-centre background colour, without its own control and without an OPC-UA subscribe.

Funk_IXA_TO_DataPanel_MI_QXA

Identify the Input DigitalInput_Key_01 etc.. – *Funk::io::DI::Funk_DI_S*
Node SA 224..239 – *USINT*
Identify the Output DigitalOutput_1A..8B and Input_Power_Port_5..8 – *DataPanel::io::MI::DQ::DataPanel_MI_DO_S*

• – ○ • – ○ • – ○ •

Introduction

The **Funk_IXA_TO_DataPanel_MI_QXA** is a generic, adapter-based subapplication that bridges a Funk (wireless) digital input to a DataPanel MI QXA output. It encapsulates the necessary internal function blocks and the type-safe adapter connection between the wireless input receiver and the data panel output controller. The subapplication is designed for reuse: by changing only its data inputs, different input keys, output channels, and node addresses can be selected without modifying the internal structure.

Interface Structure

The subapplication exposes only data inputs. It has no event inputs, event outputs, data outputs, or externally visible adapters.

Event Inputs

None.

Event Outputs

None.

Data Inputs

Name	Type	Initial Value	Comment

Input	Funk::io::DI::Funk_DI_S	Funk_DI::Invalid	Identifies the input digital input key (e.g., DigitalInput_Key_01, etc.)
u8SAMember	USINT	MI::MI_00	Node SA address in the range 224..239
Output	DataPanel::io::MI::DQ::DataPanel_MI_DO_SInvalid		Identifies the output digital output (e.g., DigitalOutput_1A..8B and Input_Power_Port_5..8)

Data Outputs

None.

Adapters

The subapplication does not expose any adapters on its interface. Internally, one adapter connection is established between the two embedded function blocks:

- IXA.IN ⟶ QXA.OUT

This internal adapter connection carries the wireless input signal from the Funk receiver to the DataPanel output controller in a type-safe manner.

Functionality

The subapplication implements a direct signal path from a selected Funk input to a selected DataPanel output. The internal network consists of two function blocks:

1. **IXA** (type Funk::io::DI::Funk_IXA) – receives the configured Input selection and produces the adapter output signal IN.
2. **QXA** (type DataPanel::io::MI::DQ::DataPanel_MI_QXA) – receives the u8SAMember node address and the Output channel selection, and accepts the adapter input OUT.

The data flow is:

- Input ⟶ IXA.Input – defines which wireless input key is monitored.
- u8SAMember ⟶ QXA.u8SAMember – sets the node SA (substation address) in the 224..239 range.
- Output ⟶ QXA.Output – defines which DataPanel digital output (or power port) is actuated.
- IXA.IN ⟶ QXA.OUT – the adapter connection routes the signal from the wireless receiver to the output controller.

Both embedded FBs are enabled with their QI parameter set to TRUE. The PARAMS parameter of IXA is set to an empty string (with visibility disabled), keeping the internal configuration hidden.

Technical Features

- **Generic adapter-based design**: The subapplication can be instantiated multiple times for different input/output combinations without internal modifications.
- **Encapsulated logic**: All internal wiring and adapter connections are hidden, reducing the risk of incorrect manual wiring.
- **Type-safe adapter connection**: The internal IXA.IN ⟶ QXA.OUT connection ensures compatibility between the Funk input adapter and the DataPanel output adapter.
- **Configuration via data inputs**: The entire behavior is controlled by three data inputs (Input, Output, u8SAMember), which can be bound to constant values or runtime variables.
- **No event interface**: The subapplication operates purely on data, simplifying integration into larger IEC 61499 networks.
- **Enabled by default**: Both internal FBs have QI set to TRUE, meaning the subapplication is operational immediately after instantiation.

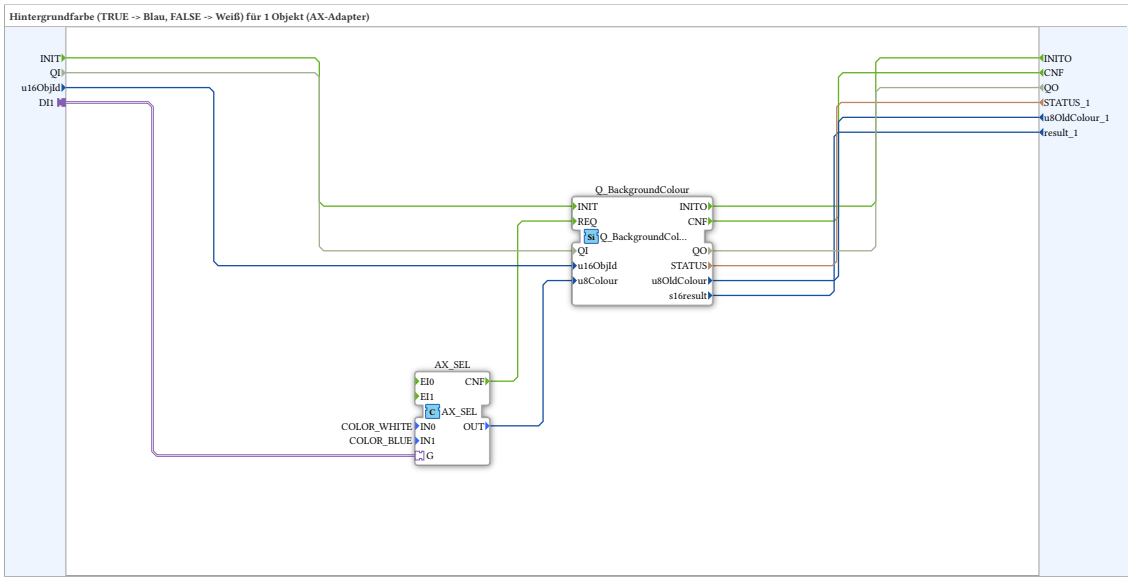
State Overview

The subapplication itself does not contain a state machine or event-triggered logic. Its behavior is purely combinatorial with respect to its data inputs: the selected input key, output channel, and node address are forwarded directly to the internal FBs. Any state handling is performed by the embedded function blocks

(`Funk_IXA` and `DataPanel_MI_QXA`), which manage their own internal states and diagnostics. Users of this subapplication do not need to manage any additional states.

Application Scenarios

- **Wireless key switching**: Connect a wireless digital input (e.g., a key switch) to a DataPanel digital output for remote or wireless activation of loads.
- **Generic I/O mapping**: Use the same subapplication to map multiple different Funk inputs to different DataPanel outputs by simply changing the `Input` and `Output` selection values.
- **Building automation**: Integrate wireless sensors or switches with central DataPanel output modules for flexible lighting, HVAC, or security control.
- **Modular control panels**: Simplify the creation of control-panel logic by reusing this subapplication for every radio-controlled output channel.



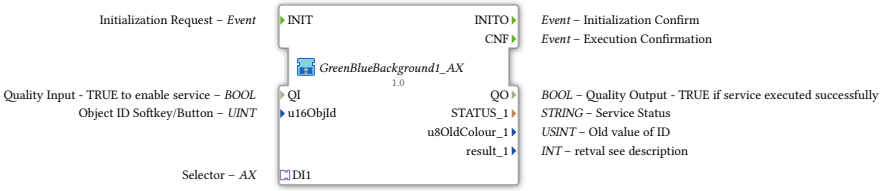
Comparison with Similar Blocks

- **vs. direct FB wiring**: Compared to manually wiring `Funk_IXA` and `DataPanel_MI_QXA` together, this subapplication encapsulates the adapter connection and exposes only the essential configuration parameters, significantly reducing wiring effort and error potential.
- **vs. an application-specific FB**: Unlike a dedicated, hard-coded function block, this subapplication is generic and can be instantiated with different parameter values, making it more flexible and reusable across projects.
- **vs. event-driven blocks**: This subapplication has no event interface, which makes it simpler to use, but it is not suitable for time-critical or sequence-dependent logic that requires explicit event synchronization.
- **vs. other mapping subapps**: This subapplication is specifically tailored for the Funk-to-DataPanel adapter pair; other mapping subapps for different device families would have a different internal structure and interface.

Conclusion

Funk_IXA_TO_DataPanel_MI_QXA offers a clean, reusable, adapter-based solution for bridging Funk wireless inputs to DataPanel MI QXA outputs. Its minimal interface – three data inputs – and fully encapsulated internal signal path make it easy to integrate and configure. The generic design ensures that the same subapplication can be leveraged across a wide range of wireless I/O mapping scenarios, improving consistency and maintainability in 4diac-based automation projects.

GreenBlueBackground1_AX



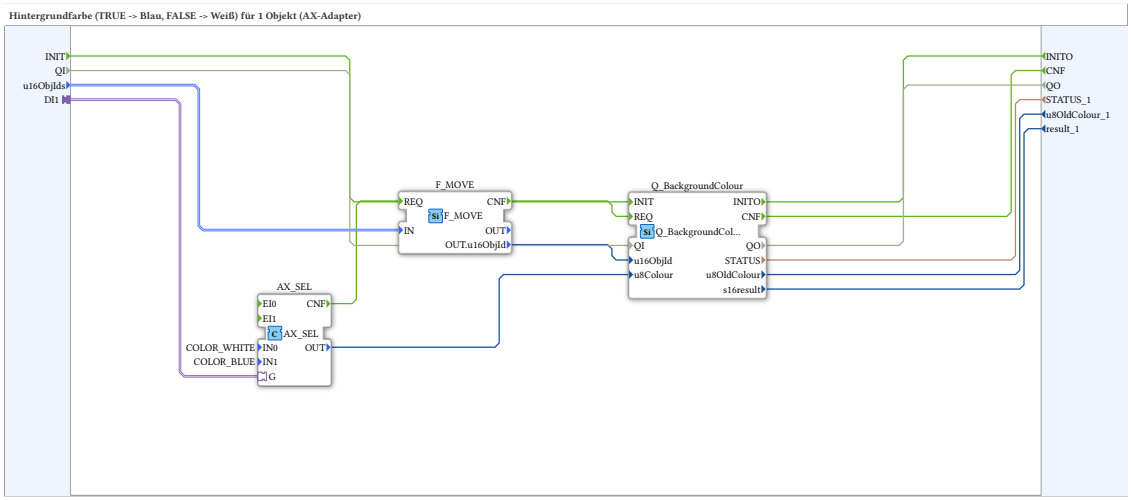
• – ○ • – ○ • – ○ •

Introduction

`GreenBlueBackground1_AX` switches the VT background color of one object based on a boolean selector signal: `TRUE` → **Blau**, `FALSE` → **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via input `u16ObjId`.

For the general pattern (selector → `AX_SEL/F_SEL` → `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Quality pattern: the SubApp has the event input `INIT`, the event output `INITO`, the data input `QI` (`BOOL`, default `TRUE`, "Quality Input - TRUE to enable service") and the data output `QO` (`BOOL`, "Quality Output - TRUE if service executed successfully"). They are passed straight through to `Q_BackgroundColour`: `INIT` → `Q_BackgroundColour.INIT`, `Q_BackgroundColour.INITO` → `INITO`, `QI` → `Q_BackgroundColour.QI`, `Q_BackgroundColour.QO` → `QO`.



Summary

One of many variants in the background color block family: color pair Blau/Weiß, 1 object, adapter selector.

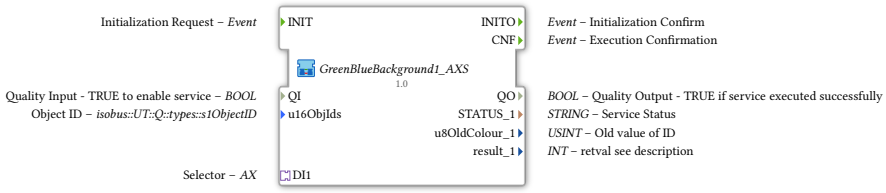
- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

GreenBlueBackground1_AXS



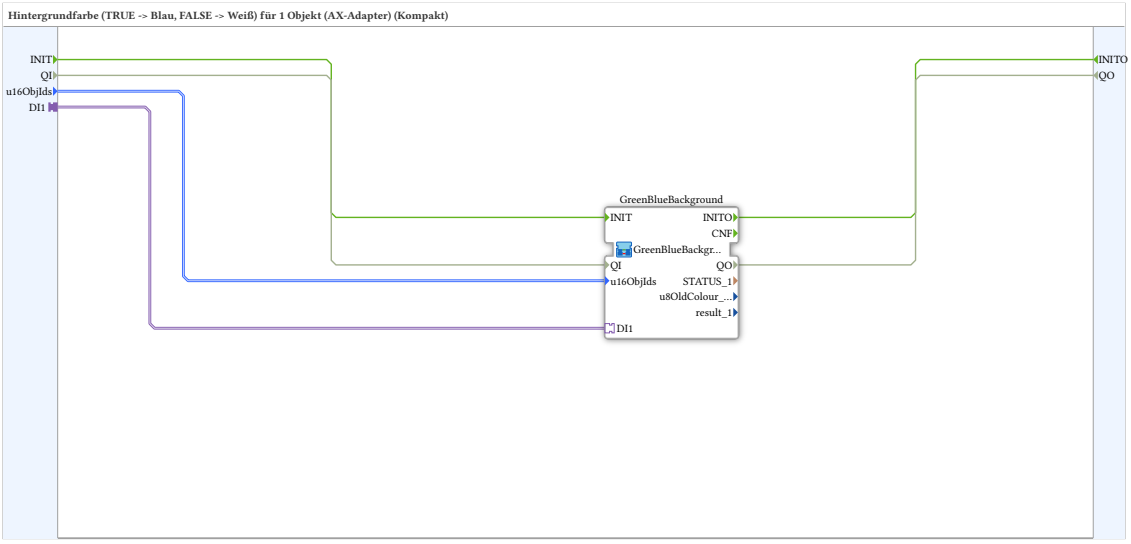
• – ○ • – ○ • – ○ •

Introduction

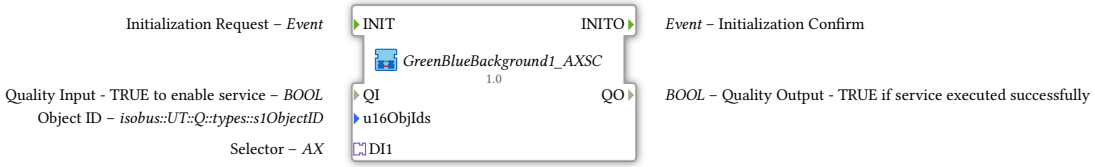
`GreenBlueBackground1_AXS` switches the VT background color of one object based on a boolean selector signal: `TRUE` → **Blau**, `FALSE` → **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

For the general pattern (selector → `AX_SEL/F_SEL` → `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Quality pattern: the SubApp has the event input `INIT`, the event output `INITO`, the data input `QI` (`BOOL`, default `TRUE`, "Quality Input - TRUE to enable service") and the data output `QO` (`BOOL`, "Quality Output - TRUE if service executed successfully"). They are passed straight through to `Q_BackgroundColour`: `INIT` → `Q_BackgroundColour.INIT`, `Q_BackgroundColour.INITO` → `INITO`, `QI` → `Q_BackgroundColour.QI`, `Q_BackgroundColour.QO` → `QO`.



Summary



One of many variants in the background color block family: color pair Blau/Weiß, 1 object, adapter selector, struct. object ID.

GreenBlueBackground1_AXSC

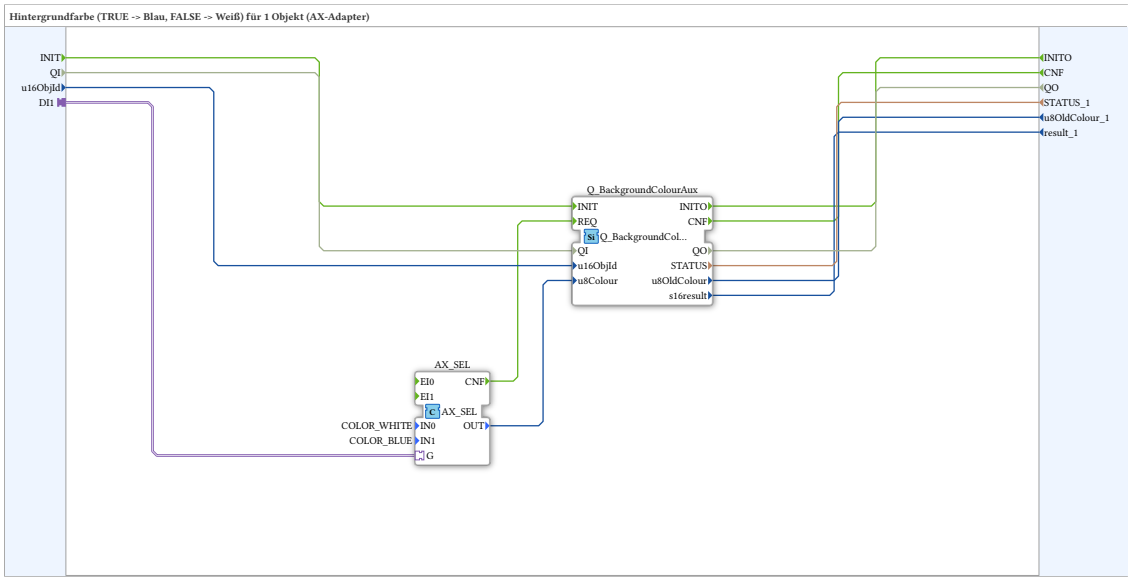
• – ○ • – ○ • – ○ •

Introduction

`GreenBlueBackground1_AXSC` is a **compact wrapper** around `GreenBlueBackground1_AXS` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

In addition, initialization and quality are passed through: `INIT` ⟶ `GreenBlueBackground.INIT`, `GreenBlueBackground.INITO` ⟶ `INITO`, `QI` (initial value `TRUE`) ⟶ `GreenBlueBackground.QI` and `GreenBlueBackground.QO` ⟶ `QO`.

For the shared pattern, see Background Color Blocks (shared pattern).



Summary

A pure pass-through to `GreenBlueBackground1_AXS` for the common case where the diagnostic values aren't needed.

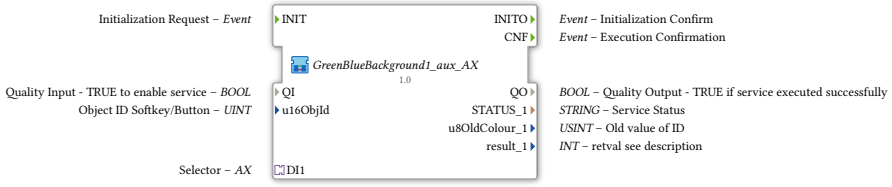
GreenBlueBackground1_aux_AX



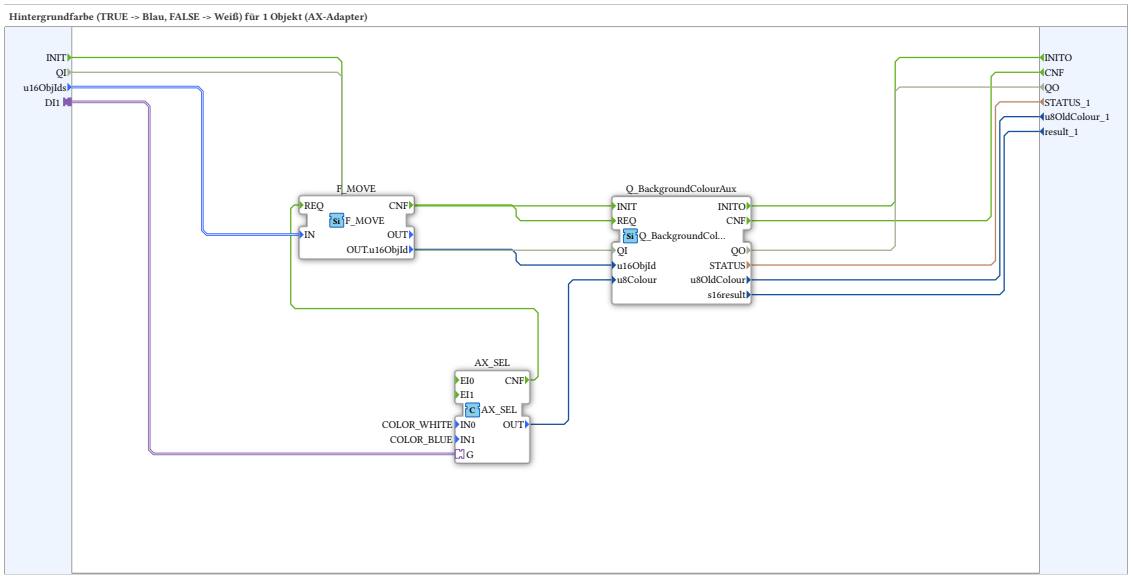
• — ○ • — ○ • — ○ •

Introduction

`GreenBlueBackground1_aux_AX` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Blau**, `FALSE` ⟶ **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via input `u16ObjId`.

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Quality pattern: the SubApp has the event input `INIT`, the event output `INITO`, the data input `QI` (`BOOL`, default `TRUE`, "Quality Input - TRUE to enable service") and the data output `QO` (`BOOL`, "Quality Output - TRUE if service executed successfully"). They are passed straight through to `Q_BackgroundColourAux`: `INIT` ⟶ `Q_BackgroundColourAux.INIT`, `Q_BackgroundColourAux.INITO` ⟶ `INITO`, `QI` ⟶ `Q_BackgroundColourAux.QI`, `Q_BackgroundColourAux.QO` ⟶ `QO`.



Summary

One of many variants in the background color block family: color pair Blau/Weiß, 1 object, adapter selector.

GreenRedBackground1_AX_UNGATED

• — ○ • — ○ • — ○ •

Introduction

`GreenRedBackground1_AX_UNGATED` sets the **background color** of a VT object via an AX adapter: `TRUE` ⟶ green, `FALSE` ⟶ red. "UNGATED" means that the selector is not gated by an additional enable signal - every update of `DI1` writes the color immediately.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request - to `Q_BackgroundColour.INIT`; further events arrive via the adapter socket

Event Outputs

- **INITO** (`EInit`): initialization confirmation (from `Q_BackgroundColour.INITO`)
- **CNF**: Execution confirmation (from `Q_BackgroundColour.CNF`)

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE to enable the service
- **u16ObjId** (`UINT`, default `ID_NULL`): Object ID of the softkey/button

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service was executed successfully (from `Q_BackgroundColour.QO`)
- **STATUS_1** (`STRING`): Service status
- **u8OldColour_1** (`USINT`): Old color value of the object
- **result_1** (`INT`): Return value (see `Q_BackgroundColour`)

Adapters

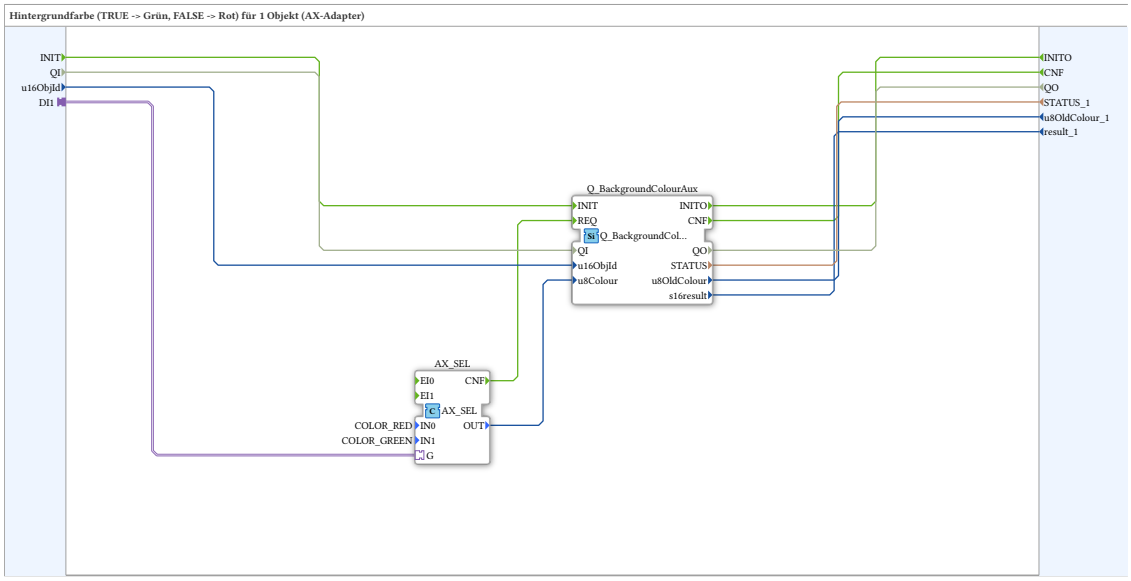
- **DI1** (socket, `adapter::types::unidirectional::AX`): Selector - `TRUE` for green, `FALSE` for red

Function Blocks (FBs) Used

- **AX_X_TO_BOOL**: `adapter::conversion::unidirectional::AX_X_TO_BOOL` - converts the AX selector into event `CNF` and value `IN` (`BOOL`)
- **AX_SEL**: `iec61131::selection::F_SEL` with `IN0 = COLOR_RED`, `IN1 = COLOR_GREEN` - selects the color
- **Q_BackgroundColour**: `isobus::UT::Q::Q_BackgroundColour` - writes the background color to the VT object

Program Flow and Connections

1. `DI1` ⟶ `AX_X_TO_BOOL.AX_IN`; `AX_X_TO_BOOL.IN` ⟶ `AX_SEL.G`; `AX_X_TO_BOOL.CNF` ⟶ `AX_SEL.REQ`.
2. `AX_SEL.OUT` ⟶ `Q_BackgroundColour.u8Colour`; `AX_SEL.CNF` ⟶ `Q_BackgroundColour.REQ`.
3. `u16ObjId` ⟶ `Q_BackgroundColour.u16ObjId`.
4. `Q_BackgroundColour.CNF` ⟶ `CNF`; `STATUS`, `u8OldColour`, `s16result` ⟶ `STATUS_1`, `u8OldColour_1`, `result_1`.
5. `INIT` ⟶ `Q_BackgroundColour.INIT`; `Q_BackgroundColour.INITO` ⟶ `INITO`; `QI` ⟶ `Q_BackgroundColour.QI`; `Q_BackgroundColour.QO` ⟶ `QO`.



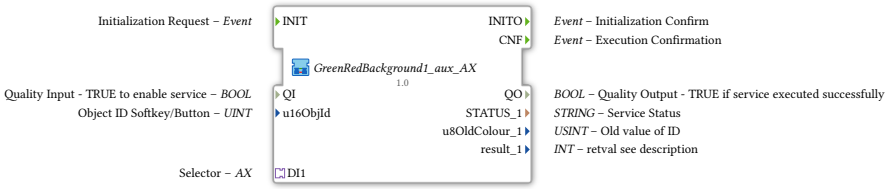
Application Scenarios

- Green/red status display for buttons or areas (e.g. operation/fault) without additional enable logic

Summary

`GreenRedBackground1_AX_UNGATED` immediately colors a VT object green or red depending on an AX signal.

GreenRedBackground1_aux_AX



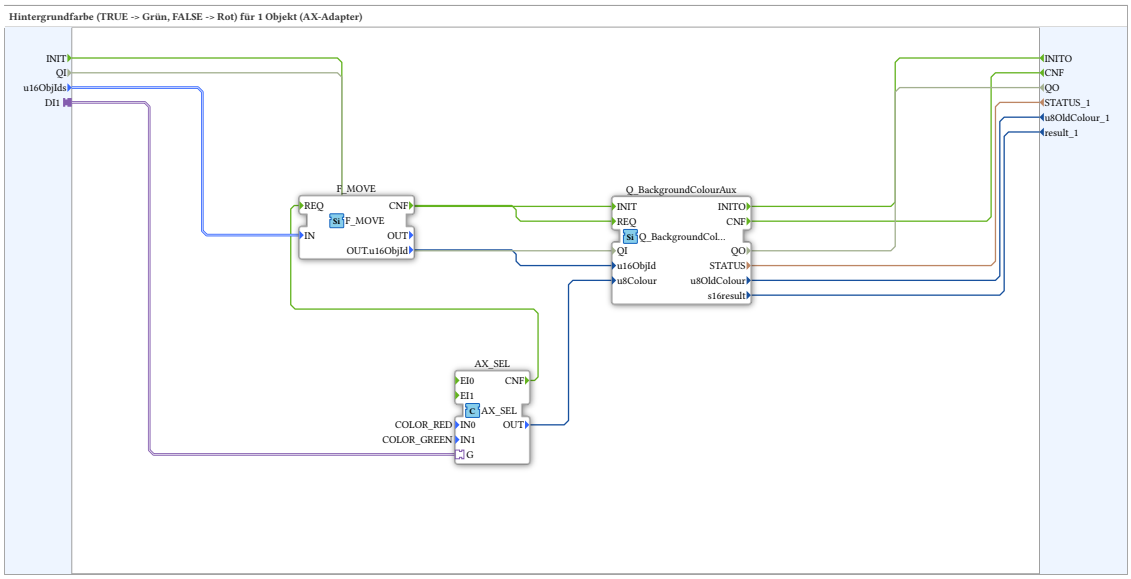
• — ○ • — ○ • — ○ •

Introduction

`GreenRedBackground1_aux_AX` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Rot**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via input `u16ObjId`.

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Quality pattern: the SubApp has the event input `INIT`, the event output `INITO`, the data input `QI` (`BOOL`, default `TRUE`, "Quality Input - TRUE to enable service") and the data output `QO` (`BOOL`, "Quality Output - TRUE if service executed successfully"). They are passed straight through to `Q_BackgroundColourAux`: `INIT` ⟶ `Q_BackgroundColourAux.INIT`, `Q_BackgroundColourAux.INITO` ⟶ `INITO`, `QI` ⟶ `Q_BackgroundColourAux.QI`, `Q_BackgroundColourAux.QO` ⟶ `QO`.



Summary

One of many variants in the background color block family: color pair Grün/Rot, 1 object, adapter selector.

GreenRedBackground1_aux_AXSC

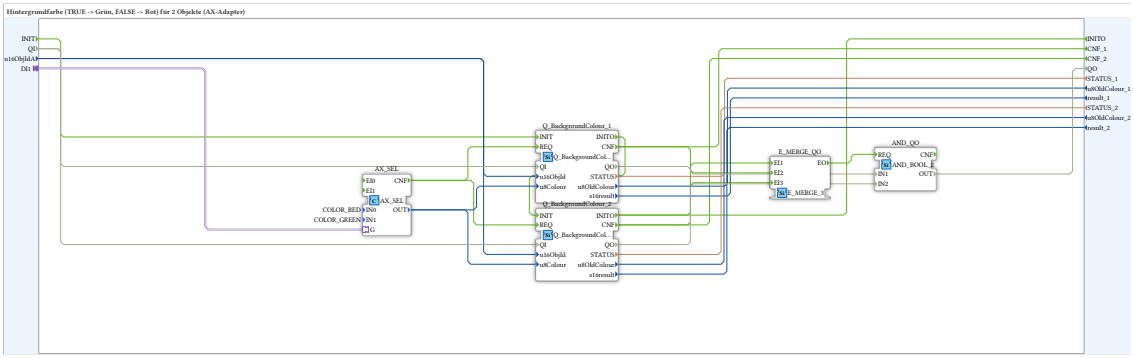
• – ○ • – ○ • – ○ •

Introduction

`GreenRedBackground1_aux_AXSC` is a **compact wrapper** around `GreenRedBackground1_aux_AXS` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

Interface (quality pattern): The wrapper additionally has the event input `INIT` and the event output `INITO` (each `EInit`) as well as the data input `QI` (`BOOL`, default `TRUE`) and the data output `QO` (`BOOL`). They are passed straight through to the inner instance `GreenRedBackground`: `INIT` ⟶ `GreenRedBackground.INIT`, `GreenRedBackground.INITO` ⟶ `INITO`, `QI` ⟶ `GreenRedBackground.QI`, `GreenRedBackground.QO` ⟶ `QO`.

For the shared pattern, see Background Color Blocks (shared pattern).



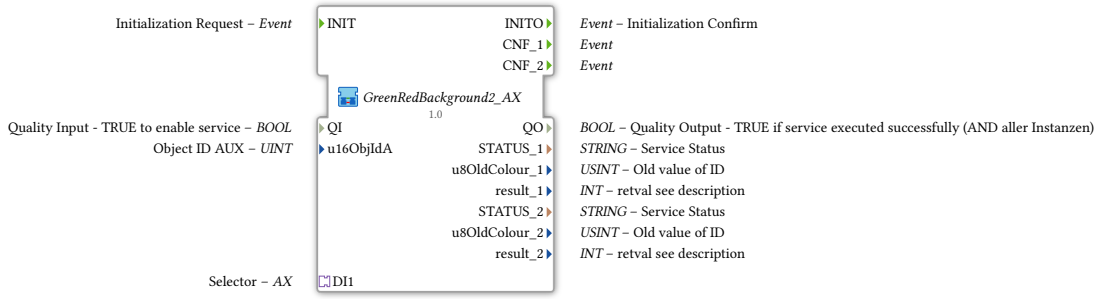
Summary

A pure pass-through to `GreenRedBackground1_aux_AXS` for the common case where the diagnostic values aren't needed.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

GreenRedBackground2_AX



• — ○ • — ○ • — ○ •

Introduction

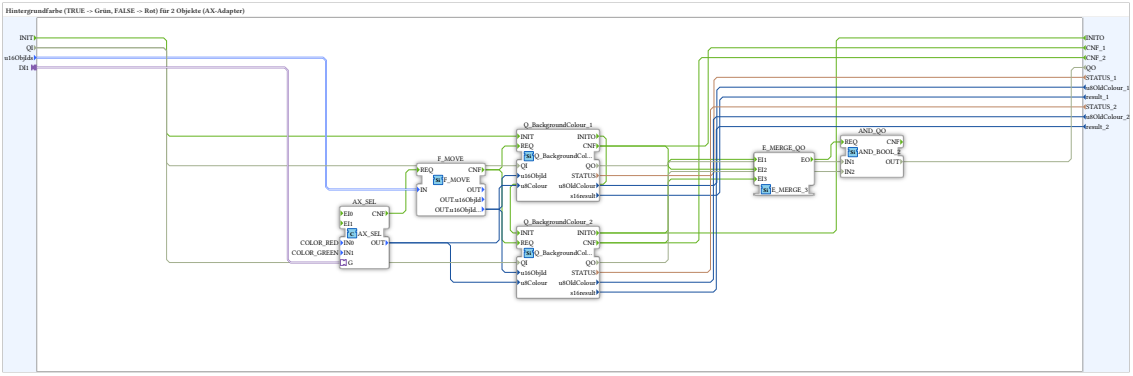
`GreenRedBackground2_AX` switches the VT background color of 2 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Rot**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via inputs `u16ObjIdA`.

Position	Object ID source	Block
1	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `Q_BackgroundColour_1.QI` and `Q_BackgroundColour_2.QI`
- **Data output** `QO` (`BOOL`, Quality Output): AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_2`) of the `QO` outputs of `Q_BackgroundColour_1.QO` and `Q_BackgroundColour_2.QO`
- **Initialization chain**: `INIT` ⟶ `Q_BackgroundColour_1.INIT`, `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` ⟶ `INITO`
- `E_MERGE_QO` (type `iec61499::events::E_MERGE_3`) merges `Q_BackgroundColour_2.INITO`, `Q_BackgroundColour_1.CNF` and `Q_BackgroundColour_2.CNF` and triggers `AND_QO.REQ`



Summary

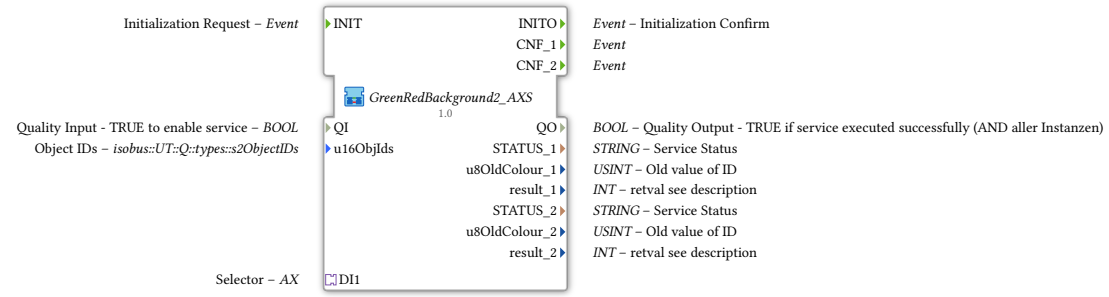
One of many variants in the background color block family: color pair Grün/Rot, 2 objects, adapter selector.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

GreenRedBackground2_AXS

• – ○ • – ○ • – ○ •



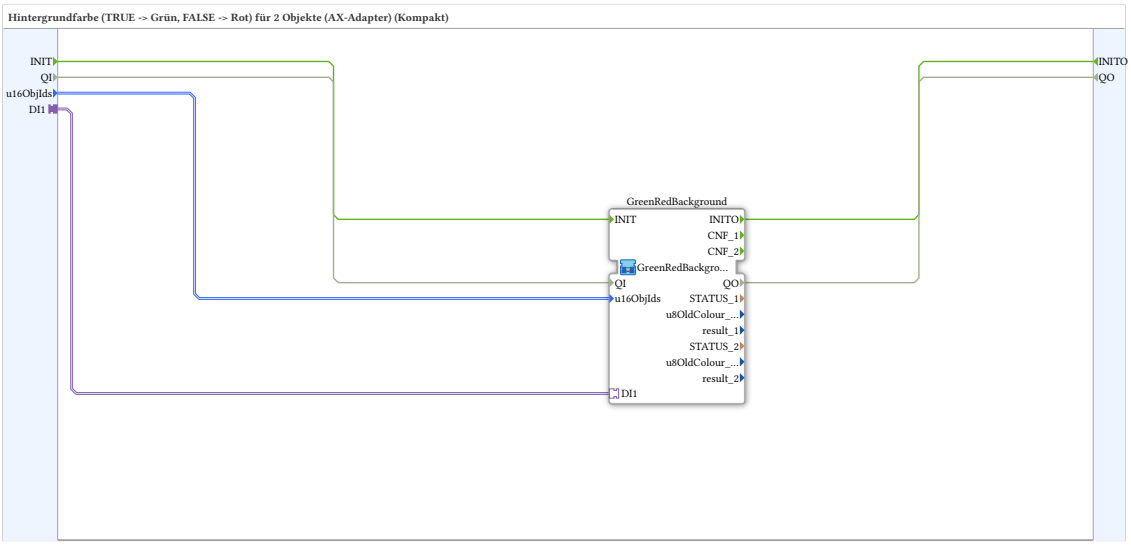
Introduction

`GreenRedBackground2_AXS` switches the VT background color of 2 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Rot**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s2ObjectIDs` (`u16ObjIds`).

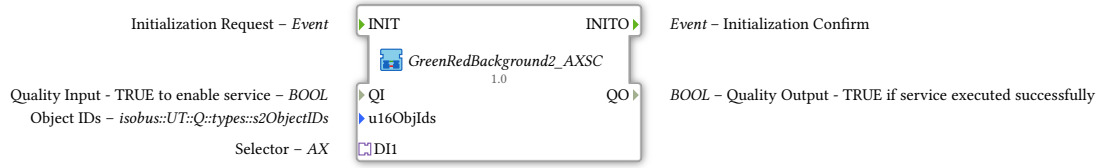
Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and quality: The SubApp has `INIT`/`INITO` and `QI`/`QO`. `INIT` ⟶ `Q_BackgroundColour_1.INIT`, `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` ⟶ `INITO`. `QI` goes to both `Q_BackgroundColour` instances. `QO` is the `AND` (`AND_QO`, `AND_BOOL_2`) of the two `QO` outputs; `AND_QO.REQ` is triggered via `E_MERGE_QO` (`E_MERGE_3`: `Q_BackgroundColour_2.INITO`, `Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF`).



Summary



One of many variants in the background color block family: color pair Grün/Rot, 2 objects, adapter selector, struct. object ID.

🌐 Related topic subpages on ms-muc-docs.de

GreenRedBackground2_AXSC

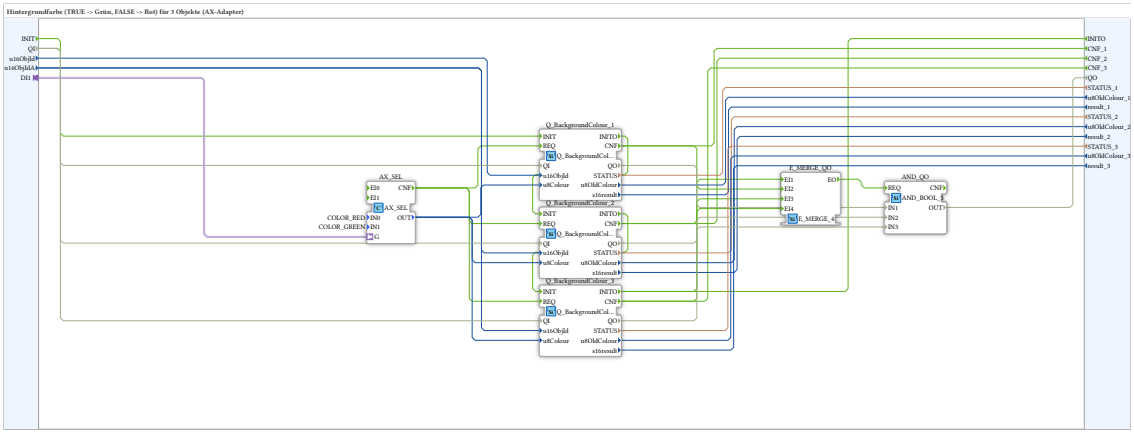
• – ○ • – ○ • – ○ •

Introduction

`GreenRedBackground2_AXSC` is a **compact wrapper** around `GreenRedBackground2_AXS` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

In addition, initialization and quality are passed through: `INIT` ⟶ `GreenRedBackground.INIT`, `GreenRedBackground.INITO` ⟶ `INITO`, `QI` (initial value `TRUE`) ⟶ `GreenRedBackground.QI` and `GreenRedBackground.QO` ⟶ `QO`.

For the shared pattern, see Background Color Blocks (shared pattern).



Summary

A pure pass-through to `GreenRedBackground2_AXS` for the common case where the diagnostic values aren't needed.

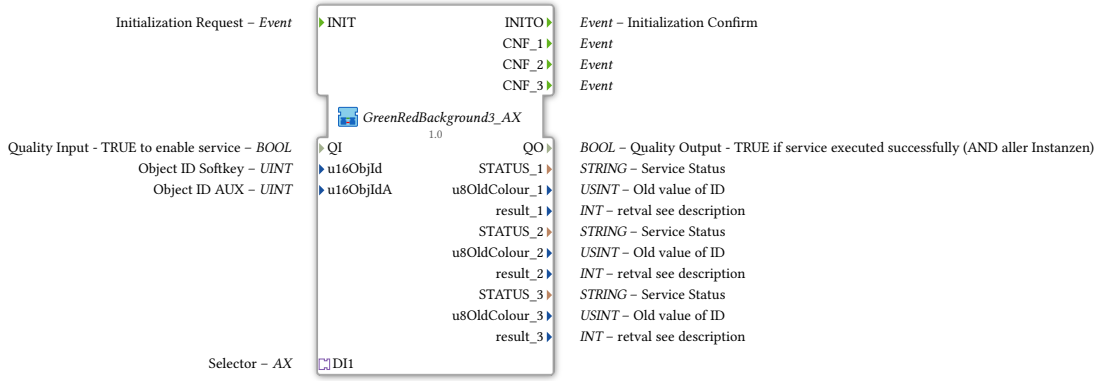
GreenRedBackground3_AX

• — ○ • — ○ • — ○ •



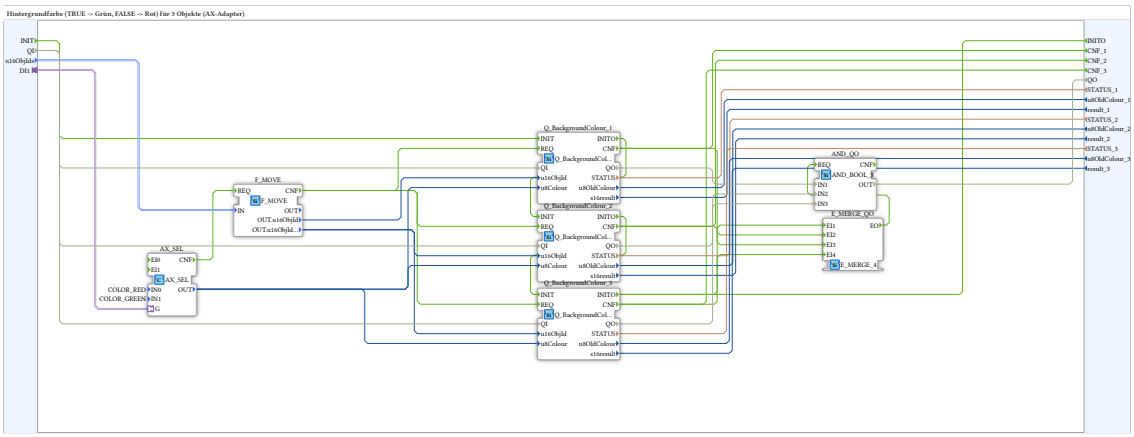
Introduction

`GreenRedBackground3_AX` switches the VT background color of 3 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Rot**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA`.

Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

In addition, the block has the initialization and quality interface: event input `INIT`, event output `INITO`, data input `QI` (`BOOL`, initial value `TRUE`) and data output `QO` (`BOOL`, AND of all instances). `INIT` ⟶ `Q_BackgroundColour_1.INIT`, `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`, `Q_BackgroundColour_3.INITO` ⟶ `INITO` (so the three instances are initialized one after another). `QI` is passed to `QI` of all three instances. `QO` is the output of the instance `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`), which combines `Q_BackgroundColour_1.QO`, `Q_BackgroundColour_2.QO` and `Q_BackgroundColour_3.QO`; its `REQ` is triggered by `E_MERGE_QO` (`iec61499::events::E_MERGE_4`), which merges `Q_BackgroundColour_3.INITO` and the `CNF` events of the three instances.



Summary

One of many variants in the background color block family: color pair Grün/Rot, 3 objects, adapter selector.

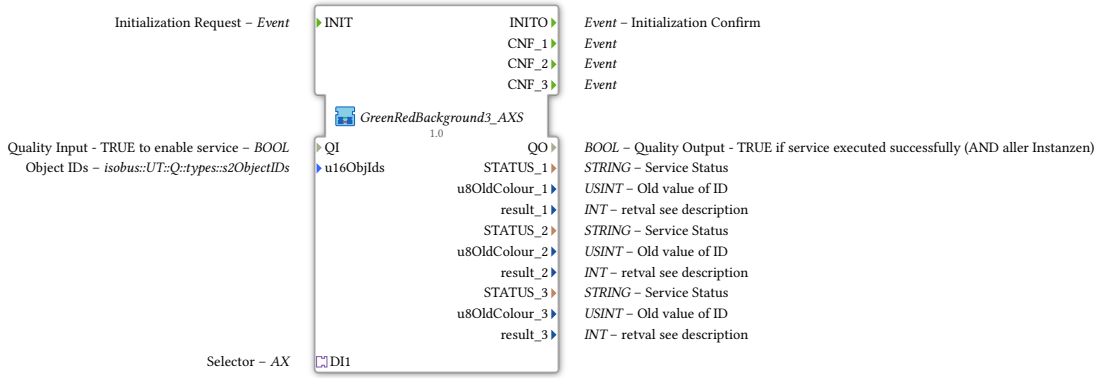
GreenRedBackground3_AXS



• — ○ • — ○ • — ○ •

Introduction

`GreenRedBackground3_AXS` switches the VT background color of 3 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Rot**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s2ObjectIDs` (`u16ObjIds`).

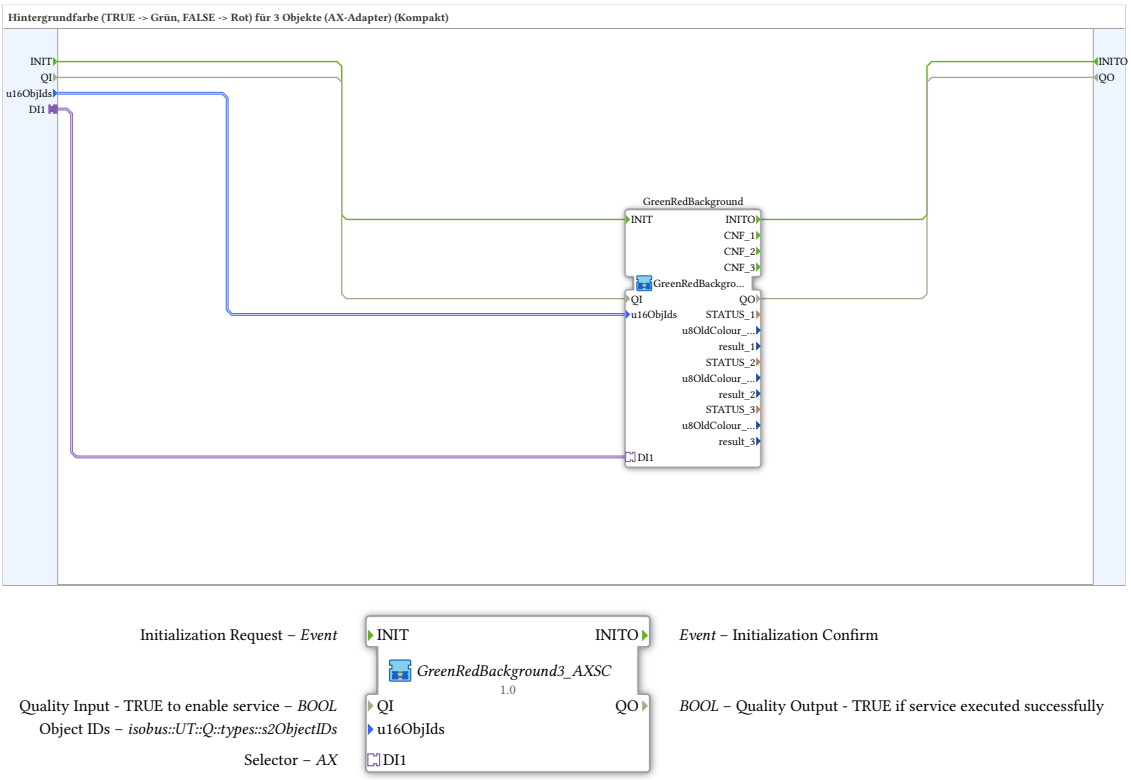
Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`): initialization is chained through the `Q_BackgroundColour` instances: `INIT` ⟶ `Q_BackgroundColour_1.INIT`; `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`; `Q_BackgroundColour_3.INITO` ⟶ `INITO`.
- **Data input `QI`** (`BOOL`, default `TRUE`) is distributed to `.QI` of all instances (`Q_BackgroundColour_1`, `Q_BackgroundColour_2`, `Q_BackgroundColour_3`).
- **Data output `QO`** (`BOOL`): AND of all instances via `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`): `Q_BackgroundColour_1.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN2`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN3`; `AND_QO.OUT` ⟶ `QO`.

- `E_MERGE_QO` (`iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_3.INITO` and the `CNF` events of all three instances (`Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF`, `Q_BackgroundColour_3.CNF`) and thereby triggers `AND_QO.REQ`.



Summary

One of many variants in the background color block family: color pair Grün/Rot, 3 objects, adapter selector, struct. object ID.

GreenRedBackground3_AXSC

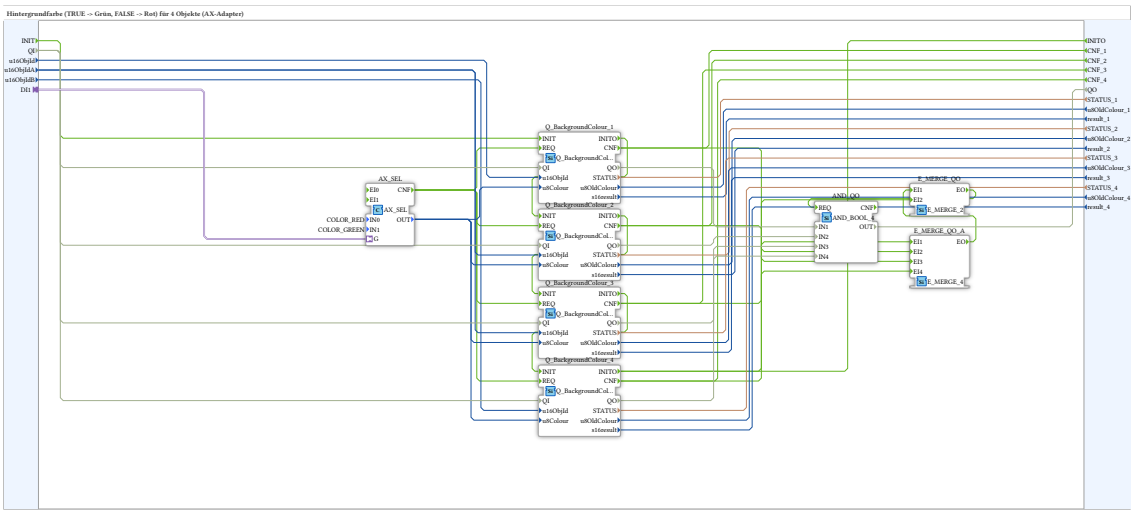
• — ○ • — ○ • — ○ •

Introduction

`GreenRedBackground3_AXSC` is a **compact wrapper** around `GreenRedBackground3_AXS` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

Interface (quality pattern): The wrapper additionally has the event input `INIT` and the event output `INITO` (each `EInit`) as well as the data input `QI` (`BOOL`, default `TRUE`) and the data output `QO` (`BOOL`). They are passed straight through to the inner instance `GreenRedBackground`: `INIT` ⟶ `GreenRedBackground.INIT`, `GreenRedBackground.INITO` ⟶ `INITO`, `QI` ⟶ `GreenRedBackground.QI`, `GreenRedBackground.QO` ⟶ `QO`.

For the shared pattern, see Background Color Blocks (shared pattern).



Summary

A pure pass-through to `GreenRedBackground3_AXS` for the common case where the diagnostic values aren't needed.

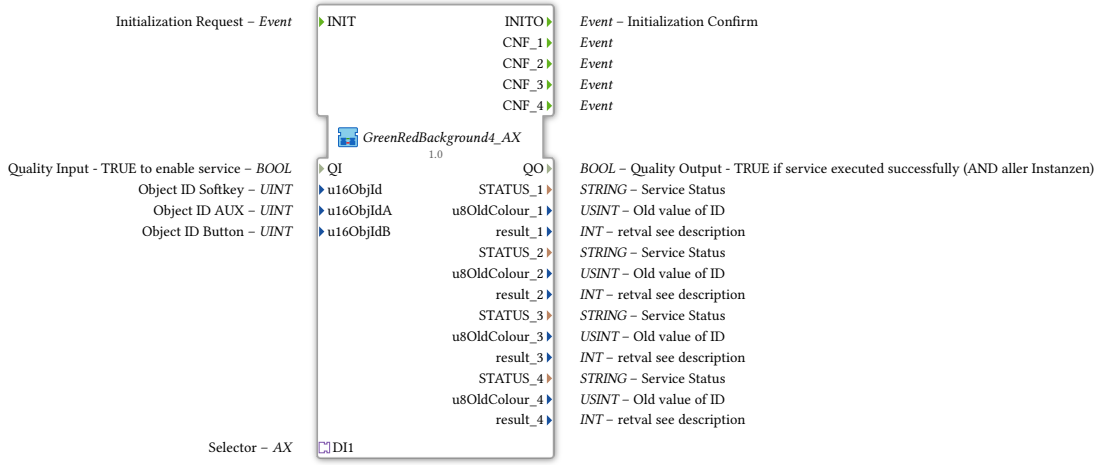
GreenRedBackground4_AX



• — ○ • — ○ • — ○ •

Introduction

`GreenRedBackground4_AX` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Rot**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA, u16ObjIdB`.

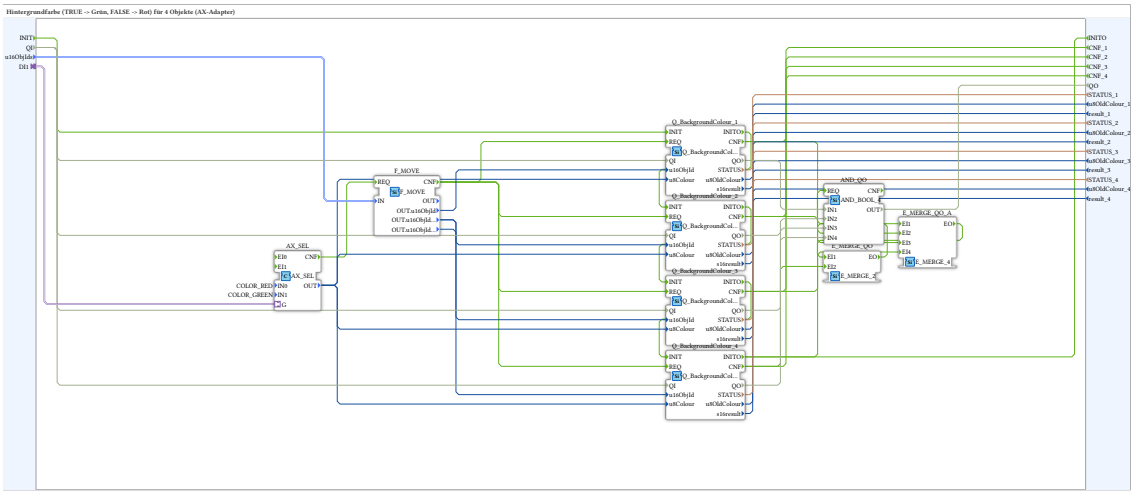
Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`u16ObjIdB`	`Q_BackgroundColour` (regular object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `Q_BackgroundColour_1.QI`, `Q_BackgroundColour_2.QI`, `Q_BackgroundColour_3.QI` and `Q_BackgroundColour_4.QI`

- **Data output** `QO` (`BOOL`, Quality Output): AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_4`) of the `QO` outputs of `Q_BackgroundColour_1.QO`, `Q_BackgroundColour_2.QO`, `Q_BackgroundColour_3.QO` and `Q_BackgroundColour_4.QO`
- **Initialization chain**: `INIT` → `Q_BackgroundColour_1.INIT`, `Q_BackgroundColour_1.INITO` → `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` → `Q_BackgroundColour_3.INIT`, `Q_BackgroundColour_3.INITO` → `Q_BackgroundColour_4.INIT`, `Q_BackgroundColour_4.INITO` → `INITO`
- `E_MERGE_QO_A` (type `iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_4.INITO`, `Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF` and `Q_BackgroundColour_3.CNF` and passes the result to `E_MERGE_QO.EI1`
- `E_MERGE_QO` (type `iec61499::events::E_MERGE_2`) merges `E_MERGE_QO_A.EO` and `Q_BackgroundColour_4.CNF` and triggers `AND_QO.REQ`



Summary

One of many variants in the background color block family: color pair Grün/Rot, 4 objects, adapter selector.

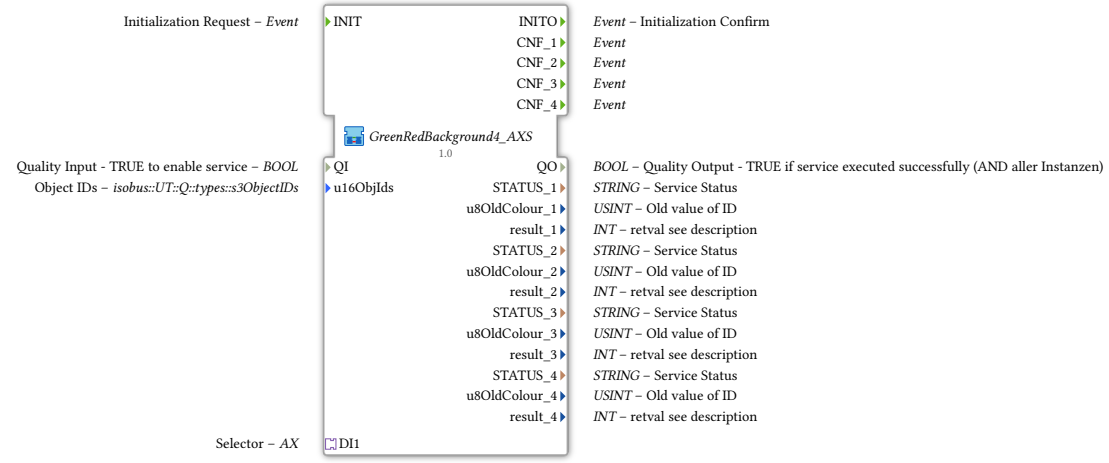
GreenRedBackground4_AXS

• – ○ • – ○ • – ○ •

Introduction



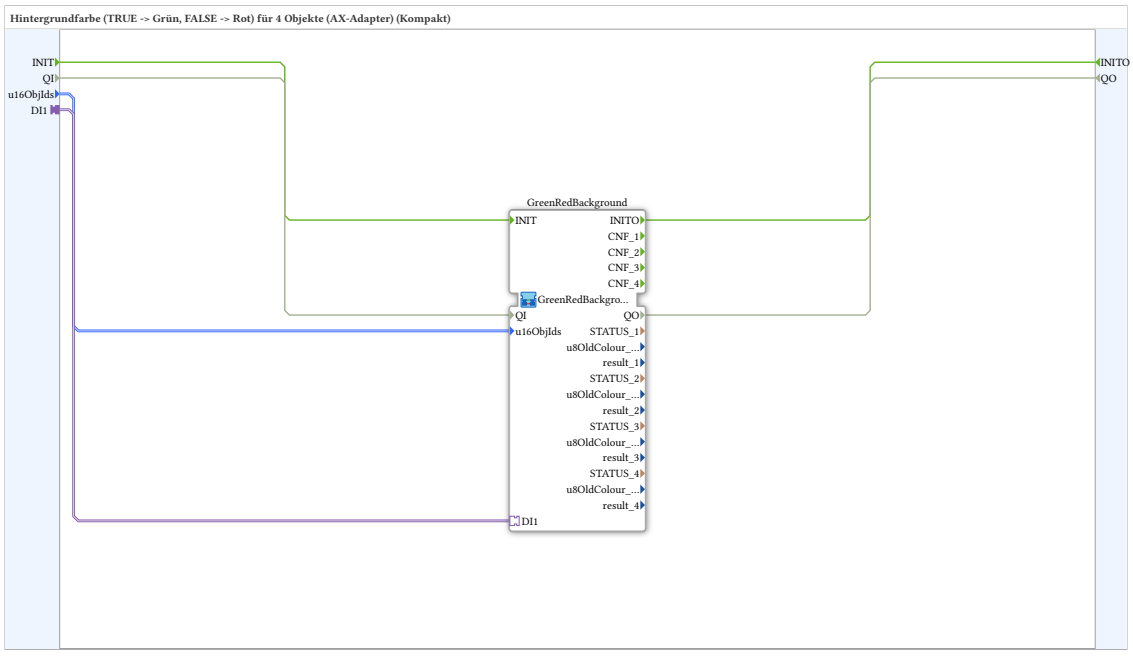
`GreenRedBackground4_AXS` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` → **Grün**, `FALSE` → **Rot**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s3ObjectIDs` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`F_MOVE.OUT.u16ObjIdB`	`Q_BackgroundColour` (regular object)

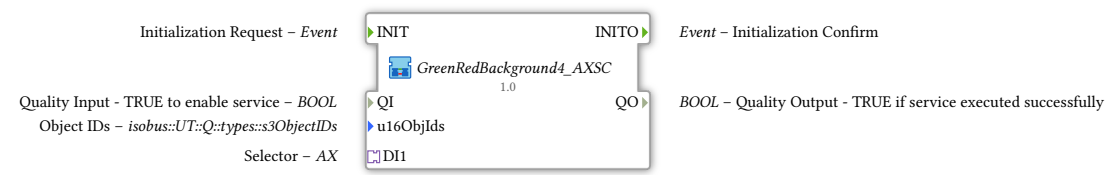
For the general pattern (selector → `AX_SEL`/`F_SEL` → `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and quality: The SubApp has `INIT`/`INITO` and `QI`/`QO`. `INIT` → `Q_BackgroundColour_1.INIT` → `Q_BackgroundColour_2.INIT` → `Q_BackgroundColour_3.INIT` → `Q_BackgroundColour_4.INIT` (each via `INITO`), `Q_BackgroundColour_4.INITO` → `INITO`. `QI` goes to all four instances. `QO` is the `AND` (`AND_QO`, `AND_BOOL_4`) of the four `QO` outputs; `AND_QO.REQ` is triggered via the

cascade `E_MERGE_QO_A` (`E_MERGE_4`: `Q_BackgroundColour_4.INITO`, `Q_BackgroundColour_1.CNF`, `_2.CNF`, `_3.CNF`) and `E_MERGE_QO` (`E_MERGE_2`: output of `E_MERGE_QO_A` and `Q_BackgroundColour_4.CNF`).



Summary



One of many variants in the background color block family: color pair Grün/Rot, 4 objects, adapter selector, struct. object ID.

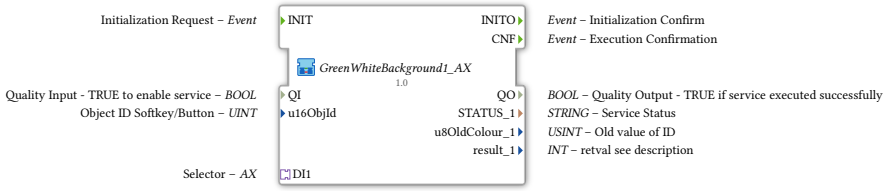
GreenWhiteBackground1_AX



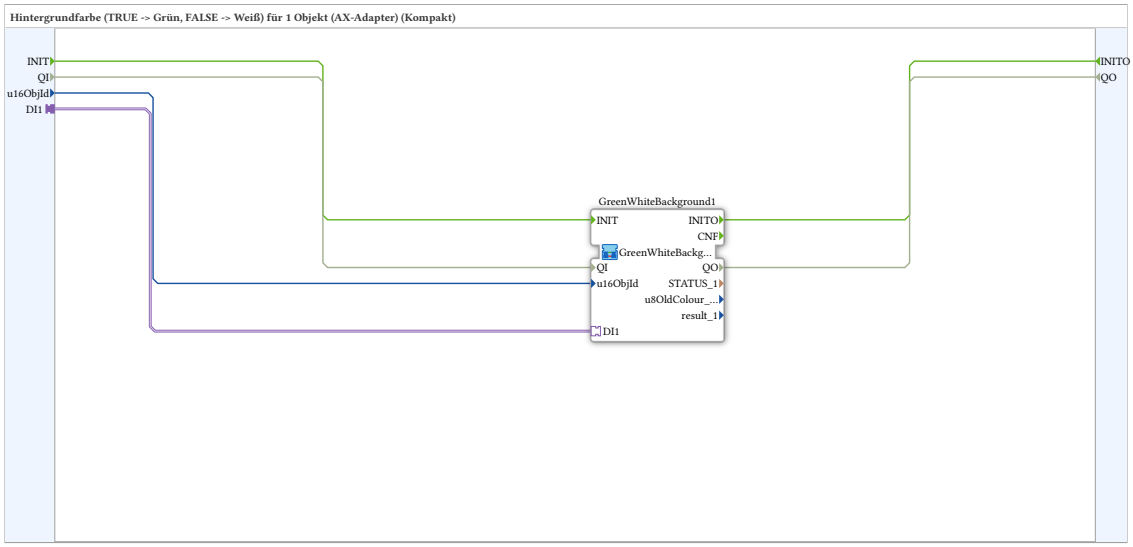
• – ○ • – ○ • – ○ •

Introduction

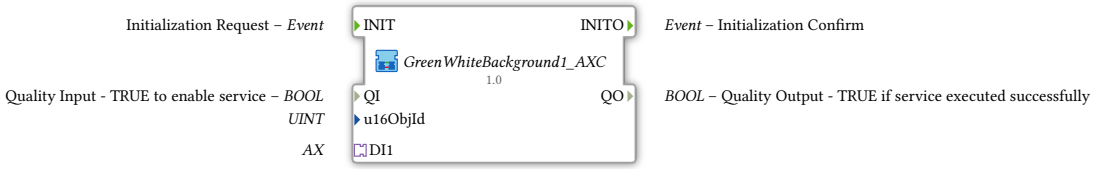
`GreenWhiteBackground1_AX` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via input `u16ObjId`.

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Quality pattern: the SubApp has the event input `INIT`, the event output `INITO`, the data input `QI` (`BOOL`, default `TRUE`, "Quality Input - TRUE to enable service") and the data output `QO` (`BOOL`, "Quality Output - TRUE if service executed successfully"). They are passed straight through to `Q_BackgroundColour`: `INIT` ⟶ `Q_BackgroundColour.INIT`, `Q_BackgroundColour.INITO` ⟶ `INITO`, `QI` ⟶ `Q_BackgroundColour.QI`, `Q_BackgroundColour.QO` ⟶ `QO`.



Summary



One of many variants in the background color block family: color pair Grün/Weiß, 1 object, adapter selector.

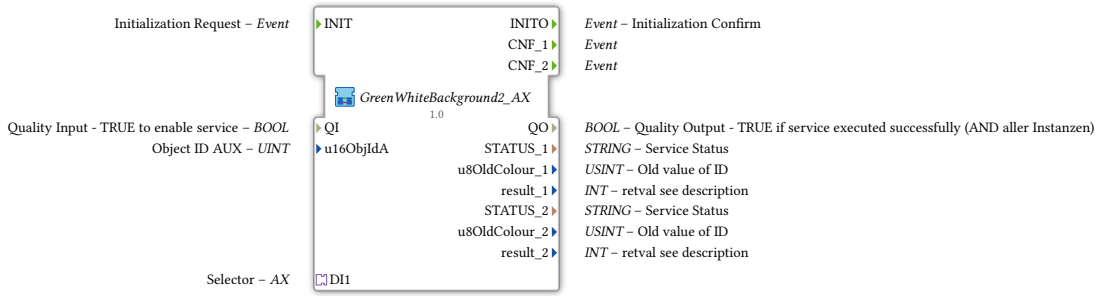
GreenWhiteBackground2_AX



• – ○ • – ○ • – ○ •

Introduction

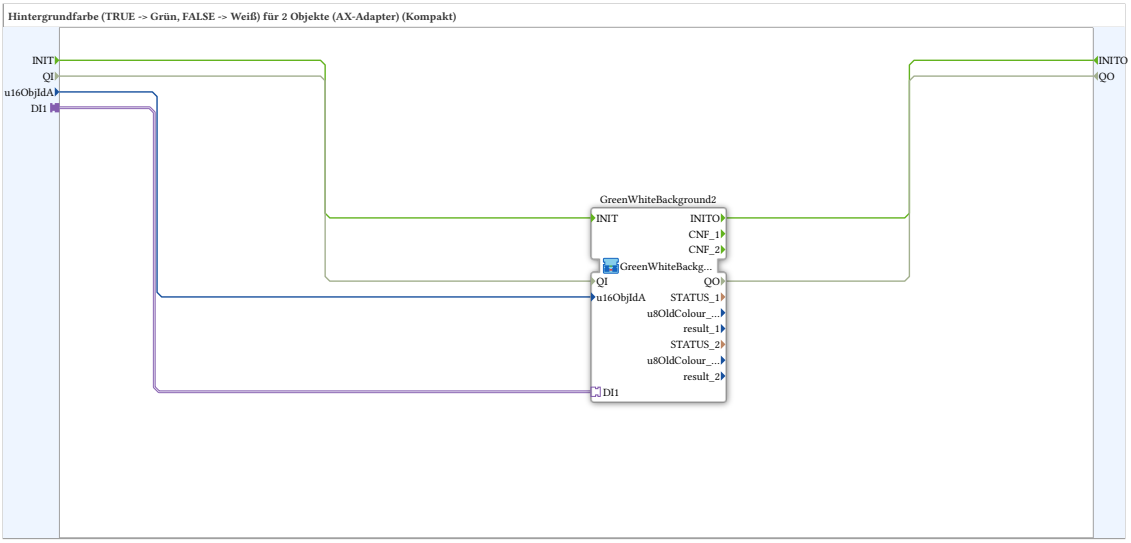
`GreenWhiteBackground2_AX` switches the VT background color of 2 objects based on a boolean selector signal: `TRUE` → **Grün**, `FALSE` → **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via inputs `u16ObjIdA`.

Position	Object ID source	Block
1	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

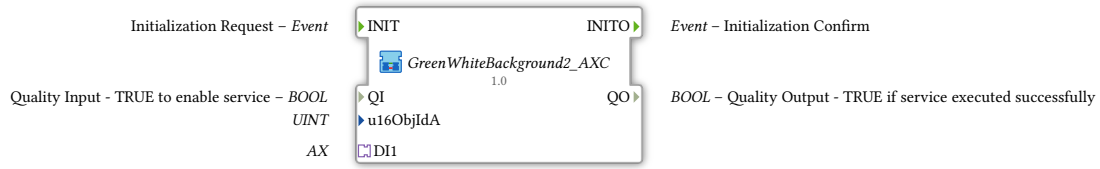
For the general pattern (selector → `AX_SEL`/`F_SEL` → `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `Q_BackgroundColour_1.QI` and `Q_BackgroundColour_2.QI`
- **Data output** `QO` (`BOOL`, Quality Output): AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_2`) of the `QO` outputs of `Q_BackgroundColour_1.QO` and `Q_BackgroundColour_2.QO`
- **Initialization chain**: `INIT` → `Q_BackgroundColour_1.INIT`, `Q_BackgroundColour_1.INITO` → `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` → `INITO`
- `E_MERGE_QO` (type `iec61499::events::E_MERGE_3`) merges `Q_BackgroundColour_2.INITO`, `Q_BackgroundColour_1.CNF` and `Q_BackgroundColour_2.CNF` and triggers `AND_QO.REQ`



Summary



One of many variants in the background color block family: color pair Grün/Weiß, 2 objects, adapter selector.

🌐 Related topic subpages on ms-muc-docs.de

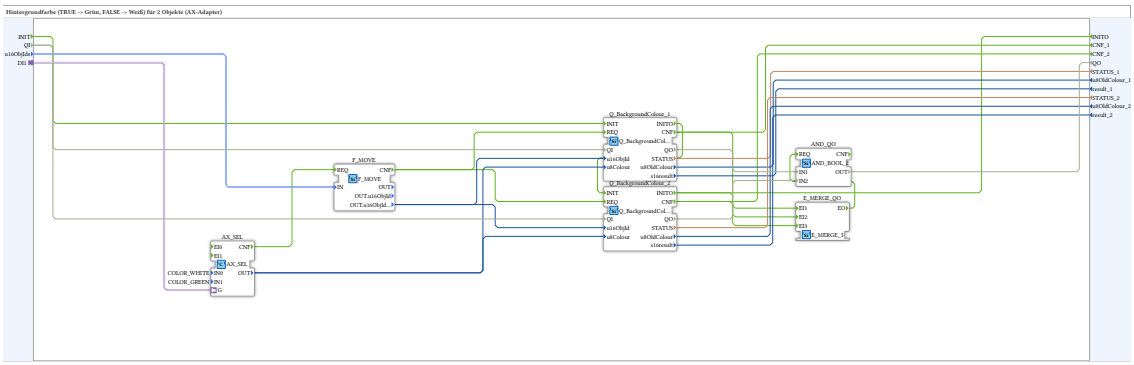
GreenWhiteBackground2_AXC

• — ○ • — ○ • — ○ •

Introduction

`GreenWhiteBackground2_AXC` is a **compact wrapper** around `GreenWhiteBackground2_AX` — passes `u16ObjId` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`). In addition, `INIT` ⟶ `GreenWhiteBackground2.INIT`, `GreenWhiteBackground2.INITO` ⟶ `INITO`, `QI` ⟶ `GreenWhiteBackground2.QI` (initial value `TRUE`) and `GreenWhiteBackground2.QO` ⟶ `QO` are passed through.

For the shared pattern, see Background Color Blocks (shared pattern).



Summary

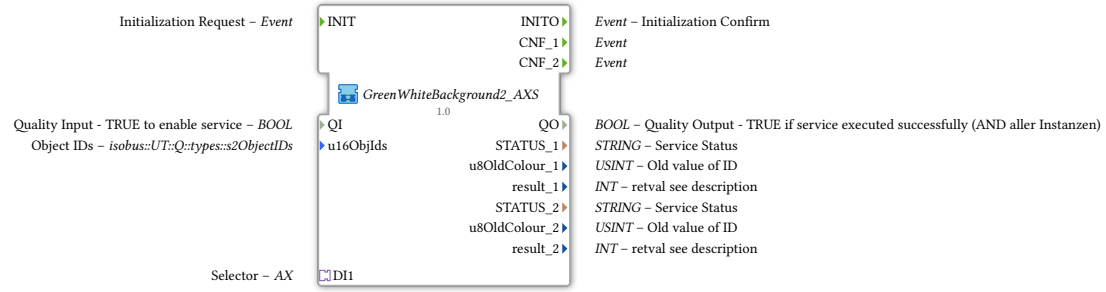
A pure pass-through to `GreenWhiteBackground2_AX` for the common case where the diagnostic values aren't needed.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

GreenWhiteBackground2_AXS

• – ○ • – ○ • – ○ •



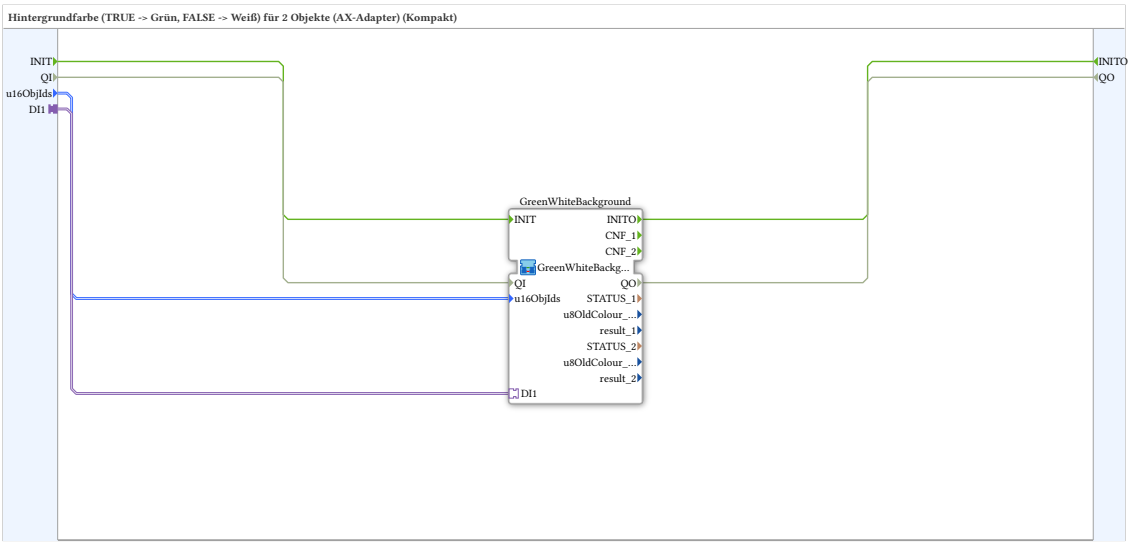
Introduction

`GreenWhiteBackground2_AXS` switches the VT background color of 2 objects based on a boolean selector signal: `TRUE` → **Grün**, `FALSE` → **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

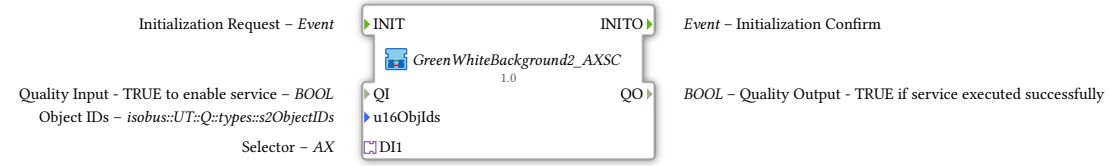
Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

Initialization and quality: In addition to the previous events, the block has the event input `INIT`, the event output `INITO`, as well as `QI` (BOOL, input, initial value `TRUE`) and `QO` (BOOL, output, AND of all instances). Init chain: `INIT` → `Q_BackgroundColour_1` → `Q_BackgroundColour_2` → `INITO` (each `INITO` → next `INIT`). `QI` is passed on to all `Q_BackgroundColour_n.QI`. `QO` is formed by `AND_QO` (`iec61131::booleanOperators::AND_BOOL_2`): `Q_BackgroundColour_1.QO` → `AND_QO.IN1`, `Q_BackgroundColour_2.QO` → `AND_QO.IN2`, `AND_QO.OUT` → `QO`. `E_MERGE_QO` (`E_MERGE_3`) merges `Q_BackgroundColour_2.INITO` and the `CNF` outputs `Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF`; `E_MERGE_QO.EO` triggers `AND_QO.REQ`.

For the general pattern (selector → `AX_SEL`/`F_SEL` → `Q_BackgroundColour`), see Background Color Blocks (shared pattern).



Summary



One of many variants in the background color block family: color pair Grün/Weiß, 2 objects, adapter selector, struct. object ID.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

GreenWhiteBackground2_AXSC

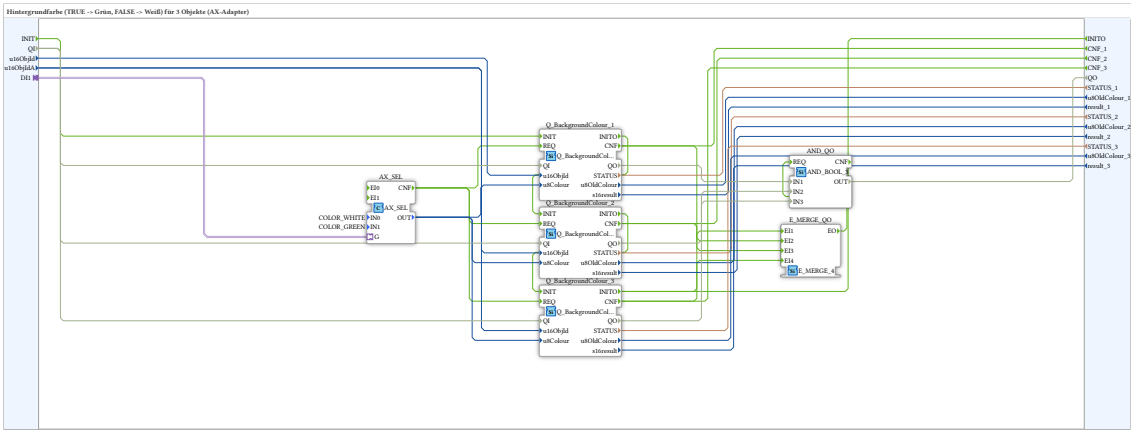
• — ○ • — ○ • — ○ •

Introduction

`GreenWhiteBackground2_AXSC` is a **compact wrapper** around `GreenWhiteBackground2_AXS` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

For the shared pattern, see Background Color Blocks (shared pattern).

In addition, the wrapper exposes the initialization and quality interface: event input `INIT`, event output `INITO`, data input `QI` (`BOOL`, initial value `TRUE`) and data output `QO` (`BOOL`). They are passed 1:1 through to the inner instance `GreenWhiteBackground`: `INIT` ⟶ `GreenWhiteBackground.INIT`, `GreenWhiteBackground.INITO` ⟶ `INITO`, `QI` ⟶ `GreenWhiteBackground.QI`, `GreenWhiteBackground.QO` ⟶ `QO`.



Summary

A pure pass-through to `GreenWhiteBackground2_AXS` for the common case where the diagnostic values aren't needed.

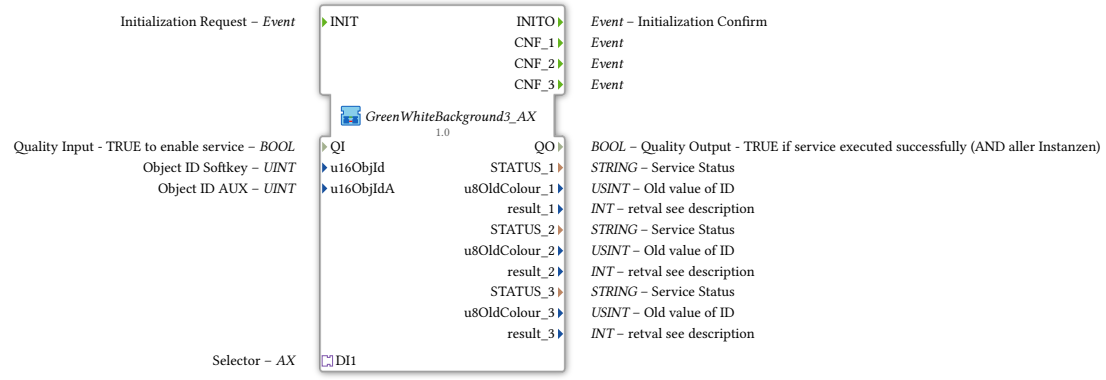
GreenWhiteBackground3_AX



• – ○ • – ○ • – ○ •

Introduction

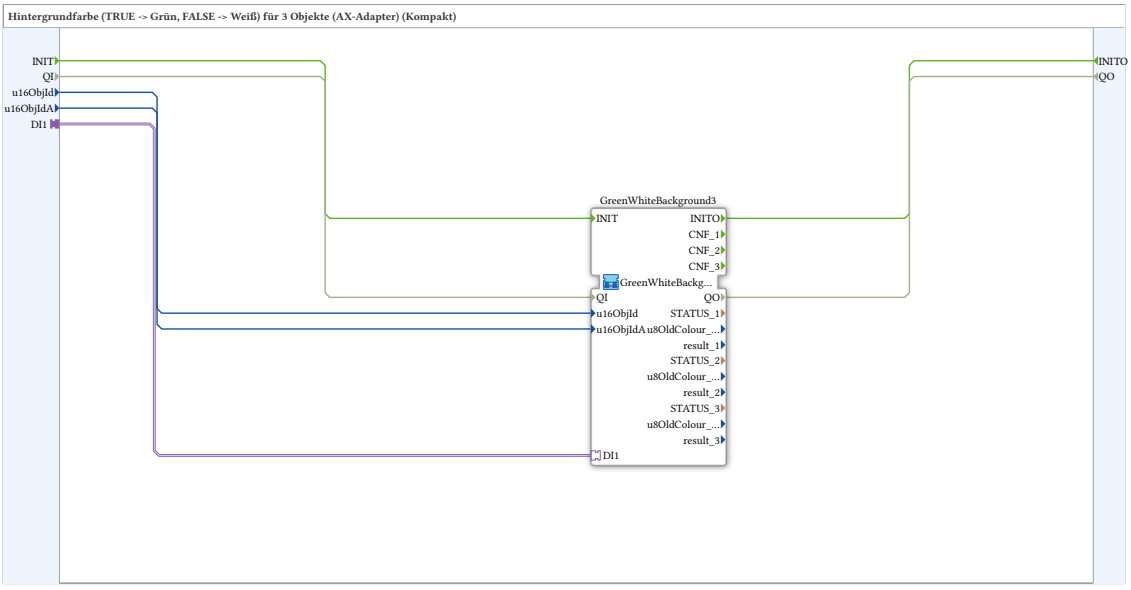
`GreenWhiteBackground3_AX` switches the VT background color of 3 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA`.

Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`): initialization is chained through the `Q_BackgroundColour` instances: `INIT` ⟶ `Q_BackgroundColour_1.INIT`; `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`; `Q_BackgroundColour_3.INITO` ⟶ `INITO`.
- **Data input `QI`** (`BOOL`, default `TRUE`) is distributed to `.QI` of all instances (`Q_BackgroundColour_1`, `Q_BackgroundColour_2`, `Q_BackgroundColour_3`).
- **Data output `QO`** (`BOOL`): AND of all instances via `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`): `Q_BackgroundColour_1.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN2`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN3`; `AND_QO.OUT` ⟶ `QO`.
- `E_MERGE_QO` (`iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_3.INITO` and the `CNF` events of all three instances (`Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF`, `Q_BackgroundColour_3.CNF`) and thereby triggers `AND_QO.REQ`.



Summary

One of many variants in the background color block family: color pair Grün/Weiß, 3 objects, adapter selector.

🌐 Related topic subpages on ms-muc-docs.de

GreenWhiteBackground3_AXC

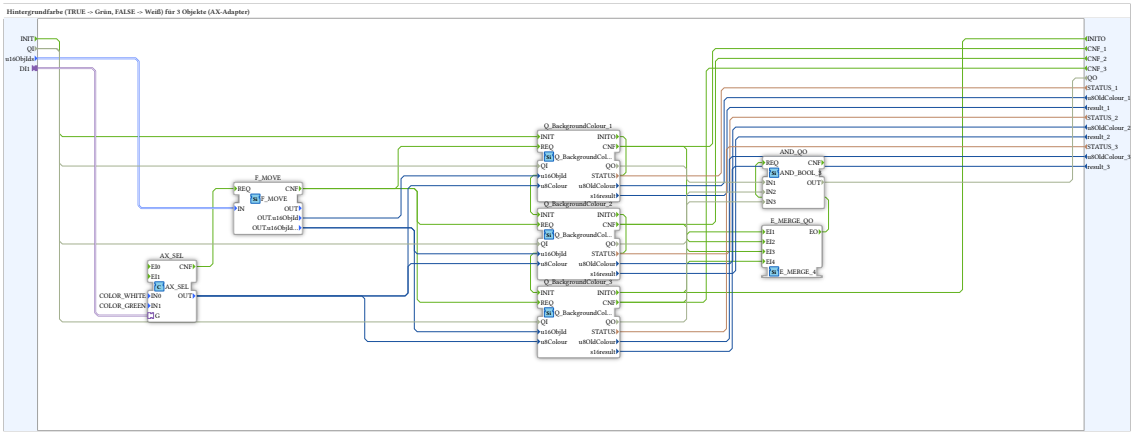
• – ○ • – ○ • – ○ •

Introduction

`GreenWhiteBackground3_AXC` is a **compact wrapper** around `GreenWhiteBackground3_AX` — passes `u16ObjId` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

Interface (quality pattern): The wrapper additionally has the event input `INIT` and the event output `INITO` (each `EInit`) as well as the data input `QI` (`BOOL`, default `TRUE`) and the data output `QO` (`BOOL`). They are passed straight through to the inner instance `GreenWhiteBackground3`: `INIT` ⟶ `GreenWhiteBackground3.INIT`, `GreenWhiteBackground3.INITO` ⟶ `INITO`, `QI` ⟶ `GreenWhiteBackground3.QI`, `GreenWhiteBackground3.QO` ⟶ `QO`.

For the shared pattern, see Background Color Blocks (shared pattern).



Summary

A pure pass-through to `GreenWhiteBackground3_AX` for the common case where the diagnostic values aren't needed.

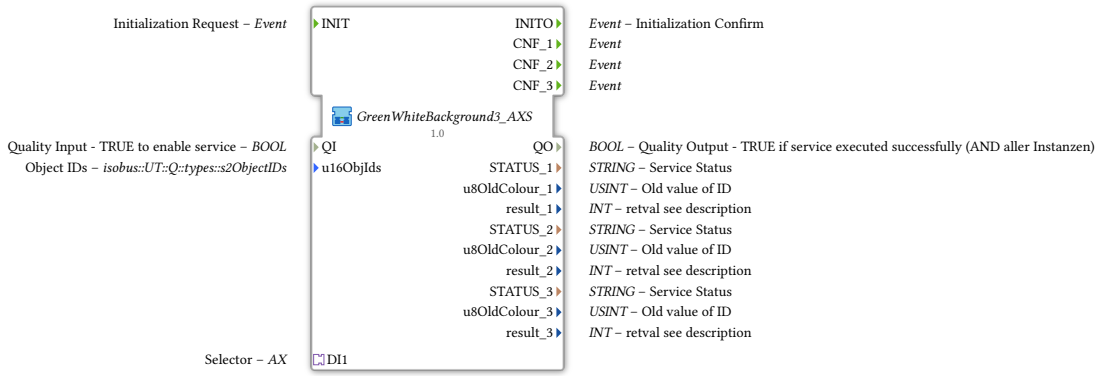
GreenWhiteBackground3_AXS



• – ○ • – ○ • – ○ •

Introduction

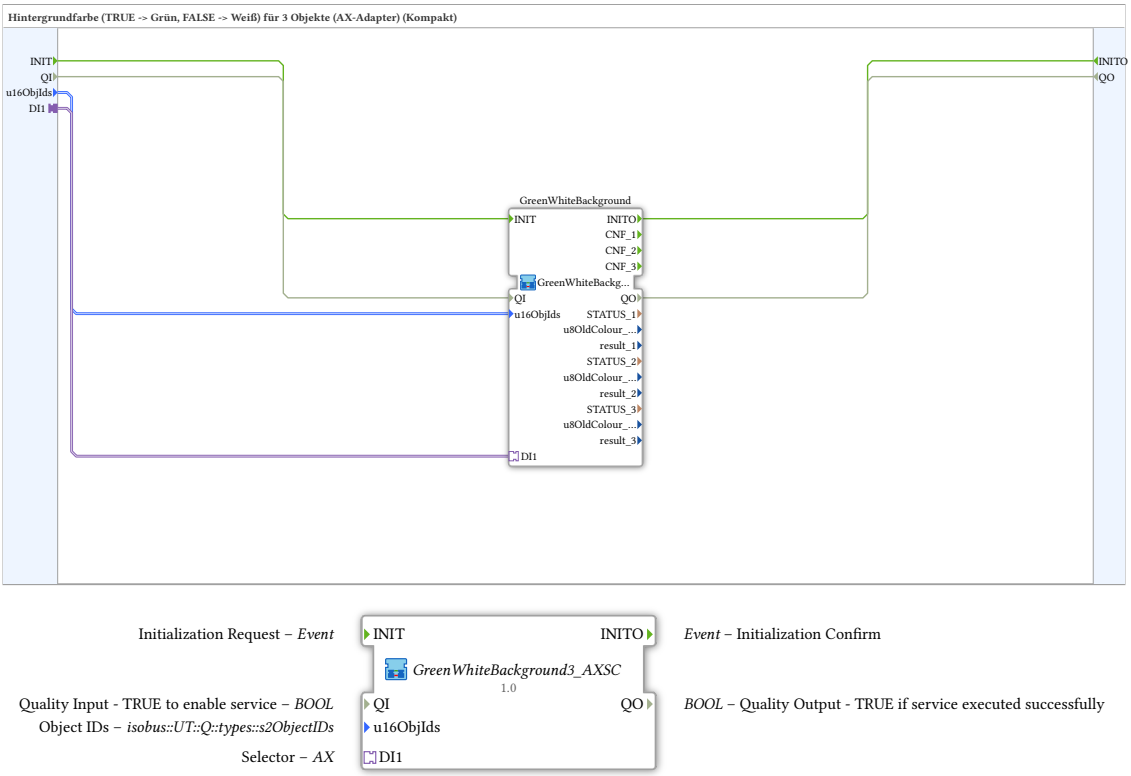
`GreenWhiteBackground3_AXS` switches the VT background color of 3 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `Q_BackgroundColour_1.QI`, `Q_BackgroundColour_2.QI` and `Q_BackgroundColour_3.QI`
- **Data output** `QO` (`BOOL`, Quality Output): AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_3`) of the `QO` outputs of `Q_BackgroundColour_1.QO`, `Q_BackgroundColour_2.QO` and `Q_BackgroundColour_3.QO`
- **Initialization chain**: `INIT` ⟶ `Q_BackgroundColour_1.INIT`, `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`, `Q_BackgroundColour_3.INITO` ⟶ `INITO`
- `E_MERGE_QO` (type `iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_3.INITO`, `Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF` and `Q_BackgroundColour_3.CNF` and triggers `AND_QO.REQ`



Summary

One of many variants in the background color block family: color pair Grün/Weiß, 3 objects, adapter selector, struct. object ID.

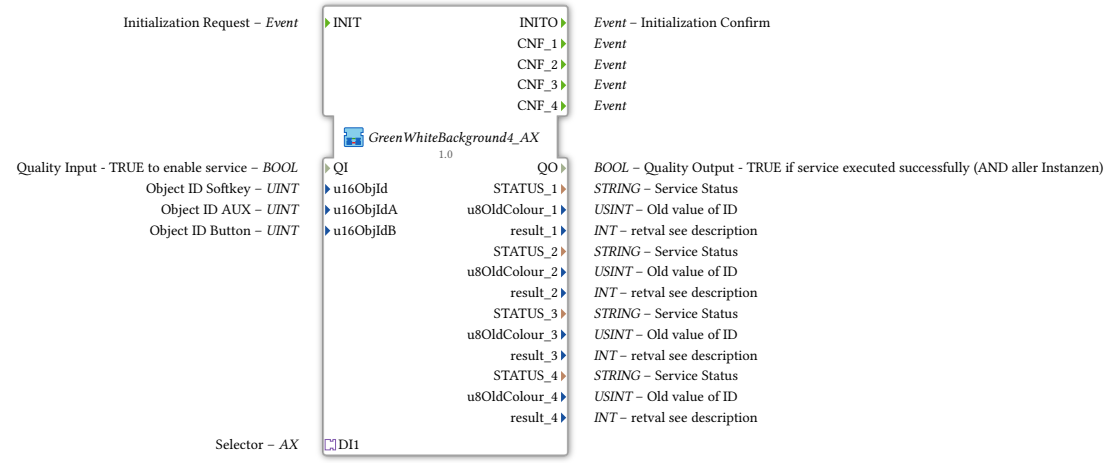
GreenWhiteBackground4_AX

• – ○ • – ○ • – ○ •



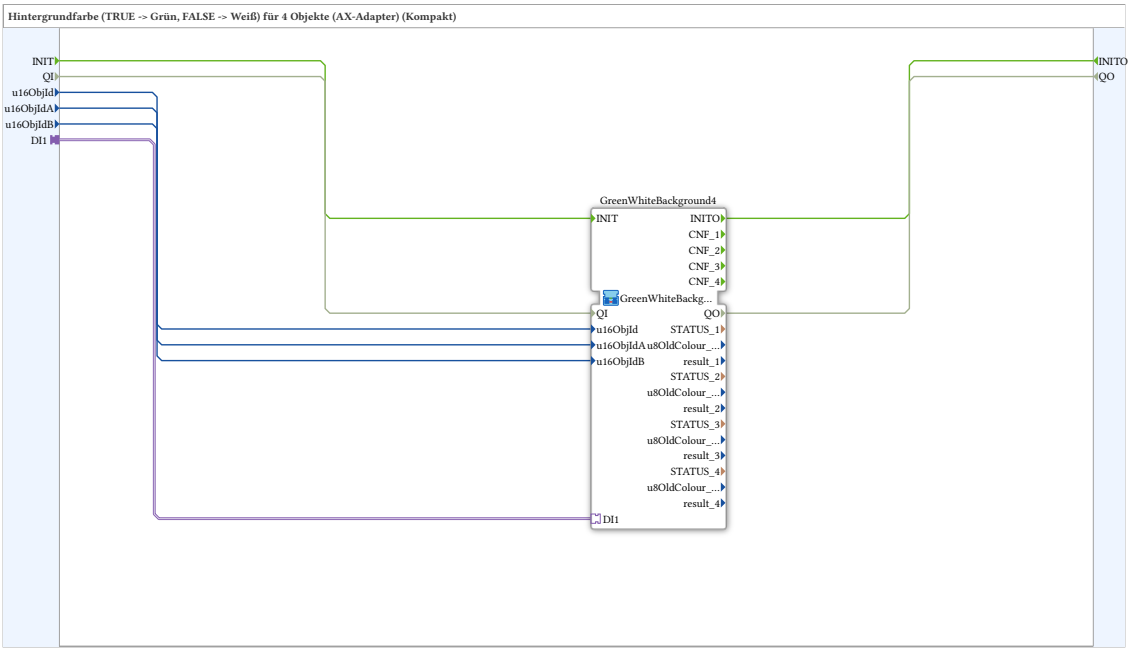
Introduction

`GreenWhiteBackground4_AX` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` → **Grün**, `FALSE` → **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA, u16ObjIdB`.

Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`u16ObjIdB`	`Q_BackgroundColour` (regular object)

Initialization and quality: In addition to the previous events, the block has the event input `INIT`, the event output `INITO`, as well as `QI` (BOOL, input, initial value `TRUE`) and `QO` (BOOL, output, AND of all instances). Init chain: `INIT` → `Q_BackgroundColour_1` → `Q_BackgroundColour_2` → `Q_BackgroundColour_3` → `Q_BackgroundColour_4` → `INITO` (each `INITO` → next `INIT`). `QI` is passed on to all `Q_BackgroundColour_n.QI`. `QO` is formed by `AND_QO` (`iec61131::booleanOperators::AND_BOOL_4`): `Q_BackgroundColour_1.QO` → `AND_QO.IN1`, `Q_BackgroundColour_2.QO` → `AND_QO.IN2`, `Q_BackgroundColour_3.QO` → `AND_QO.IN3`, `Q_BackgroundColour_4.QO` → `AND_QO.IN4`, `AND_QO.OUT` → `QO`. `E_MERGE_QO_A` (`E_MERGE_4`) merges `Q_BackgroundColour_4.INITO` and the `CNF` outputs of `Q_BackgroundColour_1`, `Q_BackgroundColour_2` and `Q_BackgroundColour_3`, `E_MERGE_QO` (`E_MERGE_2`) adds `Q_BackgroundColour_4.CNF`; `E_MERGE_QO.EO` triggers `AND_QO.REQ`.

For the general pattern (selector → `AX_SEL`/`F_SEL` → `Q_BackgroundColour`), see Background Color Blocks (shared pattern).



Summary

One of many variants in the background color block family: color pair Grün/Weiß, 4 objects, adapter selector.

GreenWhiteBackground4_AXC

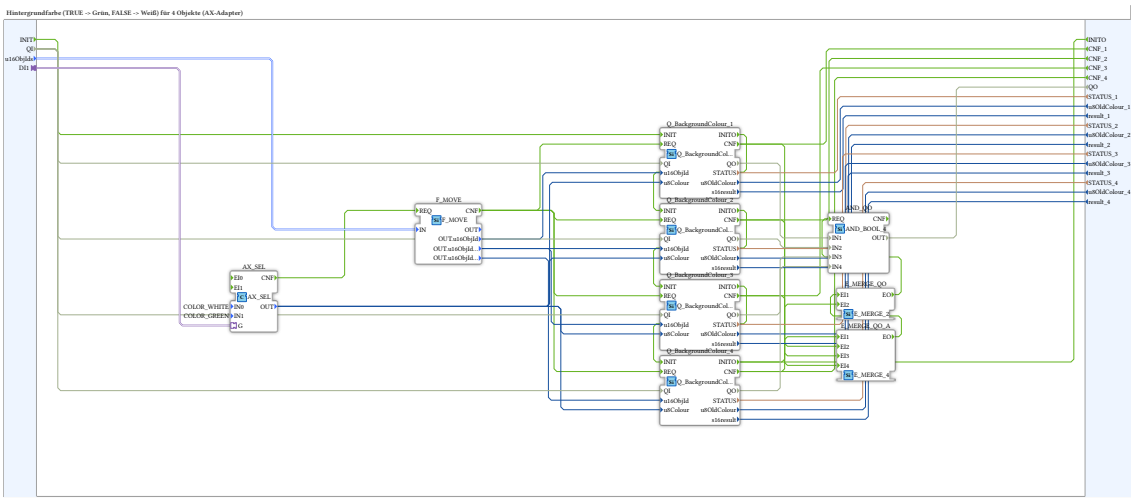
• — ○ • — ○ • — ○ •

Introduction

`GreenWhiteBackground4_AXC` is a **compact wrapper** around `GreenWhiteBackground4_AX` — passes `u16ObjId` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

For the shared pattern, see Background Color Blocks (shared pattern).

In addition, the wrapper exposes the initialization and quality interface: event input `INIT`, event output `INITO`, data input `QI` (`BOOL`, initial value `TRUE`) and data output `QO` (`BOOL`). They are passed 1:1 through to the inner instance `GreenWhiteBackground4`: `INIT` → `GreenWhiteBackground4.INIT`, `GreenWhiteBackground4.INITO` → `INITO`, `QI` → `GreenWhiteBackground4.QI`, `GreenWhiteBackground4.QO` → `QO`.



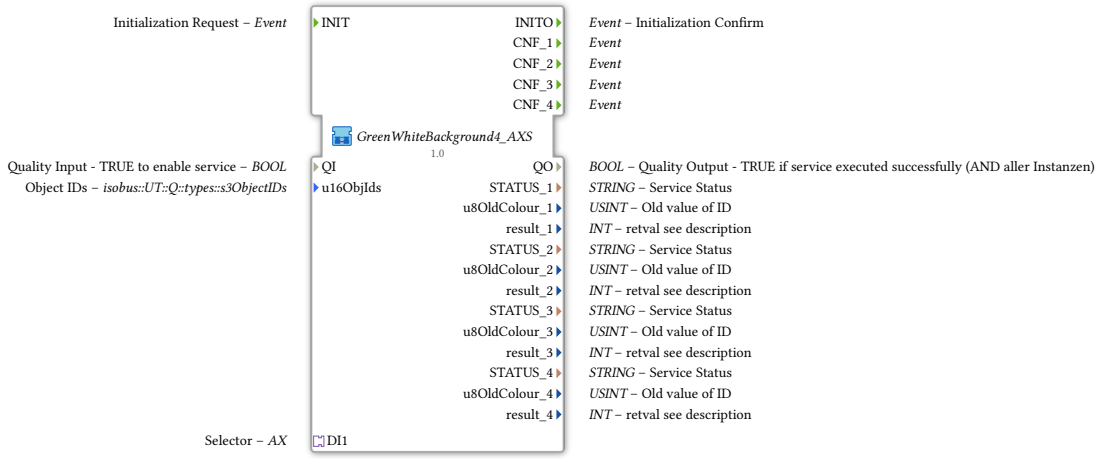
Summary

A pure pass-through to `GreenWhiteBackground4_AX` for the common case where the diagnostic values aren't needed.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

GreenWhiteBackground4_AXS



• – ○ • – ○ • – ○ •

Introduction

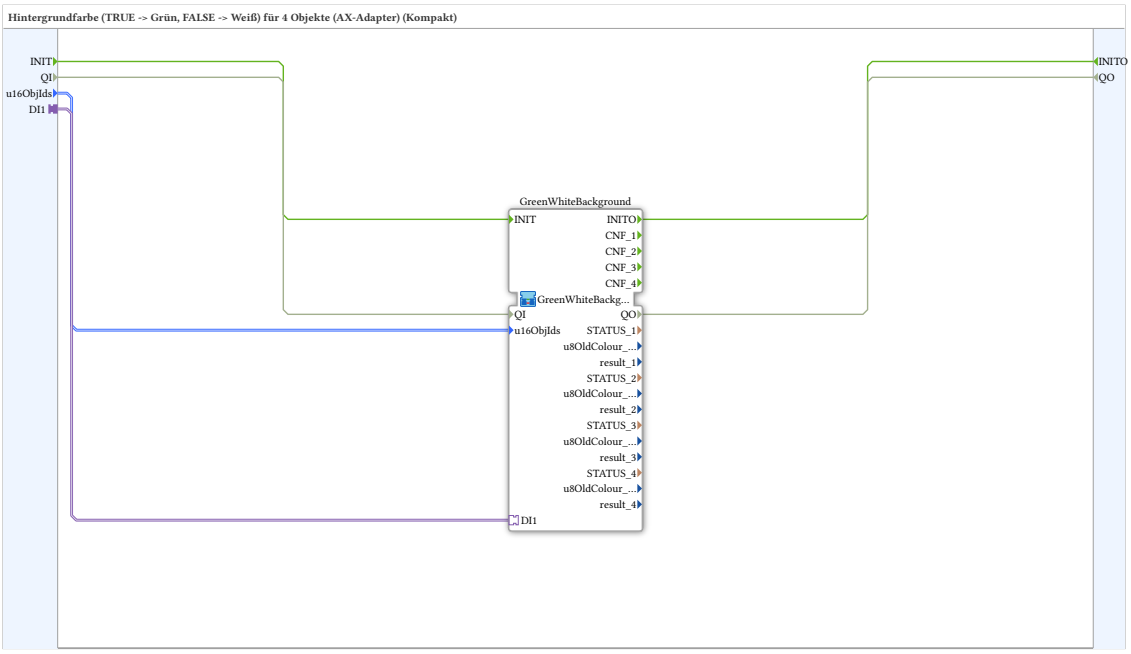
`GreenWhiteBackground4_AXS` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` → **Grün**, `FALSE` → **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s3ObjectIDs` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`F_MOVE.OUT.u16ObjIdB`	`Q_BackgroundColour` (regular object)

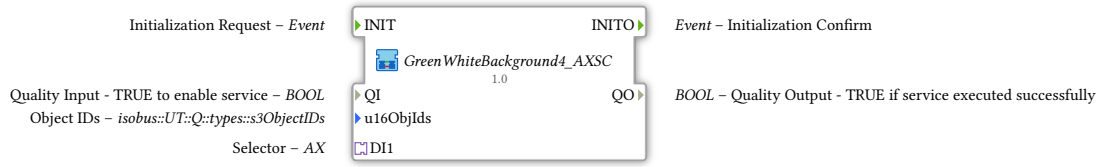
For the general pattern (selector → `AX_SEL`/`F_SEL` → `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`): initialization is chained through the `Q_BackgroundColour` instances: `INIT` ⟶ `Q_BackgroundColour_1.INIT`; `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`; `Q_BackgroundColour_3.INITO` ⟶ `Q_BackgroundColour_4.INIT`; `Q_BackgroundColour_4.INITO` ⟶ `INITO`.
- **Data input `QI`** (`BOOL`, default `TRUE`) is distributed to `.QI` of all instances (`Q_BackgroundColour_1`, `Q_BackgroundColour_2`, `Q_BackgroundColour_3`, `Q_BackgroundColour_4`).
- **Data output `QO`** (`BOOL`): AND of all instances via `AND_QO` (`iec61131::booleanOperators::AND_BOOL_4`): `Q_BackgroundColour_1.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN2`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN3`, `Q_BackgroundColour_4.QO` ⟶ `AND_QO.IN4`; `AND_QO.OUT` ⟶ `QO`.
- `E_MERGE_QO_A` (`iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_4.INITO` and the `CNF` events of instances 1 to 3; `E_MERGE_QO` (`iec61499::events::E_MERGE_2`) merges its output `E_MERGE_QO_A.EO` with `Q_BackgroundColour_4.CNF` and thereby triggers `AND_QO.REQ`.



Summary



One of many variants in the background color block family: color pair Grün/Weiß, 4 objects, adapter selector, struct. object ID.

HebenSenken_ILOCK_QDA_PWM_OPC

• – ○ • – ○ • – ○ •

Introduction

The **HebenSenken_ILOCK_QDA_PWM_OPC** subapplication combines two remote commands – **Raise** (Heben) and **Lower** (Senken) – with existing IO-test signals and generates a single ratiometric PWM output signal. The subapp is designed for Danfoss PVEA actuators with a three-stage PWM channel, where:

- **25%** duty cycle = Lower (Senken)
- **50%** duty cycle = Neutral
- **75%** duty cycle = Raise (Heben)

Each remote command path consists of a Subscribe adapter (for the actual control command) OR-combined with an existing IO-test Subscribe signal, followed by a Publish adapter for state feedback behind the interlock. An **ILOCK_SWITCH_PROTECT_AX** interlock block applies a *last-wins* strategy with a configurable protection time (`DT_PROTECT`) to guarantee that Raise and Lower are never active simultaneously. The selected duty cycle is then corrected by a load-divider compensation factor and scaled to a 13-bit PWM range before being forwarded to a physical PWM output.

The subapp is generic and can be reused with any PVEA actuator equipped with a ratiometric three-stage PWM channel.

Interface Structure

The subapplication exposes data inputs, the event input `INIT` and the event output `INITO`. It does not provide any adapter interfaces at its boundary; all other event and adapter communication occurs internally within the subapp network.

Event Inputs

- **INIT** (`EInit`): initialisation; sequenced by the caller instead of automatic distribution, so that `QI` is settled before the physical channel is bound; starts the initialisation chain `SUBSCRIBE_HEBEN` ⟶ `SUBSCRIBE_TEST_HEBEN` ⟶ `SUBSCRIBE_SENKEN` ⟶ `SUBSCRIBE_TEST_SENKEN` ⟶ `PUBLISH_STATE_HEBEN` ⟶ `PUBLISH_TEST_HEBEN` ⟶ `PUBLISH_TEST_SENKEN` ⟶ `PUBLISH_STATE_SENKEN` ⟶ `PWM_Mux` (`HebenSenken_QDA_PWM`)

All other triggering is handled internally via the subscribe/publish adapter pattern.

Event Outputs

- **INITO** (`EInit`): initialisation completed; genuine confirm from `PWM_Mux.INITO` (end of the initialisation chain)

The subapp provides no further event outputs.

Data Inputs

Name	Type	Description

QI	BOOL	Qualifier for the physical PWM output (default TRUE); FALSE keeps the instance completely inactive (no hardware binding) in case the same physical channel is used differently depending on the machine variant; passed on to all Subscribe/Publish blocks (SUBSCRIBE_*, PUBLISH_*) and to PWM_Mux.QI.
Output_PWM	logiBUS::io::DQ::logiBUS_DO_S	Physical PWM output: 25/50/75% duty cycle, ratiometric. Default: logiBUS_DO::Invalid
DT_PROTECT	TIME	Protection deadtime before direction changes. Default: T#300ms
ID_HEBEN_READ	WSTRING	Actual function command for Raise (Subscribe).
ID_HEBEN_WRITE	WSTRING	Actual function feedback for Raise, *behind* the ILOCK (Publish).
ID_SENKEN_READ	WSTRING	Actual function command for Lower (Subscribe).
ID_SENKEN_WRITE	WSTRING	Actual function feedback for Lower, *behind* the ILOCK (Publish).
ID_TEST_READ_HEBEN	WSTRING	Existing IO-test Subscribe address for Raise (e.g., STG2_Q0x_READ), OR-combined with ID_HEBEN_READ before the ILOCK.
ID_TEST_WRITE_HEBEN	WSTRING	Existing IO-test Publish address for Raise, *behind* the ILOCK (e.g., STG2_Q0x_WRITE).
ID_TEST_READ_SENKEN	WSTRING	Existing IO-test Subscribe address for Lower, OR-combined with ID_SENKEN_READ before the ILOCK.
ID_TEST_WRITE_SENKEN	WSTRING	Existing IO-test Publish address for Lower, *behind* the ILOCK.

Data Outputs

Name	Type	Description
QO	BOOL	Quality Output - TRUE if the service executed successfully; AND (AND_QO, type iec61131::booleanOperators::AND_BOOL_9) of the QO of all four SUBSCRIBE_*, all four PUBLISH_* and PWM_Mux; triggered by PWM_Mux.INITO (REQ).

Status and feedback information are published via the internal adapter network using the configured Publish addresses (ID_HEBEN_WRITE, ID_SENKEN_WRITE, ID_TEST_WRITE_HEBEN, ID_TEST_WRITE_SENKEN).

Adapters

None exposed at the interface level. All adapter communication is internal to the subapp network.

Functionality

The subapp processes two independent command sources and merges them into a single PWM output according to the following flow:

1. **Command acquisition**: The four Subscribe adapters (SUBSCRIBE_HEBEN, SUBSCRIBE_TEST_HEBEN, SUBSCRIBE_SENKEN, SUBSCRIBE_TEST_SENKEN) receive the actual function commands and the IO-test commands. Each pair is combined with an AX_OR_2 OR block, so either the real command or the IO-test command can activate the corresponding direction.
2. **Interlock protection**: The OR outputs (OR_HEBEN.OUT, OR_SENKEN.OUT) are fed into ILOCK_SWITCH_PROTECT_AX. This block implements a *last-wins* strategy with a user-configurable protection time (DT_PROTECT). It ensures that the Raise and Lower signals can never be active simultaneously. The internal timeOut event of the ILOCK is connected to an E_TimeOut FB, which provides the timing for the protection interval.
3. **Signal distribution**: The protected ILOCK outputs (UP_OUT, DOWN_OUT) are split via AX_SPLIT_3 blocks:
   - SPLIT_HEBEN_OUT: OUT1 publishes the state to PUBLISH_STATE_HEBEN, OUT2 publishes to PUBLISH_TEST_HEBEN, and OUT3 provides the Raise bit to the assembly block.
   - SPLIT_SENKEN_OUT: OUT1 provides the Lower bit to the assembly block, OUT2 publishes to PUBLISH_TEST_SENKEN, and OUT3 publishes to PUBLISH_STATE_SENKEN.
4. **Selection logic**: The two bits (BIT_00 for Raise, BIT_01 for Lower) are assembled by ASSEMBLE_AB_FROM_AX into a 2-bit pattern, which is converted to an unsigned integer value by AB_TO_AUI. This value is used as the selector input K of the AR_AUI_MUX_3 multiplexer. The MUX selects among three reference duty cycles provided by the values_50_75_25 subapp:
   - IN1 ⟶ 50% (Neutral)
   - IN2 ⟶ 75% (Raise)
   - IN3 ⟶ 25% (Lower)

   Since the ILOCK prevents both bits from being set simultaneously, a 3-way MUX is sufficient (the invalid 4th state cannot occur).
5. **Scaling and conversion**: The selected duty-cycle value passes through two AR_R_MUL multiplication stages:
   - **Correction factor** (FACTOR = REAL#1.17619, which equals 1/0.8502) compensates for the load-divider characteristics.
   - **PWM scale factor** (FACTOR = REAL#81.91, which equals 8191/100) maps the percentage value to the 13-bit PWM range (0…8191).

   The resulting analog value is converted by AR_TO_AD_NUM into a digital number, which drives the logiBUS_QDA_PWM block (DigitalOutput_PWM) that generates the physical PWM signal on the configured Output_PWM channel.
6. **Initialization and status**: QI is passed on to all Subscribe/Publish blocks and to PWM_Mux. INIT runs through the initialisation chain SUBSCRIBE_HEBEN ⟶ SUBSCRIBE_TEST_HEBEN ⟶ SUBSCRIBE_SENKEN ⟶ SUBSCRIBE_TEST_SENKEN ⟶ PUBLISH_STATE_HEBEN ⟶ PUBLISH_TEST_HEBEN ⟶ PUBLISH_TEST_SENKEN ⟶ PUBLISH_STATE_SENKEN ⟶ PWM_Mux (HebenSenken_QDA_PWM); PWM_Mux.INITO is output as INITO and also triggers AND_QO.REQ. QO is the AND (AND_QO) of the nine QO outputs.
7. **Feedback publishing**: The ILOCK-protected states are published back via four AX_PUBLISH_1 adapters (PUBLISH_STATE_HEBEN, PUBLISH_TEST_HEBEN, PUBLISH_STATE_SENKEN, PUBLISH_TEST_SENKEN) to the respective feedback addresses, ensuring that external systems only see the actual (interlock-protected) commands, not the raw inputs.

Technical Features

- **Interlock with protection time**: The ILOCK_SWITCH_PROTECT_AX block applies a *last-wins* arbitration and enforces a deadtime (DT_PROTECT, default 300 ms) between direction changes, preventing mechanical and hydraulic stress on the actuator.
- **OR-combined command sources**: Each direction can be triggered either by the actual function command or by an IO-test command, allowing test and operation modes without changing the network topology.
- **State feedback behind the ILOCK**: Published states reflect the *actual* actuator commands after interlock protection, so downstream monitoring always sees the real effective command.
- **Ratiometric PWM scaling**: The duty cycles are corrected for load-divider nonlinearity (factor 1.17619 = 1/0.8502) and scaled to a 13-bit PWM resolution (factor 81.91 = 8191/100).

- **Generic 3-stage PWM generation**: Works with any PVEA-type actuator requiring a ratiometric PWM channel with three defined levels.
- **Configurable via data inputs**: All addresses (`ID_*`) and timing parameters (`DT_PROTECT`) are exposed as data inputs, making the subapp parametrizable without internal modification.

State Overview

The subapp can be in one of the following operating states:

State	Condition	MUX Input	PWM Duty Cycle	Description
Neutral	Neither Raise nor Lower active	IN1 (50%)	50%	Actuator is idle; no direction command present.
Raise	Raise command active (after ILOCK)	IN2 (75%)	75%	Actuator moves upward (Heben).
Lower	Lower command active (after ILOCK)	IN3 (25%)	25%	Actuator moves downward (Senken).
Protection	Direction change during `DT_PROTECT`	Held at previous state	Held at previous level	ILOCK holds the last command until the protection time elapses; the new command takes effect afterwards.

The interlock ensures that the combination *Raise+Lower* (both bits set) can never occur; hence the 3-way MUX is sufficient.

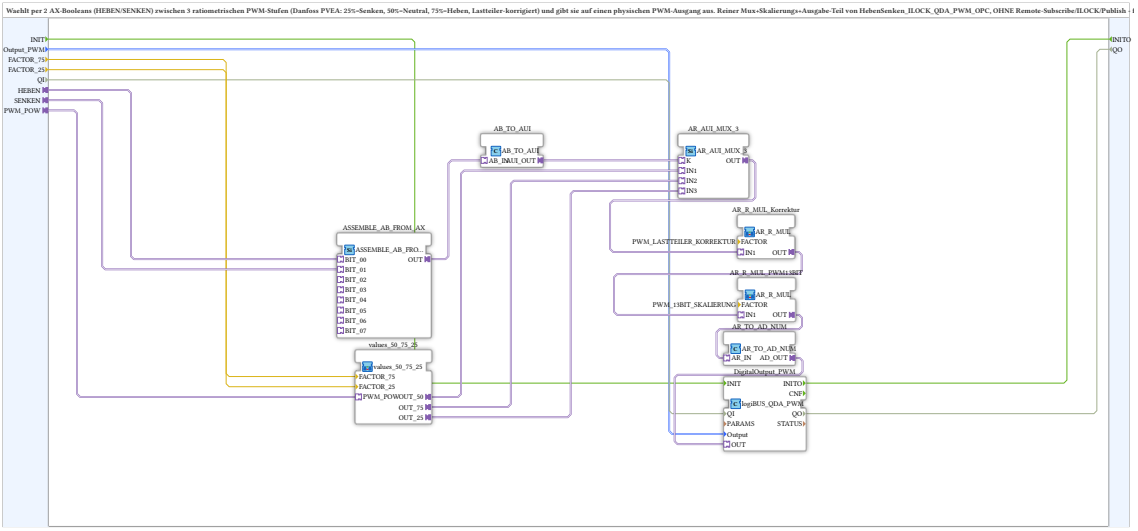
Application Scenarios

- **PVEA actuator control**: Directly controlling Danfoss PVEA hydraulic actuators that accept a ratiometric PWM signal with three discrete duty-cycle levels for Raise/Neutral/Lower.
- **Remote HMI control with IO-test integration**: Industrial systems where a remote operator station (via OPC/network subscribes) and a local IO-test panel both need to control the same actuator, with the IO-test acting as an override or backup.
- **Direction-safe switching**: Applications where simultaneous Raise and Lower commands must be impossible due to safety requirements – e.g., crane or lifting systems, agricultural machinery, or mobile hydraulics.
- **Actuator state feedback**: Systems that require publication of the *actual* (protected) command state for visualization, logging, or supervisory control.

Comparison with Similar Blocks

The subapp follows the same pattern as `ILOCK_SWITCH_2_QXA_OPC` (which also OR-combines real commands with IO-test signals and applies `ILOCK_SWITCH_PROTECT_AX` interlock protection). However, the key difference is the output stage:

- **`ILOCK_SWITCH_2_QXA_OPC`** typically produces two discrete digital outputs (QXA) for Raise and Lower.
- **`HebenSenken_ILOCK_QDA_PWM_OPC`** merges the two command bits into a *single ratiometric PWM signal* using a 3-way MUX, compensation scaling, and a PWM output stage. This reduces the output pins from two digital channels to one analog PWM channel and is specifically tailored for PVEA actuators that accept proportional PWM control.

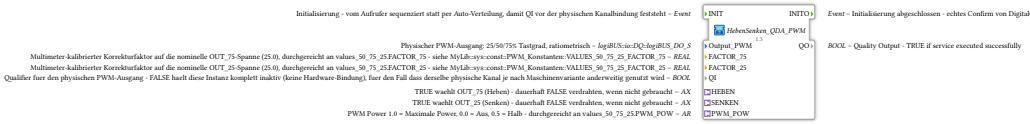


The interlock core remains identical, ensuring consistent protection behavior across both variants.

Conclusion

The `HebenSenken_ILOCK_QDA_PWM_OPC` subapplication provides a robust, generic solution for controlling three-stage PVEA actuators via a single ratiometric PWM signal. It integrates remote function commands and IO-test signals with interlock protection and configurable deadtime, guaranteeing that Raise and Lower can never be active simultaneously. The built-in load-divider correction and 13-bit PWM scaling ensure accurate and repeatable actuator positioning. With its fully parametrizable addresses and timing, the subapp can be reused across different machines and communication layouts without internal changes,

making it a valuable component for hydraulic actuation systems requiring safe and flexible command handling.



HebenSenken_QDA_PWM

• – ○ • – ○ • – ○ •

Introduction

`HebenSenken_QDA_PWM` selects, via two AX booleans (`HEBEN`/`SENKEN`), between three ratiometric PWM levels (Danfoss PVEA: 25 % = lower, 50 % = neutral, 75 % = raise, load-divider corrected) and outputs the selected level on a physical PWM output. It is the pure mux, scaling and output part of `HebenSenken_ILOCK_QDA_PWM_OPC`, without remote subscribe, ILOCK and publish. It suits callers that already supply `HEBEN`/`SENKEN` by other means (e.g. already gated/exclusive or using only one direction).

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialisation; sequenced by the caller instead of automatic distribution, so that `QI` is settled before the physical channel is bound; passed on to `DigitalOutput_PWM.INIT`

Event Outputs

- **INITO** (`EInit`): initialisation complete; real confirm from `DigitalOutput_PWM.INITO`

Data Inputs

- **Output_PWM** (`logiBUS::io::DQ::logiBUS_DO_S`): physical PWM output (25/50/75 % duty cycle, ratiometric), default `logiBUS_DO::Invalid`
- **FACTOR_75** (REAL): multimeter-calibrated correction factor on the nominal `OUT_75` span (25.0), passed on to `values_50_75_25.FACTOR_75` (default `REAL#1.0`)
- **FACTOR_25** (REAL): multimeter-calibrated correction factor on the nominal `OUT_25` span (25.0), passed on to `values_50_75_25.FACTOR_25` (default `REAL#1.0`)
- **QI** (BOOL): qualifier for the physical PWM output (default TRUE); FALSE keeps the instance completely inactive (no hardware binding) in case the same physical channel is used differently depending on the machine variant

Data Outputs

- **QO** (BOOL): quality output, comes from `DigitalOutput_PWM.QO`

Adapters

- **HEBEN** (socket, `AX`): TRUE selects `OUT_75` (raise); wire permanently to FALSE if not needed
- **SENKEN** (socket, `AX`): TRUE selects `OUT_25` (lower); wire permanently to FALSE if not needed
- **PWM_POW** (socket, `AR`): PWM power, 1.0 = maximum power, 0.0 = off, 0.5 = half; passed on to `values_50_75_25.PWM_POW`

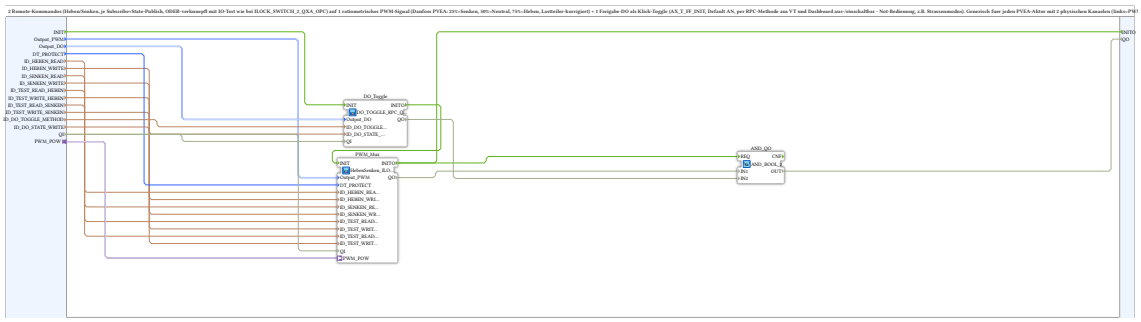
Functionality

The chain in the network:

1. `HEBEN` ⟶ `ASSEMBLE_AB_FROM_AX.BIT_00` and `SENKEN` ⟶ `ASSEMBLE_AB_FROM_AX.BIT_01`: both booleans are assembled into a byte (`HEBEN` is the least significant bit).
2. `AB_TO_AUI` converts the byte into an `AUI` value that goes to `AR_AUI_MUX_3` as the selection `K`: `K = 0` (both FALSE) selects `IN1` = `OUT_50` (neutral), `K = 1` (`HEBEN`) selects `IN2` = `OUT_75`, `K = 2` (`SENKEN`) selects `IN3` = `OUT_25`.
3. `values_50_75_25` supplies the three set values `OUT_50`, `OUT_75`, `OUT_25` from `PWM_POW` and `FACTOR_75`/`FACTOR_25`.
4. `AR_AUI_MUX_3.OUT` ⟶ `AR_R_MUL_Korrektur` (factor `PWM_LASTTEILER_KORREKTUR`) ⟶ `AR_R_MUL_PWM13BIT` (factor `PWM_13BIT_SKALIERUNG`) ⟶ `AR_TO_AD_NUM` ⟶ `DigitalOutput_PWM.OUT`.
5. `DigitalOutput_PWM` (`logiBUS::io::DQ::logiBUS_QDA_PWM`) outputs the value at `Output_PWM`; `QI` is routed directly to `DigitalOutput_PWM.QI` and the event `INIT` to `DigitalOutput_PWM.INIT`; `DigitalOutput_PWM.INITO` is output as `INITO` and `DigitalOutput_PWM.QO` as `QO`.

Technical Details

- There is **no** interlock: the caller must ensure that `HEBEN` and `SENKEN` are never TRUE at the same time, otherwise `AR_AUI_MUX_3` delivers undefined behaviour for `K = 3`
- The plug/variable names `_75`/`_25` are historical; the actually calibrated values at `PWM_POW = 1.0` are 90.0 and 15.0 (see `values_50_75_25`)
- The input `QI` (version 1.1) allows the instance to be kept completely inactive when the channel is used otherwise
- The event input `INIT` (version 1.2) replaces the automatic distribution of the initialisation: the caller triggers it itself (“init like Tecu”), so that `QI` is settled before the physical channel is bound
- The event output `INITO` and the data output `QO` (version 1.3) pass the real confirm and the quality status of `DigitalOutput_PWM` through, so the caller (e.g. `Aufnahme_Option.SUB` via the `Option::AOption` socket) can wait for a real `INIT_CNF` instead of a timing delay
- First caller: `Bunkerboden_PWM.SUB`, which uses only `SENKEN` (full throttle) and ties `HEBEN` permanently to FALSE



Application Scenarios

- Control of a proportional valve (Danfoss PVEA) with 25/50/75 % PWM for lower/neutral/raise
- Applications with already gated or only one-sidedly used direction signals

Conclusion

`HebenSenken_QDA_PWM` converts two direction booleans without interlock into one of the three ratiometric PWM levels and outputs it scaled at the physical PWM output.

Heben_Senken_TO_QDA_PWM_OPC

• — ○ • — ○ • — ○ •

Introduction

Heben_Senken_TO_QDA_PWM_OPC is a composite subapplication that integrates two independent subapplications to provide a complete control solution for a PVEA actuator with two physical channels. It combines a PWM generation module (HebenSenken_ILOCK_QDA_PWM_OPC) for lifting/lowering commands with a digital output toggle module (DO_TOGGLE_RPC_QXA_OPC) for an enable signal. The subapplication is designed for systems where the module itself has no local visualization terminal, allowing full operation via remote commands, I/O tests, and an RPC-triggered enable toggle.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialisation; sequenced by the caller instead of automatic distribution, so that `QI` is settled before the physical channel is bound; passed on to `DO_Toggle.INIT`; `DO_Toggle.INITO` starts `PWM_Mux.INIT` (sequential chain)

Event Outputs

- **INITO** (`EInit`): initialisation completed; sequential confirm: `DO_Toggle` first, then `PWM_Mux`; `INITO` comes from `PWM_Mux.INITO` (no rendezvous needed, both are plain physical output channels)

Data Inputs

Name	Type	Description
`QI`	`BOOL`	Qualifier for both physical outputs (PWM + enable DO), default `TRUE`; FALSE keeps the instance completely inactive (no hardware binding) in case the same channel is used differently depending on the machine variant.
`Output_PWM`	`logiBUS::io::DQ::logiBUS_DO_S`	Physical PWM output (left channel): 25% / 50% / 75% duty cycle, ratiometric.
`Output_DO`	`logiBUS::io::DQ::logiBUS_DO_S`	Physical enable output (right channel): click-toggle, default ON.
`DT_PROTECT`	`TIME`	Protection dead time before direction change, default `T#300ms`.
`ID_HEBEN_READ`	`WSTRING`	Actual function command “raise” (subscribe).
`ID_HEBEN_WRITE`	`WSTRING`	Actual function feedback “raise”, behind the ILOCK (publish).
`ID_SENKEN_READ`	`WSTRING`	Actual function command “lower” (subscribe).
`ID_SENKEN_WRITE`	`WSTRING`	Actual function feedback “lower”, behind the ILOCK (publish).
`ID_TEST_READ_HEBEN`	`WSTRING`	Existing IO-test subscribe address for raise (e.g., `STG2_Q0x_READ`), OR-com-

		bined with ID_HEBEN_READ before the ILOCK.
ID_TEST_WRITE_HEBEN	WSTRING	Existing IO-test publish address for raise, behind the ILOCK (e.g., STG2_Q0x_WRITE).
ID_TEST_READ_SENKEN	WSTRING	Existing IO-test subscribe address for lower, OR-combined with ID_SENKEN_READ before the ILOCK.
ID_TEST_WRITE_SENKEN	WSTRING	Existing IO-test publish address for lower, behind the ILOCK.
ID_DO_TOGGLE_METHOD	WSTRING	Local method address (ACTION=CREATE_METHOD) for the argument-less enable toggle trigger – called from STG1 (softkey relay) and directly from the OPC dashboard (CALL_METHOD).
ID_DO_STATE_WRITE	WSTRING	Local publish address (ACTION=WRITE) for the actual enable state (AX_T_FF_INIT.Q) – subscribed remotely from VT and dashboard.

Data Outputs

- **QO** (BOOL): quality output, AND combination (AND_Q0, AND_BOOL_2) of PWM_Mux.Q0 and DO_Toggle.Q0.

There are no further output variables; the physical outputs are controlled directly through the Output_PWM and Output_DO references.

Adapters

None.

Functionality

The subapplication collects remote raise/lower commands and OR-combines them with IO-test signals. The internal PWM subapplication (HebenSenken_ILOCK_QDA_PWM_OPC) generates a single ratiometric PWM signal with a duty cycle of 25% (lower), 50% (neutral), and 75% (raise), incorporating an interlock and a protection dead time. The second internal subapplication (DO_TOGGLE_RPC_QXA_OPC) manages a digital output that can be toggled via an RPC method, defaulting to ON. QI is routed jointly to PWM_Mux.QI and DO_Toggle.QI, and the event INIT to DO_Toggle.INIT; DO_Toggle.INITO triggers PWM_Mux.INIT, so both physical channels are kept inactive together or initialised one after the other by the caller. The confirmation is sequential (no E_REND_2 block): PWM_Mux.INITO → INITO and AND_Q0.REQ. AND_Q0 (iec61131::booleanOperators::AND_BOOL_2) combines PWM_Mux.Q0 (IN1) and DO_Toggle.Q0 (IN2) into the output Q0. The two modules operate independently but are combined here to provide a unified interface for a PVEA actuator with two physical channels.

Technical Features

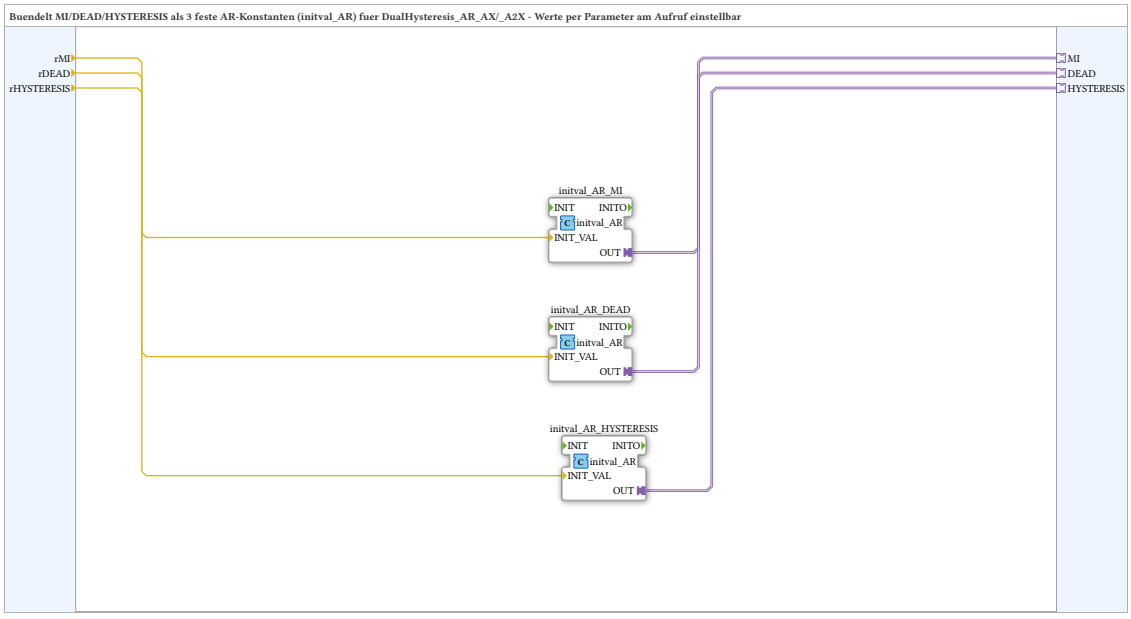
- **Composite structure**: Encapsulates two purpose-built subapplications into a single logical block.
- **Remote operation**: Supports Subscribe/Publish for command and state feedback.
- **IO-test integration**: Test signals are OR-combined with actual commands, enabling commissioning and maintenance overrides.
- **PWM generation**: Includes a programmable protection dead time (DT_PROTECT) to prevent rapid direction changes.
- **Enable toggle**: A latchable output (default ON) controlled via an RPC method, suitable for emergency stop or street mode.
- **Generic applicability**: Works with any PVEA actuator having two physical channels (left = PWM, right = enable), independent of a local visualization terminal.

State Overview

The subapplication itself does not implement an external state machine; the internal subapplications are responsible for state handling. The PWM module likely has states for neutral, raise, lower, and protection delay. The DO toggle module uses a flip-flop (`AX_T_FF_INIT`) to maintain its ON/OFF state. The composite ensures that the physical outputs reflect the combined behavior.

Application Scenarios

- **Centralized control**: Operate a Danfoss PVEA actuator lifting/lowering from a main control station without module-local visualization.
- **Remote enable control**: Toggle the enable output from a dashboard or a VT using the RPC method, e.g., to activate a street mode or an emergency stop.
- **IO testing**: Use the integrated IO-test signals to validate PWM and enable outputs during commissioning.
- **Generic usage**: Apply to any system requiring a PWM drive plus a latching enable output, with configurable dead time and command IDs.

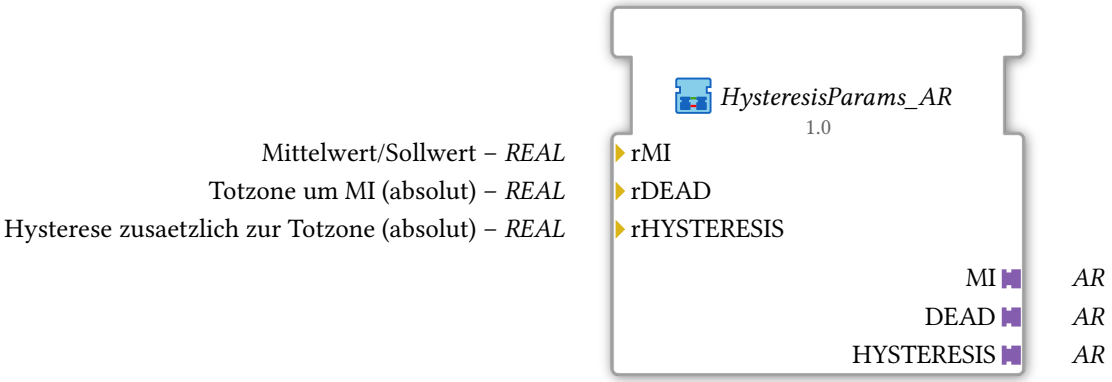


Comparison with Similar Blocks

- **Integrated vs. separate blocks**: This composite combines two essential functions (PWM control and enable toggle) in one interface, whereas separate FBs would require explicit wiring between two blocks.
- **Unified channel handling**: Directly maps the two physical channels (left PWM, right enable) to a single input set, simplifying application engineering.
- **RPC-based toggle**: Unlike simple DO control blocks, the enable output includes a latchable flip-flop triggered via an RPC method, offering more flexible remote operation.

Conclusion

Heben_Senken_TO_QDA_PWM_OPC is a composite subapplication that encapsulates the complexity of controlling a PVEA actuator with a PWM signal and a toggleable enable output. It is generic, configurable via data inputs, and provides a clean interface for modules without a local visualization, enabling remote operation, IO testing, and flexible enable control.



HysteresisParams_AR

• — ○ • — ○ • — ○ •

Introduction

`HysteresisParams_AR` bundles the three parameters `MI` (mean/target value), `DEAD` (dead zone), and `HYSTERESIS` (additional hysteresis) as fixed `AR` adapter constants for `DualHysteresis_AR_AX`/`DualHysteresis_AR_A2X`. Instead of repeating three `initval_AR` instances individually in each exercise/subapp, this building block combines them.

Function Blocks (FBs) Used

Sub-Blocks: HysteresisParams_AR

- **Type**: SubAppType
- **Internal FBs Used**:
- **initval_AR_MI** / **initval_AR_DEAD** / **initval_AR_HYSTERESIS**: each `adapter::types::unidirectional::AR::initval::initval_AR` — converts a `REAL` input value into a fixed `AR` adapter plug.
- **How it Works**: The three `InputVars`, `rMI`, `rDEAD`, and `rHYSTERESIS` are each converted into the corresponding `AR` plugs (`MI`, `DEAD`, and `HYSTERESIS`) via a `initval_AR` instance.

Program Flow and Connections

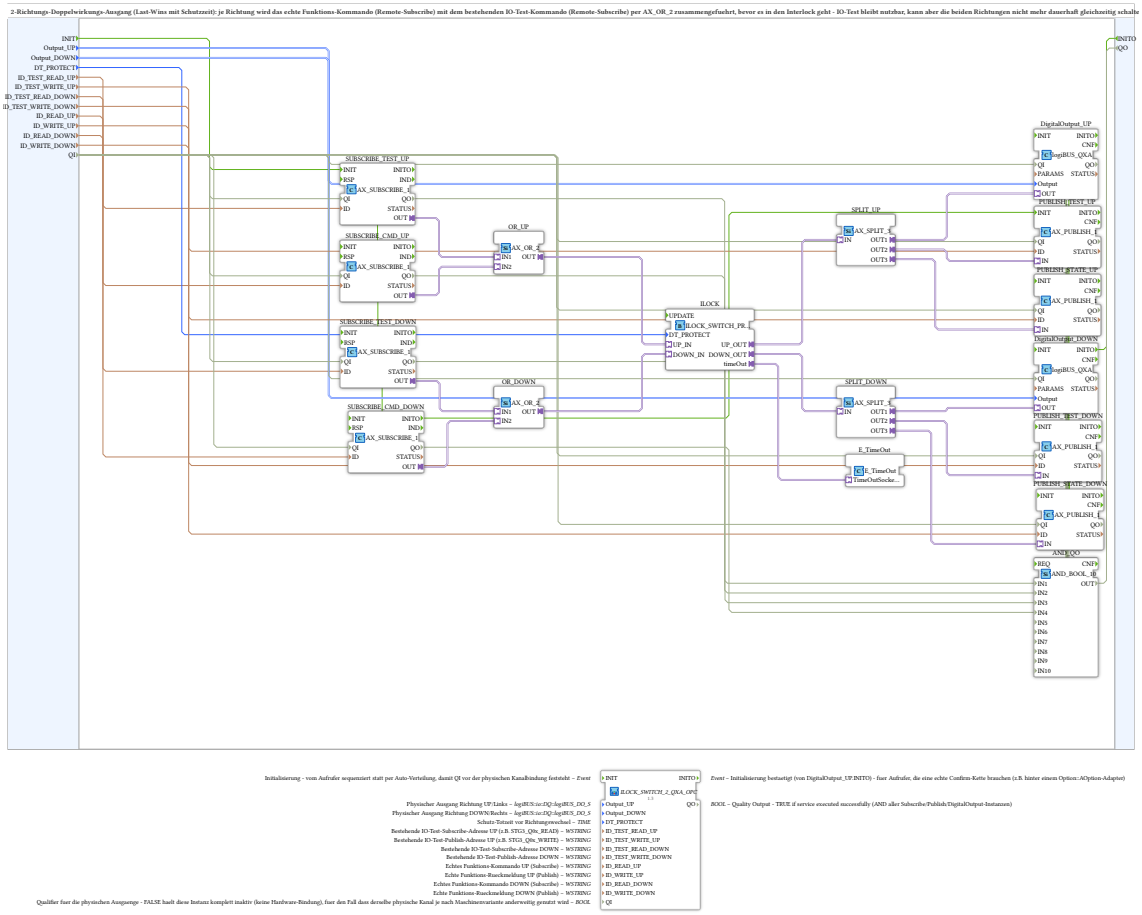
1. `rMI` ⟶ `initval_AR_MI.INIT_VAL`; `rDEAD` ⟶ `initval_AR_DEAD.INIT_VAL`; `rHYSTERESIS` ⟶ `initval_AR_HYSTERESIS.INIT_VAL` (Data connections).
2. `initval_AR_MI.OUT` ⟶ `MI`; `initval_AR_DEAD.OUT` ⟶ `DEAD`; `initval_AR_HYSTERESIS.OUT` ⟶ `HYSTERESIS` (Adapter connections, directly to the SubApp interface).

Technical Features

- **Configurable Default Values**: `rMI`/`rDEAD`/`rHYSTERESIS` have meaningful default values (`500.0`/`20.0`/`30.0`) that can be overridden via parameters when calling the function—similar to `u16ObjId` in the GreenWhiteBackground function blocks.
- **Reuse Instead of Repetition**: Replaces the manual duplication of three `initval_AR` instances, as was initially done in `Uebung_234_AX`/`Uebung_235_AX`.

Application Scenarios

- Parameterization of `DualHysteresis_AR_AX`/`DualHysteresis_AR_A2X` when setpoint, dead zone, and hysteresis are required as fixed constants that can be overridden during the call.
- Consistent parameterization of several comparable exercises (e.g., `Uebung_234_AX` for hardware and `Uebung_235_AX` for VT) that should remain directly comparable with identical values.



Summary

`HysteresisParams_AR` combines three fixed `AR` parameter constants for the hysteresis blocks into a single, parameterizable block.

ILOCK_SWITCH_2_QXA_OPC

• – ○ • – ○ • – ○ •

Introduction

The ILOCK_SWITCH_2_QXA_OPC subapplication implements a 2-direction double-acting digital output with a “last-wins” interlock and configurable protection time. For each direction, the real function command (remote subscribe) is merged with the existing IO-test command (remote subscribe) using an AX_OR_2 block before entering the interlock logic. This keeps the IO-test fully usable while preventing both directions from being permanently switched simultaneously. The interlocked output drives the physical logiBUS channel and reports its actual state both to the existing IO-test monitoring and to the real function feedback (e.g., GreenWhiteBackground on a SoftKey). It is generic for any “digital DW” actuator operated from a module without its own visualization terminal.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialisation; sequenced by the caller instead of automatic distribution, so that `QI` is settled before the physical channel is bound; starts the initialisation chain through all inner instances (`SUBSCRIBE_TEST_UP` ⟶ `SUBSCRIBE_CMD_UP` ⟶ `SUBSCRIBE_TEST_DOWN` ⟶ `SUBSCRIBE_CMD_DOWN` ⟶ `PUBLISH_TEST_UP` ⟶ `PUBLISH_STATE_UP` ⟶ `PUBLISH_TEST_DOWN` ⟶ `PUBLISH_STATE_DOWN` ⟶ `DigitalOutput_UP` ⟶ `DigitalOutput_DOWN`); the physical outputs are therefore initialised last. The caller must trigger `INIT` itself (e.g. without delay for unchanged immediate behaviour, or delayed if an INI value has to be awaited).

Event Outputs

- **INITO** (`EInit`): initialisation confirmed (from `DigitalOutput_DOWN.INITO`, the end of the chain); for callers that need a real confirm chain (e.g. behind an `Option::AOption` adapter). Purely additive, harmless if left unwired.

Data Inputs

- **QI** (BOOL): Qualifier for the physical outputs; FALSE keeps the instance completely inactive (no hardware binding). Default `TRUE`. Distributed to all subscribe, publish and DigitalOutput instances.
- **Output_UP** (logiBUS::io::DQ::logiBUS_DO_S): Physical output channel for the UP/Left direction. Initial value: `logiBUS_DO::Invalid`.
- **Output_DOWN** (logiBUS::io::DQ::logiBUS_DO_S): Physical output channel for the DOWN/Right direction. Initial value: `logiBUS_DO::Invalid`.
- **DT_PROTECT** (TIME): Protection dead time before a direction change is allowed. Default: `T#300ms`.
- **ID_TEST_READ_UP** (WSTRING): Existing IO-test subscribe address for the UP direction (e.g., `STG3_Q0x_READ`).
- **ID_TEST_WRITE_UP** (WSTRING): Existing IO-test publish address for the UP direction (e.g., `STG3_Q0x_WRITE`).
- **ID_TEST_READ_DOWN** (WSTRING): Existing IO-test subscribe address for the DOWN direction.
- **ID_TEST_WRITE_DOWN** (WSTRING): Existing IO-test publish address for the DOWN direction.
- **ID_READ_UP** (WSTRING): Real function command subscribe address for the UP direction.
- **ID_WRITE_UP** (WSTRING): Real function feedback publish address for the UP direction.
- **ID_READ_DOWN** (WSTRING): Real function command subscribe address for the DOWN direction.
- **ID_WRITE_DOWN** (WSTRING): Real function feedback publish address for the DOWN direction.

Data Outputs

- **QO** (BOOL): Quality Output - TRUE if the service was executed successfully (AND of all subscribe/publish/DigitalOutput instances).

Adapters

None.

Functionality

For each direction (UP and DOWN), the subapplication subscribes to two independent remote command sources via `AX_SUBSCRIBE_1` blocks:

1. The existing IO-test command (`ID_TEST_READ_*`).
2. The real function command (`ID_READ_*`).

Both signals are combined using an `AX_OR_2` block, so that either the IO-test command or the real function command can request the activation of that direction. The combined requests are then passed to an `ILOCK_SWITCH_PROTECT_AX` interlock block, which enforces a “last-wins” policy and a configurable protection time (`DT_PROTECT`). This ensures that both directions can never be active simultaneously and that a minimum dead time elapses before switching directions.

The interlocked output for each direction is distributed via an `AX_SPLIT_3` block into three paths:

- **Physical output**: Drives the logiBUS digital output channel (`DigitalOutput_UP` / `DigitalOutput_DOWN`).
- **IO-test feedback**: Publishes the actual state to the existing IO-test publish address (`ID_TEST_WRITE_*`).
- **Function feedback**: Publishes the actual state to the real function feedback address (`ID_WRITE_*`, e.g., for SoftKey background indication).

Initialisation and quality: `INIT` runs as a chain `SUBSCRIBE_TEST_UP` → `SUBSCRIBE_CMD_UP` → `SUBSCRIBE_TEST_DOWN` → `SUBSCRIBE_CMD_DOWN` → `PUBLISH_TEST_UP` → `PUBLISH_STATE_UP` → `PUBLISH_TEST_DOWN` → `PUBLISH_STATE_DOWN` → `DigitalOutput_UP` → `DigitalOutput_DOWN` (each `INITO` → next `INIT`); `DigitalOutput_DOWN.INITO` goes to `INITO` and to `AND_QO.REQ`. `QI` is distributed to all eight subscribe/publish instances and to both `DigitalOutput` instances. `QO` is the output of the instance `AND_QO` (`iec61131::booleanOperators::AND_BOOL_10`), which combines the `QO` of these ten instances.

The `E_TimeOut` block is connected to the interlock’s timeout event to trigger and manage the protection timer logic.

Technical Features

- Merging of IO-test and real function commands using `AX_OR_2` logic blocks.
- Last-wins interlocking via the `ILOCK_SWITCH_PROTECT_AX` block.
- Configurable protection dead time (`DT_PROTECT`), defaulting to 300 ms.
- Remote subscribe (`AX_SUBSCRIBE_1`) and publish (`AX_PUBLISH_1`) capabilities for integration into distributed control networks.

- Signal fan-out via AX_SPLIT_3 to drive the physical output, IO-test monitoring, and function feedback simultaneously.
- Fully generic design for any "digital DW" actuator, with all addresses parameterized via WSTRING inputs.
- Quality output QO as the AND of the ten inner QO outputs.
- Only INIT/INITO as events at the interface level; all other logic is driven internally by the subscribed data.

State Overview

The subapplication relies on the internal state machine of the ILOCK_SWITCH_PROTECT_AX interlock block. The relevant operating states are:

- **Idle**: No direction is requested; both outputs are inactive.
- **UP active**: The UP direction is interlocked and active; the DOWN direction is blocked.
- **DOWN active**: The DOWN direction is interlocked and active; the UP direction is blocked.
- **Switching with protection time**: After a direction change request, the protection timer (DT_PROTECT) runs before the new direction is applied, preventing rapid toggling.

Application Scenarios

- Controlling a double-acting digital actuator (e.g., a motorized valve or damper) from a control module without a local visualization terminal.
- Integrating existing IO-test functionality with real remote function commands, ensuring that both can drive the output while maintaining interlock safety.
- Providing feedback to both the legacy IO-test monitoring system and the operator interface (e.g., SoftKey background color) with the actual interlocked output state.
- Generic use in any "digital DW" actuator system where two directional commands must be merged and interlocked.

Comparison with Similar Blocks

- Compared to a simple logiBUS_QXA direct output, this subapplication adds interlock logic and protection timing.
- Compared to an interlock block that only accepts single-command inputs, this block explicitly merges remote subscribe/publish channels for both IO-test and real function commands.
- The use of AX_OR_2 before the interlock distinguishes it from pure interlock variants, enabling both test and functional commands to share the same interlock protection path.

Conclusion

ILOCK_SWITCH_2_QXA_OPC provides a robust and generic solution for driving a double-acting digital output with interlocking, protection time, and merged IO-test/function command handling. It preserves the existing IO-test infrastructure while guaranteeing safe operation and consistent feedback through both test and functional channels, making it suitable for a wide range of actuator control applications.

INI_IN_AND_STORE / NVS_IN_AND_STORE: Common Pattern

• – ◦ • – ◦ • – ◦ •

Introduction

MyLib::sys contains a family of function blocks that **persistently store** a value entered via VT and automatically reload it during initialization (INIT)—either in an INI file (INI_IN_AND_STORE_*) or in ESP32 flash memory (NVS, NVS_IN_AND_STORE_*). This page explains the common pattern.

Naming Scheme

{INI|NVS}_IN_AND_STORE_<Typ>, where <Typ> determines the data type: AIS (string adapter), AR (REAL adapter, with physical scaling NumericObjectPool_S), AUDI (UDINT adapter) in test_AX; UDINT (classic, without adapter) in test_B.

Functionality (test_AX, adapter-based)

1. A VT input field (StringValue_AIS/NumericValue_PHYSA/...) returns the value entered by the user as an adapter.

2. INI_<Typ>/NVS_<Typ> (eclipse4diac::storage::INI_* or logiBUS::storage::esp32_nvs::NVS_*) persistently stores this value under KEY/SECTION (INI only) and returns the last saved value on INIT (SETM=TRUE: saving active, DEFAULT_VALUE: initial value if nothing has been saved yet).
3. The (newly loaded or newly entered) value is distributed via <Typ>_SPLIT_2: once as a plug VALUEO to the outside (for further use in the calling network) and once to Q_StringValue_AIS/Q_NumericValue_PHYSA (written back to the VT display field so that the input field and display remain synchronized).

Functionality (test_B, classic)

The test_B variant (INI_IN_AND_STORE_UDINT/NVS_IN_AND_STORE_UDINT) is older and uses classic event/data connections instead of adapters: A NumericValue_ID input field returns a DWORD value, which is converted to UDINT via F_DWORD_TO_UDINT and passed to INI/NVS (generic, non-type-specific blocks). The stored value is sent out as VALUEO and back to Q_NumericValue for display.

Summary

Both approaches solve the same problem—"remembering a user-entered value across restarts"—using the same basic pattern (input field → memory function block with KEY/SECTION → branching to output + display writeback), only with different storage locations (INI file vs. NVS flash) and different wiring styles (adapter in test_AX, classic in test_B).

INI_IN_AND_STORE / NVS_IN_AND_STORE: Shared Pattern

• – ◦ • – ◦ • – ◦ •

Introduction

MyLib::sys contains a family of blocks that **persistently store** a value entered via the VT and automatically reload it on deployment — either in an INI file (INI_IN_AND_STORE_*) or in ESP32 flash (NVS, NVS_IN_AND_STORE_*). This page explains the shared pattern.

Naming Scheme

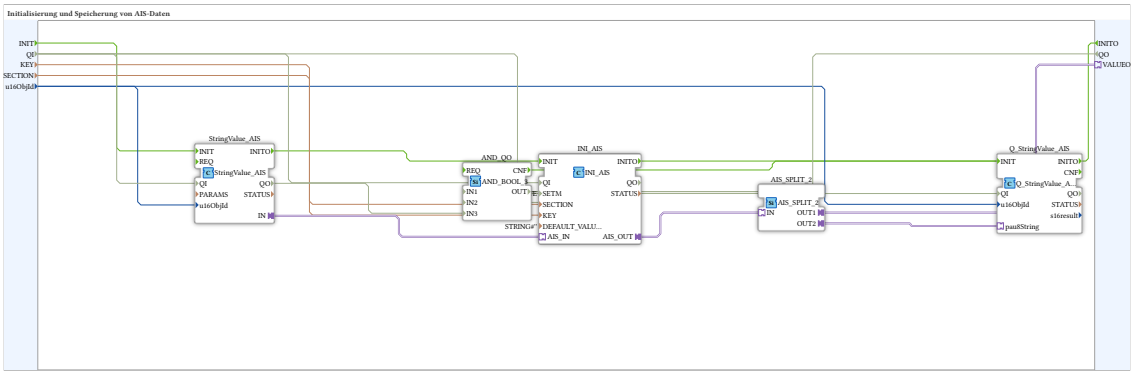
{INI|NVS}_IN_AND_STORE_<type>, where <type> determines the data type: AIS (string adapter), AR (REAL adapter, with physical scaling NumericObjectPool_S), AUDI (UDINT adapter) in test_AX; UDINT (classic, no adapter) in test_B.

Functionality (test_AX, adapter-based)

1. A VT input field (StringValue_AIS/NumericValue_PHYSA/...) delivers the user-entered value as an adapter.
2. INI_<type>/
   NVS_<type> (eclipse4diac::storage::INI_* or logiBUS::storage::esp32_nvs::NVS_*) stores this value persistently under KEY/SECTION (INI only) and returns the last stored value on INIT (SETM=TRUE: storing active, DEFAULT_VALUE: initial value if nothing has been stored yet).
3. The (newly loaded or newly entered) value is split via <type>_SPLIT_2: once as plug VALUEO outward (for reuse in the calling network) and once to Q_StringValue_AIS/Q_NumericValue_PHYSA (writing back to the VT display field, so the input field and display stay in sync).

Functionality (test_B, classic)

The test_B variant (INI_IN_AND_STORE_UDINT/NVS_IN_AND_STORE_UDINT) is older and uses classic event/data connections instead of adapters: a NumericValue_ID input field delivers a DWORD value, converted to UDINT via F_DWORD_TO_UDINT and passed to INI/NVS (generic, non-type-specific blocks). The stored value goes out as VALUEO and back to Q_NumericValue for display.



Summary

Both variants solve the same problem — "remember a user-entered value across restarts" — with the same basic pattern (input field → storage FB with KEY/SECTION → split into output + display write-back), differing only in storage location (INI file vs. NVS flash) and wiring style (adapters in test_AX, classic in test_B).

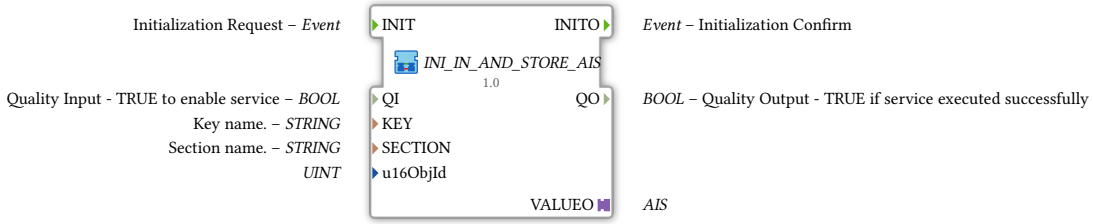
INI_IN_AND_STORE_AIS

• – ○ • – ○ • – ○ •



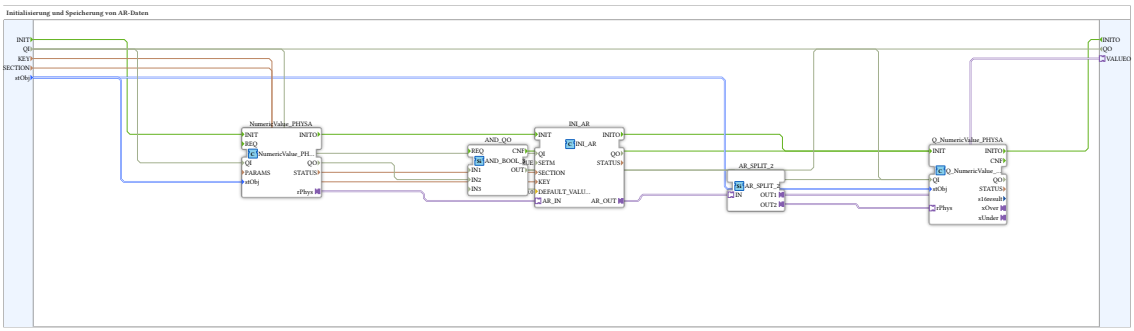
Introduction

`INI_IN_AND_STORE_AIS` persistently stores a string value entered via the VT (AIS adapter) in an INI file and automatically reloads it on deployment.

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

Interface (quality pattern): the data input `QI` (`BOOL`, default `TRUE`, "Quality Input - TRUE to enable service") and the data output `QO` (`BOOL`, "Quality Output - TRUE if service executed successfully") are connected to all three internal service blocks (`StringValue_AIS`, `INI_AIS`, `Q_StringValue_AIS`): `QI` ⟶ `Q_StringValue_AIS.QI`, `INI_AIS.QI` and `StringValue_AIS.QI`; `QO` is the AND (`AND_QO`, `iec61131::booleanOperators::AND_BOOL_3`) of `Q_StringValue_AIS.QO`, `INI_AIS.QO` and `StringValue_AIS.QO`.

In addition, the block has the events `INIT` (input, `EInit`) and `INITO` (output, `EInit`); initialization is chained: `INIT` ⟶ `StringValue_AIS.INIT`; `StringValue_AIS.INITO` ⟶ `INI_AIS.INIT`; `INI_AIS.INITO` ⟶ `Q_StringValue_AIS.INIT`; `Q_StringValue_AIS.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`).



Summary

AIS (string) variant of the INI storage family.

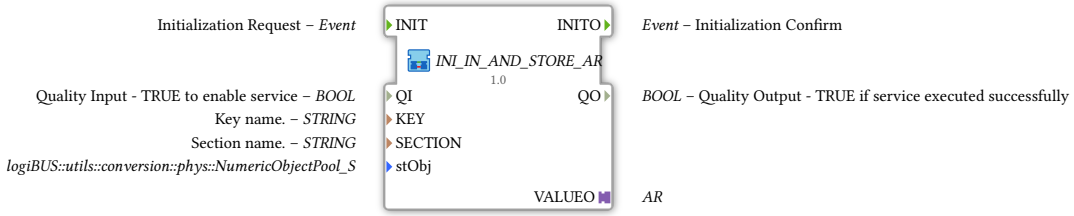
- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

INI_IN_AND_STORE_AR



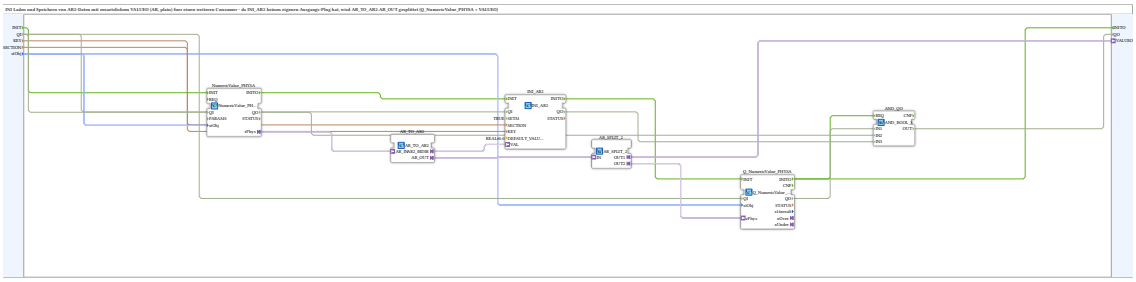
• – ○ • – ○ • – ○ •

Introduction

`INI_IN_AND_STORE_AR` persistently stores a physically scaled REAL value entered via the VT (AR adapter, `NumericValue_PHYSA`/`Q_NumericValue_PHYSA` with `NumericObjectPool_S` scaling: `r32Scale`, `i32Offset`, `u8Decimals`) in an INI file.

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

Interface (quality pattern): event input `INIT` and event output `INITO` (each `EInit`), data input `QI` (`BOOL`, default `TRUE`, "Quality Input - TRUE to enable service") and data output `QO` (`BOOL`, "Quality Output - TRUE if service executed successfully"). Initialization: `INIT` → `NumericValue_PHYSA.INIT`; `NumericValue_PHYSA.INITO` → `INI_AR.INIT`; `INI_AR.INITO` → `Q_NumericValue_PHYSA.INIT`; `Q_NumericValue_PHYSA.INITO` → `INITO` and → `AND_QO.REQ`. Quality: `QI` → `Q_NumericValue_PHYSA.QI`, `NumericValue_PHYSA.QI`, `INI_AR.QI`; `Q_NumericValue_PHYSA.QO`, `NumericValue_PHYSA.QO`, `INI_AR.QO` → `AND_QO.IN1` to `AND_QO.IN3` (in this order); `AND_QO.OUT` → `QO` (`AND_QO`: `iec61131::booleanOperators::AND_BOOL_3`).



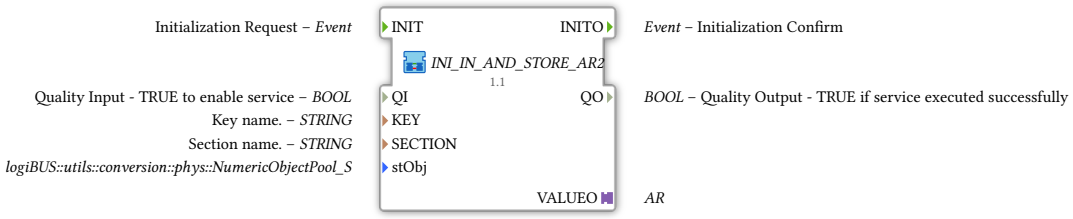
Summary

AR (physically scaled REAL) variant of the INI storage family.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

INI_IN_AND_STORE_AR2



• – ○ • – ○ • – ○ •

Introduction

`INI_IN_AND_STORE_AR2` is the AR2-adapter variant of `INI_IN_AND_STORE_AR`: a physically scaled REAL value entered via the VT (`NumericValue_PHYSA`) is persistently stored in an INI file

(`eclipse4diac::storage::INI_AR2`, storage via the AR2 adapter socket instead of a plain value). Since `INI_AR2` has no output plug of its own, the `AR_TO_AR2` output is duplicated via `AR_SPLIT_2`: once back to the VT display (`Q_NumericValue_PHYSA`), once outward on `VALUEO` for a further consumer.

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

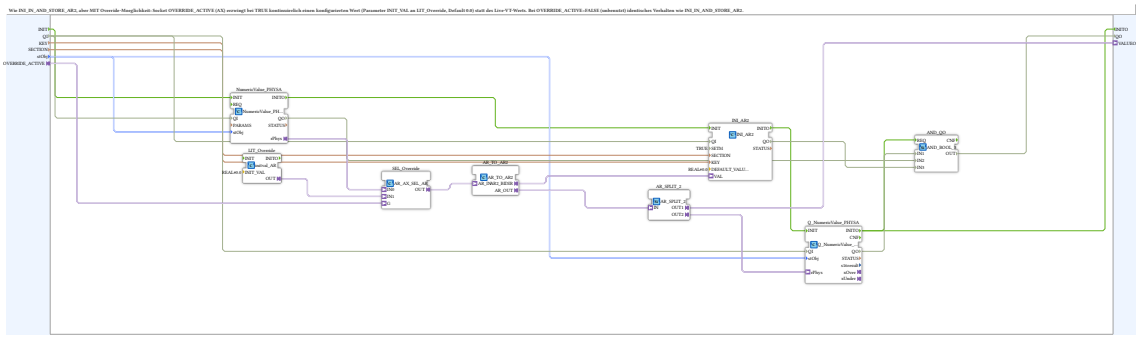
Technical notes

- `SETM=TRUE`: a live change during operation is confirmed/echoed immediately, not only at boot - important since the fresh value can be reused in the same run via `VALUEO`.
- `AR_TO_AR2` converts the plain-AR value from the VT input field into the bidirectional AR2 adapter that `INI_AR2` expects for storage.

Quality ports (QI/QO)

The block has the event input `INIT` (`EInit`, Initialization Request), the event output `INITO` (`EInit`, Initialization Confirm), the data input `QI` (`BOOL`, default `TRUE`, Quality Input - TRUE enables the service) and the data output `QO` (`BOOL`, Quality Output - TRUE if the service was executed successfully).

- Initialization chain: `INIT` ⟶ `NumericValue_PHYSA.INIT`, `NumericValue_PHYSA.INITO` ⟶ `INI_AR2.INIT`, `INI_AR2.INITO` ⟶ `Q_NumericValue_PHYSA.INIT`, `Q_NumericValue_PHYSA.INITO` ⟶ `INITO` (and additionally ⟶ `AND_QO.REQ`)
- `QI` is connected to `Q_NumericValue_PHYSA.QI`, `NumericValue_PHYSA.QI` and `INI_AR2.QI`
- `QO` is the AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_3`) of `Q_NumericValue_PHYSA.QO`, `NumericValue_PHYSA.QO` and `INI_AR2.QO`



Summary

AR2-adapter variant of the INI storage family, with an additional `VALUEO` output for a further consumer.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

INI_IN_AND_STORE_AR2_OVERRIDE

• – ○ • – ○ • – ○ •

Introduction

`INI_IN_AND_STORE_AR2_OVERRIDE` is like `INI_IN_AND_STORE_AR2`, but with an override option: while the `OVERRIDE_ACTIVE` socket (AX) is continuously TRUE, a configured value is forced instead of the live VT value (parameter `INIT_VAL` on `LIT_Override`, default `0.0`). With `OVERRIDE_ACTIVE`=FALSE (unused) the behavior is identical to `INI_IN_AND_STORE_AR2`.

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

Interface

Input variables

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE enables the service; passed through to `NumericValue_PHYSA`, `INI_AR2` and `Q_NumericValue_PHYSA`.
- `KEY` (STRING): key name in the INI file.
- `SECTION` (STRING): section name in the INI file.
- `stObj` (`logiBUS::utils::conversion::phys::NumericObjectPool_S`): VT object with `u16ObjId`, `r32Scale`, `i32Offset`, `u8Decimals` (default `u16ObjId := ID_NULL`, `r32Scale := 1.0`, `i32Offset := 0`, `u8Decimals := 0`).

Output variables

- `QO` (BOOL): Quality Output - TRUE if the service was executed successfully; `AND` of the `QO` outputs of `Q_NumericValue_PHYSA`, `NumericValue_PHYSA` and `INI_AR2` (via `AND_QO`).

Adapters

- **Plug `VALUEO`** (`adapter::types::unidirectional::AR`): value for a further consumer.
- **Socket `OVERRIDE_ACTIVE`** (`adapter::types::unidirectional::AX`): when continuously TRUE, the override value is forced.

Events

- `INIT` (EInit, input): initialization request; starts the chain `NumericValue_PHYSA` → `INI_AR2` → `Q_NumericValue_PHYSA`.
- `INITO` (EInit, output): initialization confirmation; comes from `Q_NumericValue_PHYSA.INITO`.

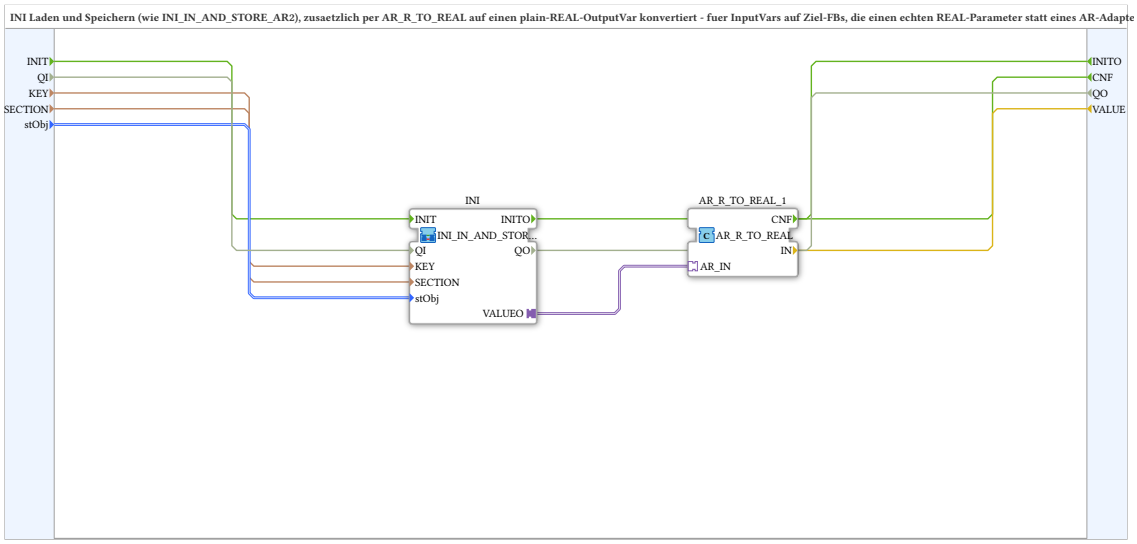
How it works

1. `NumericValue_PHYSA` reads the VT input field as a physical value (`rPhys`).
2. `SEL_Override` (`AR_AX_SEL_AR`) selects: `IN0` = live VT value, `IN1` = override value from `LIT_Override` (`initval_AR`, `INIT_VAL=REAL#0.0`), selected via `G` = `OVERRIDE_ACTIVE`.
3. `AR_TO_AR2` converts into the bidirectional AR2 adapter for `INI_AR2` (`eclipse4diac::storage::INI_AR2`; `SETM`=TRUE, `DEFAULT_VALUE=REAL#0.0`; `KEY`/`SECTION` from outside).
4. `AR_TO_AR2.AR_OUT` is duplicated via `AR_SPLIT_2`: `OUT1` to `VALUEO`, `OUT2` to `Q_NumericValue_PHYSA` (VT display, `stObj`).

`QI` is passed through to `NumericValue_PHYSA.QI`, `INI_AR2.QI` and `Q_NumericValue_PHYSA.QI` (no fixed `QI`=TRUE any more). Initialization runs as the chain `INIT` → `NumericValue_PHYSA.INIT`, `NumericValue_PHYSA.INITO` → `INI_AR2.INIT`, `INI_AR2.INITO` → `Q_NumericValue_PHYSA.INIT`, `Q_NumericValue_PHYSA.INITO` → `INITO` and → `AND_QO.REQ`. `QO` is the `AND` (`AND_QO`, `AND_BOOL_3`) of the `QO` outputs of `Q_NumericValue_PHYSA`, `NumericValue_PHYSA` and `INI_AR2`.

Technical notes

- Unlike the AUDI2 variant (`INI_IN_AND_STORE_AUDI2_OVERRIDE`, enum/dropdown, 1=disabled), AR is a continuous physical value: the override value has no fixed meaning but is freely configurable via `INIT_VAL` on `LIT_Override`.
- `SETM`=TRUE: the boot value loads automatically (INIT → INITO → GET → GETO, independent of `SETM`); `SETM`=TRUE additionally ensures that a live change during operation is confirmed/echoed immediately (e.g. for further use via `VALUEO`).



Summary

AR2 storage block with a switchable, configurable override value.

INI_IN_AND_STORE_AR2_TO_REAL

• – ○ • – ○ • – ○ •

Introduction

`INI_IN_AND_STORE_AR2_TO_REAL` loads and stores a value in the INI file (like `INI_IN_AND_STORE_AR2`) and additionally converts it to a plain REAL output variable via `AR_R_TO_REAL`. This is needed for input variables of target blocks that expect a real REAL parameter instead of an AR adapter socket (e.g. `CTRL_PID_AR.KP/TN/TV`).

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; passed on to `INI.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `INI.INITO`
- **CNF** (confirmation): fires when a (new or initially loaded) value is available. Connect it to a `REQ` input of a target FB (e.g. `CTRL_PID_AR.REQ`) so that it takes over the fresh value immediately instead of waiting for its own next adapter trigger

Data Inputs

- **QI** (BOOL, initial value `TRUE`): quality input, enables the service; passed on to `INI.QI`
- **KEY** (STRING): key name in the INI file
- **SECTION** (STRING): section name in the INI file
- **stObj** (`logiBUS::utils::conversion::phys::NumericObjectPool_S`): object pool properties of the VT number variable (default: `u16ObjId := ID_NULL, r32Scale := 1.0, i32Offset := 0, u8Decimals := 0`)

Data Outputs

- **QO** (BOOL): quality output; comes from `INI.QO`
- **VALUE** (REAL): persisted/loaded value as a plain REAL (no AR adapter)

Adapters

No adapters are used.

Functionality

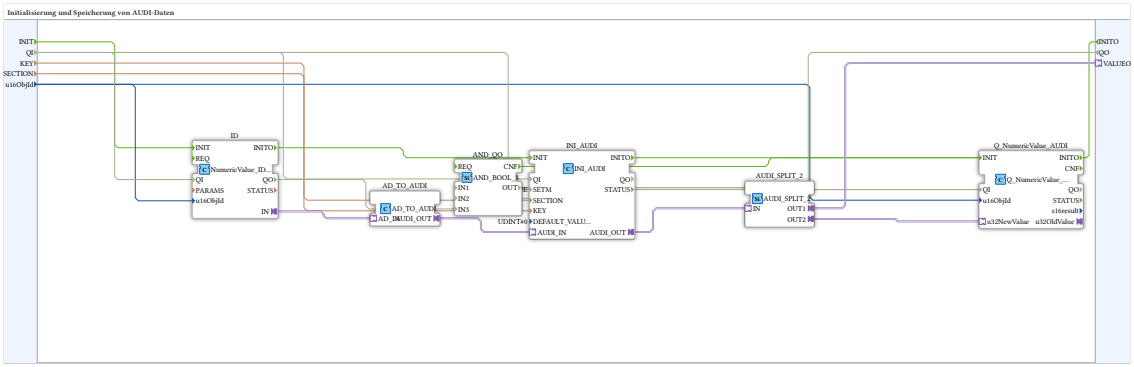
The network contains two instances:

- `INI` (`MyLib::sys::INI_IN_AND_STORE_AR2`): `KEY` ⟶ `INI.KEY`, `SECTION` ⟶ `INI.SECTION`, `stObj` ⟶ `INI.stObj`. The value is available at `INI.VALUEO` (AR).
- `AR_R_TO_REAL_1` (`adapter::conversion::unidirectional::AR_R_TO_REAL`): `INI.VALUEO` ⟶ `AR_R_TO_REAL_1.AR_IN`; `AR_R_TO_REAL_1.IN` ⟶ `VALUE` and `AR_R_TO_REAL_1.CNF` ⟶ `CNF`.

Initialization and quality are passed straight through: `INIT` ⟶ `INI.INIT`, `INI.INITO` ⟶ `INITO`, `QI` ⟶ `INI.QI` and `INI.QO` ⟶ `QO`.

Technical Details

- Extracted from `Aufnahme_Automatik.SUB`, where this combination was wired three times identically (KP/TN/TV)
- `CNF` is generated only after the AR-to-REAL conversion and thus signals that `VALUE` is up to date



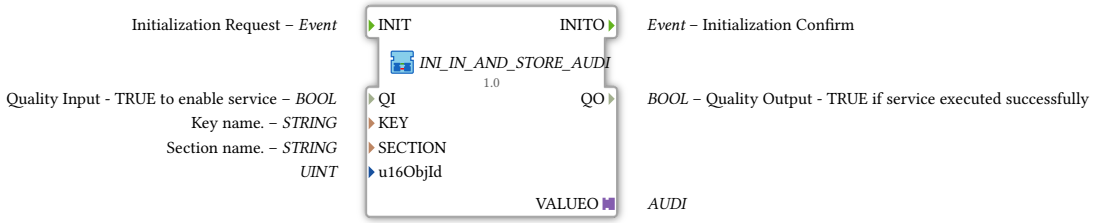
Application Scenarios

- Persisted controller parameters (e.g. KP/TN/TV of a PID controller) that are connected to REAL inputs of target FBs

Conclusion

`INI_IN_AND_STORE_AR2_TO_REAL` combines INI persistence with an AR-to-REAL conversion and delivers the value together with a `CNF` event at a plain REAL output variable.

INI_IN_AND_STORE_AUDI



• – ○ • – ○ • – ○ •

Introduction

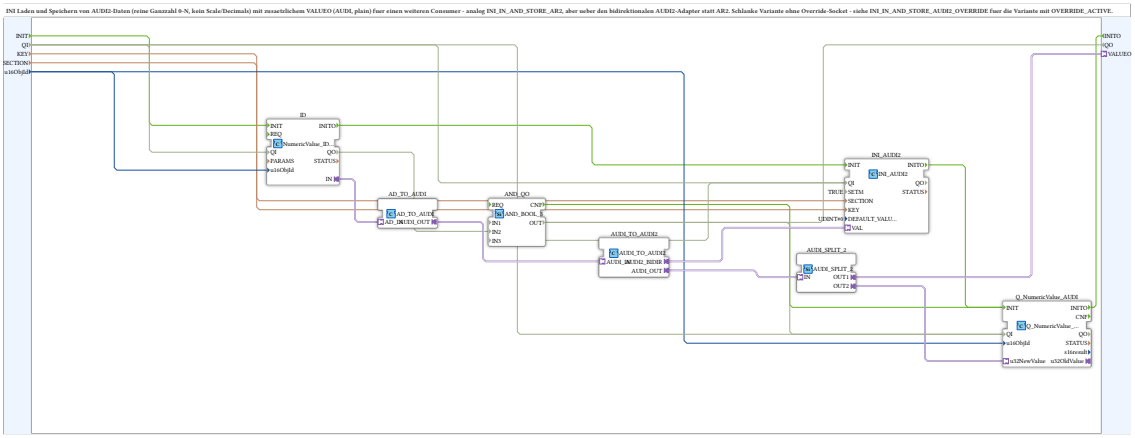
`INI_IN_AND_STORE_AUDI` persistently stores a UDINT value entered via the VT (AUDI adapter) in an INI file.

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

Event and quality ports (INIT/INITO, QI/QO)

The block has the event input `INIT` and the event output `INITO` (both `EInit`), the data input `QI` (`BOOL`, default `TRUE`, Quality Input - TRUE enables the service) and the data output `QO` (`BOOL`, Quality Output - TRUE if the service was executed successfully).

Initialization runs as a chain through the inner blocks: `INIT` ⟶ `ID.INIT`, `ID.INITO` ⟶ `INI_AUDI.INIT`, `INI_AUDI.INITO` ⟶ `Q_NumericValue_AUDI.INIT`, `Q_NumericValue_AUDI.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`). `QI` is passed to `ID`, `INI_AUDI` and `Q_NumericValue_AUDI`. `QO` is the output of the instance `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`), which combines `Q_NumericValue_AUDI.QO`, `INI_AUDI.QO` and `ID.QO`.



Summary

AUDI (UDINT) variant of the INI storage family.

INI_IN_AND_STORE_AUDI2

• — ○ • — ○ • — ○ •

Introduction

`INI_IN_AND_STORE_AUDI2` loads and stores `AUDI2` data (plain integer 0..N, without scale/decimals) persistently in an INI file and additionally provides an output `VALUEO` (`AUDI`, plain) for a further consumer. The block is analogous to `INI_IN_AND_STORE_AR2` but works via the bidirectional `AUDI2` adapter instead of `AR2`. The general pattern is described in INI_IN_AND_STORE / NVS_IN_AND_STORE a variant with `AUDI` is `INI_IN_AND_STORE_AUDI`.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirmation

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service
- **KEY** (`STRING`): key name in the INI file
- **SECTION** (`STRING`): section name in the INI file
- **u16ObjId** (`UINT`): object ID of the VT number variable (default `ID_NULL`)

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service was executed successfully (AND of `Q_NumericValue_AUDI.QO`, `ID.QO` and `INI_AUDI2.QO`)

Adapters

- **VALUEO** (plug, `adapter::types::unidirectional::AUDI`): value for a further consumer

Function Blocks (FBs) Used

- **`ID`** (`isobus::UT::io::NumericValue::NumericValue_IDA`): delivers the VT value entered by the operator
- **`AD_TO_AUDI`** (`adapter::conversion::unidirectional::AD_TO_AUDI`): converts the `AD` value to `AUDI`
- **`AUDI_TO_AUDI2`** (`adapter::conversion::bidirectional::AUDI_TO_AUDI2`): converts `AUDI` into the bidirectional `AUDI2` adapter
- **`INI_AUDI2`** (`eclipse4diac::storage::INI_AUDI2`): `SETM = TRUE`, `DEFAULT_VALUE = UDINT#0`; loads and stores the value
- **`AUDI_SPLIT_2`** (`adapter::events::unidirectional::AUDI_SPLIT_2`): duplicates the value
- **`Q_NumericValue_AUDI`** (`isobus::UT::Q::Q_NumericValue_AUDI`): writes the value into the VT number variable
- **`AND_QO`** (`iec61131::booleanOperators::AND_BOOL_3`): combines the `QO` outputs of `Q_NumericValue_AUDI`, `ID` and `INI_AUDI2`

Functionality

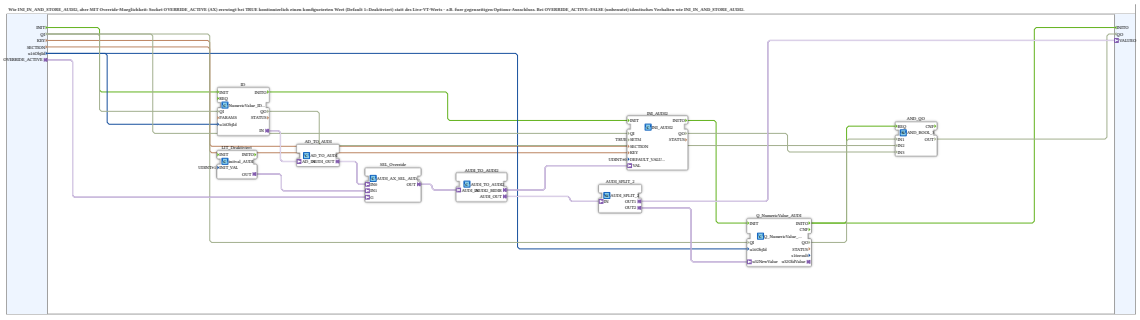
- `ID.IN` ⟶ `AD_TO_AUDI.AD_IN` ⟶ `AUDI_TO_AUDI2.AUDI_IN`
- `AUDI_TO_AUDI2.AUDI2_BIDIR` ⟶ `INI_AUDI2.VAL` (load/store)
- `AUDI_TO_AUDI2.AUDI_OUT` ⟶ `AUDI_SPLIT_2.IN`
- `AUDI_SPLIT_2.OUT1` ⟶ `VALUEO`; `AUDI_SPLIT_2.OUT2` ⟶ `Q_NumericValue_AUDI.u32NewValue` (VT display)
- `KEY`, `SECTION` ⟶ `INI_AUDI2`; `u16ObjId` ⟶ `ID` and `Q_NumericValue_AUDI`
- `INIT` ⟶ `ID.INIT`; `ID.INITO` ⟶ `INI_AUDI2.INIT`; `INI_AUDI2.INITO` ⟶ `Q_NumericValue_AUDI.INIT`; `Q_NumericValue_AUDI.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`)
- `QI` ⟶ `Q_NumericValue_AUDI.QI`, `ID.QI` and `INI_AUDI2.QI`
- `Q_NumericValue_AUDI.QO` ⟶ `AND_QO.IN1`; `ID.QO` ⟶ `AND_QO.IN2`; `INI_AUDI2.QO` ⟶ `AND_QO.IN3`; `AND_QO.OUT` ⟶ `QO`

Technical Details

- **`SETM = TRUE`:** the boot value is loaded automatically anyway (`INIT` ⟶ `INITO` ⟶ `GET` ⟶ `GETO`, independent of `SETM`). `SETM = TRUE` ensures that a live change during operation is also confirmed/reported back immediately; important if the fresh value is to be used further in the same run (here via `VALUEO`).
- `INI_AUDI2` has no output plug of its own, so the output is duplicated via `AUDI_SPLIT_2`
- Plain integer (`UDINT`) without scaling

Application Scenarios

- A persistently stored integer setting (e.g. counter, selection index) that is entered on the VT and reused



Summary

`INI_IN_AND_STORE_AUDI2` stores a VT integer value in an INI file (via `AUDI2`) and additionally outputs it as `AUDI`.

INI_IN_AND_STORE_AUDI2_OVERRIDE

• — ○ • — ○ • — ○ •

Introduction

`INI_IN_AND_STORE_AUDI2_OVERRIDE` is like `INI_IN_AND_STORE_AUDI2`, but with an override option: while the `OVERRIDE_ACTIVE` socket (AX) is continuously TRUE, the value 1 (disabled) is forced instead of the live VT value - e.g. for mutual option exclusion. With `OVERRIDE_ACTIVE`=FALSE (unused) the behavior is identical to `INI_IN_AND_STORE_AUDI2`. The variant without `OVERRIDE_ACTIVE` is available separately as `INI_IN_AND_STORE_AUDI2` (rename in version 1.2).

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

Interface

Event inputs

- `INIT` (`EInit`): initialization request.

Event outputs

- `INITO` (`EInit`): initialization confirm.

Input variables

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE enables the service.
- `KEY` (STRING): key name in the INI file.
- `SECTION` (STRING): section name in the INI file.
- `u16ObjId` (UINT, default `ID_NULL`): ObjectID of the VT input field.

Output variables

- `QO` (BOOL): Quality Output - TRUE if the service was executed successfully (AND combination `AND_QO` of the `QO` outputs of the inner blocks).

Adapters

- **Plug `VALUEO`** (`adapter::types::unidirectional::AUDI`): value for a further consumer.
- **Socket `OVERRIDE_ACTIVE`** (`adapter::types::unidirectional::AX`): when continuously TRUE, VAL=1 (disabled) is forced.

The events `INIT`/`INITO` are passed as a chain through the inner blocks (see How it works).

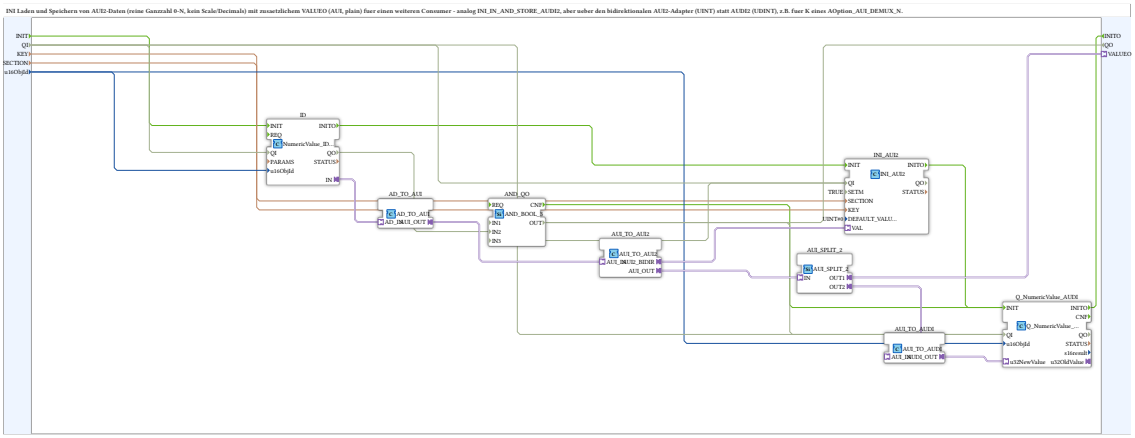
How it works

1. `ID` (`NumericValue_IDA`) reads the VT input field; `AD_TO_AUDI` converts to AUDI.
2. `SEL_Override` (`AUDI_AX_SEL_AUDI`) selects: `IN0` = live VT value, `IN1` = override value from `LIT_Deaktiviert` (`initval_AUDI`, `INIT_VAL=UDINT#1`), selected via `G` = `OVERRIDE_ACTIVE`.
3. `AUDI_TO_AUDI2` converts into the bidirectional AUDI2 adapter for `INI_AUDI2` (`eclipse4diac::storage::INI_AUDI2`; `SETM`=TRUE, `DEFAULT_VALUE=UDINT#0`).
4. `AUDI_TO_AUDI2.AUDI_OUT` is duplicated via `AUDI_SPLIT_2`: `OUT1` to `VALUEO`, `OUT2` to `Q_NumericValue_AUDI` (`u32NewValue`, VT display).

Initialization: `INIT` → `ID.INIT`; `ID.INITO` → `INI_AUDI2.INIT`; `INI_AUDI2.INITO` → `Q_NumericValue_AUDI.INIT`; `Q_NumericValue_AUDI.INITO` → `INITO` and → `AND_QO.REQ`. Quality: `QI` → `Q_NumericValue_AUDI.QI`, `ID.QI`, `INI_AUDI2.QI`; `Q_NumericValue_AUDI.QO`, `ID.QO`, `INI_AUDI2.QO` → `AND_QO.IN1` to `AND_QO.IN3` (in this order); `AND_QO.OUT` → `QO` (`AND_QO`: `iec61131::booleanOperators::AND_BOOL_3`).

Technical notes

- The override runs over the same `INI_AUDI2`/`Q_NumericValue_AUDI` path: according to its own documentation, `Q_NumericValue` allows only one instance per ObjectID, so a second writing instance is not possible.
- For pure enum/integer values (e.g. dropdowns 0-3), no decimal places.
- `SETM`=TRUE: the boot value loads automatically (INIT → INITO → GET → GETO); `SETM`=TRUE additionally ensures that a live change is confirmed/echoed immediately.



Summary

AUDI2 storage block with a switchable override to 1 (disabled), e.g. for mutual option exclusion.

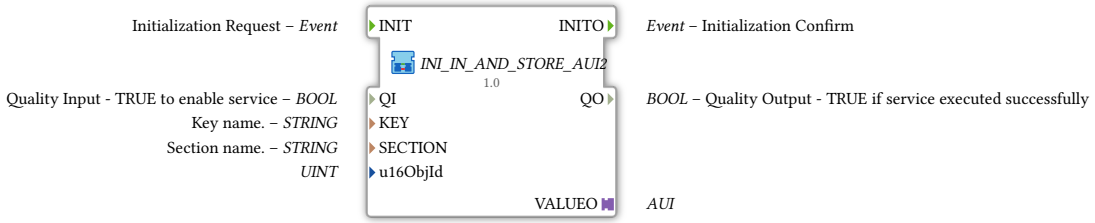
INI_IN_AND_STORE_AUI2



• – ○ • – ○ • – ○ •

Introduction

`INI_IN_AND_STORE_AUI2` loads and stores AUI2 data (pure integer 0-N, no scale/decimals) in an INI file and additionally provides `VALUEO` (AUI, plain) for a further consumer. It corresponds to `INI_IN_AND_STORE_AUDI2`, but uses the bidirectional AUI2 adapter (UINT) instead of AUDI2 (UDINT) - e.g. for `K` of an `AOption_AUI_DEMUX_N`.

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

Interface

Input variables

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE enables the service.
- `KEY` (STRING): key name in the INI file.

- `SECTION` (STRING): section name in the INI file.
- `u16ObjId` (UINT, default `ID_NULL`): ObjectID of the VT input field.

Output variables

- `QO` (BOOL): Quality Output - TRUE if the service was executed successfully (AND of `Q_NumericValue_AUDI.QO`, `ID.QO` and `INI_AUI2.QO`).

Adapters

- **Plug `VALUEO`** (`adapter::types::unidirectional::AUI`): value for a further consumer.

Events

- Input `INIT` (`EInit`): Initialization Request
- Output `INITO` (`EInit`): Initialization Confirm

How it works

1. `ID` (`NumericValue_IDA`) reads the VT input field; `AD_TO_AUI` converts to AUI.
2. `AUI_TO_AUI2` converts into the bidirectional AUI2 adapter for `INI_AUI2` (`eclipse4diac::storage::INI_AUI2`; `SETM`=TRUE, `DEFAULT_VALUE=UINT#0`).
3. `AUI_TO_AUI2.AUI_OUT` is duplicated via `AUI_SPLIT_2`: `OUT1` to `VALUEO`, `OUT2` via `AUI_TO_AUDI` to `Q_NumericValue_AUDI` (`u32NewValue`, VT display).

`QI` is passed through to `ID.QI`, `INI_AUI2.QI` and `Q_NumericValue_AUDI.QI`. The initialization chain is `INIT` ⟶ `ID.INIT`, `ID.INITO` ⟶ `INI_AUI2.INIT`, `INI_AUI2.INITO` ⟶ `Q_NumericValue_AUDI.INIT`, `Q_NumericValue_AUDI.INITO` ⟶ `INITO` (and additionally ⟶ `AND_QO.REQ`). `QO` is the AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_3`) of `Q_NumericValue_AUDI.QO`, `ID.QO` and `INI_AUI2.QO`.

Technical notes

- Structurally identical to `INI_IN_AND_STORE_AUDI2`, only with AUI2 instead of AUDI2.
- `SETM`=TRUE: the boot value loads automatically (INIT ⟶ INITO ⟶ GET ⟶ GETO); `SETM`=TRUE additionally ensures that a live change is confirmed/echoed immediately (e.g. for further use via `VALUEO`).

Summary

AUI2 variant of the INI storage family for pure integers with an additional `VALUEO` output.

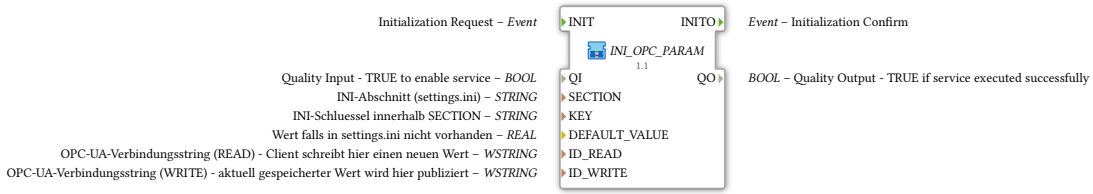
INI_OPC_PARAM



• – ○ • – ○ • – ○ •

Introduction

`INI_OPC_PARAM` reads and writes a REAL parameter via OPC UA and stores it persistently in the INI file (`settings.ini`). A client can set a new value using `ID_READ`; the currently stored value is published using

ID_WRITE. After a restart, the last stored value (or DEFAULT_VALUE, if none exists) is automatically loaded and published again.

Function Blocks (FBs) Used

Sub-Blocks: INI_OPC_PARAM

- **Type**: SubAppType
- **Internal FBs Used**:
- **AX_SUBSCRIBE_1**: `adapter::net::AR_SUBSCRIBE_1` — subscribes to new values from the OPC UA client (`ID_READ`).
- **INI_AR**: `eclipse4diac::storage::INI_AR` (`SETM=FALSE`) — persistently stores the value in the INI file under `SECTION`/`KEY`, with `DEFAULT_VALUE` as the initial value.
- **AX_PUBLISH_1**: `adapter::net::AR_PUBLISH_1` — publishes the current value via OPC UA (`ID_WRITE`).
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_3` — combines the `QO` outputs of `AX_SUBSCRIBE_1`, `AX_PUBLISH_1` and `INI_AR` into the SubApp output `QO`.
- **Interface**: event input `INIT`, event output `INITO`, data input `QI` (initial value `TRUE`, passed on to all three FBs) and data output `QO` (`AND` of the three `QO` outputs).
- **How it works**: A value received via OPC UA is forwarded to `INI_AR`, stored there, and the value (newly received or loaded at startup) is then published again via `AX_PUBLISH_1`.

Program Flow and Connections

1. **Initialization Chain**: `INIT` → `AX_SUBSCRIBE_1.INIT`; `AX_SUBSCRIBE_1.INITO` → `INI_AR.INIT`; `INI_AR.INITO` → `AX_PUBLISH_1.INIT`; `AX_PUBLISH_1.INITO` → `INITO` and → `AND_QO.REQ`.
2. **Quality**: `QI` → `AX_SUBSCRIBE_1.QI`, `AX_PUBLISH_1.QI` and `INI_AR.QI`; `AX_SUBSCRIBE_1.QO` → `AND_QO.IN1`, `AX_PUBLISH_1.QO` → `AND_QO.IN2`, `INI_AR.QO` → `AND_QO.IN3`; `AND_QO.OUT` → `QO`.
3. **Parameters**: `SECTION` → `INI_AR.SECTION`; `KEY` → `INI_AR.KEY`; `DEFAULT_VALUE` → `INI_AR.DEFAULT_VALUE`; `ID_READ` → `AX_SUBSCRIBE_1.ID`; `ID_WRITE` → `AX_PUBLISH_1.ID`.
4. **Adapter Chain**: `AX_SUBSCRIBE_1.OUT` → `INI_AR.AR_IN` (new value from the client) → `INI_AR.AR_OUT` → `AX_PUBLISH_1.IN` (saved/current value back to the client).

Technical Features

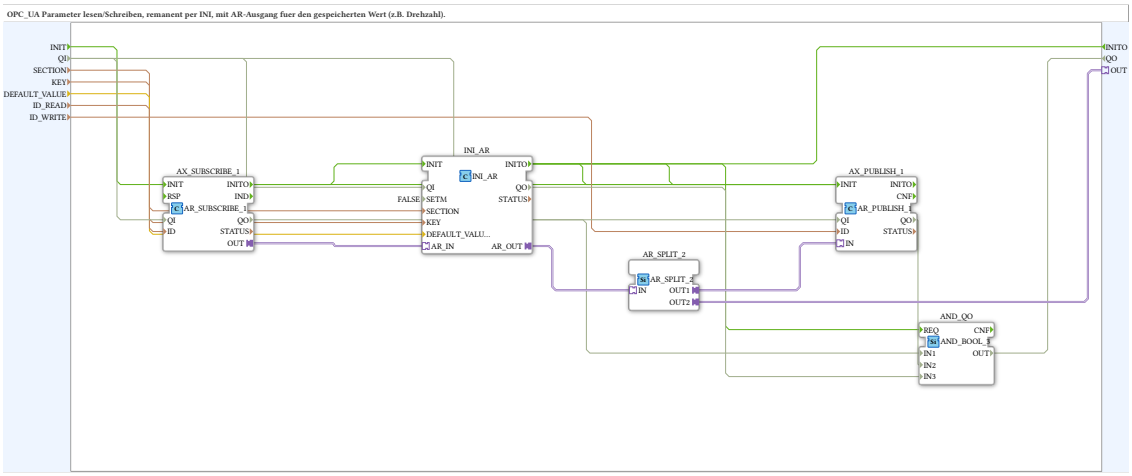
- **`SETM=FALSE`**: `INI_AR` only saves on an explicit write event via `AR_IN`, not on every cycle.
- **Sequential Initialization**: `AX_SUBSCRIBE_1.INITO` → `INI_AR.INIT` → `INI_AR.INITO` → `AX_PUBLISH_1.INIT` ensures that the stored value is loaded before being published.
- **No Dedicated Adapter Output**: Unlike `INI_OPC_PARAM_AR`, this block does not provide the stored value as a plug for other blocks in the calling network—it serves exclusively for OPC UA connectivity.

Application Scenarios

- A numerical parameter (e.g., setpoint) editable via OPC UA/Web client that must be retained across restarts but is not used further on the local network.

Comparison with Similar Function Blocks

`INI_OPC_PARAM_AR` extends this function block with an additional `AR` plug (`OUT`) for local use of the stored value. `INI_OPC_PARAM_ATM` additionally provides a `TIME` conversion, and `INI_OPC_PARAM_AX` is the BOOL variant with a `AX` output.

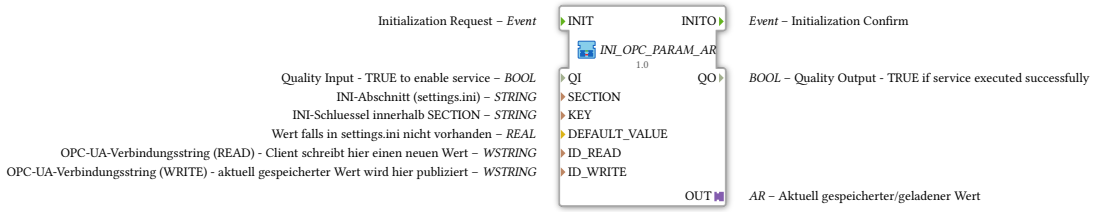


Summary

`INI_OPC_PARAM` combines OPC UA read/write access with persistent INI storage of a REAL parameter without making the value available locally as an adapter.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



INI_OPC_PARAM_AR

• — ○ • — ○ • — ○ •

Introduction

`INI_OPC_PARAM_AR` extends `INI_OPC_PARAM` with an additional `AR` adapter output (`OUT`), which provides the currently stored/loaded value directly for further use in the calling network—e.g., for a locally adjustable rotational speed that should be editable via OPC UA and also used directly in the same application.

Function Blocks (FBs) Used

Sub-Blocks: INI_OPC_PARAM_AR

- **Type**: SubAppType
- **Internal FBs Used**:
- **AX_SUBSCRIBE_1**: `adapter::net::AR_SUBSCRIBE_1` (`QI` comes from the input `QI`) — subscribes to new values from the OPC UA client (`ID_READ`).
- **INI_AR**: `eclipse4diac::storage::INI_AR` (`QI` comes from the input `QI`, `SETM=FALSE`) — persistently stores the value in the INI file under `SECTION/KEY`, with `DEFAULT_VALUE` as the initial value.
- **AX_PUBLISH_1**: `adapter::net::AR_PUBLISH_1` (`QI` comes from the input `QI`) — publishes the current value via OPC UA (`ID_WRITE`).
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_3` — combines the `QO` outputs of the three FBs into the output `QO`.
- **Functionality**: Identical to `INI_OPC_PARAM`, except that `INI_AR.AR_OUT` is directly routed to the plugin `OUT`. The SubApp interface additionally has the events `INIT`/`INITO` and the data `QI` (BOOL, initial value `TRUE`) and `QO` (BOOL).

Program Flow and Connections

1. **Initialization Chain**: `INIT` → `AX_SUBSCRIBE_1.INIT`; `AX_SUBSCRIBE_1.INITO` → `INI_AR.INIT` and → `AX_PUBLISH_1.INIT`; `AX_PUBLISH_1.INITO` → `INI_AR.INIT`; `INI_AR.INITO` → `AX_PUBLISH_1.INIT`, → `INITO` and → `AND_QO.REQ`.
2. **Parameters**: `SECTION` → `INI_AR.SECTION`; `KEY` → `INI_AR.KEY`; `DEFAULT_VALUE` → `INI_AR.DEFAULT_VALUE`; `ID_READ` → `AX_SUBSCRIBE_1.ID`; `ID_WRITE` → `AX_PUBLISH_1.ID`.
3. **Adapter Chain**: `AX_SUBSCRIBE_1.OUT` → `INI_AR.AR_IN` → `INI_AR.AR_OUT` → `AX_PUBLISH_1.IN` **and** → `OUT` (plug into the SubApp interface).
4. **Quality**: `QI` → `AX_SUBSCRIBE_1.QI`, `AX_PUBLISH_1.QI` and `INI_AR.QI`; `AX_SUBSCRIBE_1.QO` → `AND_QO.IN1`, `AX_PUBLISH_1.QO` → `AND_QO.IN2`, `INI_AR.QO` → `AND_QO.IN3`; `AND_QO.OUT` → `QO`.

Technical Features

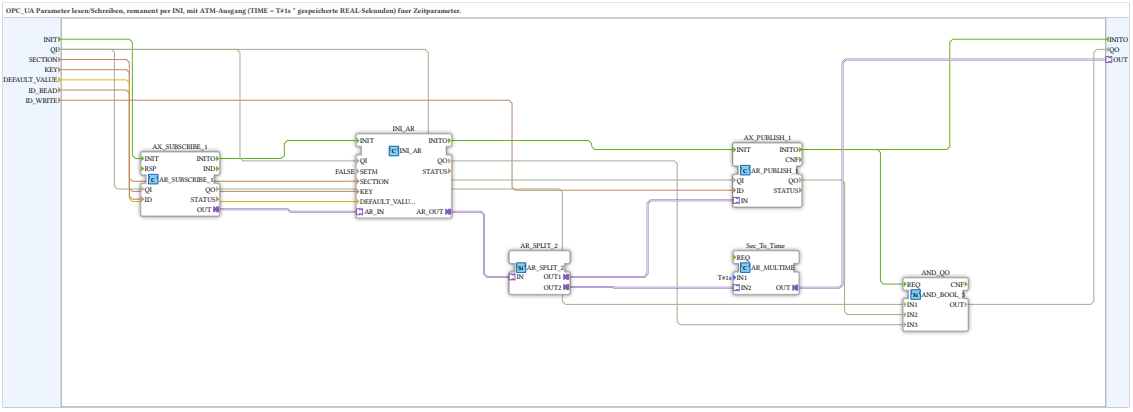
- **One output, two destinations**: `INI_AR.AR_OUT` simultaneously feeds the OPC UA publish adapter and the external `OUT` plug—both receive the same value without any additional splitting, as these are two separate adapter connections from the same source.
- Otherwise identical to `INI_OPC_PARAM` (see there for details on `SETM`/initialization sequence).

Application Scenarios

- A REAL parameter (e.g., speed setpoint) that can be edited via OPC UA/web client and is stored persistently, and which must also be directly passed to other components in the same network.

Comparison with Similar Building Blocks

Compared to `INI_OPC_PARAM`, the only difference is the additional `AR` plugin, `OUT`. `INI_OPC_PARAM_ATM` additionally converts the value to `TIME`, and `INI_OPC_PARAM_AX` is the BOOL variant.

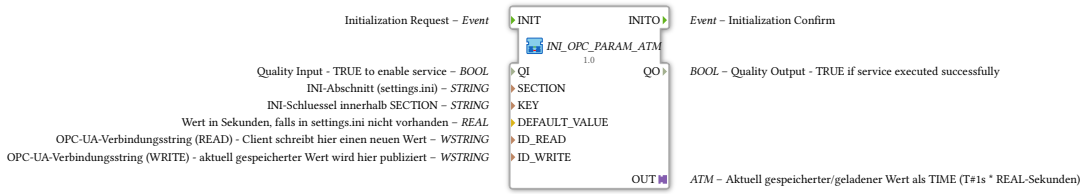


Summary

`INI_OPC_PARAM_AR` is `INI_OPC_PARAM` with an additional `AR` output for local reuse of the persistently stored parameter.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & Color Reference on ms-muc-docs.de



INI_OPC_PARAM_ATM

• – ○ • – ○ • – ○ •

Introduction

`INI_OPC_PARAM_ATM` is the time parameter variant of `INI_OPC_PARAM_AR`: The persistently stored REAL value is additionally converted into a `ATM` adapter (`TIME`) — `DEFAULT_VALUE` and the stored value are interpreted as seconds (`T#1s * Sekunden`).

Function Blocks (FBs) Used

Sub-Blocks: INI_OPC_PARAM_ATM

- **Type**: SubAppType
- **Internal FBs Used**:
- **AX_SUBSCRIBE_1**: `adapter::net::AR_SUBSCRIBE_1` (`QI` from outside) — subscribes to new values from the OPC UA client (`ID_READ`).
- **INI_AR**: `eclipse4diac::storage::INI_AR` (`SETM=FALSE`, `QI` from outside) — persistently stores the value in the INI file under `SECTION`/`KEY`, with `DEFAULT_VALUE` (in seconds) as the starting value.
- **AX_PUBLISH_1**: `adapter::net::AR_PUBLISH_1` (`QI` from outside) — publishes the current REAL value via OPC UA (`ID_WRITE`).
- **Sec_To_Time**: `adapter::iec61131::arithmetic::AR_MULTIME` (`IN1=T#1s`) — multiplies the stored REAL value (seconds) by `T#1s` to provide it as the value `TIME`.
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_3` — combines the `QO` of `AX_SUBSCRIBE_1`, `AX_PUBLISH_1` and `INI_AR` into the output `QO`.
- **How it works**: Like `INI_OPC_PARAM_AR`, except that `INI_AR.AR_OUT` is converted via `Sec_To_Time` (`AR_MULTIME`) to `TIME` and provided as the `ATM` plug `OUT`.

Program Flow and Connections

1. **Initialization Chain**: event input `INIT` ⟶ `AX_SUBSCRIBE_1.INIT`; `AX_SUBSCRIBE_1.INITO` ⟶ `INI_AR.INIT`; `INI_AR.INITO` ⟶ `AX_PUBLISH_1.INIT`; `AX_PUBLISH_1.INITO` ⟶ event output `INITO` and ⟶ `AND_QO.REQ`.
2. **Parameters**: `SECTION` ⟶ `INI_AR.SECTION`; `KEY` ⟶ `INI_AR.KEY`; `DEFAULT_VALUE` (seconds) ⟶ `INI_AR.DEFAULT_VALUE`; `ID_READ` ⟶ `AX_SUBSCRIBE_1.ID`; `ID_WRITE` ⟶ `AX_PUBLISH_1.ID`.
3. **Adapter Chain**: `AX_SUBSCRIBE_1.OUT` ⟶ `INI_AR.AR_IN` ⟶ `INI_AR.AR_OUT` ⟶ `AX_PUBLISH_1.IN` (REAL, published unchanged via OPC UA) **and** ⟶ `Sec_To_Time.IN2` ⟶ `Sec_To_Time.OUT` ⟶ `OUT` (as `TIME`).
4. **Quality**: data input `QI` (`BOOL`, default `TRUE`) ⟶ `AX_SUBSCRIBE_1.QI`, `AX_PUBLISH_1.QI` and `INI_AR.QI`; their `QO` ⟶ `AND_QO.IN1`, `AND_QO.IN2`, `AND_QO.IN3`; `AND_QO.OUT` ⟶ data output `QO`.

Technical Features

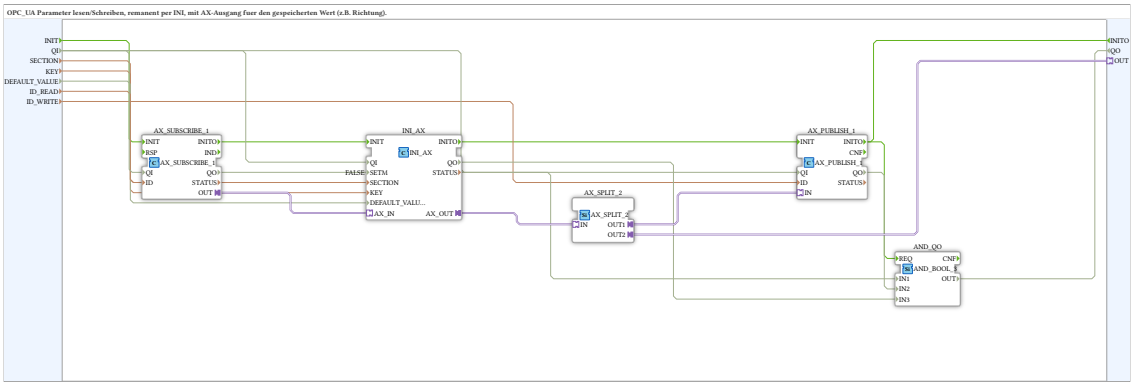
- **`AR_MULTIME` with fixed `IN1=T#1s`**: The multiplication `T#1s * REAL-Sekunden` directly converts the stored numerical value into a `TIME` value, without requiring any conversion by the caller.
- **OPC UA Publish Remains REAL**: `ID_WRITE` continues to publish the original REAL value (seconds) — only the additional `OUT` plug delivers `TIME`.
- Otherwise identical to `INI_OPC_PARAM_AR`.

Application Scenarios

- Retentive time parameters (e.g., delay or timeout times in seconds) that should be editable as a simple number via OPC UA, but are used internally as a `TIME` value (e.g., for a `E_DELAY` or `timeOut` adapter).

Comparison with Similar Function Blocks

Compared to `INI_OPC_PARAM_AR`, only the additional `Sec_To_Time` conversion (`AR_MULTIME`) is added; the `OUT` plug is of type `ATM` instead of `AR`. `INI_OPC_PARAM_AX` is the BOOL variant.

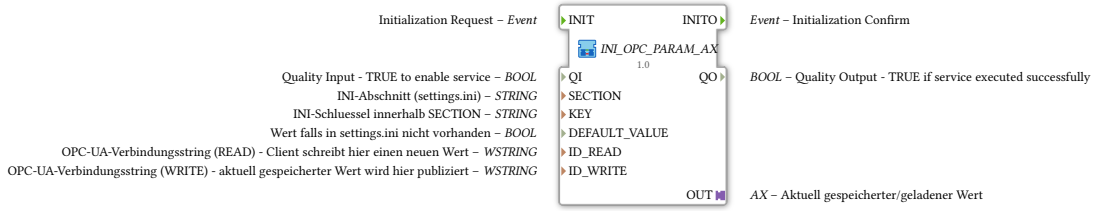


Summary

`INI_OPC_PARAM_ATM` provides a persistently stored, OPC UA editable time parameter as a ready-made `TIME` adapter, calculated from a real value stored in seconds.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & Color Reference on ms-muc-docs.de



INI_OPC_PARAM_AX

• – ○ • – ○ • – ○ •

Introduction

`INI_OPC_PARAM_AX` is the BOOL variant of `INI_OPC_PARAM_AR`: Instead of a REAL value, a BOOL parameter (e.g., a direction or operating mode switch) is read/written via OPC UA, permanently stored in the INI file, and made available as the `AX` adapter for local use.

Function Blocks (FBs) Used

Sub-Blocks: INI_OPC_PARAM_AX

- **Type**: SubAppType
- **Internal FBs Used**:
- **AX_SUBSCRIBE_1**: `adapter::net::AX_SUBSCRIBE_1` — subscribes to new BOOL values from the OPC UA client (`ID_READ`).
- **INI_AX**: `eclipse4diac::storage::INI_AX` (`SETM=FALSE`) — persistently stores the BOOL value in the INI file under `SECTION`/`KEY`, with `DEFAULT_VALUE` as the initial value.
- **AX_PUBLISH_1**: `adapter::net::AX_PUBLISH_1` — publishes the current value via OPC UA (`ID_WRITE`).
- **AX_SPLIT_2**: `adapter::events::unidirectional::AX_SPLIT_2` — branches the output of `INI_AX` to `AX_PUBLISH_1` and `OUT`.
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_3` — combines the `QO` outputs of `AX_SUBSCRIBE_1`, `AX_PUBLISH_1` and `INI_AX` into the `QO` of the SubApp.
- **Functionality**: Structurally identical to `INI_OPC_PARAM_AR`, but with `AX` adapters (`AX_SUBSCRIBE_1`/`INI_AX`/`AX_PUBLISH_1`) instead of `AR` adapters, matching the BOOL data type of `DEFAULT_VALUE`.

Program Flow and Connections

1. **Initialization Chain**: `INIT` ⟶ `AX_SUBSCRIBE_1.INIT`; `AX_SUBSCRIBE_1.INITO` ⟶ `INI_AX.INIT`; `INI_AX.INITO` ⟶ `AX_PUBLISH_1.INIT`; `AX_PUBLISH_1.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`).
2. **Parameters**: `SECTION` ⟶ `INI_AX.SECTION`; `KEY` ⟶ `INI_AX.KEY`; `DEFAULT_VALUE` (BOOL) ⟶ `INI_AX.DEFAULT_VALUE`; `ID_READ` ⟶ `AX_SUBSCRIBE_1.ID`; `ID_WRITE` ⟶ `AX_PUBLISH_1.ID`.
3. **Quality**: `QI` ⟶ `.QI` of `AX_SUBSCRIBE_1`, `AX_PUBLISH_1` and `INI_AX` (no longer hard-wired `QI=TRUE`); `AX_SUBSCRIBE_1.QO` ⟶ `AND_QO.IN1`, `AX_PUBLISH_1.QO` ⟶ `AND_QO.IN2`, `INI_AX.QO` ⟶ `AND_QO.IN3`; `AND_QO.OUT` ⟶ `QO`.
4. **Adapter Chain**: `AX_SUBSCRIBE_1.OUT` ⟶ `INI_AX.AX_IN` ⟶ `INI_AX.AX_OUT` ⟶ `AX_SPLIT_2.IN`; `AX_SPLIT_2.OUT1` ⟶ `AX_PUBLISH_1.IN` **and** `AX_SPLIT_2.OUT2` ⟶ `OUT` (plug into the SubApp interface).

Technical Features

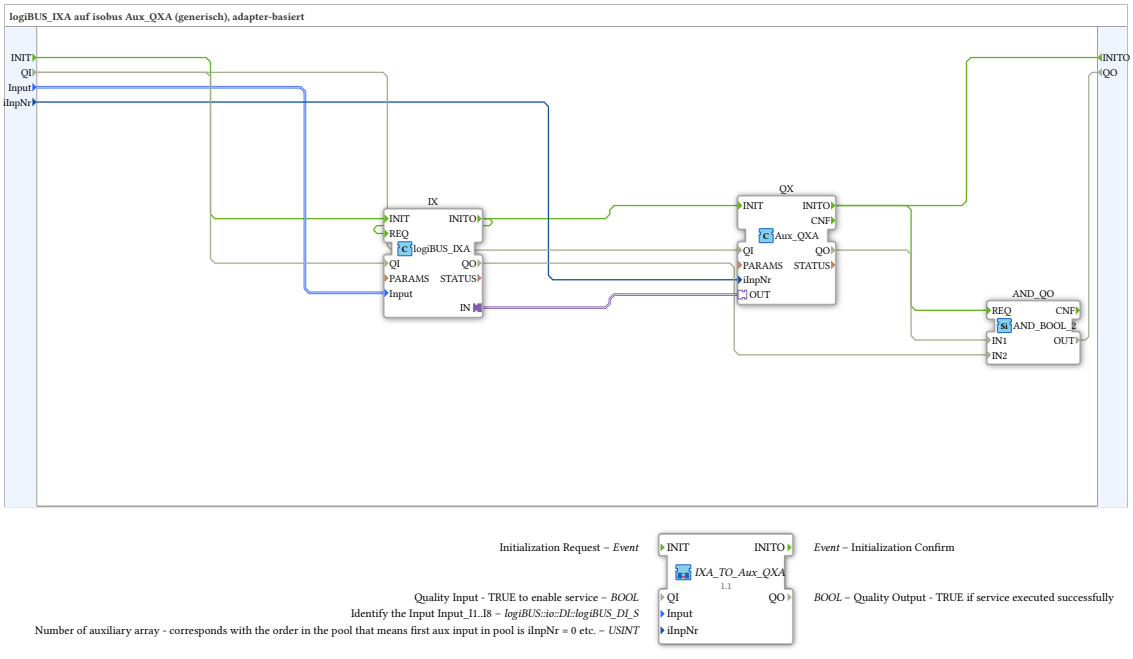
- **BOOL instead of REAL**: The only functional difference to `INI_OPC_PARAM_AR` is the data type (`DEFAULT_VALUE` is `BOOL` here) and the corresponding `AX` adapter types instead of `AR`.
- Otherwise identical to `INI_OPC_PARAM_AR` (initialization sequence, `SETM=FALSE`, one output with two destinations).

Application Scenarios

- Retentively stored BOOL parameters (e.g., direction of rotation, operating mode switch) that should be editable via OPC UA/Web client and additionally reused locally as a `AX` adapter.

Comparison with Similar Function Blocks

`INI_OPC_PARAM_AX` is to `INI_OPC_PARAM_AR` as `AX` is to `AR`: same structure, different data type. `INI_OPC_PARAM` and `INI_OPC_PARAM_ATM` are the REAL-based variants (without and with additional `TIME` conversion, respectively).



Summary

`INI_OPC_PARAM_AX` is the BOOL variant of the `INI_OPC_PARAM` family: OPC UA read/write access, persistent INI storage, and a local `AX` output for a Boolean parameter.

IXA_TO_Aux_QXA

Introduction

The **IXA_TO_Aux_QXA** subapplication serves as a generic, adapter-based bridge between a logiBUS digital input channel and an ISOBUS auxiliary output (Aux_QXA). It is designed for reuse in scenarios where a physical input from a logiBUS I/O system must be mapped to a specific auxiliary output position on an ISOBUS network, commonly found in tractor-implement control systems.

By encapsulating the internal conversion logic (from the logiBUS domain to the ISOBUS domain), the subapp provides a clean, reusable interface with only two data inputs, hiding all protocol-specific details from the surrounding logic.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; passed on to `IX.INIT`. The data path itself is purely continuous (not event-triggered).

Event Outputs

- **INITO** (`EInit`): initialization confirm; comes from `QX.INITO`.

Data Inputs

Name	Type	Initial Value	Description
`Input`	`logiBUS::io::DI::logiBUS_DI_S`	`Invalid`	Identifies the physical logiBUS digital input (e.g., `Input_I1` .. `Input_I8`) to be read.
`QI`	`BOOL`	`TRUE`	Quality input - TRUE enables the service.
`iInpNr`	`USINT`	`0`	Number of the auxiliary array entry; corresponds to the position in the pool. The first aux input in the pool is `iInpNr = 0`, the second is `1`, etc.

Data Outputs

- **QO** (`BOOL`): quality output - AND combination (`AND_QO`, `iec61131::booleanOperators::AND_BOOL_2`) of `QX.QO` and `IX.QO`. The signal itself is propagated internally via adapter connections.

Adapters

The subapp does not expose adapters at its interface. Internally, an adapter connection links the logiBUS input block to the ISOBUS auxiliary output block.

Functionality

The subapp performs the following tasks:

1. Receives a digital input identifier (`Input`) of type `logiBUS_DI_S` and an auxiliary index (`iInpNr`).
2. Internally instantiates a `logiBUS_IXA` function block, which reads and processes the specified logiBUS digital input. This block is enabled via the subapp input `QI` (default `TRUE`), and its `PARAMS` parameter is deliberately left empty (visible attribute hidden).
3. The processed input signal is forwarded through an adapter connection (`IX.IN` ⟶ `QX.OUT`) to an instantiated `Aux_QXA` function block from the ISOBUS utility library.
4. The `Aux_QXA` block maps the incoming adapter data to the auxiliary output position specified by `iInpNr`, thereby activating the corresponding ISOBUS auxiliary function.

Initialization runs as a chain: `INIT` ⟶ `IX.INIT`; `IX.INITO` ⟶ `QX.INIT`; `QX.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`. Quality: `QI` ⟶ `IX.QI` and `QX.QI`; `QX.QO` ⟶ `AND_QO.IN1`, `IX.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`. With `QI = TRUE` (default), the entire chain is active as soon as valid input data is available.

Technical Features

- **Adapter-based coupling**: The connection between the logiBUS input handling and the ISOBUS output handling is realized via a typed adapter connection, ensuring clean, protocol-compliant data transfer.

- **Generic input selection**: The `Input` parameter allows selecting any of the physical inputs `I1`..`I8`, making the subapp reusable for different wiring configurations without modification.
- **Pool-position mapping**: The `iInpNr` parameter maps the selected input to a dedicated position in the ISOBUS auxiliary output pool.
- **Hidden internal parameters**: The `PARAMS` parameter of the `logiBUS_IXA` block is hidden in the graphical representation (`Visible = false`), reducing clutter in the network editor.
- **Default-enabled operation**: Both internal function blocks receive `QI` from the subapp input `QI` (default `TRUE`), so they are enabled by default; there is no hard-wired `QI` parameter any more. Start-up sequencing is done via the `INIT`/`INITO` chain.
- **Standard-conformant types**: Uses types defined according to IEC 61499-2, with the overall subapp packaged for reuse in different projects.

State Overview

The subapp does not implement an explicit state machine. Its operational behavior is derived from the states of the internal function blocks:

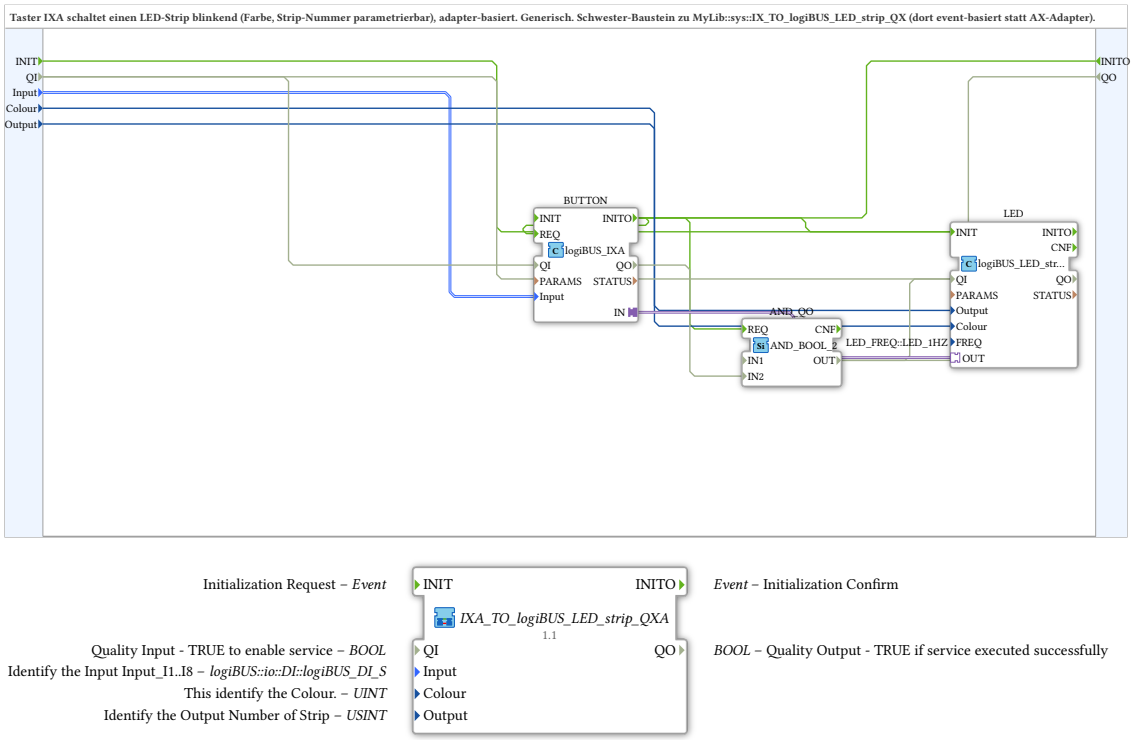
- **Idle / invalid input**: If `Input` is set to `Invalid` (as per its initial value), the `logiBUS_IXA` block will not deliver valid data, and the auxiliary output remains inactive.
- **Active input**: When a valid input identifier (`Input_I1`..`Input_I8`) is applied, the `logiBUS_IXA` block processes the signal and forwards it via the adapter to `Aux_QXA`.
- **Enabled output**: With `QI = TRUE` (default) on `Aux_QXA` and a valid adapter data stream, the auxiliary output position (`iInpNr`) is continuously updated to reflect the state of the selected logiBUS input.

Users should ensure that the `Input` value matches an actual, configured logiBUS input; otherwise, the output remains inactive.

Application Scenarios

- **Tractor implement control**: Mapping physical push-buttons or switches on an implement (connected via logiBUS) to ISOBUS auxiliary outputs for functions such as raising/lowering implements, activating PTOs, or controlling hydraulic valves.
- **Reusable input-to-output bridge**: Since the subapp is generic, it can be instantiated multiple times in a project — once for each physical input that shall control a distinct auxiliary output.
- **Migration of legacy wiring**: When upgrading from direct-wired controls to ISOBUS-based control, this subapp allows reusing existing logiBUS input modules without changing the wiring.

Comparison with Similar Blocks



Compared to a direct hard-wired connection between a logiBUS input module and an ISOBUS auxiliary output, this subapp offers:

- **Protocol abstraction**: The user does not need to interact with raw adapter types or internal FB configurations.
- **Reusability**: Extracted from a larger exercise project (previously part of `Uebung_003c_sub_AX`), it can be dropped into any 4diac project with minimal effort.
- **Clarity**: The two-parameter interface (`Input`, `iInpNr`, plus the usual `QI`/`QO` and `INIT`/`INITO` ports) is far simpler than manually wiring internal FBs and checking adapter compatibility.
- **Limitation**: It provides a one-way signal path (input → output) without bidirectional feedback. Applications requiring status readback from the ISOBUS side would need a different, more elaborate subapp.

Conclusion

The **IXA_TO_Aux_QXA** subapplication is a compact, generic, and reusable solution for connecting logiBUS digital inputs to ISOBUS auxiliary outputs. By encapsulating the protocol adaptation in an adapter-based design, it simplifies project engineering, promotes reuse, and keeps the network representation clean. It is particularly suited for agricultural and off-highway applications built on the 4diac framework.

IXA_TO_logiBUS_LED_strip_QXA

• – ○ • – ○ • – ○ •

Introduction

The `IXA_TO_logiBUS_LED_strip_QXA` is a generic composite subapplication that integrates a logiBUS push button (via the `logiBUS_IXA` function block) with an LED strip controller (`logiBUS_LED_strip_QXA`). It provides a simple, adapter-based mechanism to control an LED strip's blinking state, color, and output line based on a digital input. The subapplication is designed to be reusable across different logiBUS configurations, allowing the mapping of any input to a specific LED strip with configurable parameters.

Interface Structure

This subapplication exposes the initialization events `INIT`/`INITO`, the status ports `QI`/`QO` and data inputs; it has no adapter interfaces at its boundary. All communication between internal blocks is handled internally.

Event Inputs

Name	Type	Comment
INIT	`EInit`	Initialization Request

Event Outputs

Name	Type	Comment
INITO	`EInit`	Initialization Confirm

Data Inputs

Name	Type	Initial Value	Comment
QI	`BOOL`	`TRUE`	Quality Input - TRUE enables the service.
Input	`logiBUS::io::DI::logiBUS_DI_S`	`Invalid`	Identify the Input Input_I1..I8

Colour	UINT	LED_COLOURS::LED_GREEN	This identify the Colour.
Output	USINT	(default 0)	Identify the Output Number of Strip

Data Outputs

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if the service executed successfully (AND of LED.QO and BUTTON.QO).

Adapters

None (externally exposed).

Functionality

The subapplication routes its external data inputs to two internal function blocks:

- **BUTTON** (type logiBUS::io::DI::logiBUS_IXA): Receives the Input data; its QI comes from the subapplication's QI input.
- **LED** (type logiBUS::io::DO_LED::logiBUS_LED_strip_QXA): Receives Colour and Output data; FREQ=LED_FREQ::LED_1HZ is configured and QI comes from the subapplication's QI input.

Initialization runs as a chain INIT → LED.INIT, LED.INITO → BUTTON.INIT, BUTTON.INITO → INITO (and additionally → AND_QO.REQ). QI is forwarded to LED.QI and BUTTON.QI; LED.QO and BUTTON.QO are ANDed by the AND_QO block (type iec61131::booleanOperators::AND_BOOL_2) into QO.

An internal adapter connection links BUTTON.IN to LED.OUT, enabling the button to send state/event information directly to the LED controller via an adapter interface. This design decouples the event handling from the data path, allowing the LED strip to respond to button actions (e.g., toggling, blinking) while maintaining a simple parameterized configuration.

Technical Features

- **Adapter-based communication**: The internal connection via BUTTON.IN → LED.OUT uses an adapter, providing a flexible and type-safe link between the button and the LED controller.
- **Parameterization**: The Colour and Output data inputs allow runtime configuration of the LED color and the specific strip number.
- **Generic input mapping**: The Input data input accepts any logiBUS_DI_S value, making the subapplication adaptable to various button/input assignments.
- **Preconfigured internal blocks**: Both internal FBs receive QI from the subapplication's QI input (default TRUE), and the LED frequency is preset to 1 Hz, ensuring immediate operation upon deployment.

State Overview

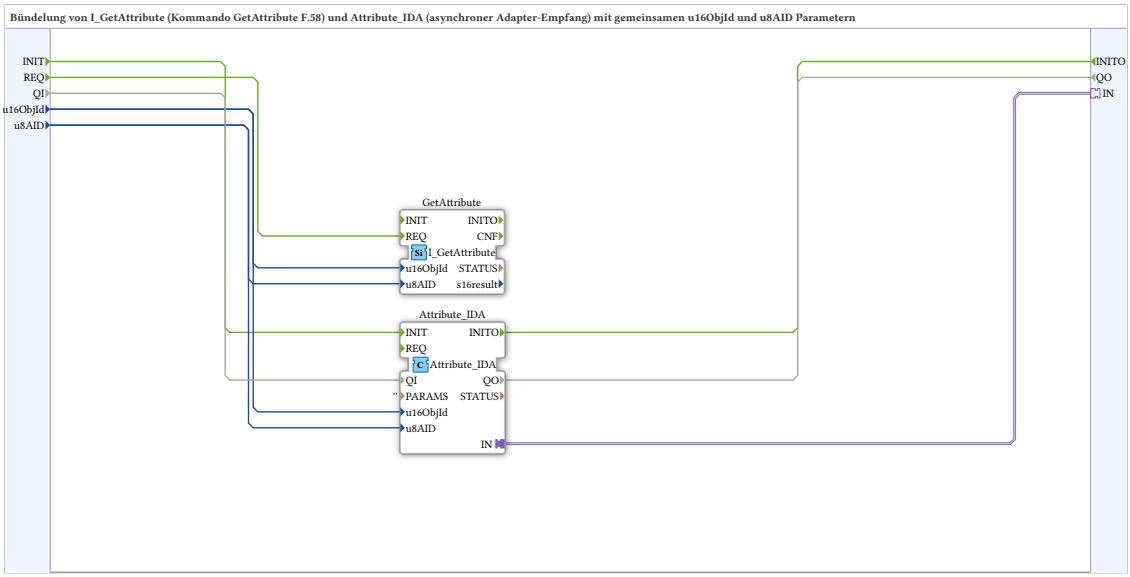
The subapplication itself does not implement a dedicated state machine. Instead, it relies on the internal behavior of the logiBUS_IXA and logiBUS_LED_strip_QXA blocks, which manage their own operational states. The subapplication serves as a static wiring and parameterization layer, passing data and adapter signals to the appropriate endpoints.

Application Scenarios

- **Building automation**: Connect a physical button (e.g., a wall switch) to control a colored LED strip on a specific output line, with configurable color and blinking frequency.
- **Status indication**: Use a button to toggle the blinking of an LED strip to indicate system states (e.g., alarm, readiness) without requiring additional logic.
- **Generic I/O mapping**: Serve as a reusable component in larger logiBUS networks to map arbitrary inputs to LED outputs, reducing development effort for similar tasks.

Comparison with Similar Blocks

The subapplication is described as a "sister block" to MyLib::sys::IX_TO_logiBUS_LED_strip_QX. The primary difference is that the sister block uses an event-based interface, whereas this subapplication uses an adapter-based internal connection. This distinction affects integration patterns:

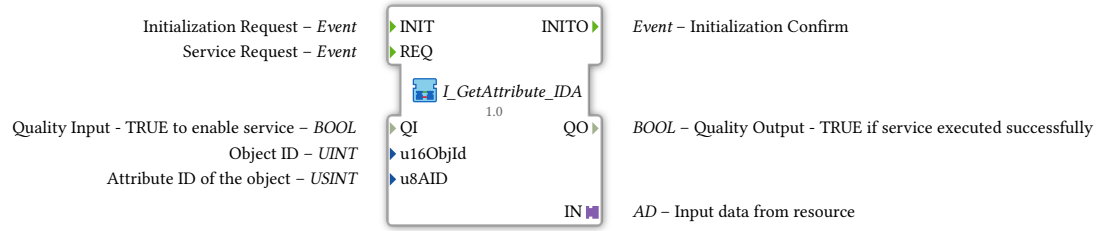


- **Adapter-based** (this block): More suitable for structured data exchange and when the button and LED controller need to share additional information beyond simple event triggers.
- **Event-based** (sister block): More lightweight for simple trigger scenarios, but may require additional event handling logic.

Both achieve similar functionality but cater to different architectural preferences.

Conclusion

`IXA_TO_logiBUS_LED_strip_QXA` provides a clean, parameterized solution for connecting a logiBUS input to a blinking LED strip. Its adapter-based design offers flexibility and easy integration into existing systems, while the explicit data inputs enable runtime customization of color and output line. As a generic, reusable component, it simplifies the development of building automation and indicator applications, making it a valuable asset in the MyLib::sys library.



I_GetAttribute_IDA

• – ○ • – ○ • – ○ •

Introduction

`I_GetAttribute_IDA` bundles `I_GetAttribute` (command *GetAttribute*, F.58) and `Attribute_IDA` (asynchronous adapter reception) with the shared parameters `u16ObjId` and `u8AID`. With `REQ`, the attribute of a VT object is requested; the response arrives asynchronously via the adapter `IN`.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request (to `Attribute_IDA.INIT`)
- **REQ**: Service request (to `GetAttribute.REQ`)

Event Outputs

- **INITO** (`EInit`): initialization confirmation (from `Attribute_IDA.INITO`)

The response itself arrives via the adapter plug.

Data Inputs

- **QI** (`BOOL`, default `TRUE`): quality input, service enable (to `Attribute_IDA.QI`)
- **u16ObjId** (`UINT`, default `ID_NULL`): Object ID
- **u8AID** (`USINT`): Attribute ID of the object

Data Outputs

- **QO** (`BOOL`): quality output (from `Attribute_IDA.QO`)

Adapters

- **IN** (plug, `adapter::types::unidirectional::AD`): Input data (response) from the resource

Function Blocks (FBs) Used

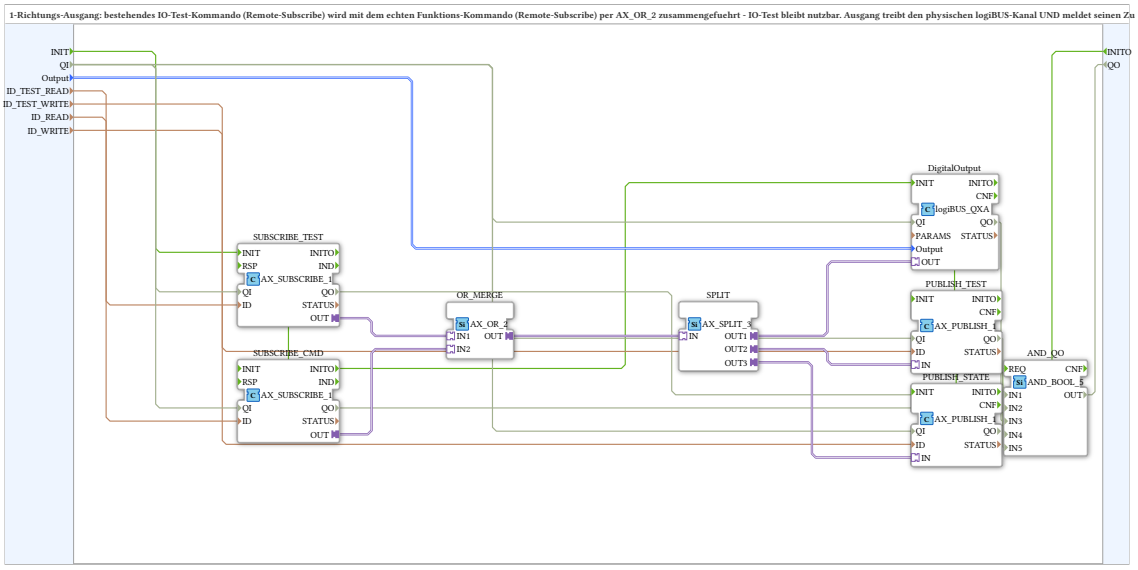
- **GetAttribute**: `isobus::UT::I::I_GetAttribute` - sends the command *GetAttribute*
- **Attribute_IDA**: `isobus::UT::io::Attribute::Attribute_IDA` (`PARAMS=''`, `QI` comes from the SubApp interface) - receives the response asynchronously as an adapter

Program Flow and Connections

- `REQ` ⟶ `GetAttribute.REQ`
- `u16ObjId` ⟶ `GetAttribute.u16ObjId` and `Attribute_IDA.u16ObjId`
- `u8AID` ⟶ `GetAttribute.u8AID` and `Attribute_IDA.u8AID`
- `Attribute_IDA.IN` ⟶ `IN`
- `INIT` ⟶ `Attribute_IDA.INIT`; `Attribute_IDA.INITO` ⟶ `INITO`
- `QI` ⟶ `Attribute_IDA.QI`; `Attribute_IDA.QO` ⟶ `QO`

Technical Details

- The shared parameters ensure that request and reception refer to the same object and attribute.



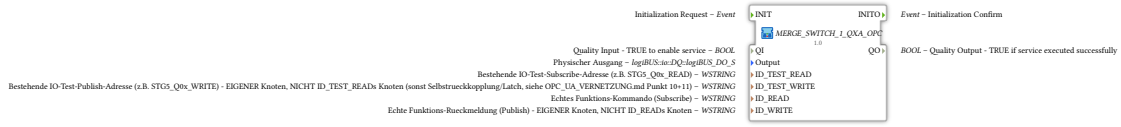
Application Scenarios

- Reading an attribute of a VT object (e.g. current value, color) and processing the response as an `AD` adapter value

Summary

`I_GetAttribute_IDA` combines the request and reception of a VT object attribute in one SubApp.

MERGE_SWITCH_1_QXA_OPC



• – ○ • – ○ • – ○ •

Introduction

`MERGE_SWITCH_1_QXA_OPC` drives a single (non-double-acting) logiBUS output from two OPC UA sources: the existing I/O test command (remote subscribe) and the actual function command (also remote subscribe,

e.g., from a soft key/AUX via `Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC`). Both are combined using a level OR gate, so the existing I/O test remains usable while the actual function can simultaneously control the same output. For double-acting actuators (left/right, up/down), use `ILOCK_SWITCH_2_QXA_OPC` instead.

Function Blocks (FBs) Used

Sub-Blocks: MERGE_SWITCH_1_QXA_OPC

- **Type**: SubAppType
- **Internal FBs Used**:
- **SUBSCRIBE_TEST** / **SUBSCRIBE_CMD**: each `adapter::net::AX_SUBSCRIBE_1` (`QI` comes from the input `QI`) — subscribe to the existing I/O test command (`ID_TEST_READ`) or the actual function command (`ID_READ`), respectively.
- **OR_MERGE**: `adapter::booleanOperators::AX_OR_2` — combines both subscribe sources using a level OR operation.
- **SPLIT**: `adapter::events::unidirectional::AX_SPLIT_3` — distributes the combined signal to the physical output and two feedback channels.
- **DigitalOutput**: `logiBUS::io::DQ::logiBUS_QXA` (`QI` comes from the input `QI`) — physical digital output.
- **PUBLISH_TEST** / **PUBLISH_STATE**: each `adapter::net::AX_PUBLISH_1` (`QI` comes from the input `QI`) — report the resulting state to the existing I/O test monitoring (`ID_TEST_WRITE`) or to the actual function feedback (`ID_WRITE`, e.g., `GreenWhiteBackground` on the soft key).
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_5` — combines the `QO` outputs of the five service FBs into the output `QO`.
- **How it Works**: Two independent remote subscribe sources are combined via `AX_OR_2` and jointly drive the physical output as well as two separate feedback channels. The SubApp interface additionally has the events `INIT`/`INITO` and the data `QI` (BOOL, initial value `TRUE`) and `QO` (BOOL).

Program Flow and Connections

1. `ID_TEST_READ` ⟶ `SUBSCRIBE_TEST.ID`; `ID_READ` ⟶ `SUBSCRIBE_CMD.ID` (Data connections, hidden).
2. `SUBSCRIBE_TEST.OUT` ⟶ `OR_MERGE.IN1`; `SUBSCRIBE_CMD.OUT` ⟶ `OR_MERGE.IN2`.
3. `OR_MERGE.OUT` ⟶ `SPLIT.IN` ⟶ `SPLIT.OUT1` ⟶ `DigitalOutput.OUT` (physical output), `SPLIT.OUT2` ⟶ `PUBLISH_TEST.IN`, `SPLIT.OUT3` ⟶ `PUBLISH_STATE.IN`.
4. Parameters: `Output` ⟶ `DigitalOutput.Output`; `ID_TEST_WRITE` ⟶ `PUBLISH_TEST.ID`; `ID_WRITE` ⟶ `PUBLISH_STATE.ID`.
5. Initialization chain: `INIT` ⟶ `SUBSCRIBE_TEST.INIT` ⟶ `SUBSCRIBE_CMD.INIT` ⟶ `DigitalOutput.INIT` ⟶ `PUBLISH_TEST.INIT` ⟶ `PUBLISH_STATE.INIT` (each `INITO` ⟶ next `INIT`); `PUBLISH_STATE.INITO` ⟶ `INITO` and `AND_QO.REQ`.
6. Quality: `QI` ⟶ `SUBSCRIBE_TEST.QI`, `SUBSCRIBE_CMD.QI`, `DigitalOutput.QI`, `PUBLISH_TEST.QI` and `PUBLISH_STATE.QI`; their `QO` outputs ⟶ `AND_QO.IN1` to `AND_QO.IN5` (in this order); `AND_QO.OUT` ⟶ `QO`.

Technical Features

- **Two Separate Feedback Nodes**: The resulting state is reported back to two separate OPC UA nodes, independent of the respective command node (`ID_TEST_WRITE` for the existing I/O diagnostic display, `ID_WRITE` for the actual function feedback). Command and status nodes must never share the same OPC UA node—otherwise, the subscribe node will interpret its own publish echo as a new command, and the output will be stuck.
- **Level OR instead of Edge Logic**: Unlike latching button blocks (e.g., `Button_IXA_TO_logiBUS_QXA_BG_OPC_LATCHING`), this block uses a simple, continuous OR (`AX_OR_2`)— suitable for a command that is held (not toggled).

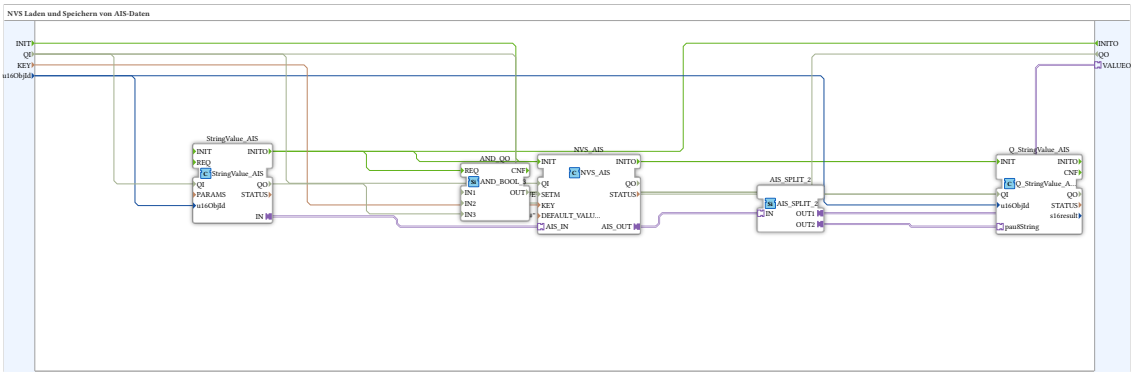
- **Generic for Simple Outputs**: Applicable to any simple, non-double-acting output controlled by a module without its own VT.

Application Scenarios

- Physical outputs whose existing I/O test channel should remain usable even after the actual function is implemented, without the two command sources blocking each other.
- Simple, non-double-acting actuators (e.g., strobe light, lighting) that can be controlled by both the I/O test and an actual operating function (SoftKey/AUX).

Comparison with Similar Function Blocks

For double-acting actuators (left/right, up/down) where the two directions must be mutually exclusive, use `ILOCK_SWITCH_2_QXA_OPC` — `MERGE_SWITCH_1_QXA_OPC` does not have an interlock because it only controls a single output direction.



Summary

`MERGE_SWITCH_1_QXA_OPC` combines an I/O test command and a real function command into a single, simple output using a level OR logic gate and reports the status separately to both monitoring paths.

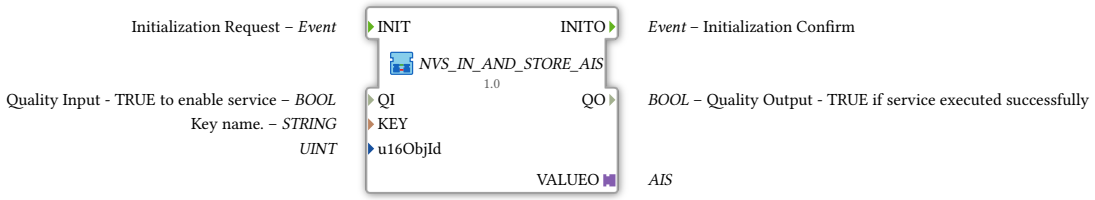
NVS_IN_AND_STORE_AIS



• — ○ • — ○ • — ○ •

Introduction

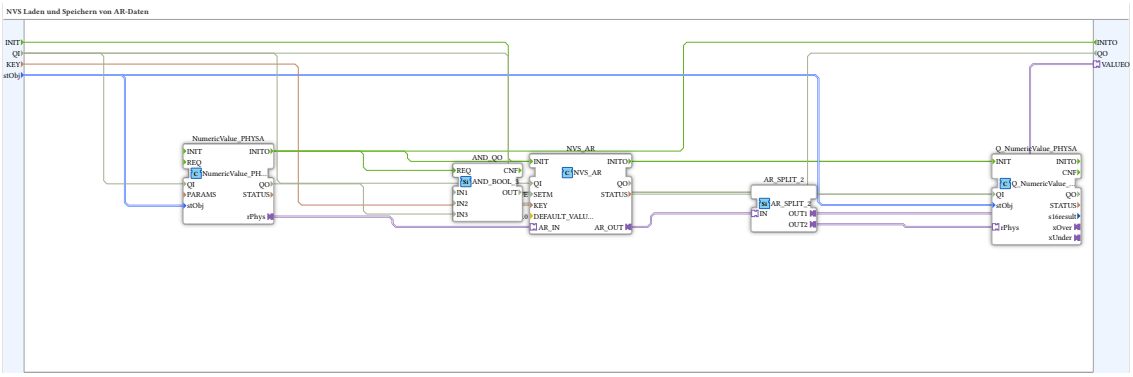
`NVS_IN_AND_STORE_AIS` persistently stores a string value entered via the VT (AIS adapter) in ESP32 flash (NVS) instead of an INI file — otherwise identical to `INI_IN_AND_STORE_AIS` (no `SECTION` parameter, since NVS is organized differently from INI files).

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

Quality ports (QI/QO)

The block has the data input `QI` (`BOOL`, default `TRUE`, Quality Input - TRUE enables the service) and the data output `QO` (`BOOL`, Quality Output - TRUE if the service was executed successfully). `QI` is passed to `Q_StringValue_AIS`, `NVS_AIS` and `StringValue_AIS`. `QO` is the output of the instance `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`), which combines `Q_StringValue_AIS.QO`, `NVS_AIS.QO` and `StringValue_AIS.QO`.

In addition, the block has the events `INIT` (input, `EInit`, initialization request) and `INITO` (output, `EInit`, initialization confirmation): `INIT` ⟶ `Q_StringValue_AIS.INIT`, `Q_StringValue_AIS.INITO` ⟶ `NVS_AIS.INIT`, `NVS_AIS.INITO` ⟶ `StringValue_AIS.INIT`, `StringValue_AIS.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`).



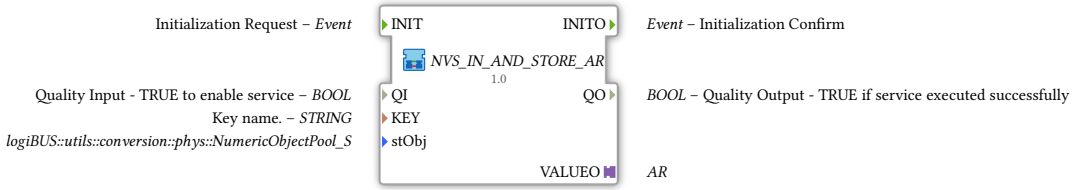
Summary

NVS counterpart to `INI_IN_AND_STORE_AIS`.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

NVS_IN_AND_STORE_AR



• – ○ • – ○ • – ○ •

Introduction

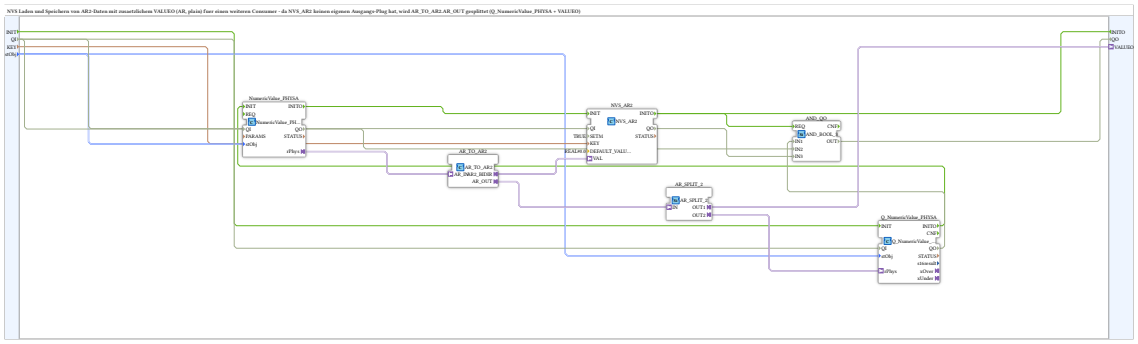
`NVS_IN_AND_STORE_AR` persistently stores a physically scaled REAL value entered via the VT (AR adapter) in ESP32 flash (NVS) — otherwise identical to `INI_IN_AND_STORE_AR`.

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

Quality ports (QI/QO)

The block has the data input `QI` (`BOOL`, default `TRUE`, Quality Input - TRUE enables the service) and the data output `QO` (`BOOL`, Quality Output - TRUE if the service was executed successfully). `QI` is connected to `Q_NumericValue_PHYSA.QI`, `NVS_AR.QI` and `NumericValue_PHYSA.QI`; `QO` is the AND (`AND_QO`, `iec61131::booleanOperators::AND_BOOL_3`) of `Q_NumericValue_PHYSA.QO`, `NVS_AR.QO` and `NumericValue_PHYSA.QO`.

In addition, the block has the events `INIT` (input, `EInit`, initialization request) and `INITO` (output, `EInit`, initialization confirmation): initialization is chained: `INIT` ⟶ `Q_NumericValue_PHYSA.INIT`; `Q_NumericValue_PHYSA.INITO` ⟶ `NVS_AR.INIT`; `NVS_AR.INITO` ⟶ `NumericValue_PHYSA.INIT`; `NumericValue_PHYSA.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`).



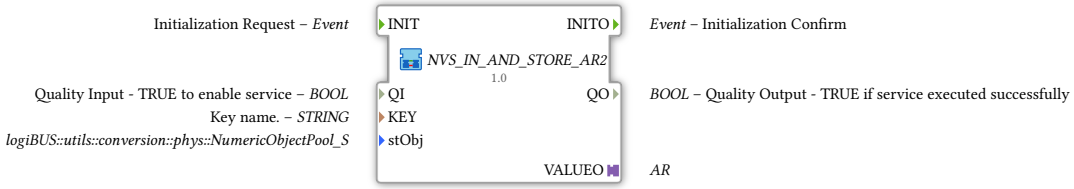
Summary

NVS counterpart to `INI_IN_AND_STORE_AR`.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

NVS_IN_AND_STORE_AR2



• – ○ • – ○ • – ○ •

Introduction

`NVS_IN_AND_STORE_AR2` is the AR2-adapter variant of `NVS_IN_AND_STORE_AR` (ESP32 flash storage instead of an INI file): a physically scaled REAL value entered via the VT is persistently stored in NVS flash via `logiBUS::storage::esp32_nvs::NVS_AR2`. Since `NVS_AR2` (unlike the INI variant) has no `SECTION` concept either, that parameter is absent compared to `INI_IN_AND_STORE_AR2`. As there, `AR_TO_AR2.AR_OUT` is duplicated via `AR_SPLIT_2`: VT display (`Q_NumericValue_PHYSA`) + `VALUEO` for a further consumer.

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

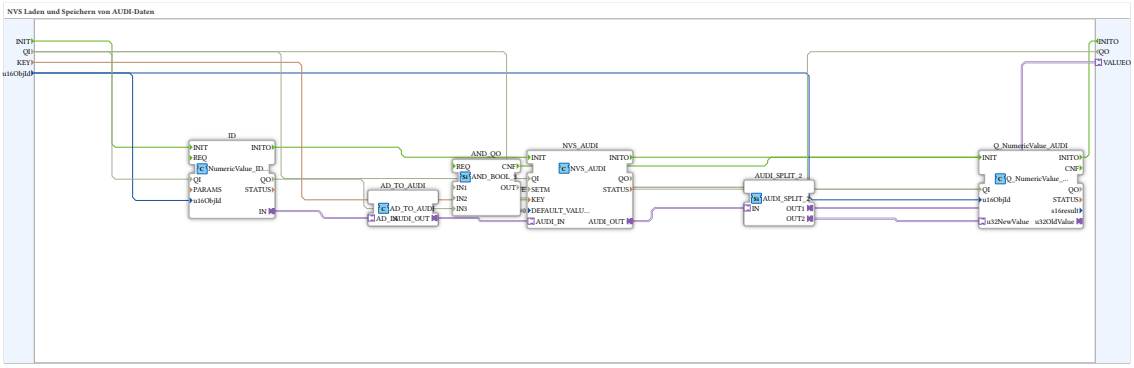
Technical notes

- `SETM=TRUE`, same reasoning as `INI_IN_AND_STORE_AR2`: live changes are confirmed immediately, not only at the next boot.
- No `SECTION` parameter, since NVS keys are flat (no INI-section concept).

Quality ports (QI/QO)

The block has the data input `QI` (`BOOL`, default `TRUE`, Quality Input - TRUE enables the service) and the data output `QO` (`BOOL`, Quality Output - TRUE if the service was executed successfully). `QI` is distributed to `Q_NumericValue_PHYSA`, `NumericValue_PHYSA` and `NVS_AR2`; their `QO` outputs are combined by `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`) into `QO`.

In addition, the block has the events `INIT` (input, `EInit`, initialization request) and `INITO` (output, `EInit`, initialization confirmation). Initialization: `INIT` ⟶ `Q_NumericValue_PHYSA.INIT`; `Q_NumericValue_PHYSA.INITO` ⟶ `NumericValue_PHYSA.INIT`; `NumericValue_PHYSA.INITO` ⟶ `NVS_AR2.INIT`; `NVS_AR2.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`. Quality: `QI` ⟶ `Q_NumericValue_PHYSA.QI`, `NumericValue_PHYSA.QI`, `NVS_AR2.QI`; `Q_NumericValue_PHYSA.QO`, `NumericValue_PHYSA.QO`, `NVS_AR2.QO` ⟶ `AND_QO.IN1` to `AND_QO.IN3` (in this order); `AND_QO.OUT` ⟶ `QO` (`AND_QO`: `iec61131::booleanOperators::AND_BOOL_3`).



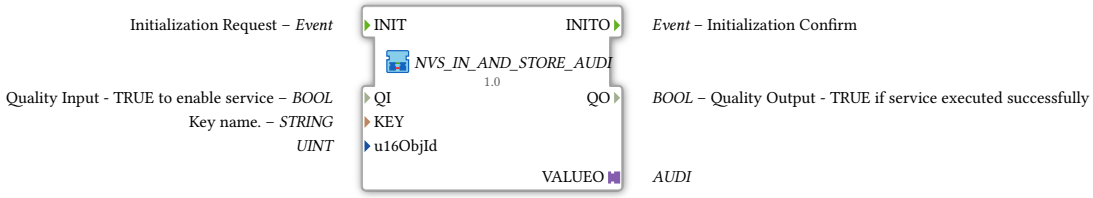
Summary

AR2-adapter variant of the NVS storage family (ESP32 flash instead of an INI file), with an additional `VALUEO` output.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

NVS_IN_AND_STORE_AUDI



• – ○ • – ○ • – ○ •

Introduction

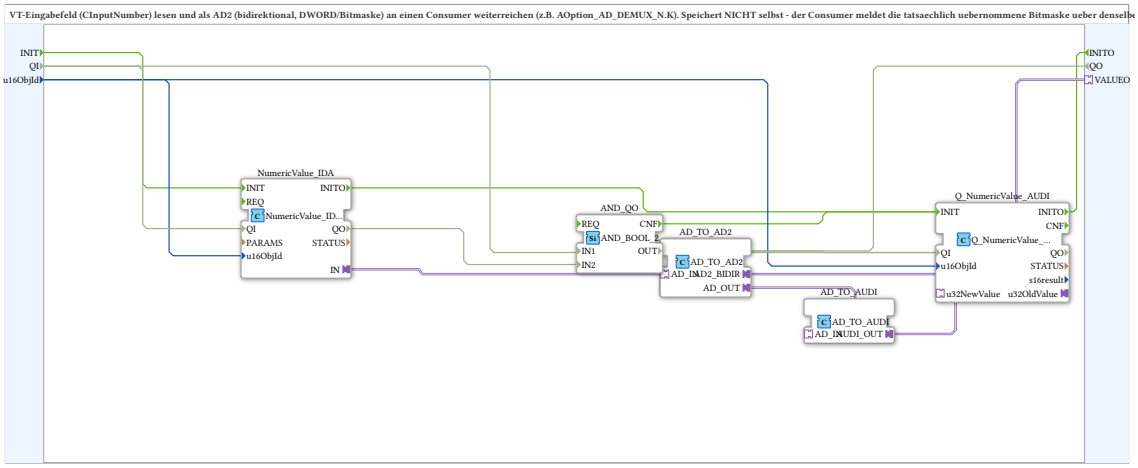
`NVS_IN_AND_STORE_AUDI` persistently stores a UDINT value entered via the VT (AUDI adapter) in ESP32 flash (NVS) — otherwise identical to `INI_IN_AND_STORE_AUDI`.

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

Quality ports (QI/QO)

The block has the event input `INIT` (`EInit`, Initialization Request), the event output `INITO` (`EInit`, Initialization Confirm), the data input `QI` (`BOOL`, default `TRUE`, Quality Input - TRUE enables the service) and the data output `QO` (`BOOL`, Quality Output - TRUE if the service was executed successfully).

- Initialization chain: `INIT` ⟶ `ID.INIT`, `ID.INITO` ⟶ `NVS_AUDI.INIT`, `NVS_AUDI.INITO` ⟶ `Q_NumericValue_AUDI.INIT`, `Q_NumericValue_AUDI.INITO` ⟶ `INITO` (and additionally ⟶ `AND_QO.REQ`)
- `QI` is connected to `Q_NumericValue_AUDI.QI`, `NVS_AUDI.QI` and `ID.QI`
- `QO` is the AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_3`) of `Q_NumericValue_AUDI.QO`, `NVS_AUDI.QO` and `ID.QO`

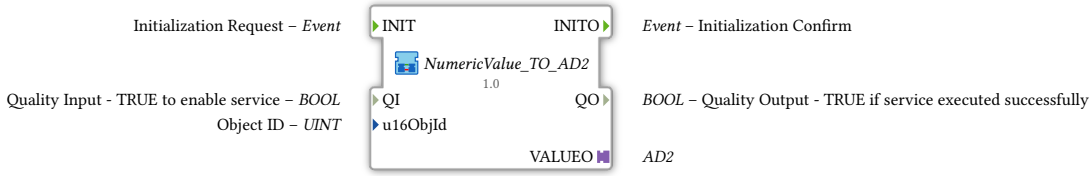


Summary

NVS counterpart to `INI_IN_AND_STORE_AUDI`.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



NumericValue_TO_AD2

• — ○ • — ○ • — ○ •

Introduction

`NumericValue_TO_AD2` reads a VT input field (CInputNumber) and passes the value bidirectionally as an AD2 adapter (DWORD/bitmask, `VALUEO`) to a consumer (e.g. `AOption_AD_DEMUX_N.K`). The block does **not** store anything itself: the consumer reports the bitmask it actually accepted back over the same AD2 plug, and the echo is written back to the VT field.

Interface

Input variables

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE enables the service; passed through to `NumericValue_IDA` and `Q_NumericValue_AUDI`.
- `u16ObjId` (UINT, default `ID_NULL`): ObjectID of the VT input field.

Output variables

- `QO` (BOOL): Quality Output - TRUE if the service was executed successfully; `AND` of the `QO` outputs of `Q_NumericValue_AUDI` and `NumericValue_IDA` (via `AND_QO`).

Adapters

- **Plug `VALUEO`** (`adapter::types::bidirectional::AD2`): bitmask to the consumer and echo back.

Events

- `INIT` (EInit, input): initialization request; starts the chain `NumericValue_IDA` ⟶ `Q_NumericValue_AUDI`.
- `INITO` (EInit, output): initialization confirmation; comes from `Q_NumericValue_AUDI.INITO`.

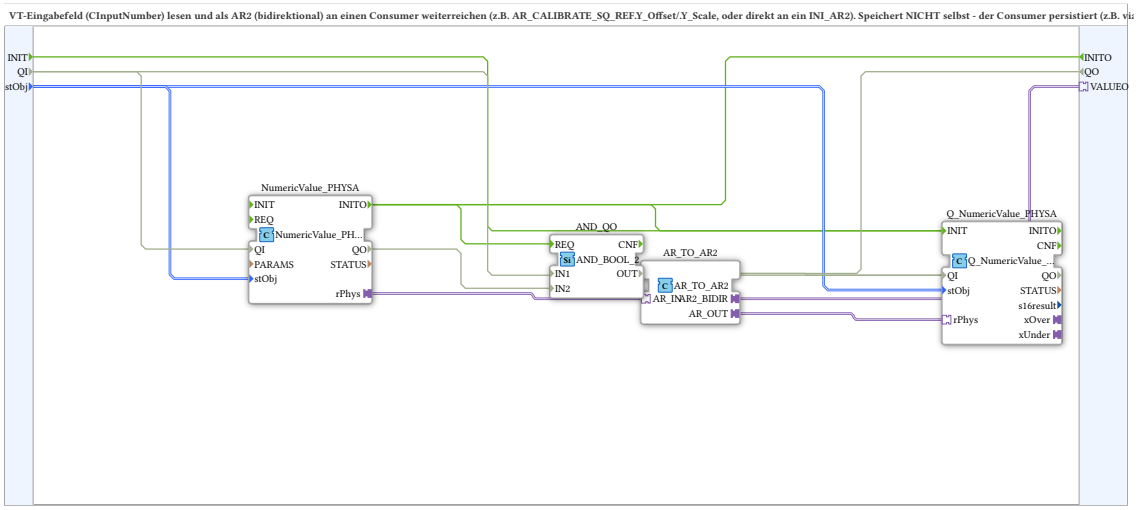
How it works

1. `NumericValue_IDA` reads the VT input field.
2. `AD_TO_AD2` converts the value into the bidirectional AD2 adapter, which is output on `VALUEO`.
3. The echo reported back by the consumer appears at `AD_TO_AD2.AD_OUT`, is converted to UDINT via `AD_TO_AUDI`, and written to the VT field under `u16ObjId` by `Q_NumericValue_AUDI` (`u32NewValue`).

`QI` is passed through to `NumericValue_IDA.QI` and `Q_NumericValue_AUDI.QI` (no fixed `QI`=TRUE any more). Initialization runs as the chain `INIT` ⟶ `NumericValue_IDA.INIT`, `NumericValue_IDA.INITO` ⟶ `Q_NumericValue_AUDI.INIT`, `Q_NumericValue_AUDI.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`. `QO` is the `AND` (`AND_QO`, `AND_BOOL_2`) of the `QO` outputs of `Q_NumericValue_AUDI` and `NumericValue_IDA`.

Technical notes

- DWORD/bitmask counterpart of `NumericValue_TO_AUI2` - for `AOption_AD_DEMUX_N` (multi-select) instead of `AOption_AUI_DEMUX_N` (single-select).
- No `AD_TO_AUI` intermediate step is needed, since AD2 is already a DWORD.
- Pure VT-to-AD2 bridge without a storage FB; compare `NumericValue_TO_AR2`.



Summary

Bidirectional bridge from the VT input field to an AD2 plug (bitmask) without its own persistence.

NumericValue_TO_AR2

• – ○ • – ○ • – ○ •

Introduction

`NumericValue_TO_AR2` reads a VT input field (`NumericValue_PHYSA`) and forwards the value bidirectionally as an AR2 adapter (`VALUEO`) to a consumer - unlike `INI_IN_AND_STORE_AR2`, this block itself stores **nothing**: persistence is the consumer's responsibility (e.g. `AR_CALIBRATE.Y_Offset/.Y_Scale`, or directly an `INI_AR2`). Whatever the consumer echoes back over the same AR2 plug is written back to the VT field - even at boot, so the input field and the actually active value stay in sync.

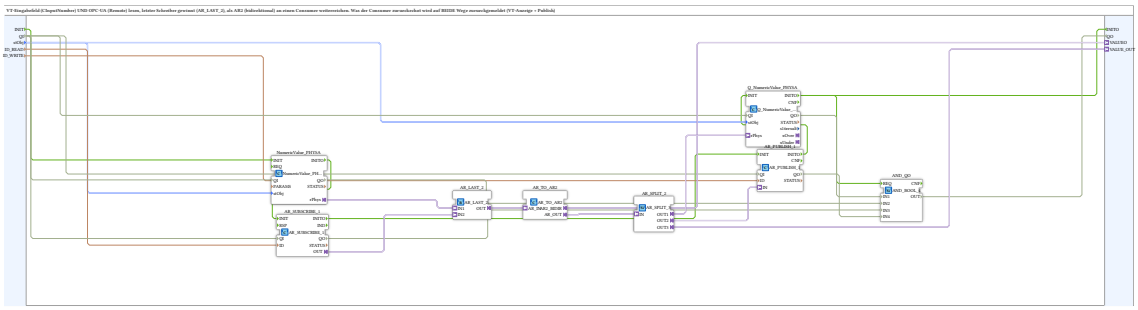
Technical notes

- Pure VT-to-AR2 bridge: no storage FB in the network, unlike the INI/NVS family.
- Historical note: per the source comment, renamed from `INI_IN_AND_STORE_AR2` when the block changed from a self-contained storage function to a pure bridge.

Quality ports (QI/QO)

The block has the data input `QI` (`BOOL`, default `TRUE`, Quality Input - TRUE enables the service) and the data output `QO` (`BOOL`, Quality Output - TRUE if the service was executed successfully). `QI` is passed on to `Q_NumericValue_PHYSA.QI` and `NumericValue_PHYSA.QI`; their `QO` outputs are combined in `AND_QO` (`iec61131::booleanOperators::AND_BOOL_2`, `Q_NumericValue_PHYSA.QO` ⟶ `IN1`, `NumericValue_PHYSA.QO` ⟶ `IN2`) into the output `QO`.

In addition, the block has the events `INIT` (input, `EInit`, initialization request) and `INITO` (output, `EInit`, initialization confirmation): Init chain: `INIT` ⟶ `Q_NumericValue_PHYSA.INIT`, `Q_NumericValue_PHYSA.INITO` ⟶ `NumericValue_PHYSA.INIT`, `NumericValue_PHYSA.INITO` ⟶ `INITO` and `AND_QO.REQ`.



Summary

Bidirectional VT-input-field-to-AR2 bridge with no storage of its own - the consumer persists, this block only displays and forwards.

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

NumericValue_TO_AR2_OPC

• – ○ • – ○ • – ○ •

Introduction

`NumericValue_TO_AR2_OPC` is the VT+OPC-UA sibling of `NumericValue_TO_AR2` (VT only) and `OPC_TO_AR2` (OPC only): both the VT input field and a remotely-written OPC-UA value (`AR_SUBSCRIBE_1`) feed `AR_LAST_2` - "last writer wins". The result goes to the consumer as an AR2 adapter (`VALUEO`); whatever the consumer echoes back is reported both ways: VT display (`Q_NumericValue_PHYSA`) and OPC-UA publish (`AR_PUBLISH_1`).

Function blocks used

- **NumericValue_PHYSA**: VT input field, local value.
- **AR_SUBSCRIBE_1**: subscribes to a remotely-written REAL value under `ID_READ`.
- **AR_LAST_2**: merges both sources, last writer wins.
- **AR_TO_AR2**: converts the merged plain-AR value into the bidirectional AR2 adapter for the consumer.
- **AR_SPLIT_2**: splits the consumer's echo to the VT display and the OPC publish.
- **AR_PUBLISH_1**: publishes the current/persisted value under `ID_WRITE` (triggered by `AR_SUBSCRIBE_1.INITO`, so the initial value is published immediately too).

Technical notes

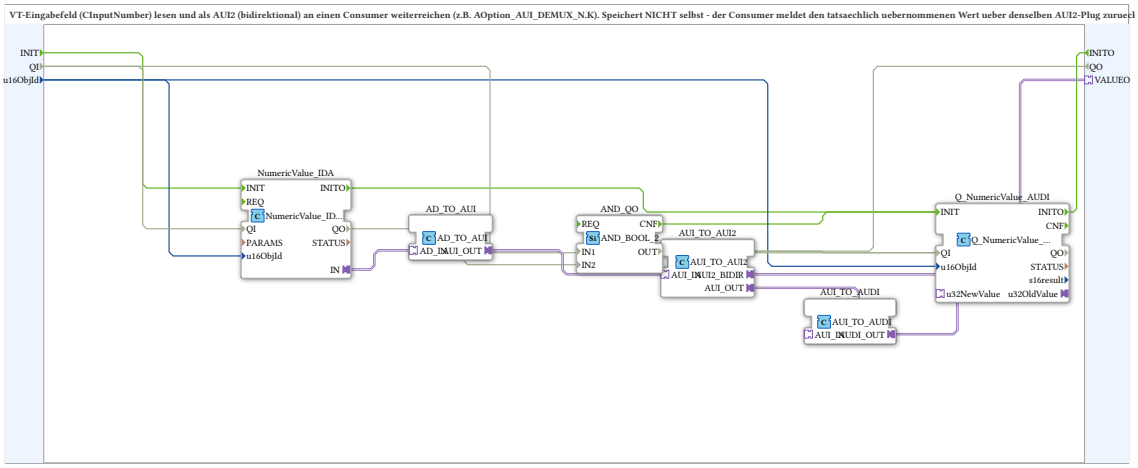
- Merge strategy identical to the VT/web merge already proven in `RampLimitFS_TO_logiBUS_QDA_PWM_OPC.SUB` (per the source comment).

Event and quality ports (INIT/INITO, QI/QO)

The block has the data input `QI` (`BOOL`, default `TRUE`, Quality Input - TRUE enables the service) and the data output `QO` (`BOOL`, Quality Output - TRUE if the service was executed successfully). `QI` is passed to `NumericValue_PHYSA`, `AR_SUBSCRIBE_1`, `AR_PUBLISH_1` and `Q_NumericValue_PHYSA`. `QO` is the output of the instance `AND_QO` (`iec61131::booleanOperators::AND_BOOL_4`), which combines `Q_NumericValue_PHYSA.QO`, `NumericValue_PHYSA.QO`, `AR_SUBSCRIBE_1.QO` and `AR_PUBLISH_1.QO`.

In addition, the block has the event input `INIT` and the event output `INITO` (both `EInit`). Initialization runs as a chain: `INIT` ⟶ `NumericValue_PHYSA.INIT`, `NumericValue_PHYSA.INITO`

⟶ `AR_SUBSCRIBE_1.INIT`, `AR_SUBSCRIBE_1.INITO` ⟶ `AR_PUBLISH_1.INIT`, `AR_PUBLISH_1.INITO` ⟶ `Q_NumericValue_PHYSA.INIT`, `Q_NumericValue_PHYSA.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`).



Summary

VT and OPC-UA input for the same AR2 consumer, with last-writer-wins merging and echo feedback on both paths.

NumericValue_TO_AUI2

• – ○ • – ○ • – ○ •

Introduction

`NumericValue_TO_AUI2` reads a VT input field (CInputNumber) and passes the value bidirectionally as an AUI2 adapter (`VALUEO`) to a consumer (e.g. `AOption_AUI_DEMUX_N.K`). The block does **not** store anything itself: the consumer reports the value it actually accepted back over the same AUI2 plug, and the echo is written back to the VT field.

Interface

Input variables

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE enables the service.
- `u16ObjId` (UINT, default `ID_NULL`): ObjectID of the VT input field.

Output variables

- `QO` (BOOL): Quality Output - TRUE if the service was executed successfully (AND of `Q_NumericValue_AUDI.QO` and `NumericValue_IDA.QO`).

Adapters

- **Plug `VALUEO`** (`adapter::types::bidirectional::AUI2`): value to the consumer and echo back.

Events

- **INIT** (event input, `EInit`): initialization request
- **INITO** (event output, `EInit`): initialization confirmation

How it works

1. `NumericValue_IDA` reads the VT input field; `AD_TO_AUI` converts to AUI.
2. `AUI_TO_AUI2` converts into the bidirectional AUI2 adapter, which is output on `VALUEO`.
3. The echo reported back by the consumer appears at `AUI_TO_AUI2.AUI_OUT`, is converted to UDINT via `AUI_TO_AUDI`, and written to the VT field under `u16ObjId` by `Q_NumericValue_AUDI` (`u32NewValue`).

`QI` is distributed to `Q_NumericValue_AUDI.QI` and `NumericValue_IDA.QI`; `Q_NumericValue_AUDI.QO` and `NumericValue_IDA.QO` are combined into `QO` via `AND_QO` (`iec61131::booleanOperators::AND_BOOL_2`).

Initialization: `INIT` ⟶ `NumericValue_IDA.INIT`; `NumericValue_IDA.INITO` ⟶ `Q_NumericValue_AUDI.INIT`; `Q_NumericValue_AUDI.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`).

Technical notes

- Extracted from `Uebung_094c_AX`, where this was duplicated inline per dropdown.
- Analogous to `NumericValue_TO_AR2`, but UINT/AUI2 instead of REAL/AR2 and a simple `u16ObjId` instead of `stObj` (no scale/offset/decimals needed for a pure index value).
- For a variant with INI persistence, see `NumericValue_TO_AUI2_AND_STORE`.

Summary

Bidirectional bridge from the VT input field to an AUI2 plug without its own persistence.

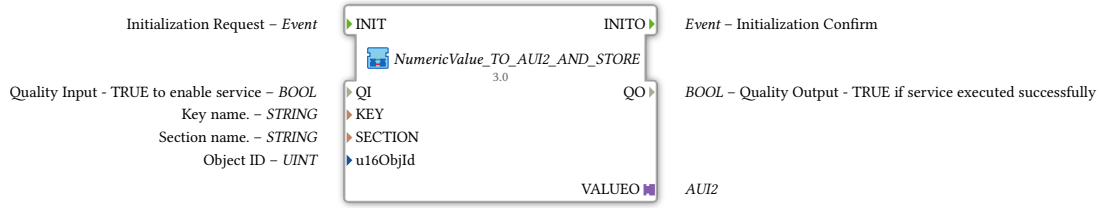
NumericValue_TO_AUI2_AND_STORE



• — ○ • — ○ • — ○ •

Introduction

`NumericValue_TO_AUI2_AND_STORE` corresponds to `NumericValue_TO_AUI2` (read the VT, pass it as a bidirectional AUI2 plug `VALUEO` to a consumer such as `AOption_AUI_DEMUX_N.K`), extended with INI persistence: at boot the value loaded from the INI file wins (merged against the live VT reading via `AUI_LAST_2`), after that every live change. What is stored is always the value **reported back** by the consumer (the one actually accepted). The block is its own class, separate from `INI_IN_AND_STORE_AUI2`/`_AUDI2`, which remain unchanged (KEY/SECTION, plain `VALUEO`) because they are used in numerous other projects.

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

Interface

Event inputs

- `INIT` (`EInit`): initialization request.

Event outputs

- `INITO` (`EInit`): initialization confirm.

Input variables

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE enables the service.
- `KEY` (STRING): key name in the INI file.
- `SECTION` (STRING): section name in the INI file.
- `u16ObjId` (UINT, default `ID_NULL`): ObjectID of the VT input field.

Output variables

- `QO` (BOOL): Quality Output - TRUE if the service was executed successfully (AND combination `AND_QO` of the `QO` outputs of the inner blocks).

Adapters

- **Plug `VALUEO`** (`adapter::types::bidirectional::AUI2`): value to the consumer and echo back.

The events `INIT`/`INITO` are passed as a chain through the inner blocks (see How it works).

How it works

1. `NumericValue_IDA` reads the VT input field; `AD_TO_AUI` converts to AUI and feeds `AUI_LAST_2.IN1`.
2. `AUI_LAST_2` (last writer wins) merges: `IN1` = live VT change, `IN2` = INI value at boot. Its output goes to `AUI_TO_AUI2` (bridge to the external consumer), whose bidirectional output goes to `VALUEO`.
3. The result reported back by the consumer appears at `AUI_TO_AUI2.AUI_OUT` and is duplicated via `AUI_SPLIT_2`: `OUT1` via `AUI_TO_AUDI` to `Q_NumericValue_AUDI` (`u32NewValue`, VT display under `u16ObjId`), `OUT2` to `INI_AUI` (`eclipse4diac::storage::INI_AUI`, `AUI_IN`; `SETM=FALSE`, `DEFAULT_VALUE=UINT#0`).
4. `INI_AUI.AUI_OUT` feeds the loaded value back to `AUI_LAST_2.IN2`.

Initialization: `INIT` → `NumericValue_IDA.INIT`; `NumericValue_IDA.INITO` → `INI_AUI.INIT`; `INI_AUI.INITO` → `Q_NumericValue_AUDI.INIT`; `Q_NumericValue_AUDI.INITO` → `INITO` and → `AND_QO.REQ`. Quality: `QI` → `Q_NumericValue_AUDI.QI`, `NumericValue_IDA.QI`, `INI_AUI.QI`; `Q_NumericValue_AUDI.QO`, `NumericValue_IDA.QO`, `INI_AUI.QO` → `AND_QO.IN1` to `AND_QO.IN3` (in this order); `AND_QO.OUT` → `QO` (`AND_QO`: `iec61131::booleanOperators::AND_BOOL_3`).

Technical notes

- `SETM=FALSE`: `INI_AUI` acknowledges automatically only at boot (INIT → INITO → GET → GETO), not on every later write. With `SETM=TRUE` every write would trigger a new echo that would arrive at `AUI_LAST_2` again and be sent towards `VALUEO` - an endless loop.
- The live VT reading goes directly to `VALUEO` (a single `AUI_TO_AUI2`); only the result reported back by the consumer is stored, via the split.
- The boot value wins once in `AUI_LAST_2` against the live VT reading.

Summary

Like `NumericValue_TO_AUI2`, with INI persistence of the consumer-confirmed value and a boot value merge.

NumericValue_TO_AUI2_AND_STORE_PUBLISH

• — ○ • — ○ • — ○ •

Introduction

`NumericValue_TO_AUI2_AND_STORE_PUBLISH` is a copy of `NumericValue_TO_AUI2_AND_STORE` that additionally publishes the confirmed value via M2M publish: `AUI_SPLIT_2` was extended to `AUI_SPLIT_3`, and the third branch feeds `AUI_PUBLISH_1`. The M2M publish thus sits on the same internal confirm return path as the VT display (`AUI_TO_AUDI`) and the INI persistence (`INI_AUI`). An additional external self-loop via an `AUI2_TO_AUI` bridge block is no longer needed.

Interface

Input variables

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE enables the service.
- `KEY` (STRING): key name in the INI file.
- `SECTION` (STRING): section name in the INI file.
- `u16ObjId` (UINT, default `ID_NULL`): ObjectID of the VT input field.
- `ID_WRITE` (WSTRING): local publish address (`ACTION=WRITE`) for the confirmed value; M2M, subscribed remotely.

Output variables

- `QO` (BOOL): Quality Output - TRUE if all blocks involved succeeded (AND over `Q_NumericValue_AUDI`, `NumericValue_IDA`, `INI_AUI`, `AUI_PUBLISH_1`).

Adapters

- **Plug `VALUEO`** (`adapter::types::bidirectional::AUI2`): value to the consumer and echo back.

The block has the events `INIT` (input) and `INITO` (output).

Function Blocks (FBs) Used

- **NumericValue_IDA** (`isobus::UT::io::NumericValue::NumericValue_IDA`): reads the VT input field.
- **AD_TO_AUI** (`adapter::conversion::unidirectional::AD_TO_AUI`): converts the value to AUI.
- **AUI_LAST_2** (`adapter::events::unidirectional::AUI_LAST_2`): last writer wins; at boot the INI value wins (`IN2`), afterwards every live VT change (`IN1`).
- **AUI_TO_AUI2** (`adapter::conversion::bidirectional::AUI_TO_AUI2`): bridge to the external consumer (e.g. `AOption_AUI_DEMUX_N.K`).
- **AUI_SPLIT_3** (`adapter::events::unidirectional::AUI_SPLIT_3`): third branch `OUT3` for `INI_AUI`, `OUT2` for `AUI_PUBLISH_1`, `OUT1` for the VT display.
- **AUI_TO_AUDI** (`adapter::conversion::unidirectional::AUI_TO_AUDI`) and **Q_NumericValue_AUDI** (`isobus::UT::Q::Q_NumericValue_AUDI`): VT display under `u16ObjId`.
- **INI_AUI** (`eclipse4diac::storage::INI_AUI`): parameters `SETM=FALSE`, `DEFAULT_VALUE=UINT#0`.

- **AUI_PUBLISH_1** (`adapter::net::AUI_PUBLISH_1`): M2M publish of the confirmed value on `ID_WRITE`.
- **AND_QO** (`iec61131::booleanOperators::AND_BOOL_4`): combines the four `QO` outputs.

How it works

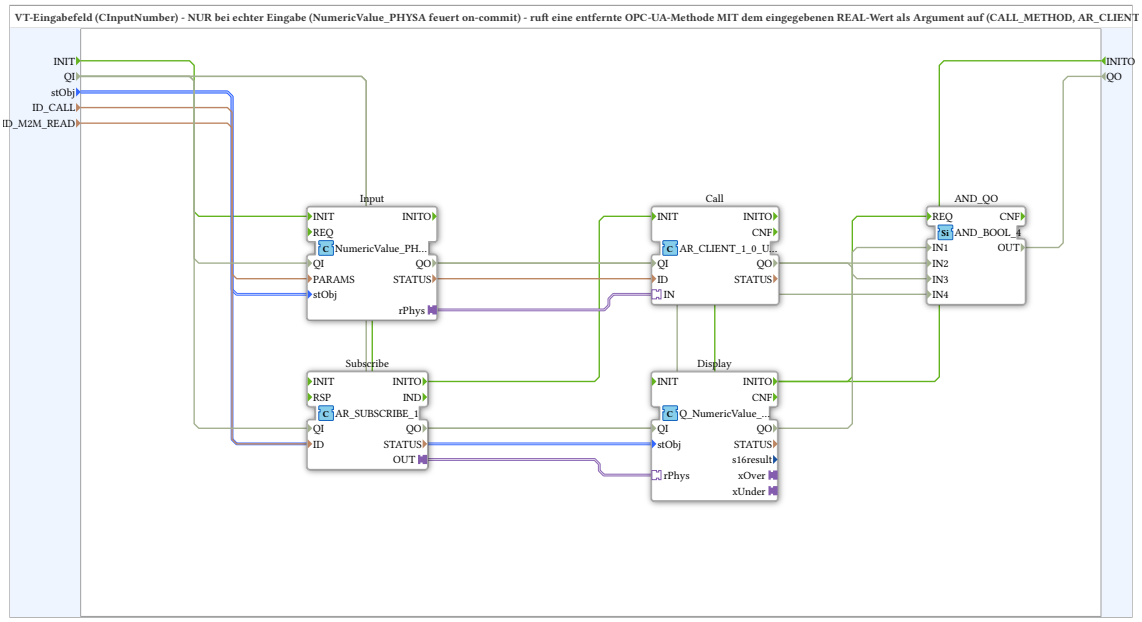
1. `NumericValue_IDA` reads the VT input field; `AD_TO_AUI` converts to AUI and feeds `AUI_LAST_2.IN1`.
2. `AUI_LAST_2` goes to `AUI_TO_AUI2`, whose bidirectional output goes to `VALUEO`.
3. The result reported back by the consumer appears at `AUI_TO_AUI2.AUI_OUT` and is distributed by `AUI_SPLIT_3`: `OUT1 -> AUI_TO_AUDI -> Q_NumericValue_AUDI.u32NewValue` (VT display), `OUT2 -> AUI_PUBLISH_1.IN` (M2M publish), `OUT3 -> INI_AUI.AUI_IN` (persistence).
4. `INI_AUI.AUI_OUT` feeds the loaded value back to `AUI_LAST_2.IN2`.
5. Initialization chain: `INIT -> NumericValue_IDA -> INI_AUI -> Q_NumericValue_AUDI -> AUI_PUBLISH_1 -> INITO`. `AUI_PUBLISH_1.INITO` also triggers `AND_QO.REQ`, whose result goes to `QO`.
6. `QI` is distributed to `Q_NumericValue_AUDI`, `NumericValue_IDA`, `INI_AUI` and `AUI_PUBLISH_1`.

Technical notes

- `SETM`=FALSE: `INI_AUI` acknowledges automatically only at boot, not on every later write. With `SETM`=TRUE every write would trigger a new echo and create an endless loop (see also `NumericValue_TO_AUI2_AND_STORE`).
- The M2M publish deliberately sits in the already proven internal return path so that it cannot get lost during an external rework.
- The block is its own class; `NumericValue_TO_AUI2_AND_STORE` remains unchanged.

Application Scenarios

- Numeric VT input field with INI persistence where the value confirmed by the consumer is additionally to be published to other modules.



Summary

Like `NumericValue_TO_AUI2_AND_STORE`, with an additional M2M publish of the confirmed value on the third branch of `AUI_SPLIT_3`.

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

NumericValue_TO_CLIENT_1_0_OPC

• – ○ • – ○ • – ○ •

Introduction

`NumericValue_TO_CLIENT_1_0_OPC` connects a VT input field (`CInputNumber`) to a remote **OPC-UA method**: **only on a genuine input** (`NumericValue_PHYSA` fires on commit) is the method (`CALL_METHOD`, `AR_CLIENT_1_0`) called with the entered `REAL` value as argument. The return path - displaying the actually effective, confirmed value on the same VT field - runs separately and uncritically via a normal subscribe (`Q_NumericValue_PHYSA`). Hence there is no circular reference and no merge/last-writer-wins: on the receiver side there is only one caller per method, serialized by the method call itself.

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization Request

Event Outputs

- **INITO** (`EInit`): Initialization Confirm

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service
- **stObj** (`logiBUS::utils::conversion::phys::NumericObjectPool_S`): Object ID and scale/offset/decimals of the VT input field; used for input and output (the confirmed value is written back here). Default: `(u16ObjId := ID_NULL, r32Scale := 1.0, i32Offset := 0, u8Decimals := 1)`
- **ID_CALL** (`WSTRING`): Remote method address (`ACTION=CALL_METHOD`); called only on a genuine VT input with the entered value as argument
- **ID_M2M_READ** (`WSTRING`): Remote subscribe address (`REAL`, `ACTION=SUBSCRIBE`); returns the actually effective value for display on the same VT field (read only)

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service was executed successfully (AND of `Display.QO`, `Input.QO`, `Call.QO` and `Subscribe.QO`)

Adapters

This function block has no adapter sockets/plugs at its interface; `AR` adapters are used internally.

Function Blocks (FBs) Used

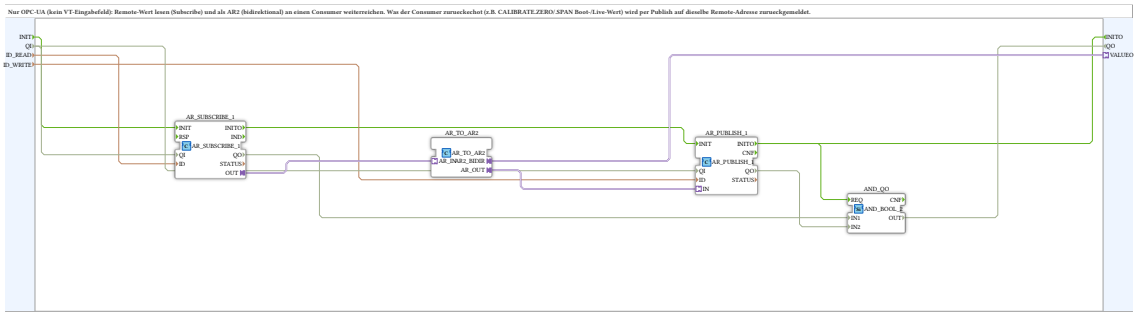
- **Input**: `isobus::UT::io::NumericValue::NumericValue_PHYSA` (`QI` from the block input) - provides the entered physical value (`rPhys`) on commit
- **Call**: `adapter::net::AR_CLIENT_1_0_UNGATED` (`QI` from the block input) - calls the remote method with the value as argument
- **Subscribe**: `adapter::net::AR_SUBSCRIBE_1` (`QI` from the block input) - subscribes to the confirmed value
- **Display**: `isobus::UT::Q::Q_NumericValue_PHYSA` - writes the value to the VT field
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_4` - ANDs the `QO` outputs of `Display`, `Input`, `Call` and `Subscribe`

Program Flow and Connections

1. **Forward path**: `Input.rPhys` ⟶ `Call.IN` (input ⟶ method call).
2. **Return path**: `Subscribe.OUT` ⟶ `Display.rPhys` (confirmed value ⟶ VT display).
3. Initialization chain: `INIT` ⟶ `Input.INIT`, `Input.INITO` ⟶ `Subscribe.INIT`, `Subscribe.INITO` ⟶ `Call.INIT` (the client is initialized only after the subscribe has been initialized), `Call.INITO` ⟶ `Display.INIT`, `Display.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`.
4. `stObj` ⟶ `Input.stObj` and `Display.stObj`; `ID_CALL` ⟶ `Call.ID`; `ID_M2M_READ` ⟶ `Subscribe.ID`.
5. `QI` ⟶ `Display.QI`, `Input.QI`, `Call.QI` and `Subscribe.QI`; `Display.QO` ⟶ `AND_QO.IN1`, `Input.QO` ⟶ `AND_QO.IN2`, `Call.QO` ⟶ `AND_QO.IN3`, `Subscribe.QO` ⟶ `AND_QO.IN4`; `AND_QO.OUT` ⟶ `QO`

Technical Details

- Forward and return paths are separate, so no merge is needed.
- `AR_CLIENT_1_0_UNGATED` is the ungated variant of the client.

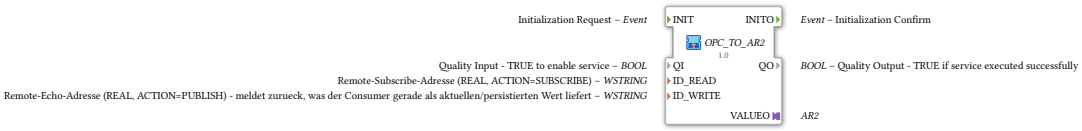


Application Scenarios

- Setpoint entry on the VT that takes effect on another station via an OPC-UA method, with feedback of the actually valid value

Summary

`NumericValue_TO_CLIENT_1_0_OPC` writes VT inputs to the target station via an OPC-UA method call and displays the confirmed value independently via a subscribe.



OPC_TO_AR2

• — ○ • — ○ • — ○ •

Introduction

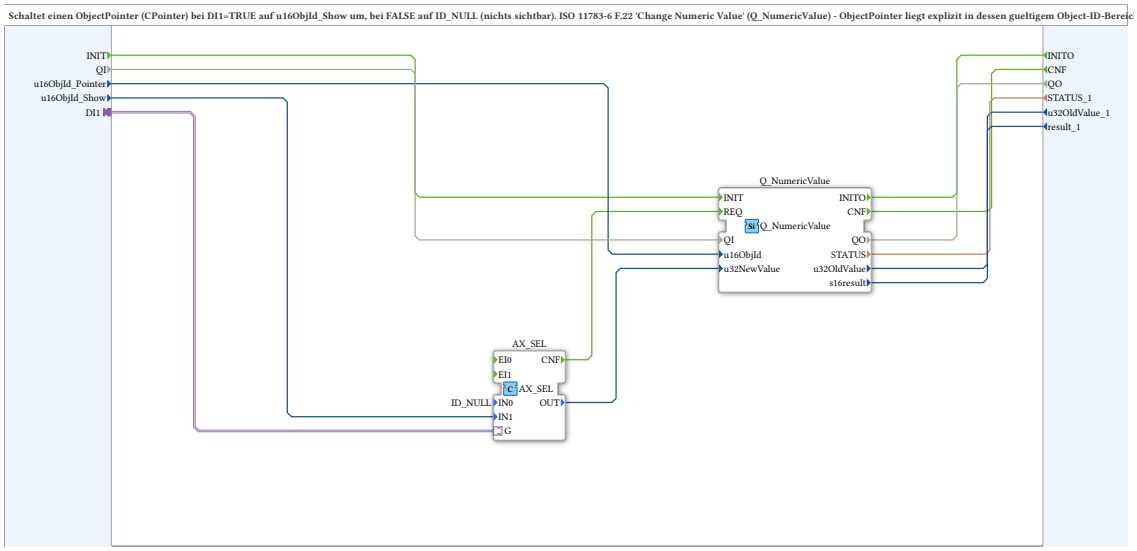
`OPC_TO_AR2` is the pure OPC-UA sibling of `NumericValue_TO_AR2` - no VT input field involved. A remotely-written value is subscribed via `AR_SUBSCRIBE_1` and forwarded to a consumer as an AR2 adapter (`VALUEO`), e.g. `CALIBRATE.ZERO`/`.SPAN`. Whatever the consumer echoes back (current/persisted value) is reported back to the same remote address via `AR_PUBLISH_1`.

Interface and initialization

- Events: `INIT` (EInit, input) and `INITO` (EInit, output, comes from `AR_PUBLISH_1.INITO`).
- Data: `QI` (BOOL, default `TRUE`) as well as `ID_READ` and `ID_WRITE` (WSTRING) as inputs, `QO` (BOOL) as output; adapter plug `VALUEO` (AR2).
- Initialization: `INIT` ⟶ `AR_SUBSCRIBE_1.INIT`, `AR_SUBSCRIBE_1.INITO` ⟶ `AR_PUBLISH_1.INIT`, `AR_PUBLISH_1.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`.
- Quality: `QI` ⟶ `AR_SUBSCRIBE_1.QI` and `AR_PUBLISH_1.QI` (no fixed `QI=TRUE` any more); `AR_SUBSCRIBE_1.QO` ⟶ `AND_QO.IN1`, `AR_PUBLISH_1.QO` ⟶ `AND_QO.IN2` (`AND_BOOL_2`), `AND_QO.OUT` ⟶ `QO`.

Technical notes

- `AR_PUBLISH_1` is triggered by `AR_SUBSCRIBE_1.INITO` so the boot value is published immediately, not only on the first change.



Summary

Purely remote (OPC-UA) driven AR2 bridge with no VT involvement at all - for consumers parameterized exclusively from a control room.

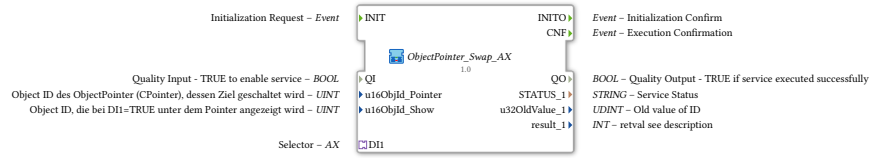
- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



ObjectPointer_Swap_AX

• — ○ • — ○ • — ○ •

Introduction

`ObjectPointer_Swap_AX` switches an object pointer (CPointer) in the VT: with `DI1 = TRUE` it points to `u16ObjId_Show`, with FALSE to `ID_NULL` (nothing visible). The switching uses ISO 11783-6 F.22 “Change Numeric Value” (`Q_NumericValue`); the object pointer lies explicitly within its valid object ID range (27000-27999). F.38 “Change Attribute” (`Q_Attribute`) must not be used because `AID_OP_PTR.VALUE` is read-only there.

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization request (to `Q_NumericValue.INIT`)

Event Outputs

- **INITO** (`EInit`): Initialization confirmation (from `Q_NumericValue.INITO`)
- **CNF**: execution confirmation, passed through from `Q_NumericValue.CNF`

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service
- **u16ObjId_Pointer** (UINT): object ID of the object pointer (CPointer) whose target is switched (default `ID_NULL`)
- **u16ObjId_Show** (UINT): object ID that is shown under the pointer when `DI1 = TRUE` (default `ID_NULL`)

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service was executed successfully
- **STATUS_1** (STRING): service status of `Q_NumericValue`
- **u32OldValue_1** (UDINT): old value of the ID
- **result_1** (INT): return value (see `Q_NumericValue`)

Adapters

- **DI1** (socket, `adapter::types::unidirectional::AX`): selector

Functionality

The network consists of two blocks:

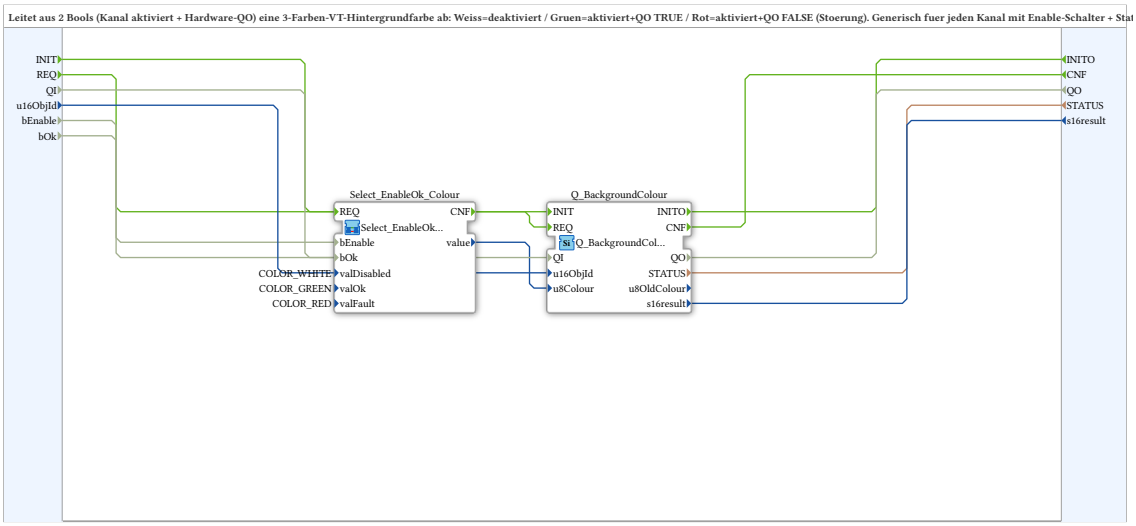
- `AX_SEL` (`adapter::iec61131::selection::AX_SEL`): binary selection with `IN0 = ID_NULL` (parameter), `IN1` = `u16ObjId_Show` and selector `G` = `DI1`. An output event is generated only when `G` changes.
- `Q_NumericValue` (`isobus::UT::Q::Q_NumericValue`): `AX_SEL.OUT` ⟶ `u32NewValue`, `u16ObjId_Pointer` ⟶ `u16ObjId`, triggered by `AX_SEL.CNF` ⟶ `Q_NumericValue.REQ`. `Q_NumericValue.CNF` ⟶ `CNF`; `STATUS`, `u32OldValue` and `s16result` are output as `STATUS_1`, `u32OldValue_1` and `result_1`.

When `DI1` changes, the new target value (`u16ObjId_Show` or `ID_NULL`) is thereby written as a numeric value to the object pointer.

In addition: `INIT` ⟶ `Q_NumericValue.INIT`; `Q_NumericValue.INITO` ⟶ `INITO`; `QI` ⟶ `Q_NumericValue.QI`; `Q_NumericValue.QO` ⟶ `QO`.

Technical Details

- Structure analogous to `GreenWhiteBackground1_AX` (AX_SEL wrapper around a `Q_` FB)
- `Q_NumericValue` (F.22) is the right way for object pointers; `Q_Attribute` (F.38) was discarded
- For the pattern see the exercise `Uebung_015` in the workspace `test_B`



Application Scenarios

- Showing and hiding a VT object (e.g. warning symbol) at a fixed place via an AX state
- Switching between an empty state and a content via object pointer

Conclusion

`ObjectPointer_Swap_AX` translates an AX state into an object pointer switch between `u16ObjId_Show` and `ID_NULL` via `Q_NumericValue`.

Q_BackgroundColour_EnableOk_A

• – ○ • – ○ • – ○ •

Introduction

`Q_BackgroundColour_EnableOk_A` derives a 3-colour VT background colour from two Boolean values (channel enabled and hardware `QO`): **White** = disabled, **Green** = enabled and `QO` TRUE, **Red** = enabled and `QO` FALSE (fault). Generic for any channel with an enable switch and status LED (PWM, PI, ...).

Function Blocks (FBs) Used

Sub-blocks: Q_BackgroundColour_EnableOk_A

- **Type**: SubAppType

- **Internal blocks used**:
  - **Select_EnableOk_Colour**: SubApp `MyLib::sys::Select_EnableOk_a` with `valDisabled=COLOR_WHITE`, `valOk=COLOR_GREEN`, `valFault=COLOR_RED` - selects one of the three colours based on `bEnable` and `bOk`
  - **Q_BackgroundColour**: `isobus::UT::Q::Q_BackgroundColour` - writes the selected colour to the VT object `u16ObjId`
- **Imports**: `COLOR_GREEN`, `COLOR_RED`, `COLOR_WHITE`

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization request (to `Q_BackgroundColour.INIT`)
- **REQ**: Re-evaluate - fired by the caller once per possible change of `bEnable` or `bOk` (switch toggled or fresh `QO` arrived); both values are supplied together

Event Outputs

- **INITO** (`EInit`): Initialization confirmation (from `Q_BackgroundColour.INITO`)
- **CNF**: Colour sent (passthrough of `Q_BackgroundColour.CNF`)

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service
- **u16ObjId** (`UINT`): Object ID of the status display (`CButton`, background colour only, no text) - set once via parameter at instantiation
- **bEnable** (`BOOL`): Channel enabled (e.g. enable flip-flop `Q`)
- **bOk** (`BOOL`): Hardware confirms active (e.g. `logiBUS_..._IDA.QO`) - only relevant if `bEnable=TRUE`

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service was executed successfully
- **STATUS** (`STRING`): Service status (passthrough of `Q_BackgroundColour.STATUS`)
- **s16result** (`INT`): Return value (passthrough of `Q_BackgroundColour.s16result`)

Program Flow and Connections

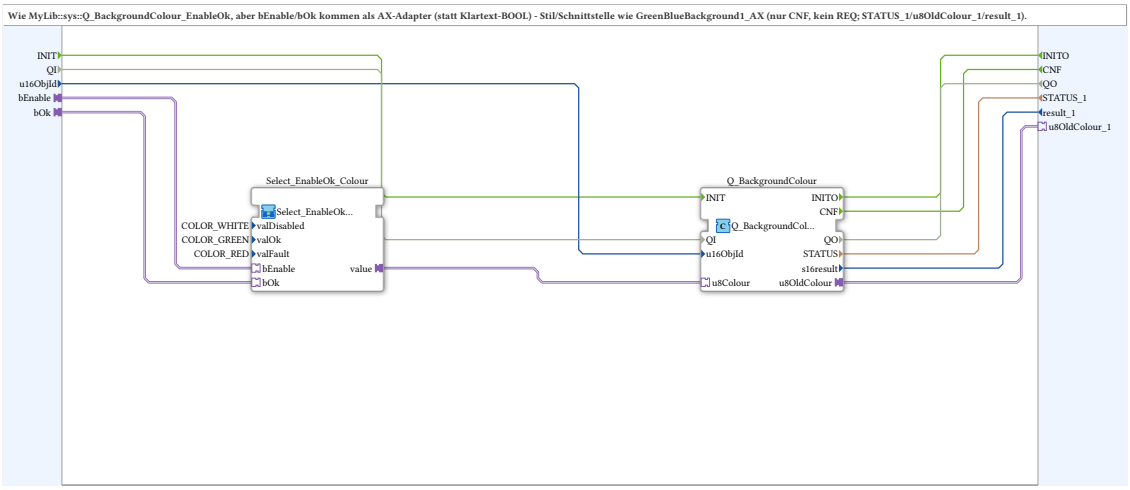
- `REQ` ⟶ `Select_EnableOk_Colour.REQ`; `Select_EnableOk_Colour.CNF` ⟶ `Q_BackgroundColour.REQ`; `Q_BackgroundColour.CNF` ⟶ `CNF`
- `bEnable` ⟶ `Select_EnableOk_Colour.bEnable`; `bOk` ⟶ `Select_EnableOk_Colour.bOk`
- `Select_EnableOk_Colour.value` ⟶ `Q_BackgroundColour.u8Colour`
- `u16ObjId` ⟶ `Q_BackgroundColour.u16ObjId`
- `Q_BackgroundColour.STATUS` ⟶ `STATUS`; `Q_BackgroundColour.s16result` ⟶ `s16result`
- `INIT` ⟶ `Q_BackgroundColour.INIT`; `Q_BackgroundColour.INITO` ⟶ `INITO`
- `QI` ⟶ `Q_BackgroundColour.QI`; `Q_BackgroundColour.QO` ⟶ `QO`

Technical Details

- The pure "2 bools ⟶ 1 of 3 values" logic is factored out into `MyLib::sys::Select_EnableOk` (generic, not limited to colours); this block merely instantiates it with the three colours as parameters
- Variant with AX adapters: `Q_BackgroundColour_EnableOk_AX`
- Version 1.1 (2026-08-31)

State Overview

bEnable	bOk	Colour
FALSE	any	White (`COLOR_WHITE`)
TRUE	TRUE	Green (`COLOR_GREEN`)
TRUE	FALSE	Red (`COLOR_RED`)

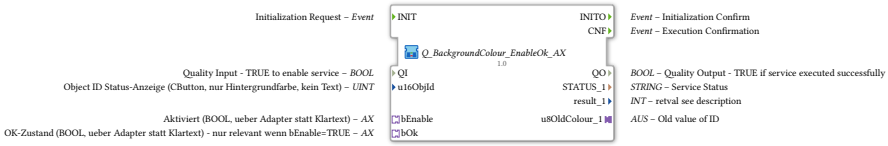


Application Scenarios

- Status display of a channel with an enable switch and hardware feedback (PWM, PI, ...)

Summary

`Q_BackgroundColour_EnableOk_A` sets the background colour of a VT object following the white/green/red scheme from `bEnable` and `bOk`.



Q_BackgroundColour_EnableOk_AX

• – ○ • – ○ • – ○ •

Introduction

`Q_BackgroundColour_EnableOk_AX` corresponds to `Q_BackgroundColour_EnableOk`, but `bEnable`/`bOk` arrive as AX adapters (instead of plain BOOL) - style/interface matching the existing GreenBlueBackground1_AX/GreenRedBackground1_AX family: only `CNF` (no `REQ`), plus `INIT`/`INITO` and `QI`/`QO`, as well as `STATUS_1`/`u8OldColour_1`/`result_1` as named outputs.

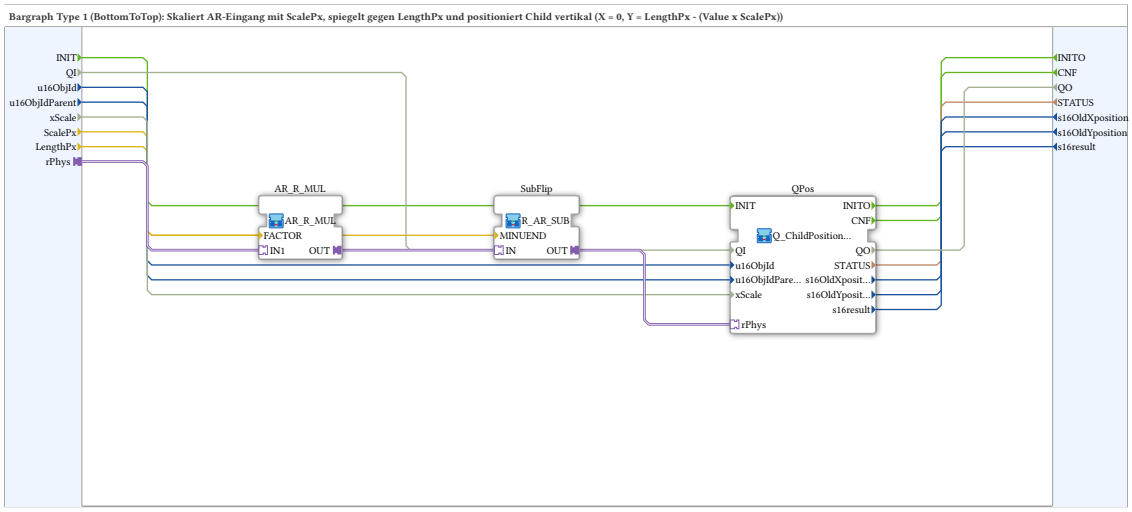
Function blocks used

- **Select_EnableOk_Colour** (SubApp, type `MyLib::sys::Select_EnableOk_AX`): `valDisabled=COLOR_WHITE`, `valOk=COLOR_GREEN`, `valFault=COLOR_RED`.
- **Q_BackgroundColour** (`isobus::UT::Q::Q_BackgroundColour_AUS`): AUS-adapter variant, writes the color to `u16ObjId` and returns `u8OldColour_1` (previous color) as an AUS adapter.

Quality ports (QI/QO)

The block has the data input `QI` (`BOOL`, default `TRUE`, Quality Input - TRUE enables the service) and the data output `QO` (`BOOL`, Quality Output - TRUE if the service was executed successfully). `QI` is connected to `Q_BackgroundColour.QI`, and `Q_BackgroundColour.QO` to `QO`.

In addition, the block has the events `INIT` (input, `EInit`, initialization request) and `INITO` (output, `EInit`, initialization confirmation): `INIT` ⟶ `Q_BackgroundColour.INIT`, `Q_BackgroundColour.INITO` ⟶ `INITO`.



Summary

AX-adapter variant of `Q_BackgroundColour_EnableOk`, matching the existing GreenBlueBackground1_AX/GreenRedBackground1_AX family.

Q_ChildPosition_AR_Bargraph_BottomToTop

• — ○ • — ○ • — ○ •

Introduction

`Q_ChildPosition_AR_Bargraph_BottomToTop` is a **bar graph type 1 (bottom to top)**: the AR input is scaled with `ScalePx`, mirrored against `LengthPx` and output as the vertical position of the child object in the VT (`X = 0`, `Y = LengthPx - (value × ScalePx)`). A larger value thus moves the child upwards.

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization (to `QPos.INIT`)

Event Outputs

- **INITO** (`EInit`): Initialization confirmation (from `QPos.INITO`)
- **CNF**: Confirmation of the requested service (from `QPos.CNF`)

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality input – TRUE enables the service (to `QPos.QI`)
- **u16ObjId** (`UINT`, default `ID_NULL`): Object ID of the child object
- **u16ObjIdParent** (`UINT`, default `ID_NULL`): Object ID of the parent object
- **xScale** (`BOOL`, default `TRUE`): `FALSE` = bypass; `TRUE` = scale by the DM/SKM factor for `u16ObjIdParent`
- **ScalePx** (`REAL`, default `1.0`): Pixels per value unit (multiplication factor)
- **LengthPx** (`REAL`, default `100.0`): Total length of the bar graph in pixels (for mirroring)

Data Outputs

- **QO** (`BOOL`): Quality output – TRUE if the service was executed successfully (from `QPos.QO`)
- **STATUS** (`STRING`): Service status (passthrough from the inner `Q_ChildPosition`)
- **s16OldXposition** (`INT`): Old X position (passthrough)
- **s16OldYposition** (`INT`): Old Y position (passthrough)
- **s16result** (`INT`): Return value (passthrough, see `Q_ChildPosition`)

Adapters

- **rPhys** (socket, `adapter::types::unidirectional::AR`): Physical `REAL` input value (scaled, mirrored and mapped to the Y position)

Function Blocks (FBs) Used

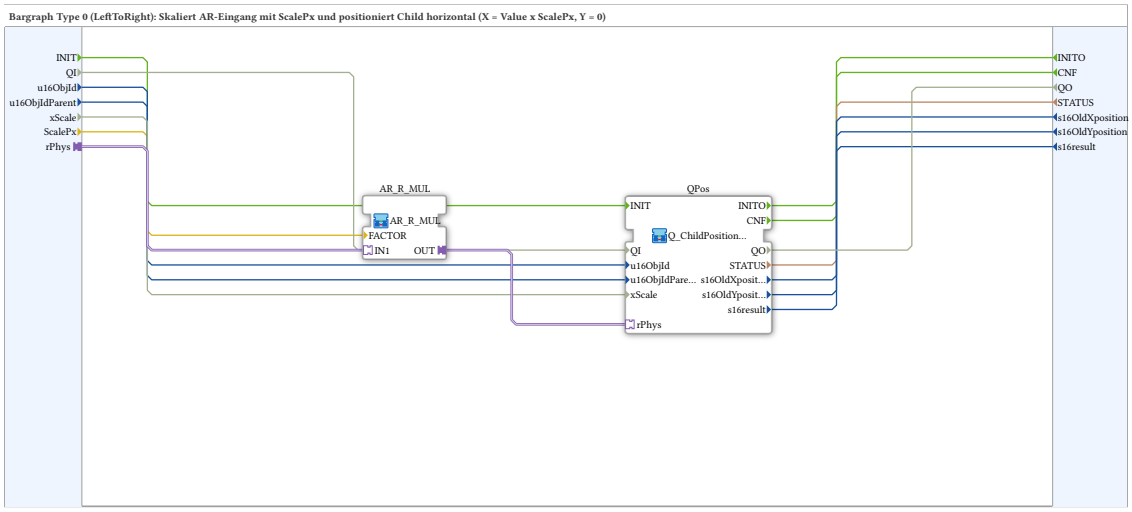
- **AR_R_MUL**: SubApp `MyLib::sys::AR_R_MUL` - multiplies the value by `ScalePx` (`FACTOR`)
- **SubFlip**: SubApp `MyLib::sys::R_AR_SUB` - subtracts from the `MINUEND` (`LengthPx`) and thereby mirrors
- **QPos**: SubApp `MyLib::sys::Q_ChildPosition_AR_Vertikal` - sets the vertical child position

Program Flow and Connections

1. `rPhys` ⟶ `AR_R_MUL.IN1`; `ScalePx` ⟶ `AR_R_MUL.FACTOR`.
2. `AR_R_MUL.OUT` ⟶ `SubFlip.IN`; `LengthPx` ⟶ `SubFlip.MINUEND`.
3. `SubFlip.OUT` ⟶ `QPos.rPhys`.
4. `INIT` ⟶ `QPos.INIT`; `QPos.INITO` ⟶ `INITO`; `QPos.CNF` ⟶ `CNF`; `QI` ⟶ `QPos.QI`; `QPos.QO` ⟶ `QO`.
5. `u16ObjId`, `u16ObjIdParent`, `xScale` ⟶ `QPos`; `STATUS`, `s16OldXposition`, `s16OldYposition`, `s16result` from `QPos` to the outside.

Technical Details

- The mirroring is necessary because the VT Y coordinate grows from top to bottom.
- `xScale` defaults to `TRUE` here (whereas to `FALSE` in `Q_ChildPosition_AR_Horizontal`).

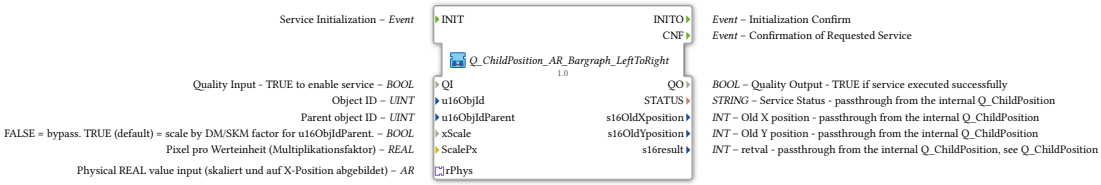


Application Scenarios

- Vertical bar/level display that grows from bottom to top

Summary

`Q_ChildPosition_AR_Bargraph_BottomToTop` maps an AR value to the vertical position of a VT child object via scaling and mirroring.



Q_ChildPosition_AR_Bargraph_LeftToRight

• — ○ • — ○ • — ○ •

Introduction

`Q_ChildPosition_AR_Bargraph_LeftToRight` implements a bargraph of type 0 (left to right): the AR input `rPhys` is scaled with `ScalePx` (pixels per value unit) and positions the child object horizontally (X = value × `ScalePx`, Y = 0).

Interface Structure

Event Inputs

- **INIT**: service initialisation (`EInit`)

Event Outputs

- **INITO**: initialisation confirmation (`EInit`)
- **CNF**: confirmation of the requested service

Data Inputs

- **QI** (BOOL): quality input - TRUE enables the service (default `TRUE`), goes to `QPos.QI`
- **u16ObjId** (UINT): object ID of the child object (default `ID_NULL`)
- **u16ObjIdParent** (UINT): object ID of the parent object (default `ID_NULL`)
- **xScale** (BOOL): FALSE = bypass; TRUE (default) = scale by the DM/SKM factor for `u16ObjIdParent`
- **ScalePx** (REAL): pixels per value unit (multiplication factor), default `REAL#1.0`

Data Outputs

- **QO** (BOOL): quality output - TRUE if the service was executed successfully, comes from `QPos.QO`
- **STATUS** (STRING): service status, passed through from the internal `Q_ChildPosition`
- **s16OldXposition** (INT): old X position, passed through
- **s16OldYposition** (INT): old Y position, passed through
- **s16result** (INT): return value, passed through (see `Q_ChildPosition`)

Adapters

- **rPhys** (socket, `adapter::types::unidirectional::AR`): physical REAL value (scaled and mapped to the X position)

Functionality

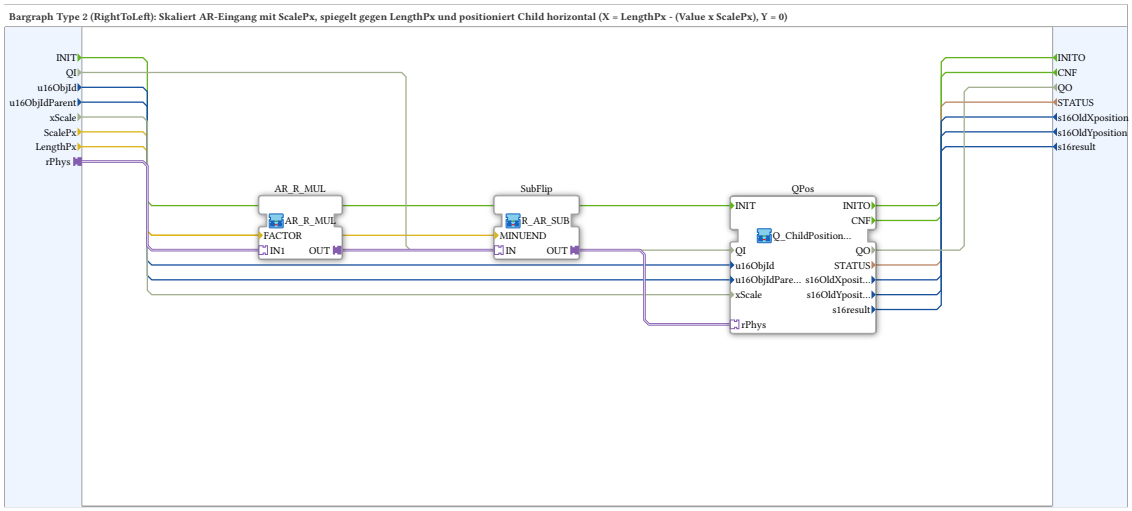
The network consists of two SubApps:

- `AR_R_MUL` (`MyLib::sys::AR_R_MUL`): `rPhys` ⟶ `AR_R_MUL.IN1`, `ScalePx` ⟶ `AR_R_MUL.FACTOR`; multiplies the AR value by the factor.
- `QPos` (`MyLib::sys::Q_ChildPosition_AR_Horizontal`): `AR_R_MUL.OUT` ⟶ `QPos.rPhys`; sets the X position of the child object via the AR adapter (Y fixed 0).

The events `INIT`, `INITO` and `CNF` as well as `QI`, `u16ObjId`, `u16ObjIdParent`, `xScale` and the outputs `QO` and the four status outputs are passed directly from/to `QPos`.

Technical Details

- Type 0 (LeftToRight) of the bargraph variants: the position grows with the value in X direction, Y stays 0
- `xScale` defaults to TRUE here (scaling by DM/SKM factor), in contrast to `Q_ChildPosition_AR_Vertikal` with default FALSE
- Stateless at SubApp level; all status outputs come from the inner `Q_ChildPosition`

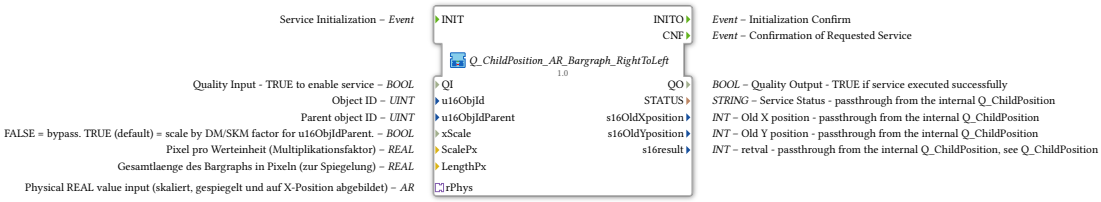


Application Scenarios

- Bar display in which a child object is shifted horizontally proportionally to a measured value

Conclusion

`Q_ChildPosition_AR_Bargraph_LeftToRight` scales an AR value with `ScalePx` and thereby sets the X position of a child object for a left-to-right bargraph.



Q_ChildPosition_AR_Bargraph_RightToLeft

• — ○ • — ○ • — ○ •

Introduction

`Q_ChildPosition_AR_Bargraph_RightToLeft` is a bargraph of type 2 (right to left): the `AR` input is scaled with `ScalePx`, mirrored against `LengthPx` and set as the horizontal position of a child object in the VT (`X = LengthPx - (value × ScalePx)`, `Y = 0`). Counterpart of `Q_ChildPosition_AR_Bargraph_LeftToRight`.

Interface Structure

Event Inputs

- **INIT** (`EInit`): service initialisation (passed on to `QPos.INIT`)

Event Outputs

- **INITO** (`EInit`): initialisation confirm (from `QPos.INITO`)
- **CNF**: confirmation of the requested positioning (from `QPos.CNF`)

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service (passed on to `QPos.QI`)
- **u16ObjId** (`UINT`): object ID of the child object (default `ID_NULL`)
- **u16ObjIdParent** (`UINT`): object ID of the parent object (default `ID_NULL`)
- **xScale** (`BOOL`): `FALSE` = bypass; `TRUE` (default) = scale by the DM/SKM factor for `u16ObjIdParent`
- **ScalePx** (`REAL`): pixels per value unit (multiplication factor), default `REAL#1.0`
- **LengthPx** (`REAL`): total length of the bargraph in pixels (for mirroring), default `REAL#100.0`

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service was executed successfully (from `QPos.QO`)
- **STATUS** (`STRING`): service status, passed through from the internal `Q_ChildPosition`
- **s16OldXposition** (`INT`): old X position, passed through
- **s16OldYposition** (`INT`): old Y position, passed through
- **s16result** (`INT`): return value, passed through from the internal `Q_ChildPosition`

Adapters

- **rPhys** (socket, `adapter::types::unidirectional::AR`): physical `REAL` value; scaled, mirrored and mapped to the X position

Function Blocks (FBs) Used

- **`AR_R_MUL`** (SubApp `MyLib::sys::AR_R_MUL`, AR_R_MUL): multiplies the value by `ScalePx`
- **`SubFlip`** (SubApp `MyLib::sys::R_AR_SUB`): subtracts the scaled value from `LengthPx` (`MINUEND = LengthPx`)
- **`QPos`** (SubApp `MyLib::sys::Q_ChildPosition_AR_Horizontal`, Q_ChildPosition_AR_Horizontal): sets the horizontal position of the child object

Functionality

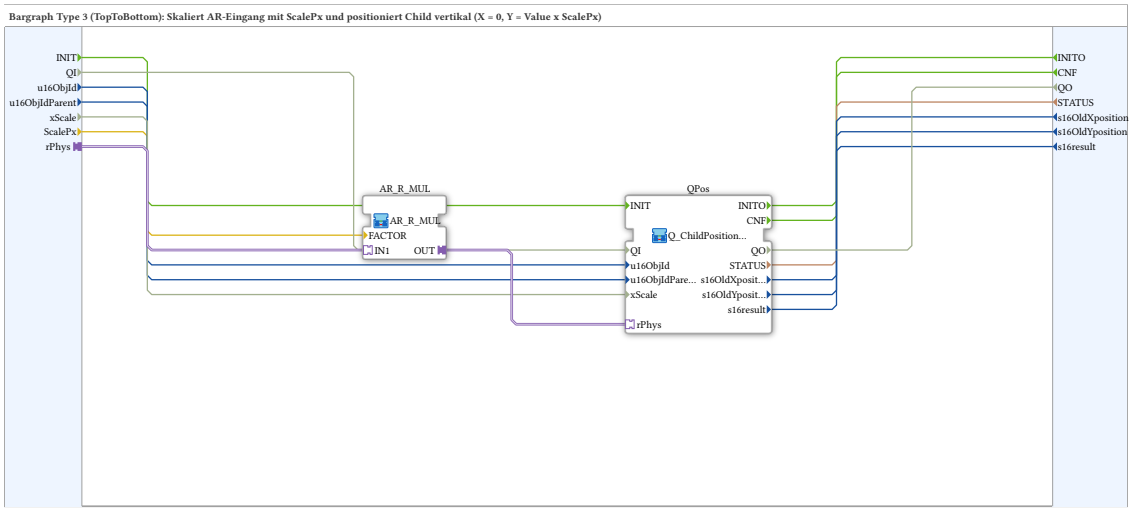
- `rPhys` ⟶ `AR_R_MUL.IN1`; `ScalePx` ⟶ `AR_R_MUL.FACTOR`
- `AR_R_MUL.OUT` ⟶ `SubFlip.IN`; `LengthPx` ⟶ `SubFlip.MINUEND`
- `SubFlip.OUT` ⟶ `QPos.rPhys`
- `INIT` ⟶ `QPos.INIT`; `QPos.INITO` ⟶ `INITO`; `QPos.CNF` ⟶ `CNF`
- `QI` ⟶ `QPos.QI`; `QPos.QO` ⟶ `QO`
- `u16ObjId`, `u16ObjIdParent`, `xScale` ⟶ the like-named inputs of `QPos`
- `QPos.STATUS`, `QPos.s16OldXposition`, `QPos.s16OldYposition`, `QPos.s16result` ⟶ the like-named outputs

Technical Details

- The mirroring (`LengthPx - value × ScalePx`) lets the bar grow from right to left
- All status and position outputs are pure pass-throughs of the internal `Q_ChildPosition`

Application Scenarios

- A horizontal bar display in the VT that grows from right to left (e.g. fill level, utilisation)



Summary

`Q_ChildPosition_AR_Bargraph_RightToLeft` maps an `AR` value, mirrored, to the X position of a VT child object.

Q_ChildPosition_AR_Bargraph_TopToBottom

• – ○ • – ○ • – ○ •

Introduction

`Q_ChildPosition_AR_Bargraph_TopToBottom` is a **bar graph type 3 (top to bottom)**: the AR input is scaled with `ScalePx` and output as the vertical position of the child object in the VT (`X = 0`, `Y = value × ScalePx`). A larger value thus moves the child downwards. In contrast to `Q_ChildPosition_AR_Bargraph_BottomToTop`, no mirroring takes place.

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization (to `QPos.INIT`)

Event Outputs

- **INITO** (`EInit`): Initialization confirmation (from `QPos.INITO`)
- **CNF**: Confirmation of the requested service (from `QPos.CNF`)

Data Inputs

- **QI** (`BOOL`, default `TRUE`): quality input, TRUE enables the service
- **u16ObjId** (`UINT`, default `ID_NULL`): Object ID of the child object
- **u16ObjIdParent** (`UINT`, default `ID_NULL`): Object ID of the parent object
- **xScale** (`BOOL`, default `TRUE`): `FALSE` = bypass; `TRUE` = scale by the DM/SKM factor for `u16ObjIdParent`
- **ScalePx** (`REAL`, default `1.0`): Pixels per value unit (multiplication factor)

Data Outputs

- **QO** (`BOOL`): quality output (from `QPos.QO`)
- **STATUS** (`STRING`): Service status (passthrough from the inner `Q_ChildPosition`)
- **s16OldXposition** (`INT`): Old X position (passthrough)
- **s16OldYposition** (`INT`): Old Y position (passthrough)
- **s16result** (`INT`): Return value (passthrough, see `Q_ChildPosition`)

Adapters

- **rPhys** (socket, `adapter::types::unidirectional::AR`): Physical `REAL` input value (scaled and mapped to the Y position)

Function Blocks (FBs) Used

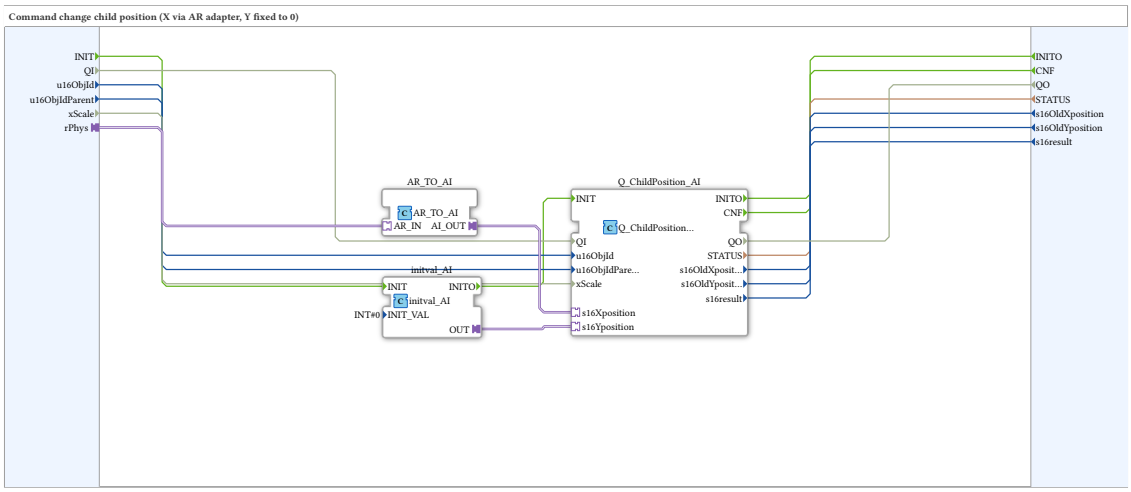
- **AR_R_MUL**: SubApp `MyLib::sys::AR_R_MUL` - multiplies the value by `ScalePx` (`FACTOR`)
- **QPos**: SubApp `MyLib::sys::Q_ChildPosition_AR_Vertikal` - sets the vertical child position

Program Flow and Connections

1. `rPhys` ⟶ `AR_R_MUL.IN1`; `ScalePx` ⟶ `AR_R_MUL.FACTOR`.
2. `AR_R_MUL.OUT` ⟶ `QPos.rPhys`.
3. `INIT` ⟶ `QPos.INIT`; `QPos.INITO` ⟶ `INITO`; `QPos.CNF` ⟶ `CNF`; `QI` ⟶ `QPos.QI`; `QPos.QO` ⟶ `QO`.
4. `u16ObjId`, `u16ObjIdParent`, `xScale` ⟶ `QPos`; `STATUS`, `s16OldXposition`, `s16OldYposition`, `s16result` from `QPos` to the outside.

Technical Details

- No mirroring: since the VT Y coordinate grows from top to bottom, a larger value corresponds directly to a position further down.
- `xScale` defaults to `TRUE` here.
- Version 1.0 (2026-09-27): `AR_R_MUL` + `Q_ChildPosition_AR_Vertikal`



Application Scenarios

- Vertical bar/display that grows from top to bottom

Summary

`Q_ChildPosition_AR_Bargraph_TopToBottom` maps an AR value directly to the vertical position of a VT child object via scaling.

Q_ChildPosition_AR_Horizontal

• – ○ • – ○ • – ○ •

Introduction

`Q_ChildPosition_AR_Horizontal` changes the position of a VT child object (command *Change Child Position*): the **X position** arrives via an AR adapter, the **Y position is fixed at 0**. The `REAL` value is converted to `INT` and mapped to the X position.

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization (to `initval_AI.INIT`)

Event Outputs

- **INITO** (`EInit`): Initialization confirmation (from `Q_ChildPosition_AI.INITO`)
- **CNF**: Confirmation of the requested service (from `Q_ChildPosition_AI.CNF`)

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service
- **u16ObjId** (`UINT`, default `ID_NULL`): Object ID of the child object
- **u16ObjIdParent** (`UINT`, default `ID_NULL`): Object ID of the parent object
- **xScale** (`BOOL`, default `FALSE`): `FALSE` = bypass, X/Y position are sent unchanged; `TRUE` = scale by the DM/SKM factor for `u16ObjIdParent`

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service was executed successfully
- **STATUS** (`STRING`): Service status (passthrough from the inner `Q_ChildPosition`)
- **s16OldXposition** (`INT`): Old X position (passthrough)
- **s16OldYposition** (`INT`): Old Y position (passthrough)
- **s16result** (`INT`): Return value (passthrough, see `Q_ChildPosition`)

Adapters

- **rPhys** (socket, `adapter::types::unidirectional::AR`): Physical `REAL` input value (converted to `INT` and mapped to the X position)

Function Blocks (FBs) Used

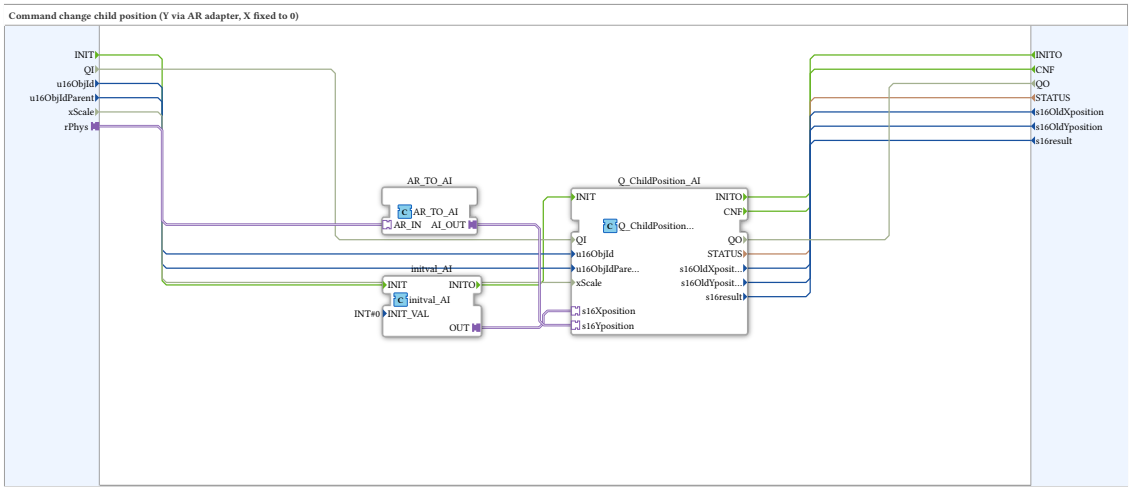
- **AR_TO_AI**: `adapter::conversion::unidirectional::AR_TO_AI` - converts `REAL` to `INT`
- **initval_AI**: `adapter::types::unidirectional::AI::initval::initval_AI` (`INIT_VAL=0`) - provides the constant Y position 0
- **Q_ChildPosition_AI**: `isobus::UT::Q::Q_ChildPosition_AI` - sends the position change

Program Flow and Connections

1. `rPhys` ⟶ `AR_TO_AI.AR_IN`; `AR_TO_AI.AI_OUT` ⟶ `Q_ChildPosition_AI.s16Xposition`.
2. `initval_AI.OUT` ⟶ `Q_ChildPosition_AI.s16Yposition` (constant 0).
3. `INIT` ⟶ `initval_AI.INIT`; `initval_AI.INITO` ⟶ `Q_ChildPosition_AI.INIT`; `Q_ChildPosition_AI.INITO` ⟶ `INITO`; `Q_ChildPosition_AI.CNF` ⟶ `CNF`.
4. `u16ObjId`, `u16ObjIdParent`, `xScale` ⟶ `Q_ChildPosition_AI`; status outputs from there to the outside.
5. `QI` ⟶ `Q_ChildPosition_AI.QI`; `Q_ChildPosition_AI.QO` ⟶ `QO`

Technical Details

- Initialization runs in series: first `initval_AI`, then `Q_ChildPosition_AI`.
- Unlike `Q_ChildPosition_AR_Bargraph_BottomToTop` there is no scaling/mirroring; `xScale` defaults to `FALSE`.

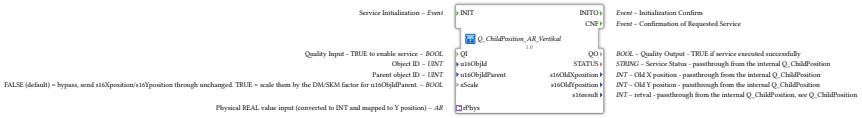


Application Scenarios

- Moving a VT object horizontally (e.g. pointer or bar) depending on a `REAL` value

Summary

`Q_ChildPosition_AR_Horizontal` moves a VT child object horizontally based on an AR value at a fixed Y position of 0.



Q_ChildPosition_AR_Vertikal

• — ○ • — ○ • — ○ •

Introduction

`Q_ChildPosition_AR_Vertikal` sets the position of a child object in the VT: the Y position comes via an AR adapter (`rPhys`, converted to INT), the X position is fixed at 0.

Interface Structure

Event Inputs

- **INIT**: service initialisation (`EInit`)

Event Outputs

- **INITO**: initialisation confirmation (`EInit`)
- **CNF**: confirmation of the requested service

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service
- **u16ObjId** (UINT): object ID of the child object (default `ID_NULL`)
- **u16ObjIdParent** (UINT): object ID of the parent object (default `ID_NULL`)
- **xScale** (BOOL): FALSE (default) = bypass, send X/Y position unchanged; TRUE = scale them by the DM/SKM factor for `u16ObjIdParent`

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service was executed successfully
- **STATUS** (STRING): service status, passed through from the internal `Q_ChildPosition`
- **s16OldXposition** (INT): old X position, passed through
- **s16OldYposition** (INT): old Y position, passed through
- **s16result** (INT): return value, passed through (see `Q_ChildPosition`)

Adapters

- **rPhys** (socket, `adapter::types::unidirectional::AR`): physical REAL value (converted to INT and mapped to the Y position)

Functionality

The network consists of three blocks:

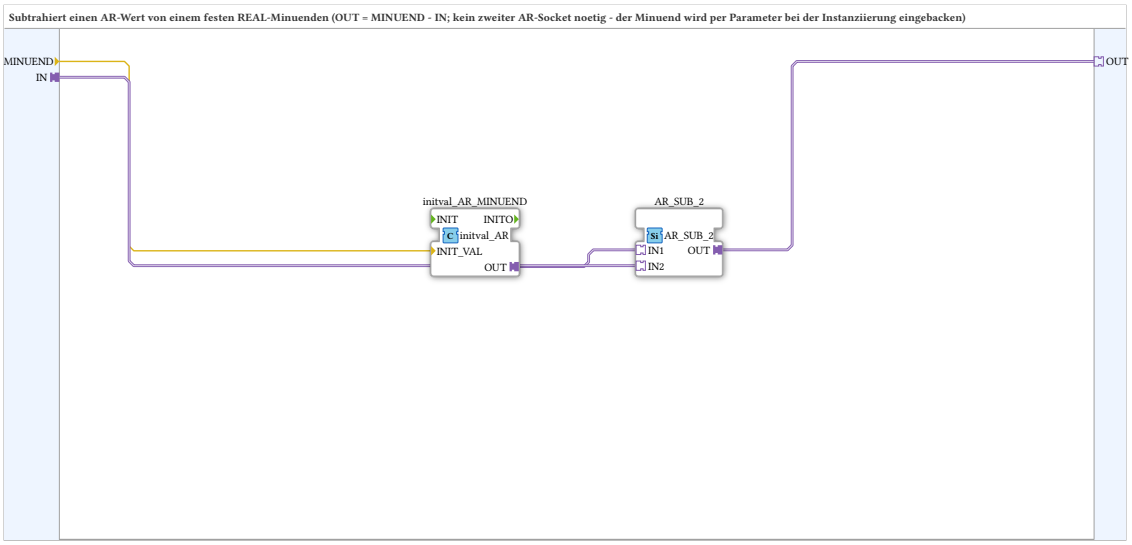
- `AR_TO_AI` (`adapter::conversion::unidirectional::AR_TO_AI`): `rPhys` ⟶ `AR_TO_AI.AR_IN`; converts the REAL value into an INT adapter value.
- `initval_AI` (`adapter::types::unidirectional::AI::initval::initval_AI`, `INIT_VAL = 0`): supplies the fixed value 0 for the X position.
- `Q_ChildPosition_AI` (`isobus::UT::Q::Q_ChildPosition_AI`): `initval_AI.OUT` ⟶ `s16Xposition`, `AR_TO_AI.AI_OUT` ⟶ `s16Yposition`.

Initialisation: `INIT` ⟶ `initval_AI.INIT`, `initval_AI.INITO` ⟶ `Q_ChildPosition_AI.INIT`, `Q_ChildPosition_AI.INITO` ⟶ `INITO`. `Q_ChildPosition_AI.CNF` ⟶ `CNF`. `u16ObjId`, `u16ObjIdParent`, `xScale` and the four outputs go directly from/to `Q_ChildPosition_AI`.

`QI` is passed through to `Q_ChildPosition_AI.QI`, and `Q_ChildPosition_AI.QO` to `QO`.

Technical Details

- Initialisation runs in series: first `initval_AI`, then `Q_ChildPosition_AI`
- `xScale` defaults to FALSE (bypass) here; in contrast, `Q_ChildPosition_AR_Bargraph_LeftToRight` defaults to TRUE
- The AR value is not scaled: `rPhys` is only converted to INT and used directly as the Y position



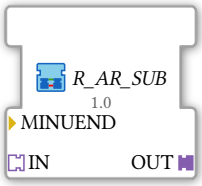
Application Scenarios

- Vertical shifting of a VT object (e.g. marker) proportionally to a measured value, X position fixed at the left

Conclusion

`Q_ChildPosition_AR_Vertikal` maps an AR value to the Y position of a child object via `AR_TO_AI` and holds the X position fixed at 0.

R_AR_SUB



• – ◦ • – ◦ • – ◦ •

Introduction

`R_AR_SUB` subtracts an `AR` value from a fixed `REAL` minuend: `OUT = MINUEND - IN`. A second `AR` socket is not needed, since the minuend is baked in via a parameter at instantiation.

Fester Minuend, ueber Parameter bei der Instanziierung gesetzt – *REAL*

Zu subtrahierender Subtrahend – *AR*

AR – MINUEND - IN

Function Blocks (FBs) Used

Sub-blocks: R_AR_SUB

- **Type**: SubAppType
- **Internal FBs used**:
  - **initval_AR_MINUEND**: `adapter::types::unidirectional::AR::initval::initval_AR` - converts the parameter `MINUEND` into an `AR` signal
  - **AR_SUB_2**: `adapter::iec61131::arithmetic::AR_SUB_2` - forms the difference `IN1 - IN2`

Interface Structure

Event Inputs / Event Outputs

None - events travel via the adapters.

Data Inputs

- **MINUEND** (`REAL`, initial value `0.0`): Fixed minuend, set via parameter at instantiation

Data Outputs

None.

Adapters

- **IN** (socket): `adapter::types::unidirectional::AR` - subtrahend to be subtracted
- **OUT** (plug): `adapter::types::unidirectional::AR` - `MINUEND - IN`

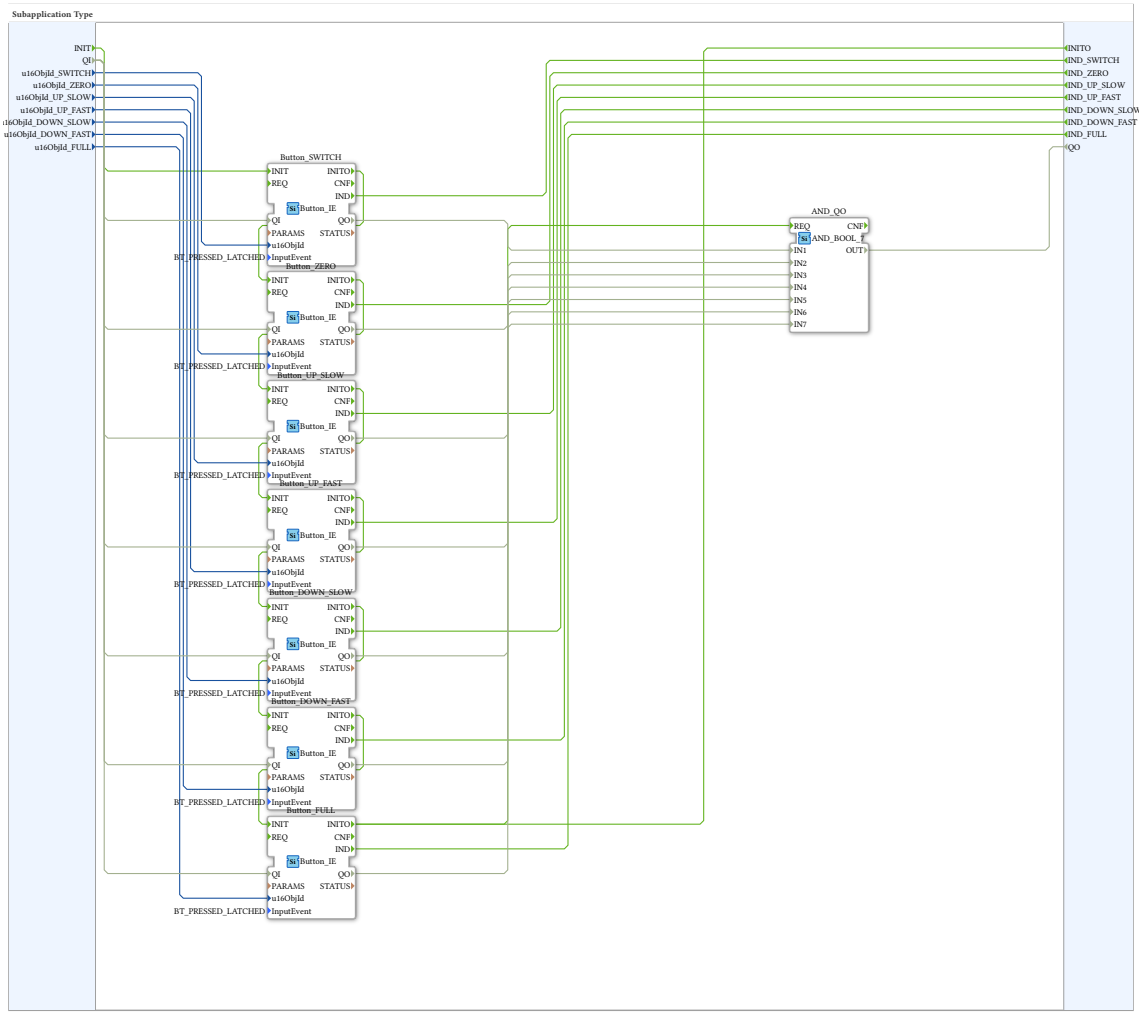
Program Flow and Connections

- `MINUEND` ⟶ `initval_AR_MINUEND.INIT_VAL`
- `initval_AR_MINUEND.OUT` ⟶ `AR_SUB_2.IN1`

- `IN` ⟶ `AR_SUB_2.IN2`
- `AR_SUB_2.OUT` ⟶ `OUT`

Technical Details

- The minuend is fixed as a parameter; no second `AR` input is needed
- Version 1.0 (2026-09-27)

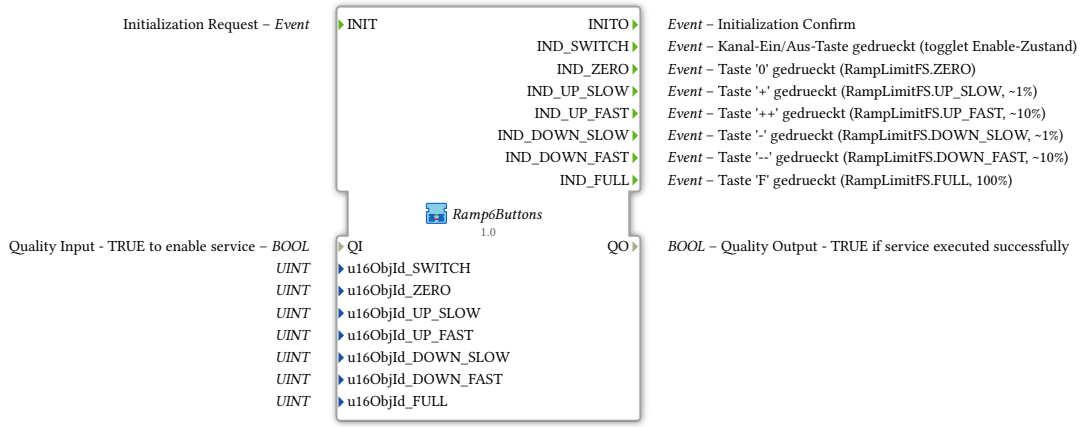


Application Scenarios

- Inversion relative to a fixed quantity, e.g. `100 - value`

Summary

`R_AR_SUB` provides `MINUEND - IN` for an `AR` value with a minuend fixed by parameter.



Ramp6Buttons

• — ○ • — ○ • — ○ •

Introduction

`Ramp6Buttons` encapsulates the **7 VT buttons of a PWM channel** — the 6 ramp buttons (`0 -- - + ++ F`) plus the channel enable/disable switch — as its own reusable SubApp. It was extracted from `RampLimitFS_TO_logiBUS_QDA_PWM_OPC` to declutter that block's network and make the button logic independently reusable.

Interface

- **Event input**: `INIT` (`EInit`, Initialization Request)
- **Event outputs**: `INITO` (`EInit`, Initialization Confirm), `IND_SWITCH`, `IND_ZERO`, `IND_UP_SLOW`, `IND_UP_FAST`, `IND_DOWN_SLOW`, `IND_DOWN_FAST`, `IND_FULL`
- **Data inputs**: `QI` (`BOOL`, default `TRUE`, Quality Input) as well as `u16ObjId_SWITCH`, `u16ObjId_ZERO`, `u16ObjId_UP_SLOW`, `u16ObjId_UP_FAST`, `u16ObjId_DOWN_SLOW`, `u16ObjId_DOWN_FAST`, `u16ObjId_FULL`
- **Data output**: `QO` (`BOOL`, Quality Output)

Function Blocks (FBs) Used

Sub-blocks: Ramp6Buttons

- **Type**: SubAppType
- **Internal FBs used**:
  - **Button_SWITCH**, **Button_ZERO**, **Button_UP_SLOW**, **Button_UP_FAST**, **Button_DOWN_SLOW**, **Button_DOWN_FAST**, **Button_FULL**: each `isobus::UT::io::Button::Button_IE`
    - Parameter: `InputEvent=BT_PRESSED_LATCHED` (a latched press/release event, no adapter bridging via `AX_RF_TRIG` needed)
    - Data inputs: `u16ObjId` (object ID of the respective VT button), `QI` (from the SubApp input `QI`)
    - Event output: `IND` (button pressed)
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_7` — ANDs the `QO` outputs of all seven `Button_*` instances into the SubApp output `QO`
- **Functionality**: Seven identical `Button_IE` instances, each bound to its own VT object ID, pass their `IND` event straight through as their own SubApp output event — a pure 1:1 pass-through with no additional logic. In addition, the initialization is chained through all seven instances and the status `QO` is aggregated.

Program Flow and Connections

The same pattern applies to all 7 buttons (`u16ObjId_<NAME>` ⟶ `Button_<NAME>.u16ObjId`, `Button_<NAME>.IND` ⟶ `IND_<NAME>`):

- `u16ObjId_SWITCH` ⟶ `Button_SWITCH.u16ObjId`; `Button_SWITCH.IND` ⟶ `IND_SWITCH` (toggles channel enable)
- `u16ObjId_ZERO` ⟶ `Button_ZERO.u16ObjId`; `Button_ZERO.IND` ⟶ `IND_ZERO` (`RampLimitFS.ZERO`)
- `u16ObjId_UP_SLOW` ⟶ `Button_UP_SLOW.u16ObjId`; `Button_UP_SLOW.IND` ⟶ `IND_UP_SLOW` (`RampLimitFS.UP_SLOW`, 1 %)
- `u16ObjId_UP_FAST` ⟶ `Button_UP_FAST.u16ObjId`; `Button_UP_FAST.IND` ⟶ `IND_UP_FAST` (`RampLimitFS.UP_FAST`, 10 %)
- `u16ObjId_DOWN_SLOW` ⟶ `Button_DOWN_SLOW.u16ObjId`; `Button_DOWN_SLOW.IND` ⟶ `IND_DOWN_SLOW` (`RampLimitFS.DOWN_SLOW`, 1 %)
- `u16ObjId_DOWN_FAST` ⟶ `Button_DOWN_FAST.u16ObjId`; `Button_DOWN_FAST.IND` ⟶ `IND_DOWN_FAST` (`RampLimitFS.DOWN_FAST`, 10 %)
- `u16ObjId_FULL` ⟶ `Button_FULL.u16ObjId`; `Button_FULL.IND` ⟶ `IND_FULL` (`RampLimitFS.FULL`, 100 %)

In addition:

- Initialization chain: `INIT` ⟶ `Button_SWITCH.INIT`, `Button_SWITCH.INITO` ⟶ `Button_ZERO.INIT`, `Button_ZERO.INITO` ⟶ `Button_UP_SLOW.INIT`, `Button_UP_SLOW.INITO` ⟶ `Button_UP_FAST.INIT`, `Button_UP_FAST.INITO` ⟶ `Button_DOWN_SLOW.INIT`, `Button_DOWN_SLOW.INITO` ⟶ `Button_DOWN_FAST.INIT`, `Button_DOWN_FAST.INITO` ⟶ `Button_FULL.INIT`, `Button_FULL.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`
- `QI` ⟶ `QI` of all seven `Button_*` instances
- `Button_SWITCH.QO`, `Button_ZERO.QO`, `Button_UP_SLOW.QO`, `Button_UP_FAST.QO`, `Button_DOWN_SLOW.QO`, `Button_DOWN_FAST.QO`, `Button_FULL.QO` ⟶ `AND_QO.IN1..IN7`; `AND_QO.OUT` ⟶ `QO`

The calling block wires `IND_ZERO`/`IND_UP_SLOW`/`IND_UP_FAST`/`IND_DOWN_SLOW`/`IND_DOWN_FAST`/`IND_FULL` directly to the like-named event inputs of `RampLimitFS`, and `IND_SWITCH` to the channel enable flip-flop.

Technical Details

- **`BT_PRESSED_LATCHED` instead of `Button_IXA+AX_RF_TRIG`**: a simpler pattern with no adapter bridging, since `Button_IE` outputs the press event directly as `IND`.
- **Event order aligned with `RampLimitFS`**: The output events (`SWITCH, ZERO, UP_SLOW, UP_FAST, DOWN_SLOW, DOWN_FAST, FULL`) deliberately follow the order in which `RampLimitFS` declares its own event inputs, to make wiring easier.

Application Scenarios

- Any exercise with a ramped setpoint (`RampLimitFS` or similar) that should be operated via 6 buttons plus one enable switch.

Summary

`Ramp6Buttons` bundles seven identical `Button_IE` instances into a single reusable SubApp, keeping the button wiring out of the actual PWM channel block.

RampLimitFS_TO_logiBUS_QDA_PWM_OPC

• – ◦ • – ◦ • – ◦ •

Introduction

`RampLimitFS_TO_logiBUS_QDA_PWM_OPC` is the reusable block for **a single PWM output channel (0–100 % duty cycle)** with a VT number field, bar graph, 6 ramp buttons, channel enable/disable switch, 3-color status indicator, and bidirectional OPC-UA connectivity. It is instantiated 12× with different parameters in `InputOutputTesterButton_PWM_OPC_UA` and is the PWM counterpart of the simpler, purely digital `RampLimitFS_TO_logiBUS_QDA_OPC`.

Function Blocks (FBs) Used

Sub-blocks: RampLimitFS_TO_logiBUS_QDA_PWM_OPC

- **Type**: SubAppType
- **Internal FBs used**:
  - **RampLimitFS**: `eclipse4diac::signalprocessing::RampLimitFS`
    - Parameters: `VAL_ZERO=DINT#0`, `SLOW=DINT#643` (1 %), `FAST=DINT#6426` (10 %), `VAL_FULL=DINT#64255`
    - Data input: `PV` (setpoint mux output), event inputs: `ZERO/UP_SLOW/UP_FAST/DOWN_SLOW/DOWN_FAST/FULL/LOAD`
    - Data output: `OUT` (0–64255)
  - **Ramp6Buttons** (SubApp, `MyLib::sys`): encapsulates the 7 VT buttons (6 ramp buttons + channel switch), see its own documentation
  - **F_PWM_PERCENT_TO_RAW** / **F_PWM_RAW_TO_PERCENT** (SubApp, `MyLib::sys`): conversion between fraction 0.0-1.0 and fieldbus raw value, see F_PWM_PERCENT_TO_RAW / F_PWM_RAW_TO_PERCENT
  - **F_PERCENT_TO_FRACTION_SUB** / **F_FRACTION_TO_PERCENT_PUB**: `logiBUS::signalprocessing::fieldbus::F_PERCENT_TO_FRACTION/F_FRACTION_TO_PERCENT` — percent 0-100 ↔ fraction 0.0-1.0
  - **E_RS_PV** (`iec61499::events::E_RS`) + **F_SEL_PV** (`iec61131::selection::F_SEL`): two-source merge (VT number field and web setpoint) onto the single data input `RampLimitFS.PV`, since the 4diac IDE does not allow multiple connections into one data input
  - **E_T_FF_SR_SYM_INIT** (`E_T_FF_SR_SWITCH`): channel enable state, set/reset by the VT button (`CLK`, a real toggle) and by web writes (`S/R`, an edge change detected via `AX_RF_TRIG`, not a toggle)
  - **F_MUL_TO_PWM13BIT/F_DIV_TO_PWM13BIT** (`iec61131::arithmetic::F_MUL/F_DIV`): convert `RampLimitFS.OUT` (0-64255) via `×8191 ÷ 64255` into the 13-bit raw value (0-8191) for `logiBUS_QD_PWM.OUT`
  - **logiBUS_QD_PWM**: physical PWM output (the `Output` parameter identifies `Output_Q1..Q12`)
  - **F_SEL_OK_FAULT/F_SEL_STATUS** (`iec61131::selection::F_SEL`) + **Q_BackgroundColour**: 3-color status logic (white=disabled, green=active+`QO`=TRUE, red=active+`QO`=FALSE)
  - **AR_SUBSCRIBE_1/AR_PUBLISH_1**, **AX_SUBSCRIBE_1/AX_PUBLISH_1** (×2): OPC-UA adapters for setpoint (REAL), switch (BOOL), and status (BOOL)
  - **AND_QO** (`iec61131::booleanOperators::AND_BOOL_10`): combines ten `QO` sources into the SubApp output `QO`
- **Functionality**: Two independent setpoint sources — the VT number field/ramp buttons and a web percent value received via OPC-UA subscribe — are muxed onto the same `RampLimitFS` ramp block via `E_RS+F_SEL` (whichever source was most recently active wins). The ramp output (0-64255) feeds three destinations: the 13-bit raw value going to the physical `logiBUS_QD_PWM` output, a percent value going back to the VT number field/bar graph, and a percent value published via OPC-UA to the web client. In parallel, a VT button press or a web write toggles the channel enable state (`E_T_FF_SR_SWITCH`), which arms/disarms the physical output via `logiBUS_QD_PWM.QI` and feeds into the 3-color status display.

Program Flow and Connections

1. **VT setpoint path**: `NumericValue_Duty.IND` (number field changed) ⟶ `F_DWORD_TO_UDINT_VT` ⟶ `F_UDINT_TO_DINT_VT` ⟶ `E_SPLIT_VT` ⟶ on one branch `E_RS_PV.R` (reset: "web takes precedence until VT becomes active again" — see below), on the other `E_MERGE_SEL` ⟶ `F_SEL_PV.REQ`.
2. **Web setpoint path**: `AR_SUBSCRIBE_1` (OPC-UA subscribe, percent REAL) ⟶ `AR_R_TO_REAL_SUB` ⟶ `F_PERCENT_TO_FRACTION_SUB` (percent ⟶ fraction) ⟶ `F_PWM_PERCENT_TO_RAW` (fraction ⟶ fieldbus

raw value) → E_SPLIT_WEB → on one branch E_RS_PV.S (set: web source active), on the other E_MERGE_SEL → F_SEL_PV.REQ.

3. **Mux and ramp**: E_RS_PV.Q drives F_SEL_PV.G (0=VT value IN0, 1=web value IN1); F_SEL_PV.OUT loads RampLimitFS.PV via the LOAD event. Ramp6Buttons additionally supplies the 6 ramp events directly to RampLimitFS (ZERO/UP_SLOW/UP_FAST/DOWN_SLOW/DOWN_FAST/FULL).
4. **Physical output**: RampLimitFS.OUT (0-64255) → F_MUL_TO_PWM13BIT (×8191) → F_DIV_TO_PWM13BIT (÷64255) → F_DINT_TO_DWORD_OUT → logiBUS_QD_PWM.OUT.
5. **VT display**: RampLimitFS.OUT → F_DINT_TO_UDINT_DISP → Q_NumericValue.REQ (updates the number field + the bar graph sharing the same variable).
6. **OPC-UA publish**: RampLimitFS.OUT → F_PWM_RAW_TO_PERCENT (raw value → fraction) → F_FRACTION_TO_PERCENT_PUB (fraction → percent) → AR_REAL_TO_R_PUB → AR_PUBLISH_1.
7. **Channel switch**: Ramp6Buttons.IND_SWITCH (VT button) → E_T_FF_SR_SWITCH.CLK (toggles). AX_SUBSCRIBE_SWITCH (web write, BOOL) → AX_RF_TRIG_SWITCH detects a real edge change → ER→S / EF→R (sets instead of toggling, so two identical web writes cannot accidentally invert the state). bDefaultEnabled feeds E_T_FF_SR_SWITCH.Q_INIT for the initial state.
8. **Status chain**: E_T_FF_SR_SWITCH.Q → logiBUS_QD_PWM.QI (armed/disarmed) and → F_SEL_STATUS.G. logiBUS_QD_PWM.INITO/.QO feed F_SEL_OK_FAULT (red/green based on QO), whose result goes through F_SEL_STATUS (white if disabled) to Q_BackgroundColour_STATUS. In addition, AX_BOOL_TO_X_SWITCH/AX_PUBLISH_SWITCH and AX_BOOL_TO_X_STATUS/AX_PUBLISH_STATUS mirror the enable state and QO to the web client via OPC-UA publish.
9. **Boot sequence**: The SubApp has the event input INIT and the event output INITO (both new). INIT → AR_SUBSCRIBE_1.INIT; the five OPC-UA adapters are initialized in a strict chain (AR_SUBSCRIBE_1.INITO → AR_PUBLISH_1.INIT → AX_SUBSCRIBE_SWITCH.INIT → AX_PUBLISH_SWITCH.INIT → AX_PUBLISH_STATUS.INIT); only afterward does AX_PUBLISH_STATUS.INITO fire E_T_FF_SR_SWITCH.INIT, so the first published enable state is not dropped by an adapter that is not yet ready. Also starting from AX_PUBLISH_STATUS.INITO, the VT initialization chain runs Q_NumericValue.INIT → Q_BackgroundColour_EnableOk_STATUS.INIT → Ramp6Buttons.INIT → NumericValue_Duty.INIT; NumericValue_Duty.INITO → INITO and → AND_QO.REQ.
10. **QI/QO pass-through**: QI (BOOL, default TRUE) is distributed to ten instances: Q_NumericValue, NumericValue_Duty, AR_SUBSCRIBE_1, AR_PUBLISH_1, E_T_FF_SR_SWITCH, AX_SUBSCRIBE_SWITCH, AX_PUBLISH_SWITCH, AX_PUBLISH_STATUS, Q_BackgroundColour_EnableOk_STATUS and Ramp6Buttons (the internal FBs no longer carry a fixed QI=TRUE). Their QO outputs — Q_NumericValue (IN1), Q_BackgroundColour_EnableOk_STATUS (IN2), Ramp6Buttons (IN3), NumericValue_Duty (IN4), AR_SUBSCRIBE_1 (IN5), AR_PUBLISH_1 (IN6), E_T_FF_SR_SWITCH (IN7), AX_SUBSCRIBE_SWITCH (IN8), AX_PUBLISH_SWITCH (IN9), AX_PUBLISH_STATUS (IN10) — feed AND_QO (AND_BOOL_10), and AND_QO.OUT drives QO (BOOL, quality output). This QO is independent of the logiBUS_QD_PWM.QO used in the status chain.

Technical Details

- **Value range**: Consistently uses the SAE J1939/ISO 11783 fieldbus convention VALID_SIGNAL_W (0-64255) internally, not percent — avoids rounding errors and stays consistent with RampLimitFS.
- **13-bit PWM raw value**: logiBUS_QD_PWM.OUT was empirically confirmed to expect 0-8191 (not 0-64255) — hence the additional ×8191÷64255 conversion chain.
- **Multi-connection workaround**: E_RS+F_SEL instead of a (disallowed in the 4diac IDE) duplicate data connection into RampLimitFS.PV.
- **No PERMIT gating**: The channel switch wires QI directly as a data connection (the pattern from Uebung_094a), no E_PERMIT blocks.
- **Set/reset instead of toggle for web writes**: AX_RF_TRIG + E_T_FF_SR_SYM_INIT instead of a pure toggle flip-flop, so repeated writes with the same value do not randomly invert the state.

Application Scenarios

- Training example for analog (PWM) outputs with remote control via OPC-UA/web, alongside classic VT operation.
- Template for any further multi-channel analog output exercise with setpoint ramping and per-channel enable.

Comparison with Similar Blocks

Compared to the simpler, purely digital counterpart `RampLimitFS_TO_logiBUS_QDA_OPC`, `RampLimitFS_TO_logiBUS_QDA_PWM_OPC` differs in its analog setpoint (a ramp instead of a bit), the additional scaling chain (percent ↔ fraction ↔ fieldbus raw value ↔ 13-bit PWM), and the 3-color instead of 2-color status logic.

Summary

`RampLimitFS_TO_logiBUS_QDA_PWM_OPC` encapsulates a complete PWM channel — setpoint ramping, two-source mux between VT and web, scaling down to the physical 13-bit PWM output, a channel enable switch with robust set/reset behavior, and 3-color status feedback — in a single block that is reused 12 times.

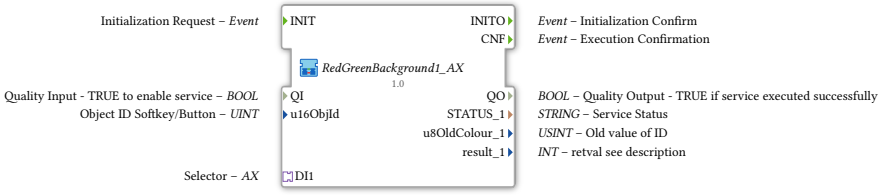
RedGreenBackground1_AX



• – ○ • – ○ • – ○ •

Introduction

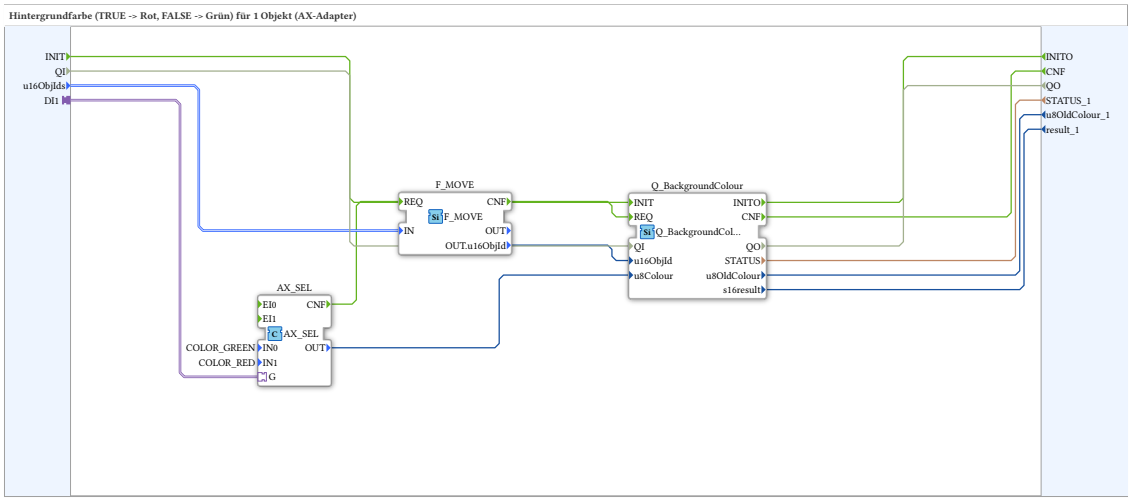
`RedGreenBackground1_AX` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Grün**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via input `u16ObjId`.

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Interface: Initialization and Quality

- **INIT** (event input, `EInit`) ⟶ `Q_BackgroundColour.INIT`; `Q_BackgroundColour.INITO` ⟶ **INITO** (event output, `EInit`).

- **QI** (data input, `BOOL`, default `TRUE`): Quality Input - `TRUE` enables the service; passed through to `Q_BackgroundColour.QI`.
- **QO** (data output, `BOOL`): Quality Output - `TRUE` if the service executed successfully; comes from `Q_BackgroundColour.QO`.



Summary

One of many variants in the background color block family: color pair Rot/Grün, 1 object, adapter selector.

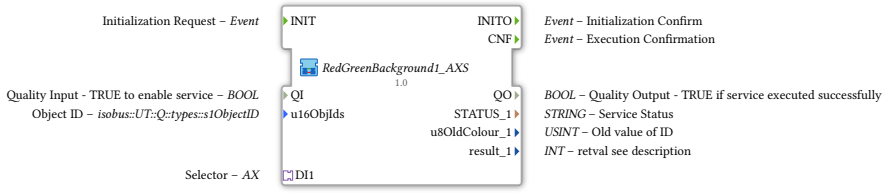
RedGreenBackground1_AXS



• — ○ • — ○ • — ○ •

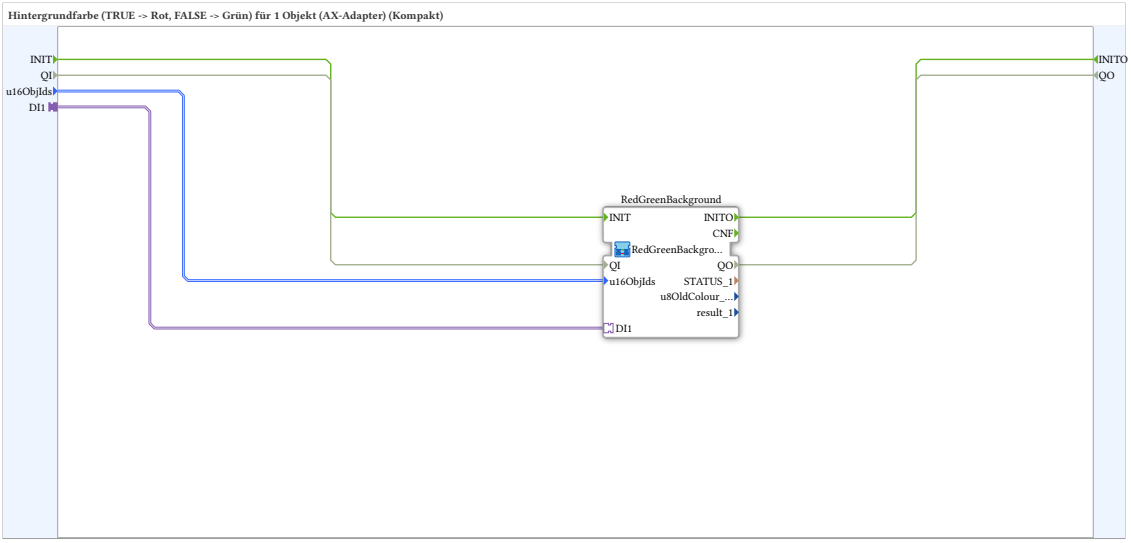
Introduction

`RedGreenBackground1_AXS` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Grün**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

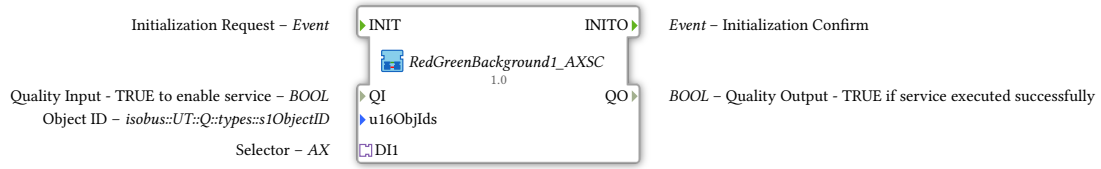
For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Interface: Initialization and Quality

- **INIT** (event input, `EInit`) ⟶ `Q_BackgroundColour.INIT`; `Q_BackgroundColour.INITO` ⟶ **INITO** (event output, `EInit`).
- **QI** (data input, `BOOL`, default `TRUE`): Quality Input - `TRUE` enables the service; passed through to `Q_BackgroundColour.QI`.
- **QO** (data output, `BOOL`): Quality Output - `TRUE` if the service executed successfully; comes from `Q_BackgroundColour.QO`.



Summary



One of many variants in the background color block family: color pair Rot/Grün, 1 object, adapter selector, struct. object ID.

RedGreenBackground1_AXSC

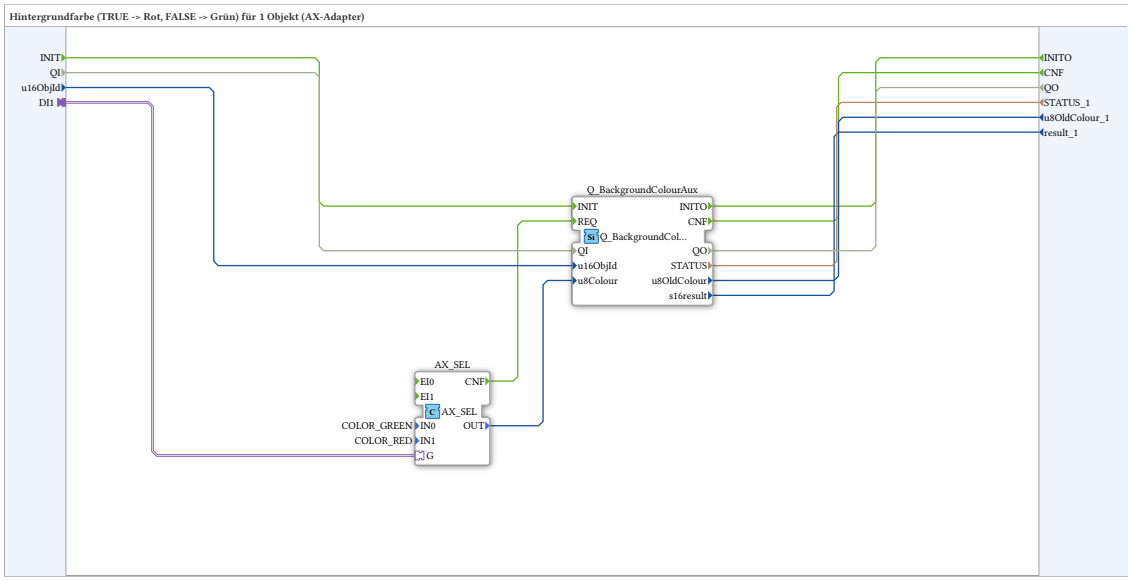
• — ○ • — ○ • — ○ •

Introduction

`RedGreenBackground1_AXSC` is a **compact wrapper** around `RedGreenBackground1_AXS` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

In addition, initialization and quality are passed through: `INIT` ⟶ `RedGreenBackground.INIT`, `RedGreenBackground.INITO` ⟶ `INITO`, `QI` (initial value `TRUE`) ⟶ `RedGreenBackground.QI` and `RedGreenBackground.QO` ⟶ `QO`.

For the shared pattern, see Background Color Blocks (shared pattern).



Summary

A pure pass-through to `RedGreenBackground1_AXS` for the common case where the diagnostic values aren't needed.

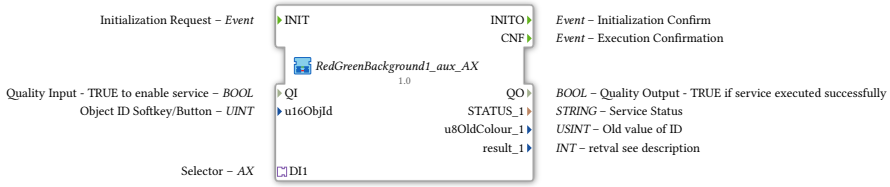
RedGreenBackground1_aux_AX



• — ○ • — ○ • — ○ •

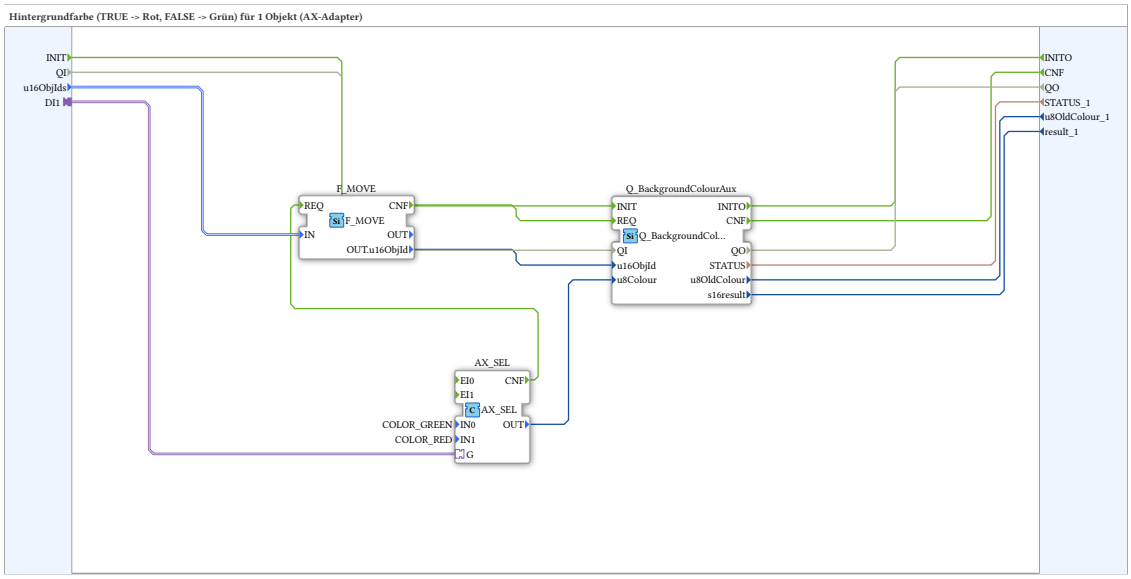
Introduction

`RedGreenBackground1_aux_AX` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Grün**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via input `u16ObjId`.

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Interface: Initialization and Quality

- **INIT** (event input, `EInit`) ⟶ `Q_BackgroundColourAux.INIT`; `Q_BackgroundColourAux.INITO` ⟶ **INITO** (event output, `EInit`).
- **QI** (data input, `BOOL`, default `TRUE`): Quality Input - `TRUE` enables the service; passed through to `Q_BackgroundColourAux.QI`.
- **QO** (data output, `BOOL`): Quality Output - `TRUE` if the service executed successfully; comes from `Q_BackgroundColourAux.QO`.



Summary

One of many variants in the background color block family: color pair Rot/Grün, 1 object, adapter selector.

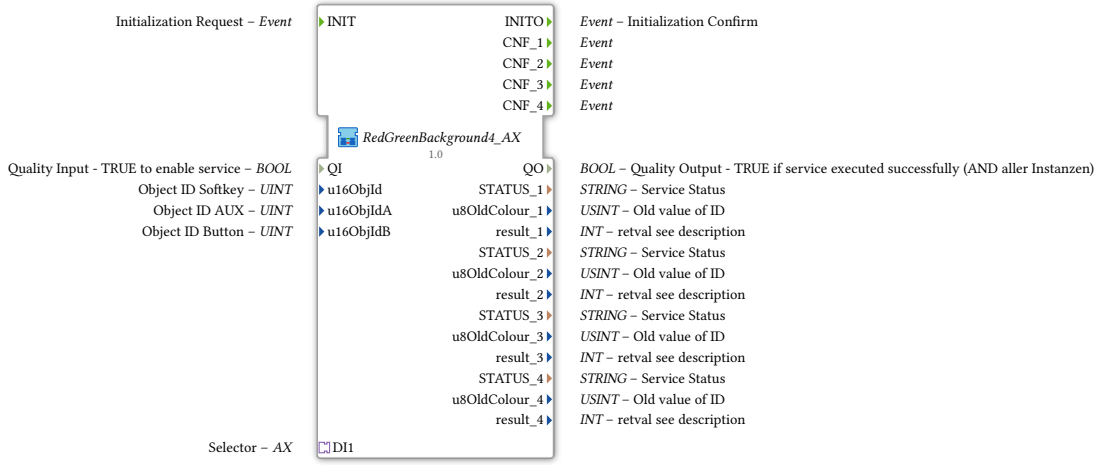
RedGreenBackground4_AX



• — ○ • — ○ • — ○ •

Introduction

`RedGreenBackground4_AX` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Grün**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA, u16ObjIdB`.

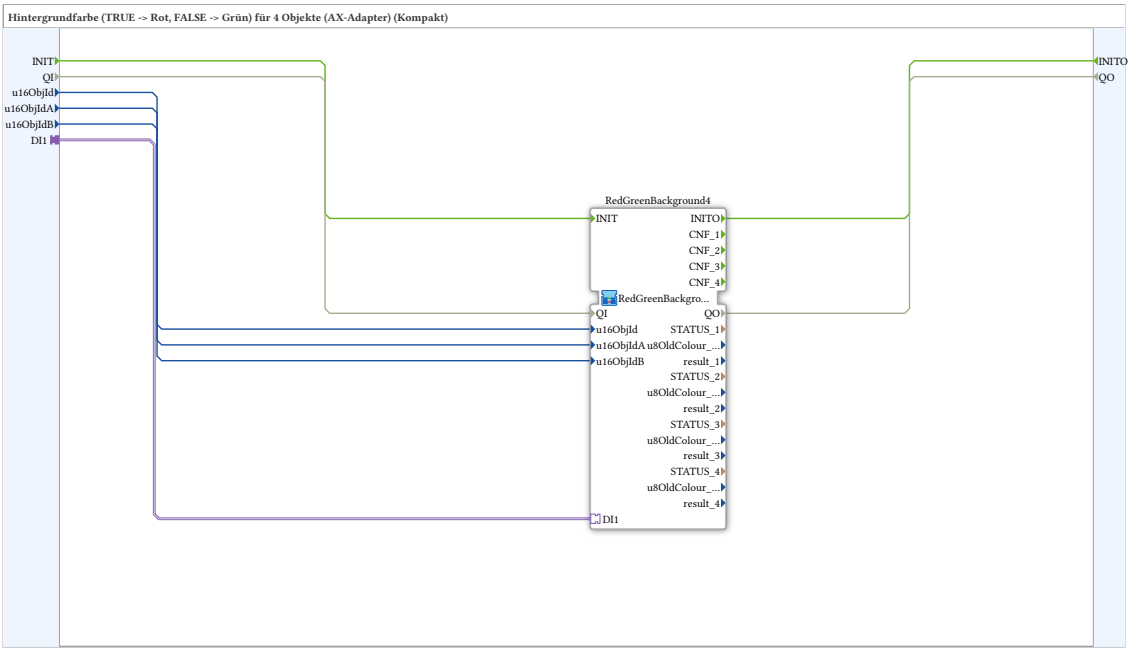
Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`u16ObjIdB`	`Q_BackgroundColour` (regular object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

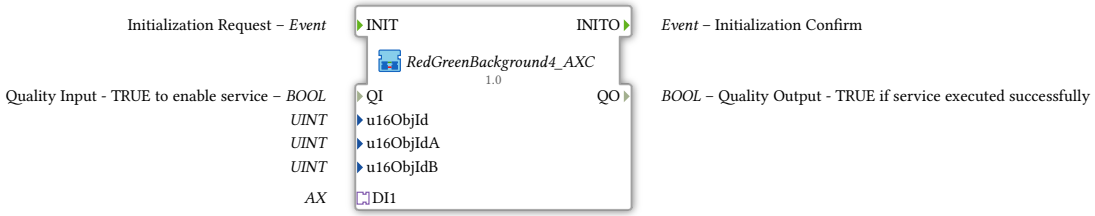
Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`): initialization is chained through the `Q_BackgroundColour` instances: `INIT` ⟶ `Q_BackgroundColour_1.INIT`; `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`; `Q_BackgroundColour_3.INITO` ⟶ `Q_BackgroundColour_4.INIT`; `Q_BackgroundColour_4.INITO` ⟶ `INITO`.

- **Data input `QI`** (`BOOL`, default `TRUE`) is distributed to `.QI` of all instances (`Q_BackgroundColour_1`, `Q_BackgroundColour_2`, `Q_BackgroundColour_3`, `Q_BackgroundColour_4`).
- **Data output `QO`** (`BOOL`): AND of all instances via `AND_QO` (`iec61131::booleanOperators::AND_BOOL_4`): `Q_BackgroundColour_1.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN2`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN3`, `Q_BackgroundColour_4.QO` ⟶ `AND_QO.IN4`; `AND_QO.OUT` ⟶ `QO`.
- `E_MERGE_QO_A` (`iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_4.INITO` and the `CNF` events of instances 1 to 3; `E_MERGE_QO` (`iec61499::events::E_MERGE_2`) merges its output `E_MERGE_QO_A.EO` with `Q_BackgroundColour_4.CNF` and thereby triggers `AND_QO.REQ`.



Summary



One of many variants in the background color block family: color pair Rot/Grün, 4 objects, adapter selector.

🌐 Related topic subpages on ms-muc-docs.de

RedGreenBackground4_AXC

• – ◦ • – ◦ • – ◦ •

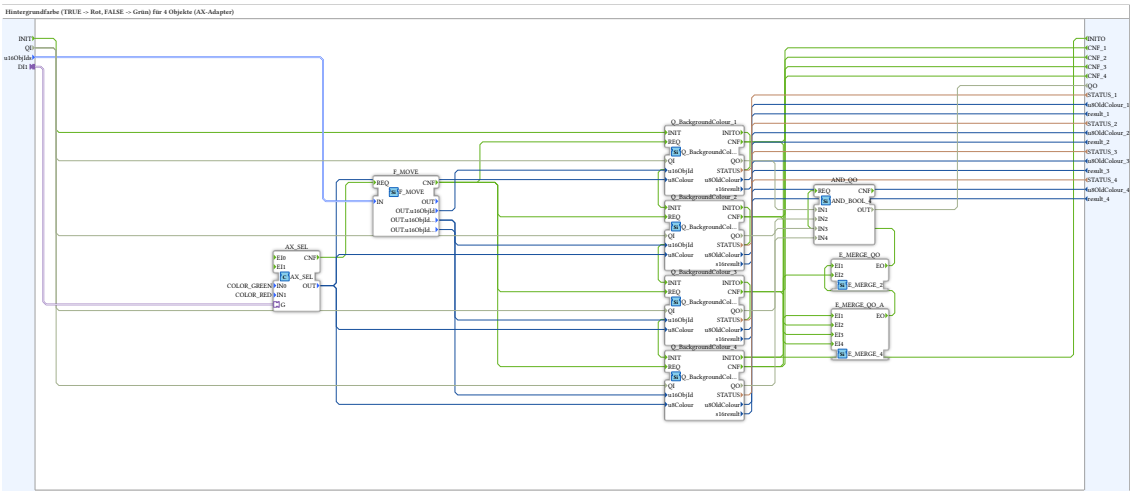
Introduction

`RedGreenBackground4_AXC` is a **compact wrapper** around `RedGreenBackground4_AX` — passes `u16ObjId` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

Interface (quality pattern): The wrapper additionally has the event input `INIT` and the event output `INITO` (each `EInit`) as well as the data input `QI` (`BOOL`, default `TRUE`) and the data output `QO` (`BOOL`). They are passed straight through to the inner instance `RedGreenBackground4`: `INIT` ⟶

`RedGreenBackground4.INIT`, `RedGreenBackground4.INITO` ⟶ `INITO`, `QI` ⟶ `RedGreenBackground4.QI`, `RedGreenBackground4.QO` ⟶ `QO`.

For the shared pattern, see Background Color Blocks (shared pattern).



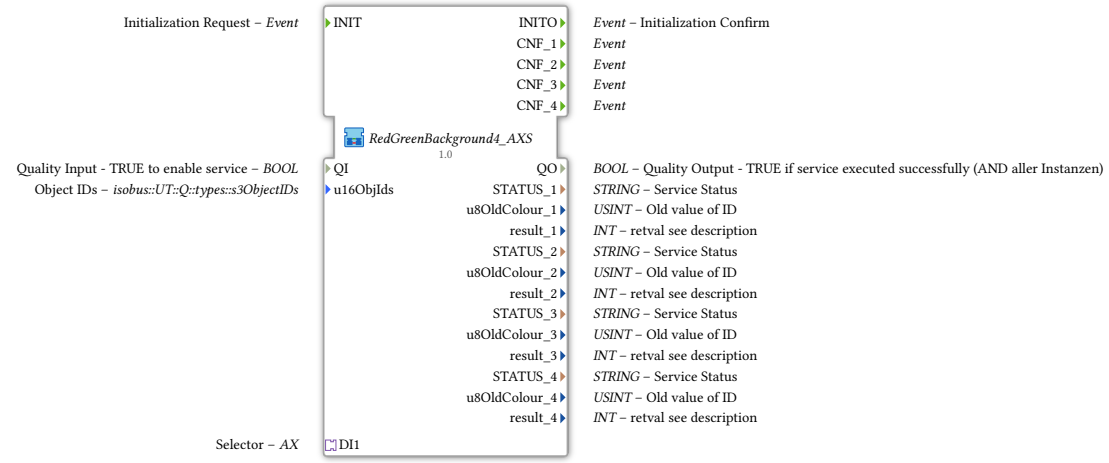
Summary

A pure pass-through to `RedGreenBackground4_AX` for the common case where the diagnostic values aren't needed.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

RedGreenBackground4_AXS



• – ○ • – ○ • – ○ •

Introduction

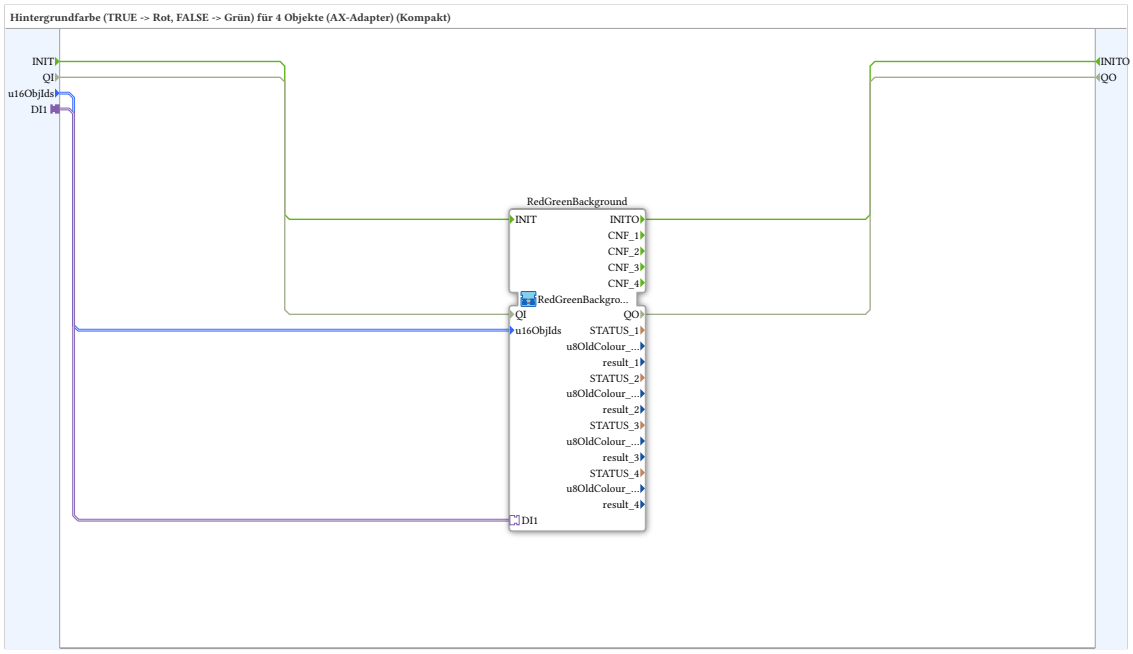
`RedGreenBackground4_AXS` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Grün**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`F_MOVE.OUT.u16ObjIdB`	`Q_BackgroundColour` (regular object)

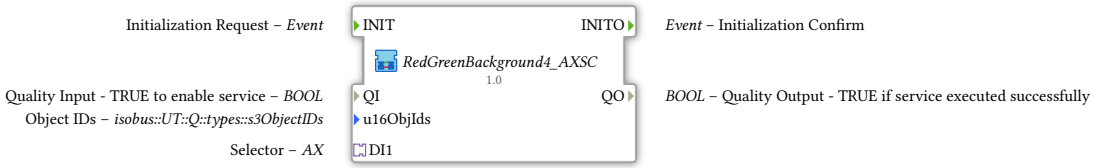
For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `Q_BackgroundColour_1.QI`, `Q_BackgroundColour_2.QI`, `Q_BackgroundColour_3.QI` and `Q_BackgroundColour_4.QI`
- **Data output** `QO` (`BOOL`, Quality Output): AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_4`) of the `QO` outputs of `Q_BackgroundColour_1.QO`, `Q_BackgroundColour_2.QO`, `Q_BackgroundColour_3.QO` and `Q_BackgroundColour_4.QO`
- **Initialization chain**: `INIT` → `Q_BackgroundColour_1.INIT`, `Q_BackgroundColour_1.INITO` → `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` → `Q_BackgroundColour_3.INIT`, `Q_BackgroundColour_3.INITO` → `Q_BackgroundColour_4.INIT`, `Q_BackgroundColour_4.INITO` → `INITO`
- `E_MERGE_QO_A` (type `iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_4.INITO`, `Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF` and `Q_BackgroundColour_3.CNF` and passes the result to `E_MERGE_QO.EI1`
- `E_MERGE_QO` (type `iec61499::events::E_MERGE_2`) merges `E_MERGE_QO_A.EO` and `Q_BackgroundColour_4.CNF` and triggers `AND_QO.REQ`



Summary



One of many variants in the background color block family: color pair Rot/Grün, 4 objects, adapter selector, struct. object ID.

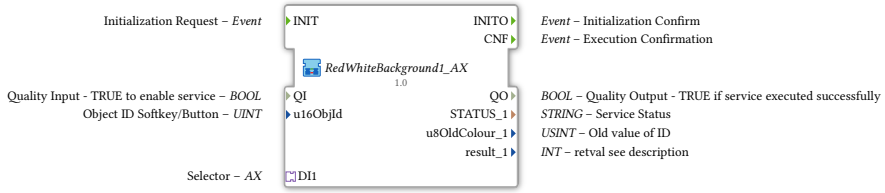
RedWhiteBackground1_AX



• — ○ • — ○ • — ○ •

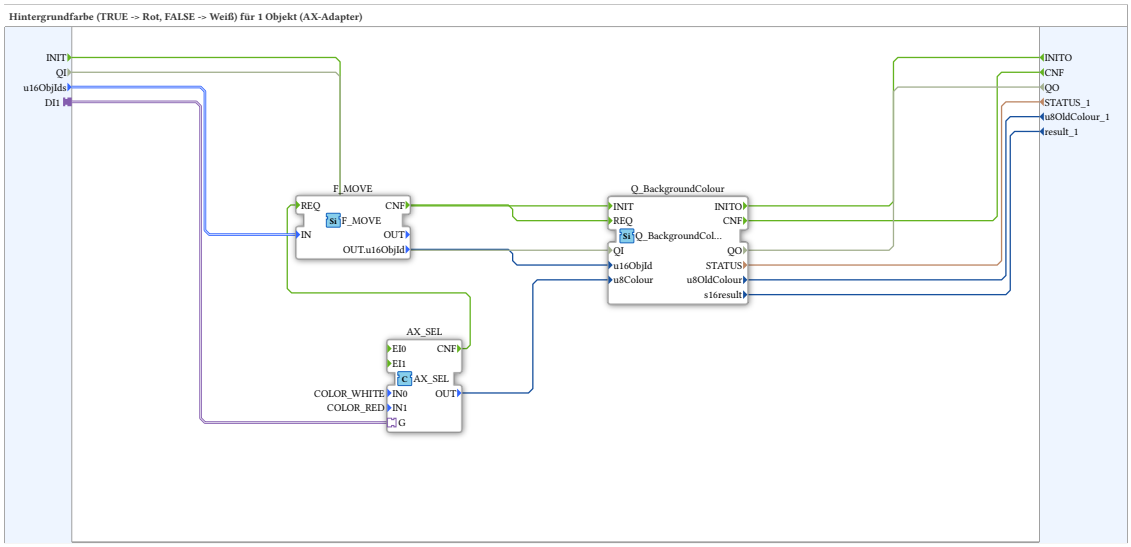
Introduction

`RedWhiteBackground1_AX` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via input `u16ObjId`.

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Interface: Initialization and Quality

- **INIT** (event input, `EInit`) ⟶ `Q_BackgroundColour.INIT`; `Q_BackgroundColour.INITO` ⟶ **INITO** (event output, `EInit`).
- **QI** (data input, `BOOL`, default `TRUE`): Quality Input - `TRUE` enables the service; passed through to `Q_BackgroundColour.QI`.
- **QO** (data output, `BOOL`): Quality Output - `TRUE` if the service executed successfully; comes from `Q_BackgroundColour.QO`.



Summary

One of many variants in the background color block family: color pair Rot/Weiß, 1 object, adapter selector.

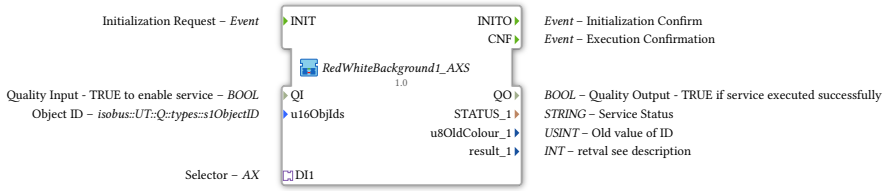
RedWhiteBackground1_AXS



• – ○ • – ○ • – ○ •

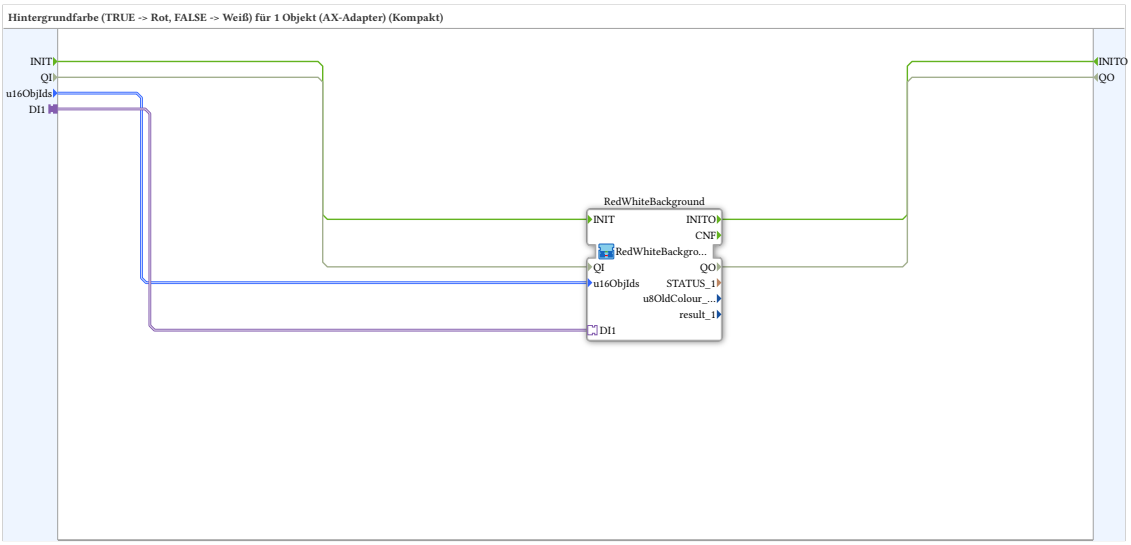
Introduction

`RedWhiteBackground1_AXS` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

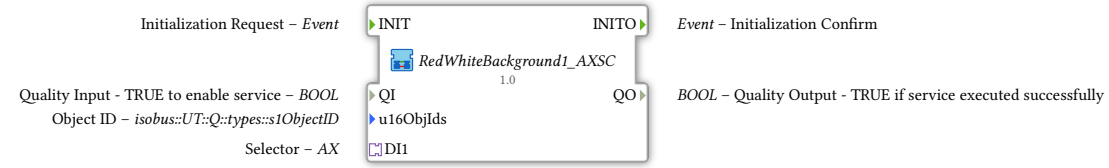
For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Interface: Initialization and Quality

- **INIT** (event input, `EInit`) ⟶ `Q_BackgroundColour.INIT`; `Q_BackgroundColour.INITO` ⟶ **INITO** (event output, `EInit`).
- **QI** (data input, `BOOL`, default `TRUE`): Quality Input - `TRUE` enables the service; passed through to `Q_BackgroundColour.QI`.
- **QO** (data output, `BOOL`): Quality Output - `TRUE` if the service executed successfully; comes from `Q_BackgroundColour.QO`.



Summary



One of many variants in the background color block family: color pair Rot/Weiß, 1 object, adapter selector, struct. object ID.

RedWhiteBackground1_AXSC

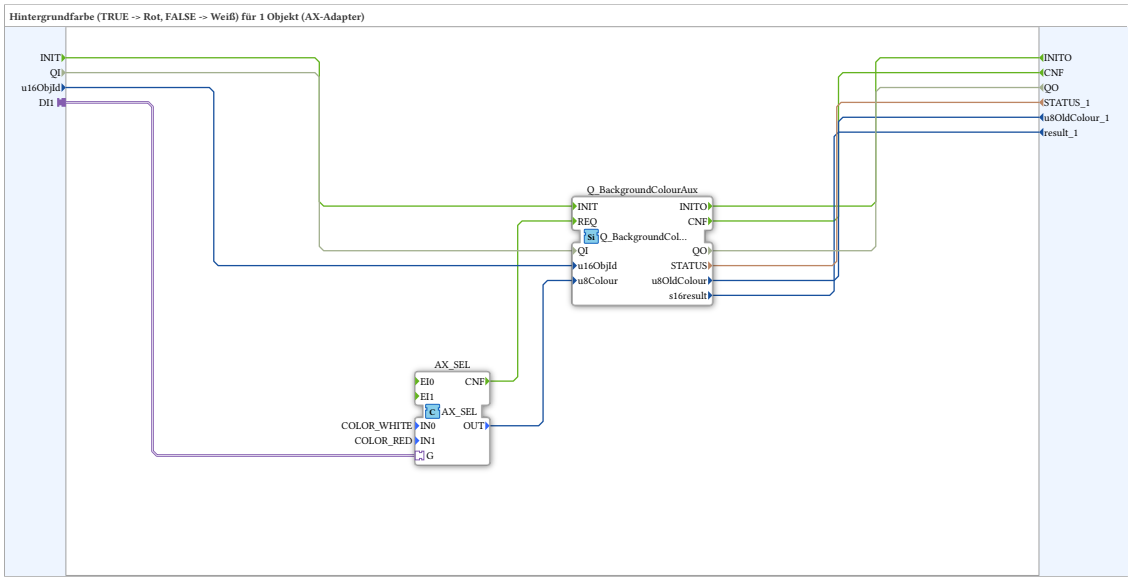
• – ○ • – ○ • – ○ •

Introduction

`RedWhiteBackground1_AXSC` is a **compact wrapper** around `RedWhiteBackground1_AXS` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

In addition, initialization and quality are passed through: `INIT` ⟶ `RedWhiteBackground.INIT`, `RedWhiteBackground.INITO` ⟶ `INITO`, `QI` (initial value `TRUE`) ⟶ `RedWhiteBackground.QI` and `RedWhiteBackground.QO` ⟶ `QO`.

For the shared pattern, see Background Color Blocks (shared pattern).



Summary

A pure pass-through to `RedWhiteBackground1_AXS` for the common case where the diagnostic values aren't needed.

RedWhiteBackground1_aux_AX

• — ○ • — ○ • — ○ •

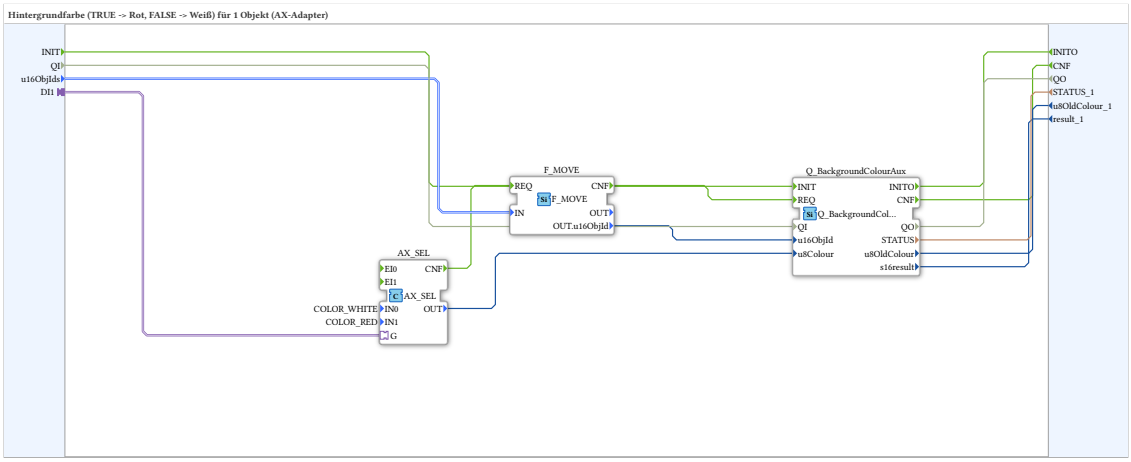
Introduction

`RedWhiteBackground1_aux_AX` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via input `u16ObjId`.

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Interface: Initialization and Quality

- **INIT** (event input, `EInit`) ⟶ `Q_BackgroundColourAux.INIT`; `Q_BackgroundColourAux.INITO` ⟶ **INITO** (event output, `EInit`).
- **QI** (data input, `BOOL`, default `TRUE`): Quality Input - `TRUE` enables the service; passed through to `Q_BackgroundColourAux.QI`.
- **QO** (data output, `BOOL`): Quality Output - `TRUE` if the service executed successfully; comes from `Q_BackgroundColourAux.QO`.



Summary

One of many variants in the background color block family: color pair Rot/Weiß, 1 object, adapter selector.

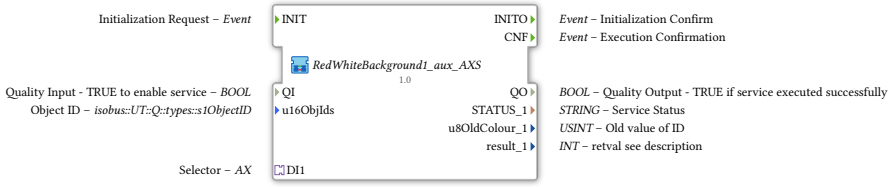
RedWhiteBackground1_aux_AXS



• – ○ • – ○ • – ○ •

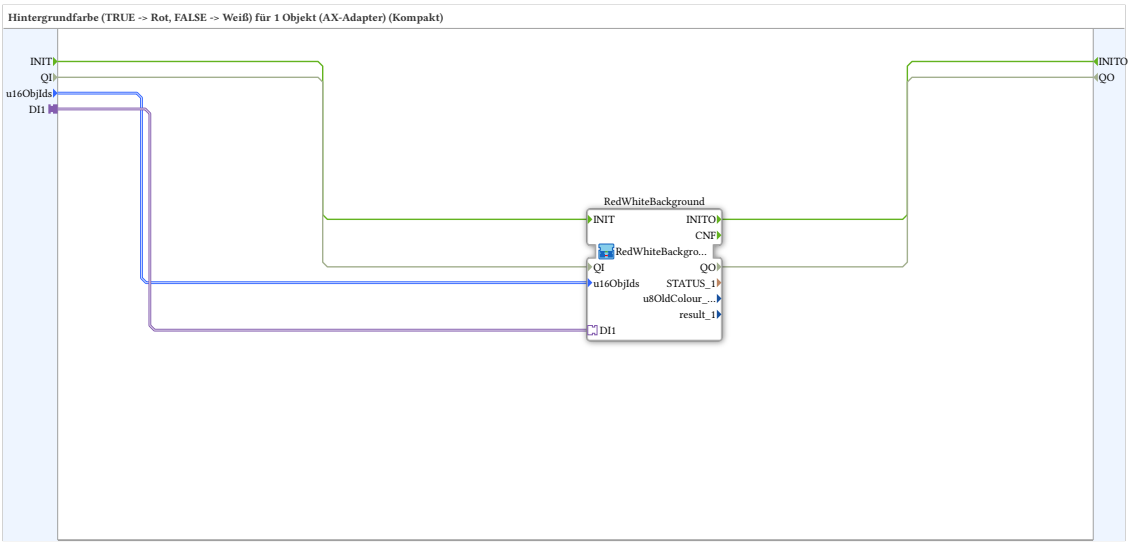
Introduction

`RedWhiteBackground1_aux_AXS` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

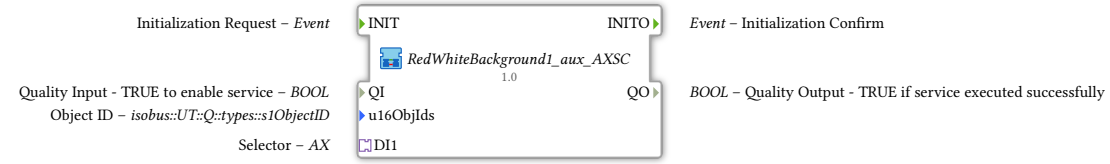
For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Interface: Initialization and Quality

- **INIT** (event input, `EInit`) ⟶ `Q_BackgroundColourAux.INIT`; `Q_BackgroundColourAux.INITO` ⟶ **INITO** (event output, `EInit`).
- **QI** (data input, `BOOL`, default `TRUE`): Quality Input - `TRUE` enables the service; passed through to `Q_BackgroundColourAux.QI`.
- **QO** (data output, `BOOL`): Quality Output - `TRUE` if the service executed successfully; comes from `Q_BackgroundColourAux.QO`.



Summary



One of many variants in the background color block family: color pair Rot/Weiß, 1 object, adapter selector, struct. object ID.

RedWhiteBackground1_aux_AXSC

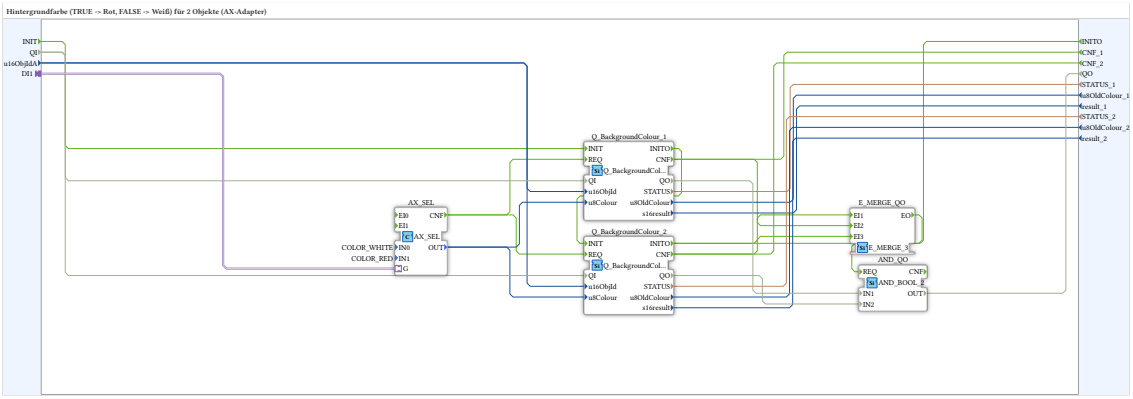
• — ○ • — ○ • — ○ •

Introduction

`RedWhiteBackground1_aux_AXSC` is a **compact wrapper** around `RedWhiteBackground1_aux_AXS` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

For the shared pattern, see Background Color Blocks (shared pattern).

In addition, the wrapper exposes the initialization and quality interface: event input `INIT`, event output `INITO`, data input `QI` (`BOOL`, initial value `TRUE`) and data output `QO` (`BOOL`). They are passed 1:1 through to the inner instance `RedWhiteBackground`: `INIT` ⟶ `RedWhiteBackground.INIT`, `RedWhiteBackground.INITO` ⟶ `INITO`, `QI` ⟶ `RedWhiteBackground.QI`, `RedWhiteBackground.QO` ⟶ `QO`.



Summary

A pure pass-through to `RedWhiteBackground1_aux_AXS` for the common case where the diagnostic values aren't needed.

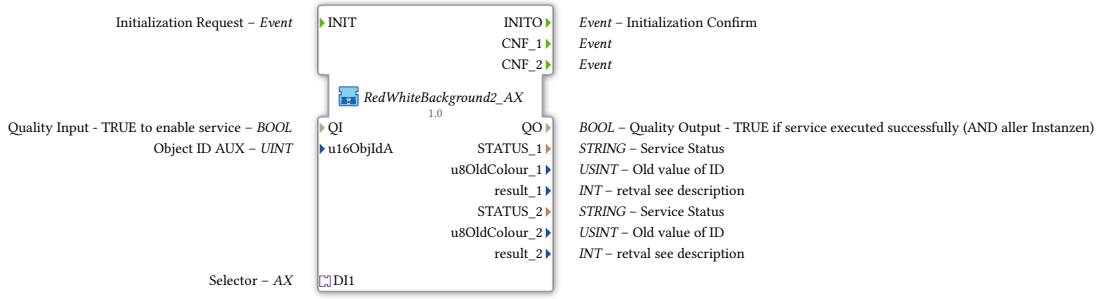
- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

RedWhiteBackground2_AX



• — ○ • — ○ • — ○ •

Introduction

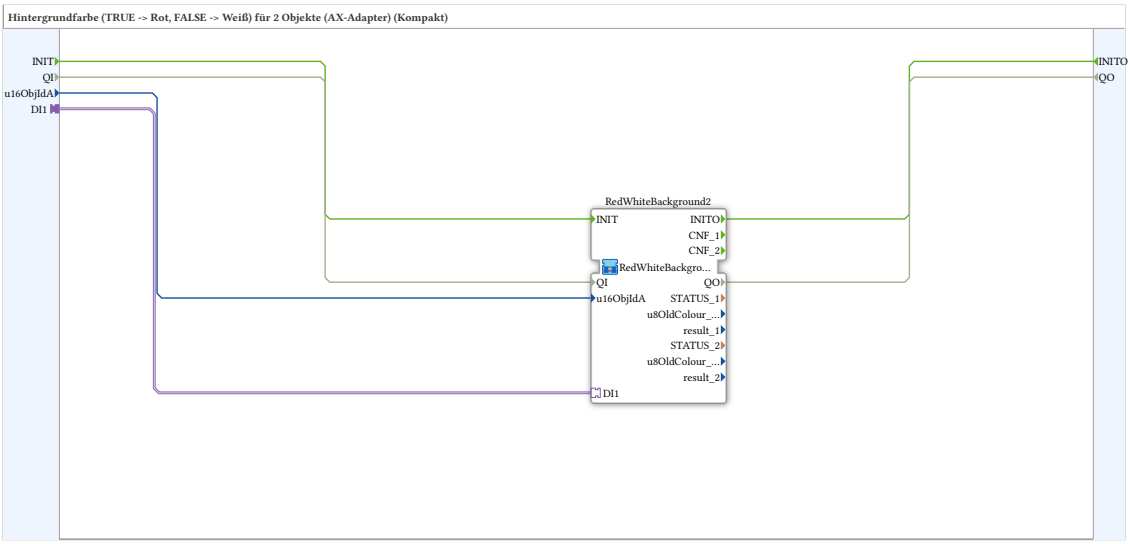
`RedWhiteBackground2_AX` switches the VT background color of 2 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via inputs `u16ObjIdA`.

Position	Object ID source	Block
1	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

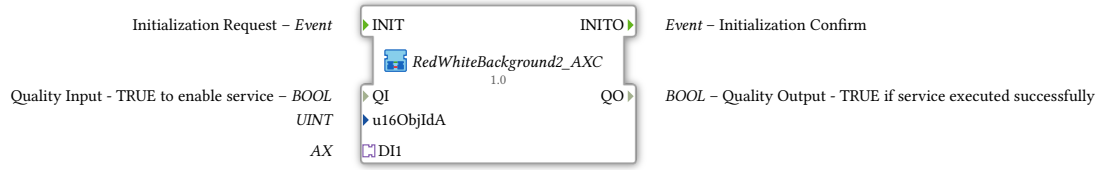
For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`): initialization is chained through the `Q_BackgroundColour` instances: `INIT` ⟶ `Q_BackgroundColour_1.INIT`; `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` ⟶ `INITO`.
- **Data input `QI`** (`BOOL`, default `TRUE`) is distributed to `.QI` of all instances (`Q_BackgroundColour_1`, `Q_BackgroundColour_2`).
- **Data output `QO`** (`BOOL`): AND of all instances via `AND_QO` (`iec61131::booleanOperators::AND_BOOL_2`): `Q_BackgroundColour_1.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.
- `E_MERGE_QO` (`iec61499::events::E_MERGE_3`) merges `Q_BackgroundColour_2.INITO` and the `CNF` events of both instances (`Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF`) and thereby triggers `AND_QO.REQ`.



Summary



One of many variants in the background color block family: color pair Rot/Weiß, 2 objects, adapter selector.

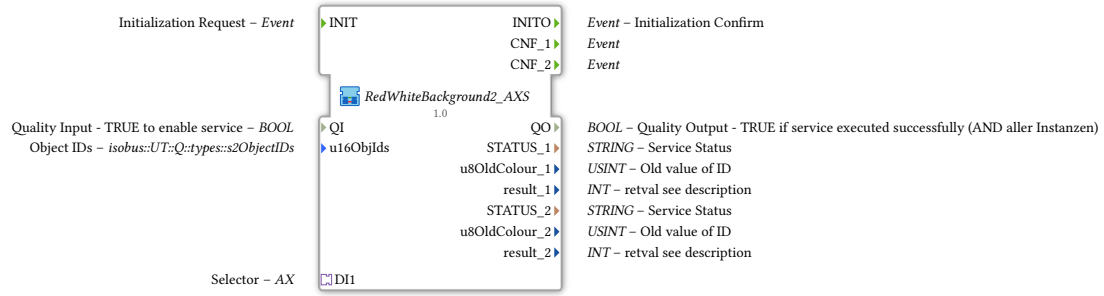
RedWhiteBackground2_AXS



• – ○ • – ○ • – ○ •

Introduction

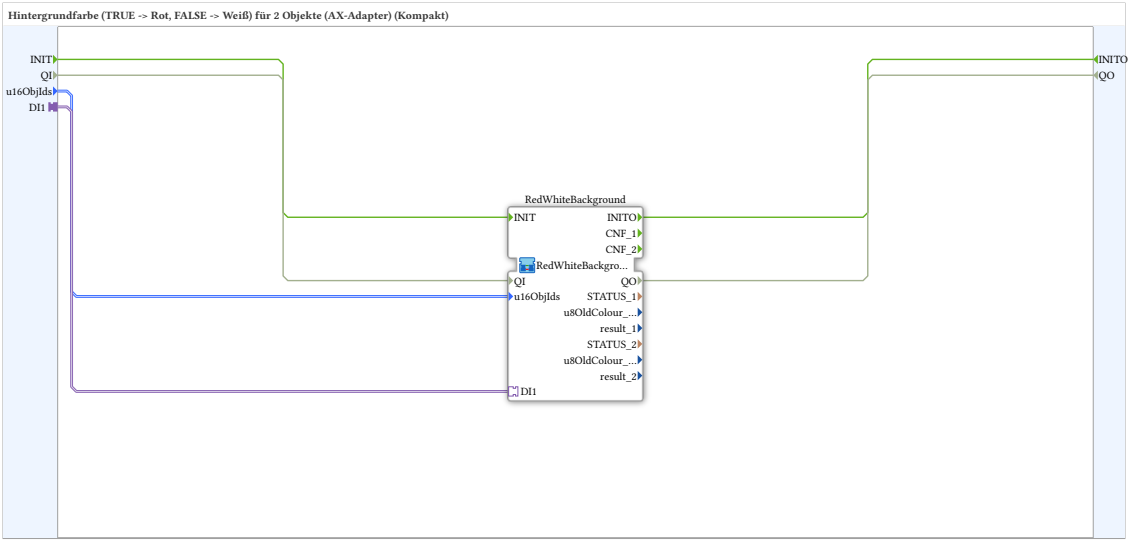
`RedWhiteBackground2_AXS` switches the VT background color of 2 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

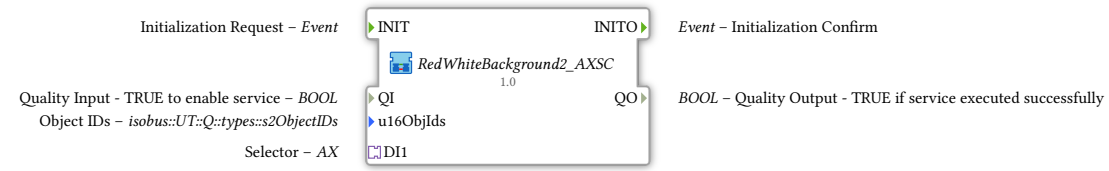
For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `Q_BackgroundColour_1.QI` and `Q_BackgroundColour_2.QI`
- **Data output** `QO` (`BOOL`, Quality Output): AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_2`) of the `QO` outputs of `Q_BackgroundColour_1.QO` and `Q_BackgroundColour_2.QO`
- **Initialization chain**: `INIT` ⟶ `Q_BackgroundColour_1.INIT`, `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` ⟶ `INITO`
- `E_MERGE_QO` (type `iec61499::events::E_MERGE_3`) merges `Q_BackgroundColour_2.INITO`, `Q_BackgroundColour_1.CNF` and `Q_BackgroundColour_2.CNF` and triggers `AND_QO.REQ`



Summary



One of many variants in the background color block family: color pair Rot/Weiß, 2 objects, adapter selector, struct. object ID.

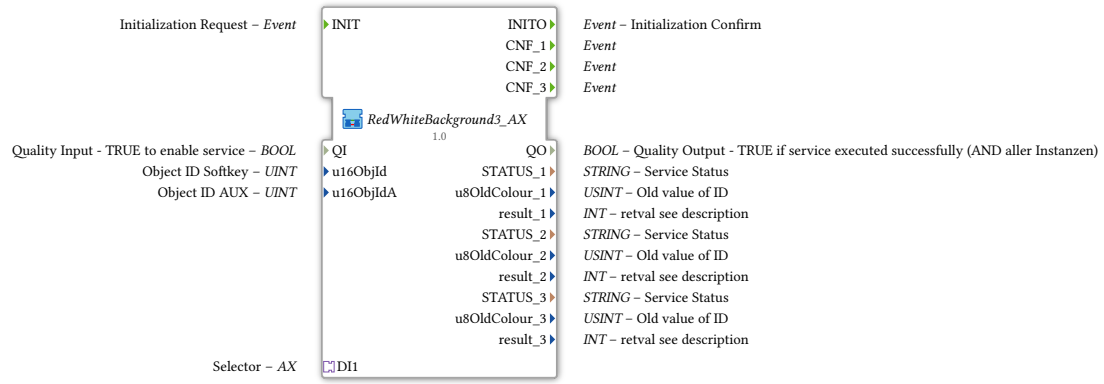
RedWhiteBackground3_AX

• – ○ • – ○ • – ○ •



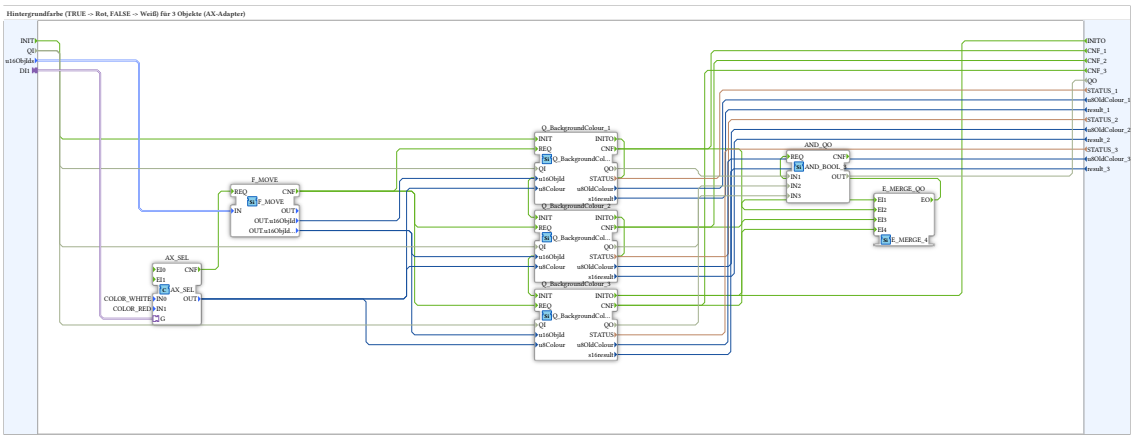
Introduction

`RedWhiteBackground3_AX` switches the VT background color of 3 objects based on a boolean selector signal: `TRUE` → **Rot**, `FALSE` → **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA`.

Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

Initialization and quality: In addition to the previous events, the block has the event input `INIT`, the event output `INITO`, as well as `QI` (BOOL, input, initial value `TRUE`) and `QO` (BOOL, output, AND of all instances). Init chain: `INIT` → `Q_BackgroundColour_1` → `Q_BackgroundColour_2` → `Q_BackgroundColour_3` → `INITO` (each `INITO` → next `INIT`). `QI` is passed on to all `Q_BackgroundColour_n.QI`. `QO` is formed by `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`): `Q_BackgroundColour_1.QO` → `AND_QO.IN1`, `Q_BackgroundColour_2.QO` → `AND_QO.IN2`, `Q_BackgroundColour_3.QO` → `AND_QO.IN3`, `AND_QO.OUT` → `QO`. `E_MERGE_QO` (`E_MERGE_4`) merges `Q_BackgroundColour_3.INITO` and the `CNF` outputs `Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF`, `Q_BackgroundColour_3.CNF`; `E_MERGE_QO.EO` triggers `AND_QO.REQ`.

For the general pattern (selector → `AX_SEL/F_SEL` → `Q_BackgroundColour`), see Background Color Blocks (shared pattern).



Summary

One of many variants in the background color block family: color pair Rot/Weiß, 3 objects, adapter selector.

🌐 Related topic subpages on ms-muc-docs.de

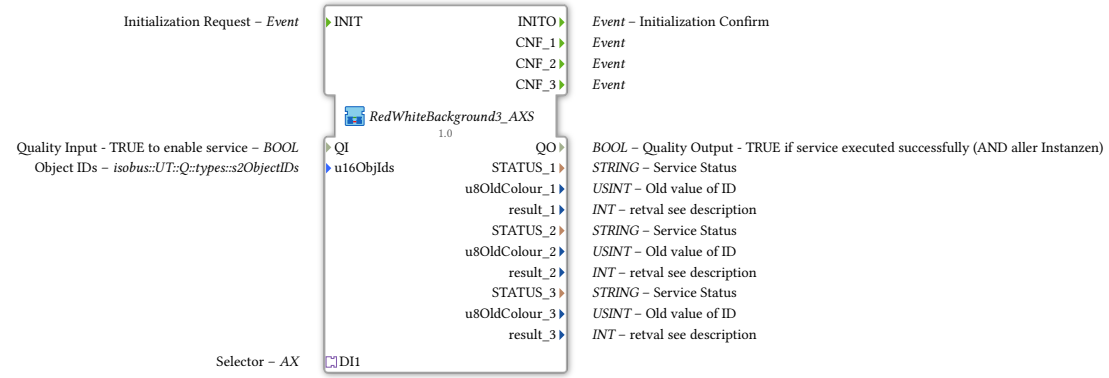
RedWhiteBackground3_AXS

• – ○ • – ○ • – ○ •



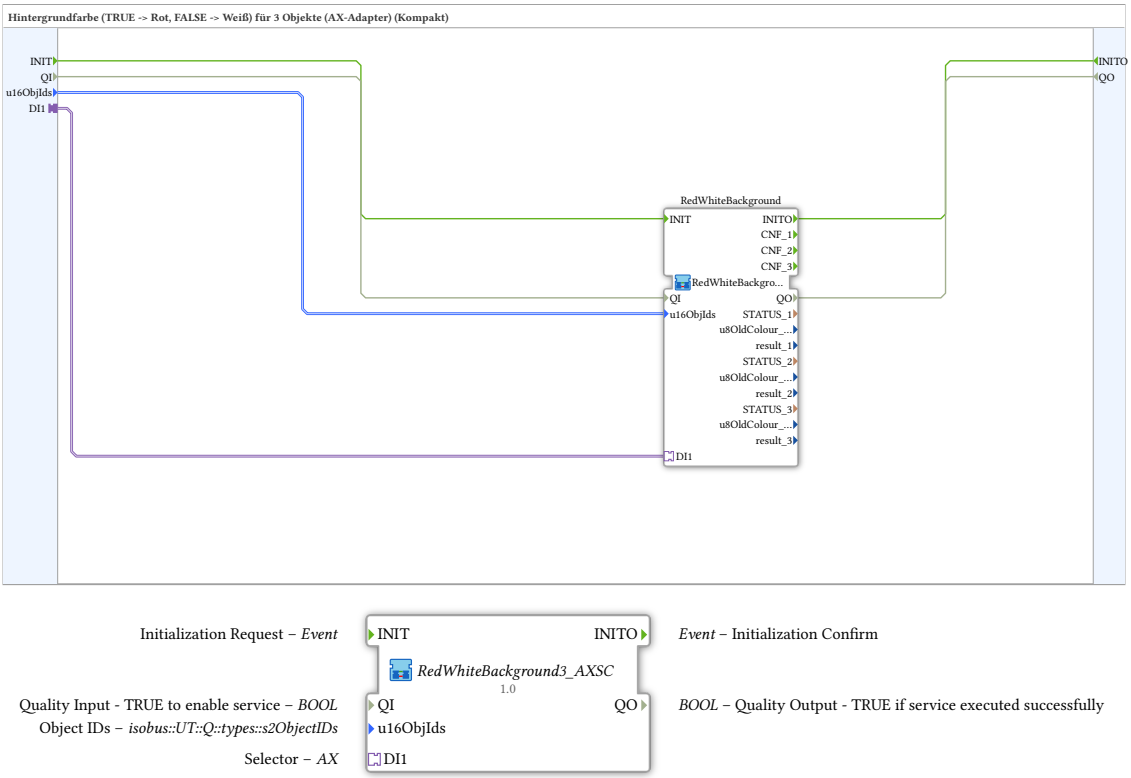
Introduction

`RedWhiteBackground3_AXS` switches the VT background color of 3 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

In addition, the block has the initialization and quality interface: event input `INIT`, event output `INITO`, data input `QI` (`BOOL`, initial value `TRUE`) and data output `QO` (`BOOL`, AND of all instances). `INIT` ⟶ `Q_BackgroundColour_1.INIT`, `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`, `Q_BackgroundColour_3.INITO` ⟶ `INITO` (so the three instances are initialized one after another). `QI` is passed to `QI` of all three instances. `QO` is the output of the instance `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`), which combines `Q_BackgroundColour_1.QO`, `Q_BackgroundColour_2.QO` and `Q_BackgroundColour_3.QO`; its `REQ` is triggered by `E_MERGE_QO` (`iec61499::events::E_MERGE_4`), which merges `Q_BackgroundColour_3.INITO` and the `CNF` events of the three instances.



Summary

One of many variants in the background color block family: color pair Rot/Weiß, 3 objects, adapter selector, struct. object ID.

RedWhiteBackground3_AXSC

• — ○ • — ○ • — ○ •

Introduction

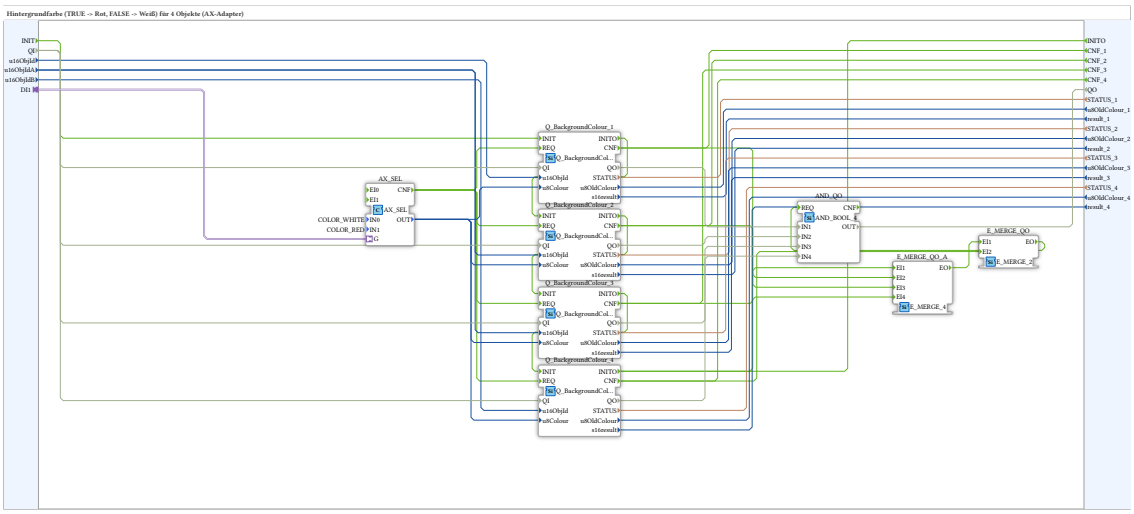
`RedWhiteBackground3_AXSC` is a **compact wrapper** around `RedWhiteBackground3_AXS` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

For the shared pattern, see Background Color Blocks (shared pattern).

Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`) are passed through: `INIT` → `RedWhiteBackground.INIT`; `RedWhiteBackground.INITO` → `INITO`.
- **Data input `QI`** (`BOOL`, default `TRUE`) → `RedWhiteBackground.QI`; **data output `QO`** (`BOOL`) ← `RedWhiteBackground.QO`.

The inner SubApp instance `RedWhiteBackground` is of type `RedWhiteBackground3_AXS`.



Summary

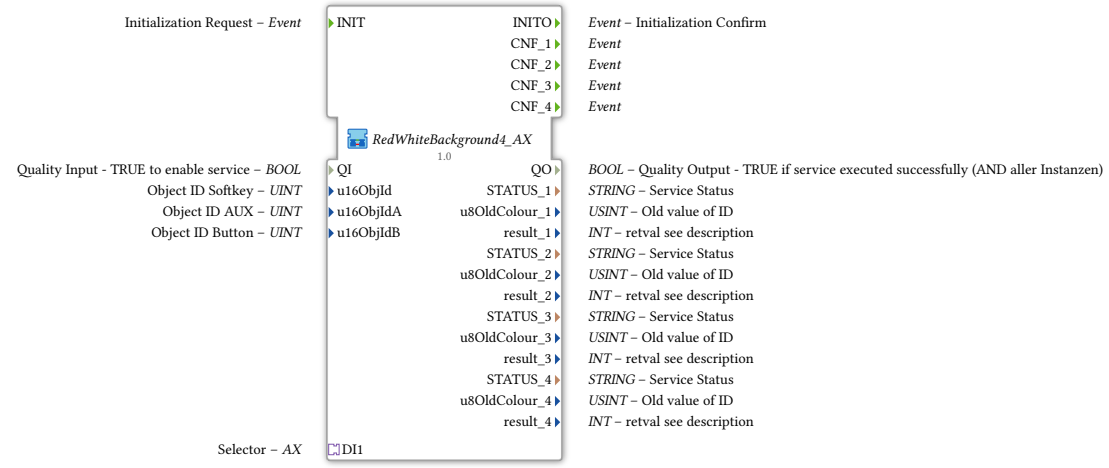
A pure pass-through to `RedWhiteBackground3_AXS` for the common case where the diagnostic values aren't needed.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

RedWhiteBackground4_AX

• – ○ • – ○ • – ○ •



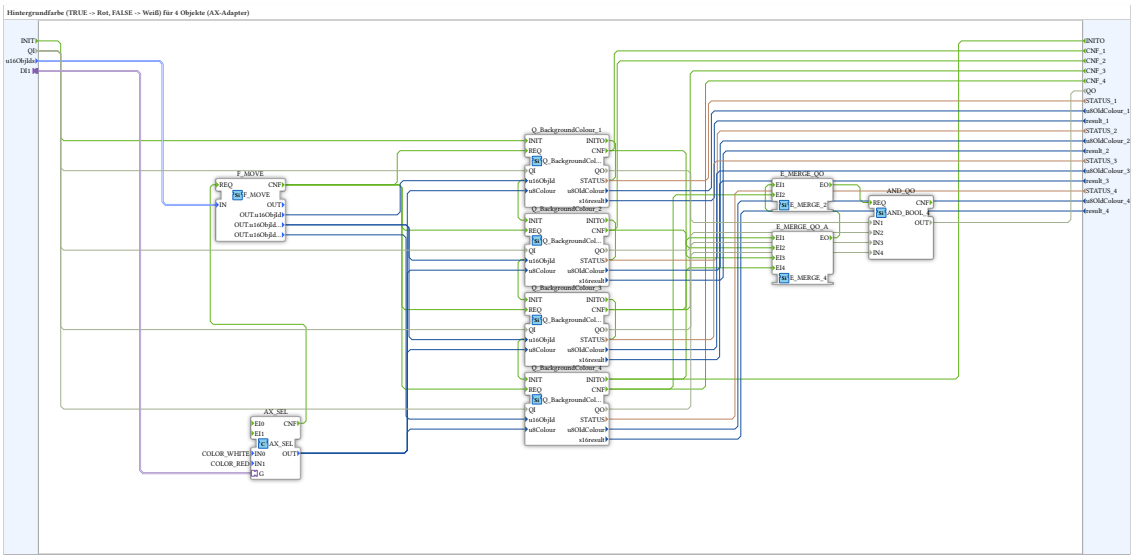
Introduction

`RedWhiteBackground4_AX` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` → **Rot**, `FALSE` → **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA, u16ObjIdB`.

Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`u16ObjIdB`	`Q_BackgroundColour` (regular object)

Interface (quality pattern): event input `INIT` and event output `INITO` (each `EInit`), data input `QI` (`BOOL`, default `TRUE`) and data output `QO` (`BOOL`, AND of all instances). Initialization: `INIT` → `Q_BackgroundColour_1.INIT`; `Q_BackgroundColour_1.INITO` → `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` → `Q_BackgroundColour_3.INIT`; `Q_BackgroundColour_3.INITO` → `Q_BackgroundColour_4.INIT`; `Q_BackgroundColour_4.INITO` → `INITO`. Quality: `QI` → `Q_BackgroundColour_1.QI`, `Q_BackgroundColour_2.QI`, `Q_BackgroundColour_3.QI`, `Q_BackgroundColour_4.QI`; `Q_BackgroundColour_1.QO`, `Q_BackgroundColour_2.QO`, `Q_BackgroundColour_3.QO`, `Q_BackgroundColour_4.QO` → `AND_QO.IN1` to `AND_QO.IN4` (`AND_QO`: `iec61131::booleanOperators::AND_BOOL_4`); `AND_QO.OUT` → `QO`. The trigger `AND_QO.REQ` comes via two merge blocks: `E_MERGE_QO_A` (`E_MERGE_4`) merges `Q_BackgroundColour_4.INITO` and the `CNF` of `Q_BackgroundColour_1` to _3, and `E_MERGE_QO` (`E_MERGE_2`) merges its output with `Q_BackgroundColour_4.CNF`; `E_MERGE_QO.EO` → `AND_QO.REQ`.

For the general pattern (selector → `AX_SEL/F_SEL` → `Q_BackgroundColour`), see Background Color Blocks (shared pattern).



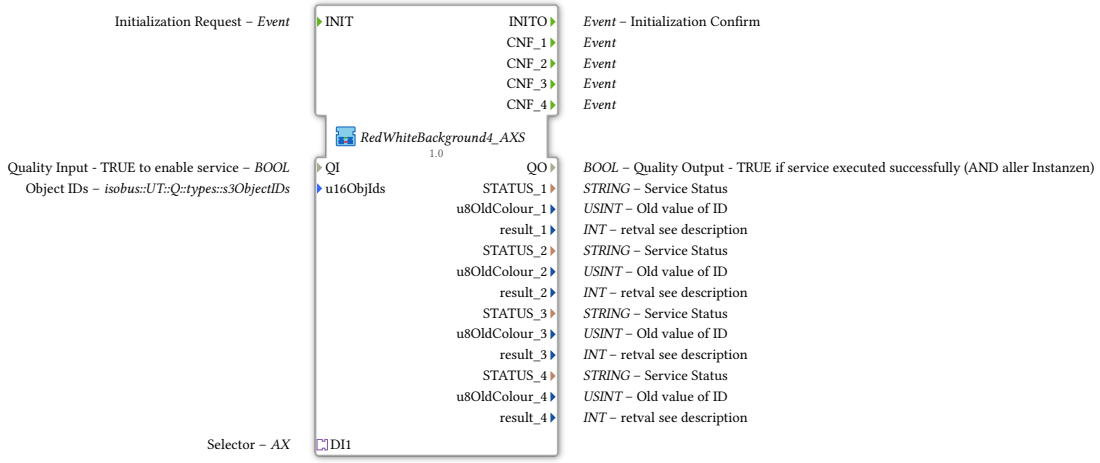
Summary

One of many variants in the background color block family: color pair Rot/Weiß, 4 objects, adapter selector.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

RedWhiteBackground4_AXS



• — ○ • — ○ • — ○ •

Introduction

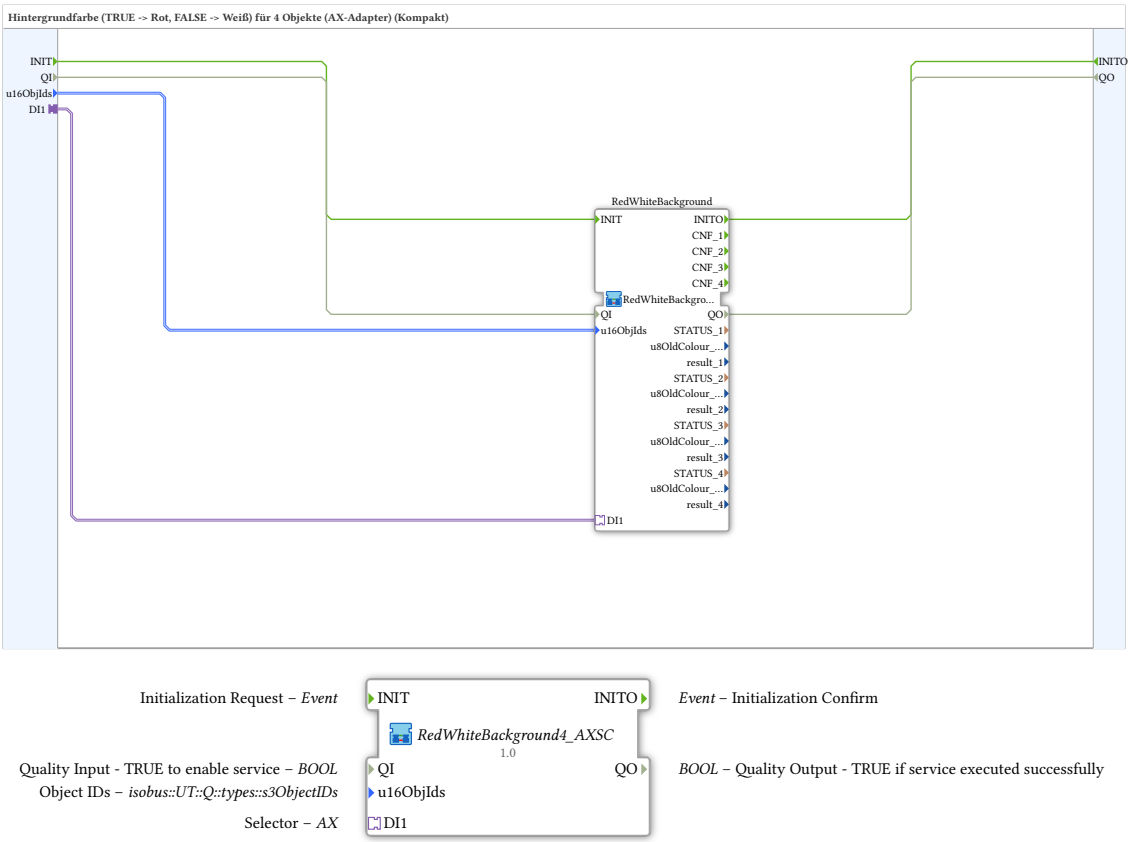
`RedWhiteBackground4_AXS` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Weiß**. The selector signal arrives via an `AX` adapter socket (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`F_MOVE.OUT.u16ObjIdB`	`Q_BackgroundColour` (regular object)

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `Q_BackgroundColour_1.QI`, `Q_BackgroundColour_2.QI`, `Q_BackgroundColour_3.QI` and `Q_BackgroundColour_4.QI`
- **Data output** `QO` (`BOOL`, Quality Output): AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_4`) of the `QO` outputs of `Q_BackgroundColour_1.QO`, `Q_BackgroundColour_2.QO`, `Q_BackgroundColour_3.QO` and `Q_BackgroundColour_4.QO`
- **Initialization chain**: `INIT` ⟶ `Q_BackgroundColour_1.INIT`, `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`, `Q_BackgroundColour_3.INITO` ⟶ `Q_BackgroundColour_4.INIT`, `Q_BackgroundColour_4.INITO` ⟶ `INITO`
- `E_MERGE_QO_A` (type `iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_4.INITO`, `Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF` and `Q_BackgroundColour_3.CNF` and passes the result to `E_MERGE_QO.EI1`
- `E_MERGE_QO` (type `iec61499::events::E_MERGE_2`) merges `E_MERGE_QO_A.EO` and `Q_BackgroundColour_4.CNF` and triggers `AND_QO.REQ`



Summary

One of many variants in the background color block family: color pair Rot/Weiß, 4 objects, adapter selector, struct. object ID.

SRT_RPC_FROM_Remote_QXA_OPC

• — ○ • — ○ • — ○ •

Introduction

SRT_RPC_FROM_Remote_QXA_OPC is a composite subapplication designed for device B (Station 12, IP 192.168.1.12) that receives Set, Reset, and Toggle commands via three independent OPC-UA server method calls. Unlike approaches that rely on value-change tricks or bridging, this subapp uses pure RPC triggers — each command is delivered through its own `SERVER_0` method invocation initiated by device A.

The subapp contains the actual flip-flop logic based on the `AX_T_FF_SR` adapter, which combines SR and toggle behavior. The resulting state drives a physical digital output (`DigitalOutput_Q1`) and is actively written back to device A via an `AX_CLIENT_1_0` client, ensuring that the central controller always has the current output state. The entire protocol is encapsulated within the `MyLib::sys` composite, following a "SUB style" design where the resource of the device remains free of protocol-specific logic.

Interface Structure

The subapplication exposes the events `INIT`/`INITO`, the data `QI`/`QO` and the data inputs for output and addresses at its boundary; it has no external adapters.

Event Inputs

- **INIT** (`EInit`): initialization request; starts the init chain at `TRIGGER_SET_SERVER.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `STATE_CLIENT.INITO`, the end of the init chain

Data Inputs

Name	Type	Initial Value	Description
`QI`	`BOOL`	`TRUE`	Quality input; passed on to all five service FBs (three `SERVER_0`, `DigitalOutput_Q1`, `STATE_CLIENT`).
`Output`	`logiBUS::io::DQ::logiBUS_DO_S`	`logiBUS_DO::Invalid`	Identifies the target digital output (Output_Q1..Q8).

ID_SET_METHOD	WSTRING	—	Local method address (ACTION=CREATE_METHOD) for the Set method, invoked by device A via CALL_METHOD.
ID_RESET_METHOD	WSTRING	—	Local method address (ACTION=CREATE_METHOD) for the Reset method, invoked by device A via CALL_METHOD.
ID_TOGGLE_METHOD	WSTRING	—	Local method address (ACTION=CREATE_METHOD) for the Toggle method, invoked by device A via CALL_METHOD.
ID_STATE_WRITE	WSTRING	—	Remote target address (BOOL, ACTION=WRITE) for writing the flip-flop state back to device A.

Data Outputs

- **QO** (BOOL): quality output, AND combination (AND_QO, AND_BOOL_5) of the QO outputs of the three SERVER_0 instances, of DigitalOutput_Q1 and of STATE_CLIENT

Adapters

None at the subapplication interface. All adapter connections are internal to the network.

Functionality

The subapp implements a complete remote-controlled SR/T flip-flop with output feedback:

1. **Command reception**: Three SERVER_0 instances (TRIGGER_SET_SERVER, TRIGGER_RESET_SERVER, TRIGGER_TOGGLE_SERVER) each listen for a specific OPC-UA method call. Device A invokes these methods remotely to send Set, Reset, or Toggle commands.
2. **Flip-flop logic**: The incoming event from each server is forwarded to the AX_T_FF_SR block:
   - Set event (TRIGGER_SET_SERVER.IND) drives the S input ⟶ sets the output Q to TRUE.
   - Reset event (TRIGGER_RESET_SERVER.IND) drives the R input ⟶ sets the output Q to FALSE.
   - Toggle event (TRIGGER_TOGGLE_SERVER.IND) drives the CLK input ⟶ inverts the current Q state.
3. **Immediate response**: Each server's IND event is directly wired back to its own RSP output. This ensures the OPC-UA server thread is released instantly, preventing long blocking periods (a known issue fixed in version 1.1).
4. **Signal distribution**: The flip-flop output Q is fed into AX_SPLIT_2, which fans it out to two consumers:
   - **OUT1** ⟶ DigitalOutput_Q1 (logiBUS_QXA) — switches the physical digital output on the logiBUS device.
   - **OUT2** ⟶ STATE_CLIENT (AX_CLIENT_1_0) — sends the new state back to device A via an OPC-UA write operation at the address specified by ID_STATE_WRITE.
5. **Initialization and quality**: INIT is chained: INIT ⟶ TRIGGER_SET_SERVER ⟶ TRIGGER_RESET_SERVER ⟶ TRIGGER_TOGGLE_SERVER ⟶ DigitalOutput_Q1 ⟶ STATE_CLIENT (each INITO ⟶ next INIT); STATE_CLIENT.INITO ⟶ INITO and AND_QO.REQ. QI goes to all five FBs; their QO outputs go in this order to AND_QO.IN1 to AND_QO.IN5 (iec61131::booleanOperators::AND_BOOL_5), AND_QO.OUT ⟶ QO.
6. **Configuration inputs**: All method addresses and the output channel are configured via the subapp's data inputs, making the block reusable for different method IDs and output channels without modifying the internal structure.

Technical Features

- **RPC-based trigger**: Commands are delivered as explicit OPC-UA method calls, eliminating the need for value-change detection tricks or intermediate bridge FBs.
- **Tailored server instances**: Separate `SERVER_0` for Set, Reset, and Toggle allows independent method addresses and clear segregation of control semantics.
- **Non-blocking response handling**: The `IND → RSP` direct connection prevents the open62541 server thread from being held, avoiding global `serviceMutex` contention (critical fix in version 1.1 that improved project-wide OPC-UA responsiveness).
- **Combined SR + T flip-flop**: The `AX_T_FF_SR` adapter provides both deterministic Set/Reset behavior and toggle functionality in one compact element.
- **Active state feedback**: The current flip-flop state is actively written back to the controlling device, ensuring synchronized state awareness without poll requests.
- **Protocol encapsulation**: All communication logic resides within the `MyLib::sys` composite, keeping the device resource clean and the subapp portable across resources and devices.
- **Structured configuration**: All network addresses and output identifiers are externalized as WSTRING/ struct inputs, enabling easy adaptation to different OPC-UA topologies.

State Overview

The core state machine is implemented by the `AX_T_FF_SR` block, which operates as follows:

Input Event	Condition	Resulting State (Q)
Set (`S`)	Always	`TRUE`
Reset (`R`)	Always	`FALSE`
Toggle (`CLK`)	Rising edge	Invert current Q: `TRUE → FALSE` or `FALSE → TRUE`

- **Initial state**: `FALSE` (after startup or explicit Reset).
- **Stable states**: `TRUE` (output active) or `FALSE` (output inactive), with no undefined or metastable conditions.
- **Conflict handling**: If Set and Reset arrive simultaneously, priority behavior follows the `AX_T_FF_SR` adapter semantics (typically Reset dominates, depending on the underlying implementation).

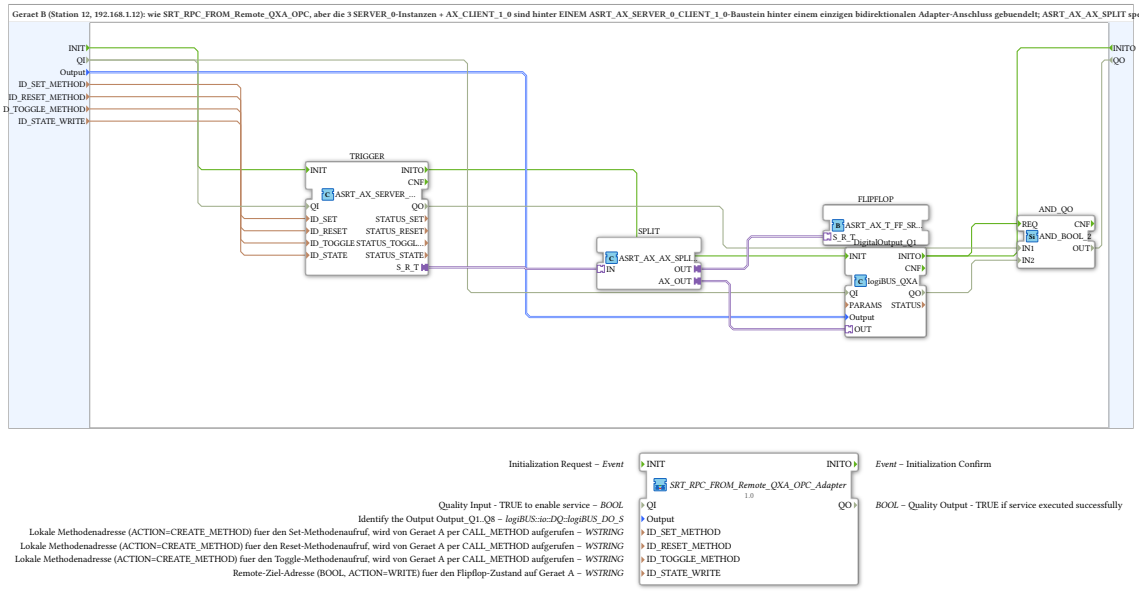
The `Q` output is then split and routed to both the digital output and the remote feedback client, so the observed physical state always matches the state reported back to device A.

Application Scenarios

- **Remote output control**: A central controller (device A) remotely sets, resets, or toggles digital output Q1 on a field device (device B) over OPC-UA.
- **Distributed automation networks**: Coordinating outputs across multiple stations (e.g., Station 12 in a larger plant) where each station hosts its own OPC-UA server and receives commands on demand.
- **State-synchronized systems**: Scenarios where the controller must know the exact output state after each command — the active write-back via `CLIENT_1_0` guarantees this without extra polling.
- **Integration in machine safety or indicator logic**: Toggle functionality is useful for alternating signals (blinking lamps, periodic valve switching), while Set/Reset provides deterministic latching.

Comparison with Similar Blocks

Feature	SRT_RPC_FROM_Remote_QXA_OPC	Typical local I/O FB	Bridge-based remote FB
Command transport	OPC-UA method calls (RPC)	Local event connections	Value-change signals
State feedback	Active write-back via client	Direct wiring	Requires extra feedback FB
Server thread blocking	Avoided (IND→RSP direct)	N/A	Can block if RSP unconnected
Protocol location	Inside subapp (SUB style)	In resource	In resource



Reusability	High — copy subapp between devices	Low — tied to resource	Medium
Toggle capability	Built-in (`AX_T_FF_SR`)	Usually only Set/Reset	Depends on logic

Compared to a bridge-based solution that translates value changes into commands, this subapp provides a cleaner, semantically richer interface. Compared to placing the protocol in the device resource, the SUB style allows the same communication pattern to be reused across multiple devices without duplicating resource-level wiring.

Conclusion

SRT_RPC_FROM_Remote_QXA_OPC is a well-structured subapplication that encapsulates remote OPC-UA-based control of a digital output in a compact, reusable composite. Its three dedicated server instances allow precise Set, Reset, and Toggle semantics through pure RPC calls, while the direct `IND→RSP` wiring ensures responsive OPC-UA behavior. The integrated `AX_T_FF_SR` flip-flop provides reliable state management, and the active feedback via `CLIENT_1_0` keeps the controlling device synchronized. By keeping all protocol logic inside the subapp, the design enhances modularity, reusability, and maintainability across distributed IEC 61499 applications.

SRT_RPC_FROM_Remote_QXA_OPC_Adapter

• — ○ • — ○ • — ○ •

Introduction

The **SRT_RPC_FROM_Remote_QXA_OPC_Adapter** is a subapplication (SUB-style) that provides remote control of a digital output (QXA) via a single bidirectional adapter connection. It is intended for Device B (Station 12, 192.168.1.12) and is structurally an optimized variant of the SRT_RPC_FROM_Remote_QXA_OPC subapplication: instead of exposing multiple server/client instances separately, all protocol handling is bundled behind one `ASRT_AX_SERVER_0_CLIENT_1_0` block, and the incoming adapter stream is split to drive both the digital output and a Set/Reset/Toggle flip-flop logic. The communication protocol itself is embedded in the MyLib::sys composite type, not in the device resource.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; goes to `TRIGGER.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirm; comes from `DigitalOutput_Q1.INITO`

Data Inputs

Name	Type	Initial Value	Description
QI	BOOL	TRUE	Quality input - TRUE enables the service; goes to TRIGGER.QI and DigitalOutput_Q1.QI.
Output	logiBUS::io::DQ::logiBUS_DQ_8	logiBUS_DO::Invalid	Identifies which physical output (Q1..Q8) is to be controlled.
ID_SET_METHOD	WSTRING	–	Local method address (ACTION=CREATE_METHOD) used for the Set method call, invoked remotely by Device A via CALL_METHOD.
ID_RESET_METHOD	WSTRING	–	Local method address used for the Reset method call, invoked remotely by Device A via CALL_METHOD.
ID_TOGGLE_METHOD	WSTRING	–	Local method address used for the Toggle method call, invoked remotely by Device A via CALL_METHOD.
ID_STATE_WRITE	WSTRING	–	Remote target address (BOOL, ACTION=WRITE) for writing back the flip-flop state to Device A.

Data Outputs

- **QO** (BOOL): quality output - TRUE if the service was executed successfully (AND of TRIGGER.QO and DigitalOutput_Q1.QO)

Adapters

The subapplication exposes no interface-level adapter ports. All adapter communication is performed internally through the TRIGGER block, which bundles the server/client functionality. No external adapter is visible at the subapplication boundary.

Functionality

The subapplication processes an incoming bidirectional adapter stream that carries Set, Reset, and Toggle commands from a remote device (Device A). The internal flow is as follows:

1. **TRIGGER** (adapter::net::ASRT_AX_SERVER_0_CLIENT_1_0) – receives the remote command stream over its S_R_T adapter port. Its data inputs are bound to the subapplication's method address variables (ID_SET_METHOD, ID_RESET_METHOD, ID_TOGGLE_METHOD, ID_STATE_WRITE) to enable remote method invocation. QI is passed on from the subapplication input QI.
2. **SPLIT** (adapter::events::bidirectional::ASRT_AX_AX_SPLIT) – takes the incoming stream from TRIGGER.S_R_T and splits it into two parallel paths:
   - OUT → forwarded to the flip-flop logic
   - AX_OUT → forwarded to the digital output block

3. **FLIPFLOP** (`adapter::events::bidirectional::ASRT_AX_T_FF_SR_2`) – implements the Set/Reset/Toggle flip-flop behavior. It consumes the `OUT` path from the splitter and maintains the internal state. The current state is written back to Device A using the `ID_STATE_WRITE` remote address.
4. **DigitalOutput_Q1** (`logiBUS::io::DQ::logiBUS_QXA`) – receives the `AX_OUT` path from the splitter and drives the physical output selected by the `Output` data input. `QI` is passed on to it as well.

Initialization and quality: `INIT` → `TRIGGER.INIT`, `TRIGGER.INITO` → `DigitalOutput_Q1.INIT`, `DigitalOutput_Q1.INITO` → `INITO` and → `AND_QO.REQ`. `QO` is the output of the instance `AND_QO` (`iec61131::booleanOperators::AND_BOOL_2`), which combines `TRIGGER.QO` and `DigitalOutput_Q1.QO`.

The data flow ensures that the same incoming command stream simultaneously updates both the flip-flop state and the physical output, while maintaining a single bidirectional adapter connection to the remote controller.

Technical Features

- **Single bundled adapter connection**: All three server instances and one client instance are consolidated behind a single `ASRT_AX_SERVER_0_CLIENT_1_0` block, reducing connection complexity at the subapplication boundary.
- **Method-based remote control**: Set, Reset, and Toggle operations are exposed as local methods (CREATE_METHOD) and invoked remotely via CALL_METHOD, with addresses supplied through WSTRING inputs.
- **Bidirectional state synchronization**: The flip-flop state is written back to the remote device via a configurable target address (`ID_STATE_WRITE`), enabling closed-loop monitoring.
- **Signal splitting**: The `ASRT_AX_AX_SPLIT` block distributes the incoming adapter stream to two consumers without losing information.
- **SUB-style architecture**: Protocol logic is contained within the MyLib::sys composite type, keeping the device resource free from protocol-specific configuration.
- **Output selection**: The physical output (Q1..Q8) is selected at runtime via the `Output` data input.

State Overview

The internal state machine is governed by the `ASRT_AX_T_FF_SR_2` flip-flop, which combines Set (S), Reset (R), and Toggle (T) semantics:

- **Set**: Forces the flip-flop output to TRUE.
- **Reset**: Forces the flip-flop output to FALSE.
- **Toggle**: Inverts the current flip-flop output.

The flip-flop state is kept consistent with the physical output `DigitalOutput_Q1` because both are driven by the same split adapter stream. The current state is reported back to the remote device via the write address provided in `ID_STATE_WRITE`.

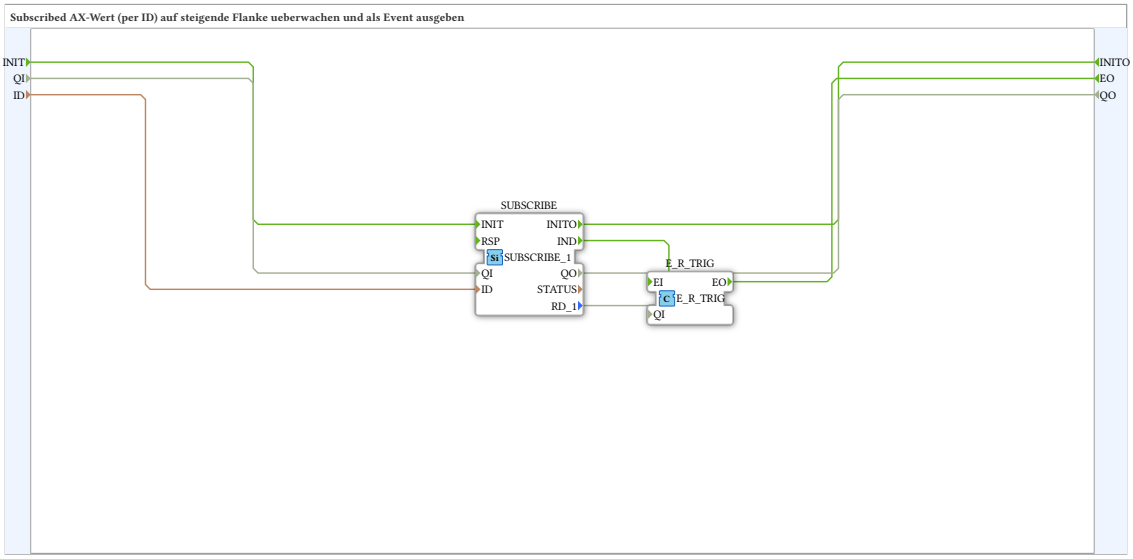
Application Scenarios

- **Remote I/O control over LAN**: Device A (a controller or HMI) issues Set/Reset/Toggle commands to Device B over an Ethernet link, controlling a discrete digital output on Device B.
- **Distributed automation cells**: Suitable for stations where a single bidirectional channel must carry both control commands and status feedback for a flip-flop-driven actuator.
- **PLC-to-PLC communication**: Can be used in multi-device production lines where a central PLC manages outputs on peripheral stations via structured method calls.
- **Reusable subapplication**: Because the protocol stack is embedded in a composite type, the subapplication can be instantiated multiple times within the same device or across devices without resource-level modifications.

Comparison with Similar Blocks

Compared to its predecessor **SRT_RPC_FROM_Remote_QXA_OPC**, this subapplication offers the following differences:

Aspect	SRT_RPC_FROM_Remote_QXA_OPC	SRT_RPC_FROM_Remote_QXA_OPC_Adapter
Adapter ports	Three separate SERVER_0 instances plus one AX_CLIENT_1_0	One bundled `ASRT_AX_SERVER_0_CLIENT_1_0` behind a single bidirectional port

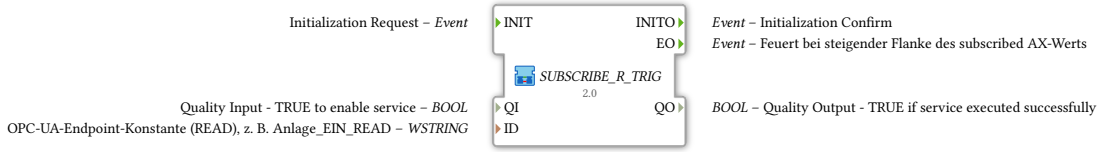


Signal distribution	Dedicated wiring per function	Centralized splitting via `ASRT_AX_AX_SPLIT`
Flip-flop integration	Separate logic paths	Shared adapter stream feeding both output and flip-flop
Resource footprint	Higher (more connections)	Lower (reduced connection count)

The bundled approach reduces wiring overhead and makes the subapplication easier to integrate into larger systems.

Conclusion

The **SRT_RPC_FROM_Remote_QXA_OPC_Adapter** subapplication provides a compact, protocol-encapsulated solution for remote digital output control with flip-flop semantics. By bundling server/client functionality behind a single adapter connection and using a splitter to feed both the output stage and the state logic, it achieves a clean and efficient design. Its method-based RPC architecture and state write-back capability make it well suited for distributed automation environments where centralized control of remote I/O is required.



SUBSCRIBE_R_TRIG

• – ○ • – ○ • – ○ •

Introduction

`SUBSCRIBE_R_TRIG` monitors a `AX` value (BOOL) subscribed to via OPC UA for a rising edge and outputs it as a single event (`EO`). This allows a remotely set BOOL value to be used directly as a triggering event without having to process the level itself further.

Function Blocks (FBs) Used

Sub-Blocks: SUBSCRIBE_R_TRIG

- **Type**: SubAppType
- **Internal FBs Used**:
- **SUBSCRIBE**: `iec61499::net::SUBSCRIBE_1` — subscribes to the remote BOOL value (`ID`, e.g., `Anlage_EIN_READ`).

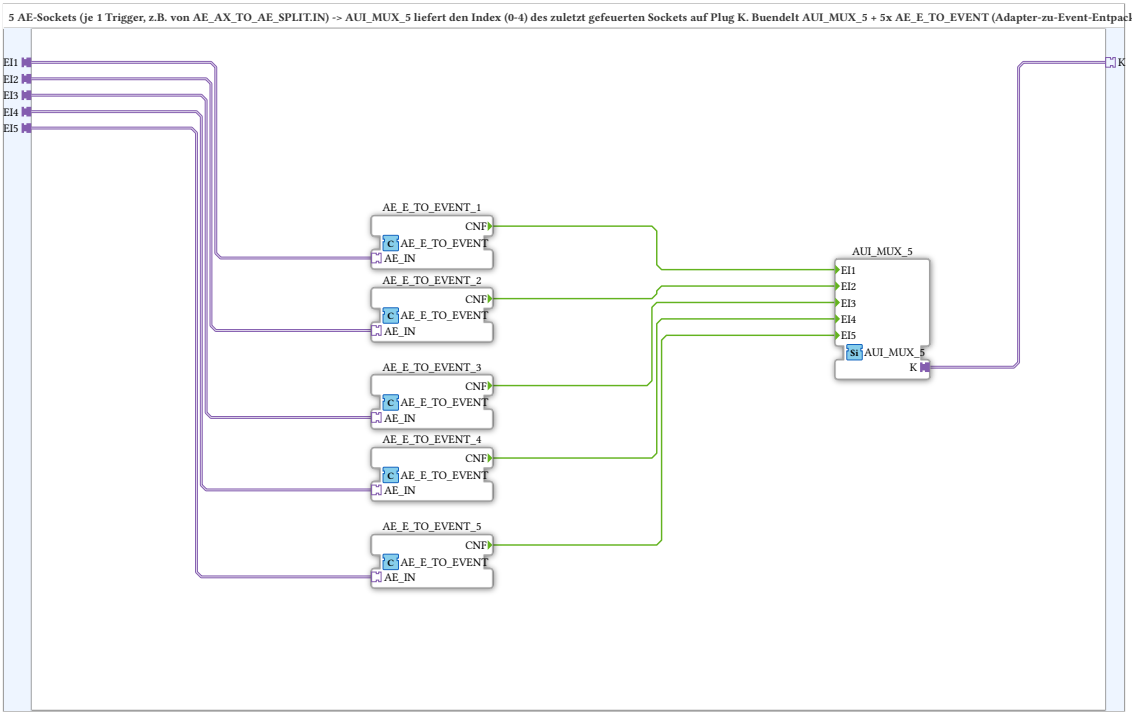
- **E_R_TRIG**: `iec61499::events::E_R_TRIG` — detects the rising edge of the subscribed value and fires `EO`.
- **How it Works**: Since version 2.0 the raw `SUBSCRIBE_1` and `E_R_TRIG` are wired directly (no duplicate edge memory any more): `SUBSCRIBE.IND` and `SUBSCRIBE.RD_1` go directly into `E_R_TRIG`, whose edge detection triggers the SubApp event `EO`.
- **Interface**: event input `INIT` (`EInit`), event outputs `INITO` (`EInit`) and `EO`; data inputs `QI` (`BOOL`, default `TRUE`) and `ID` (`WSTRING`); data output `QO` (`BOOL`).

Program Flow and Connections

1. `ID` ⟶ `SUBSCRIBE.ID` (Data connection, hidden).
2. `SUBSCRIBE.IND` ⟶ `E_R_TRIG.EI`; `SUBSCRIBE.RD_1` ⟶ `E_R_TRIG.QI`.
3. `E_R_TRIG.EO` ⟶ `EO` (SubApp event output).
4. `INIT` ⟶ `SUBSCRIBE.INIT`; `SUBSCRIBE.INITO` ⟶ `INITO`.
5. `QI` ⟶ `SUBSCRIBE.QI`; `SUBSCRIBE.QO` ⟶ `QO`.

Application Scenarios

- A remote OPC UA signal (e.g., “Plant ON”) should trigger a one-time event (e.g., start an initialization) instead of being processed as a continuous level.



Summary

`SUBSCRIBE_R_TRIG` directly combines OPC UA Subscribe with edge detection and delivers a single event on the rising edge of the remote value.

Select5_AE_AUI

• – ○ • – ○ • – ○ •

Introduction

`Select5_AE_AUI` accepts five `AE` sockets (one trigger each, e.g. from `AE_AX_TO_AE_SPLIT.IN`) and provides on plug `K` the index (0-4) of the socket that fired last. The block bundles `AUI_MUX_5` and five `AE_E_TO_EVENT` (adapter-to-event unpackers) into a reusable block.

Function Blocks (FBs) Used

Sub-blocks: Select5_AE_AUI

- **Type**: SubAppType
- **Internal FBs used**:
  - **AE_E_TO_EVENT_1** to **AE_E_TO_EVENT_5**: each `adapter::conversion::unidirectional::AE_E_TO_EVENT` - converts an `AE` adapter event into a normal event (`CNF`)
  - **AUI_MUX_5**: `adapter::events::unidirectional::AUI_MUX_5` - provides the index of the most recently active input on `K`

Interface Structure

Event Inputs / Event Outputs

None - events travel via the adapters.

Data Inputs / Data Outputs

No direct data ports.

Adapters

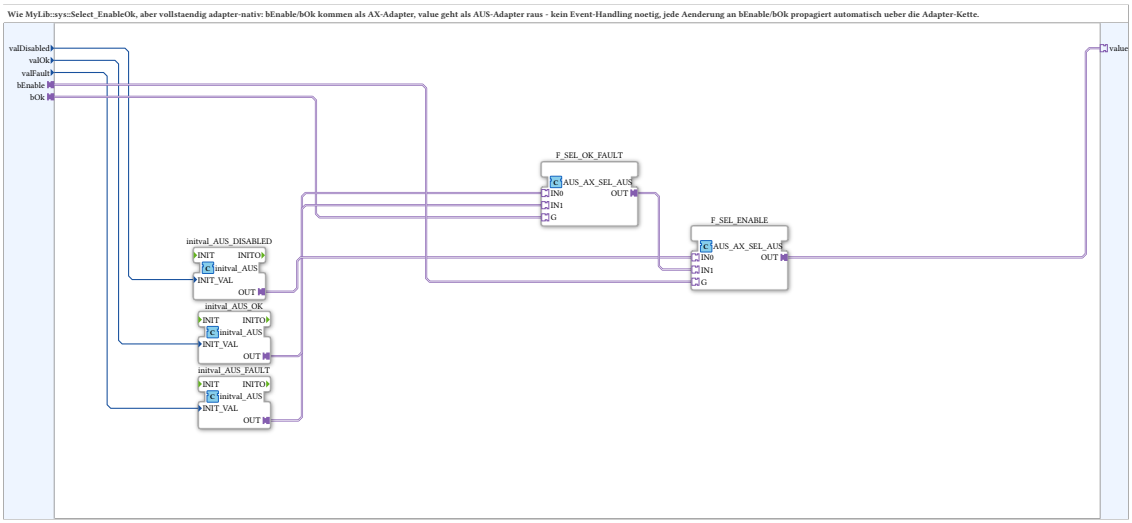
- **EI1** (socket, `adapter::types::unidirectional::AE`): Trigger 1 (index 0)
- **EI2** (socket, `AE`): Trigger 2 (index 1)
- **EI3** (socket, `AE`): Trigger 3 (index 2)
- **EI4** (socket, `AE`): Trigger 4 (index 3)
- **EI5** (socket, `AE`): Trigger 5 (index 4)
- **K** (plug, `adapter::types::unidirectional::AUI`): Index (0-4) of the socket that fired last

Program Flow and Connections

- `EI1`…`EI5` ⟶ `AE_E_TO_EVENT_1`…`AE_E_TO_EVENT_5` (`AE_IN`)
- `AE_E_TO_EVENT_n.CNF` ⟶ `AUI_MUX_5.EIn` (n = 1…5)
- `AUI_MUX_5.K` ⟶ `K`

Technical Details

- Index mapping: `EI1` ⟶ 0, `EI2` ⟶ 1, `EI3` ⟶ 2, `EI4` ⟶ 3, `EI5` ⟶ 4
- Version 1.0 (2026-09-12): encapsulated for the exclusive TECU speed source selection (5x `AE_AX_TO_AE_SPLIT.IN` as source)

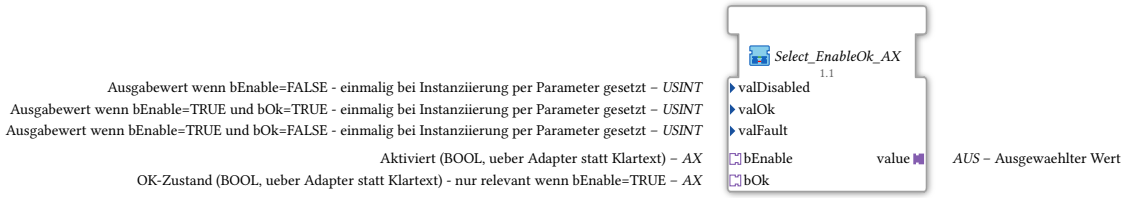


Application Scenarios

- Exclusive source selection: the most recently activated of five triggers determines the selected index (e.g. TECU speed source)

Summary

`Select5_AE_AUI` converts five `AE` triggers into the index of the most recently fired trigger as an `AUI` signal.



Select_EnableOk_AX

• – ○ • – ○ • – ○ •

Introduction

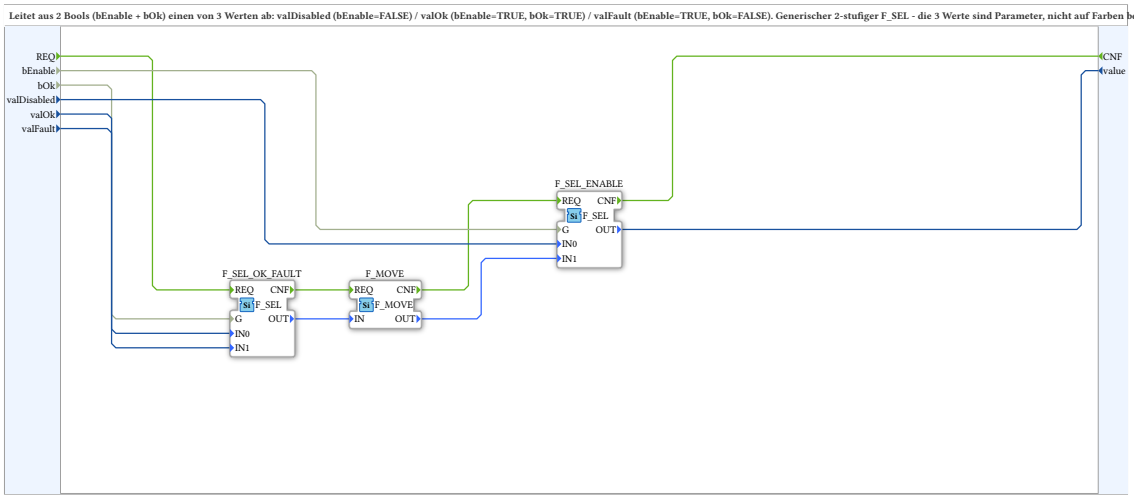
`Select_EnableOk_AX` is the adapter-native variant of `Select_EnableOk`: `bEnable`/`bOk` arrive as AX adapters (instead of plain BOOL), `value` leaves as an AUS adapter. No event handling needed - any change to `bEnable`/`bOk` propagates automatically through the adapter chain.

Function blocks used

- **initval_AUS_DISABLED** / **initval_AUS_OK** / **initval_AUS_FAULT** (`adapter::types::unidirectional::AUS::initval::initval_AUS`): feed the 3 parameter values (`valDisabled`/`valOk`/`valFault`) in as AUS adapters, once at instantiation.
- **F_SEL_OK_FAULT** (`adapter::iec61131::selection::AUS_AX_SEL_AUS`): selects between the fault/ok adapter based on `bOk` (adapter gate instead of an event selector).
- **F_SEL_ENABLE** (`adapter::iec61131::selection::AUS_AX_SEL_AUS`): selects between the disabled adapter/intermediate result based on `bEnable`.

Technical notes

- Two-stage like the event variant `Select_EnableOk`, but with no `REQ`/`CNF` at this level - the adapter connections themselves propagate every change.



Summary

Fully adapter-native variant of `Select_EnableOk`, matching the GreenBlueBackground1_AX/GreenRedBackground1_AX family's style.

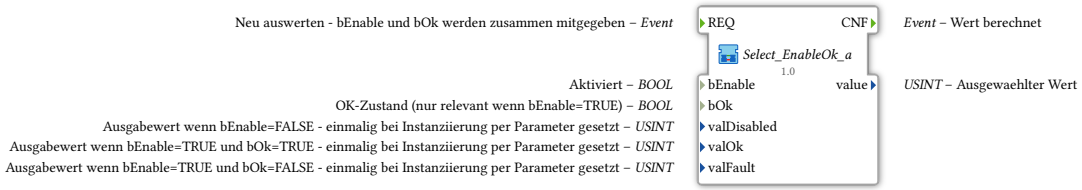
- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



Select_EnableOk_a

• — ○ • — ○ • — ○ •

Introduction

`Select_EnableOk_a` derives one of three values from two `BOOL` values (`bEnable` and `bOk`): `valDisabled` (`bEnable = FALSE`), `valOk` (`bEnable = TRUE`, `bOk = TRUE`) or `valFault` (`bEnable = TRUE`, `bOk = FALSE`). It is a generic, two-stage `F_SEL`; the three values are parameters and not restricted to colors.

Interface Structure

Event Inputs

- **REQ**: Re-evaluate - `bEnable` and `bOk` are supplied together

Event Outputs

- **CNF**: Value calculated

Data Inputs

- **bEnable** (`BOOL`): Enabled
- **bOk** (`BOOL`): OK state (only relevant if `bEnable = TRUE`)
- **valDisabled** (`USINT`): Output value if `bEnable = FALSE`; set once at instantiation via parameter
- **valOk** (`USINT`): Output value if `bEnable = TRUE` and `bOk = TRUE`; set once at instantiation via parameter
- **valFault** (`USINT`): Output value if `bEnable = TRUE` and `bOk = FALSE`; set once at instantiation via parameter

Data Outputs

- **value** (`USINT`): Selected value

Adapters

This function block uses no adapters.

Function Blocks (FBs) Used

- **F_SEL_OK_FAULT**: `iec61131::selection::F_SEL` - selects with `G = bOk` between `IN0 = valFault` and `IN1 = valOk`
- **F_MOVE**: `iec61131::selection::F_MOVE` (`DataType=USINT`) - passes the result on

- **F_SEL_ENABLE**: `iec61131::selection::F_SEL` - selects with `G = bEnable` between `IN0 = valDisabled` and `IN1` = result of `F_MOVE`

Program Flow and Connections

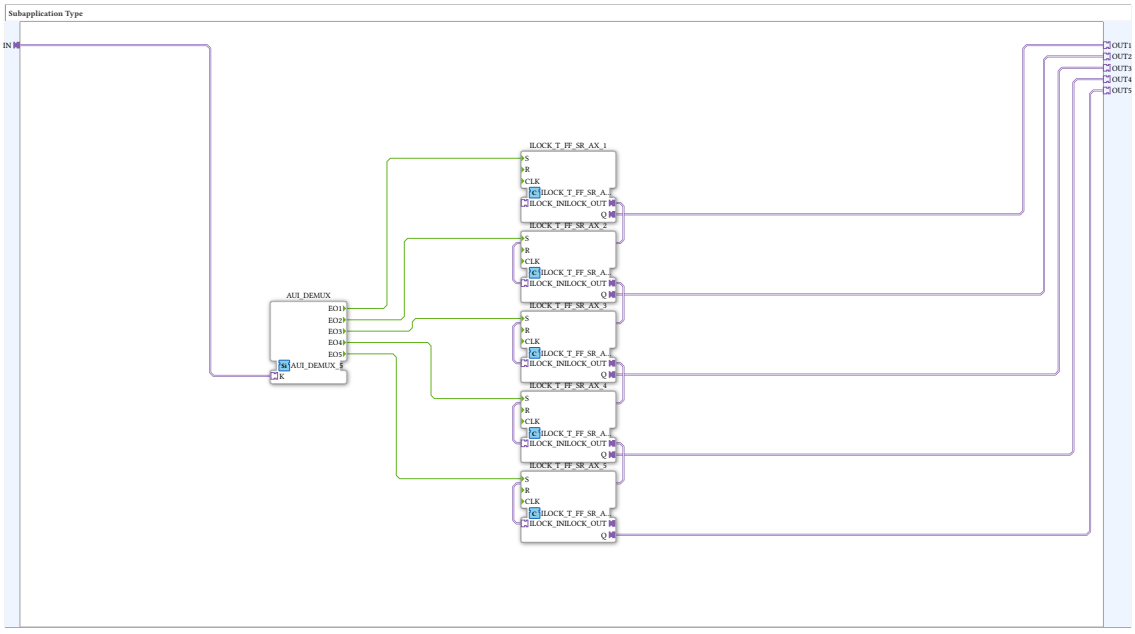
1. `REQ` ⟶ `F_SEL_OK_FAULT.REQ` ⟶ `F_MOVE.REQ` ⟶ `F_SEL_ENABLE.REQ` ⟶ `CNF` (event chain).
2. `bOk` ⟶ `F_SEL_OK_FAULT.G`; `valFault` ⟶ `IN0`; `valOk` ⟶ `IN1`.
3. `F_SEL_OK_FAULT.OUT` ⟶ `F_MOVE.IN` ⟶ `F_SEL_ENABLE.IN1`.
4. `bEnable` ⟶ `F_SEL_ENABLE.G`; `valDisabled` ⟶ `F_SEL_ENABLE.IN0`.
5. `F_SEL_ENABLE.OUT` ⟶ `value`.

Technical Details

- The value table:

bEnable	bOk	value
FALSE	any	`valDisabled`
TRUE	TRUE	`valOk`
TRUE	FALSE	`valFault`

- The three values are `USINT` and can be e.g. color codes, but also any other state values.
- The AX variant of the block is `Select_EnableOk_AX`.

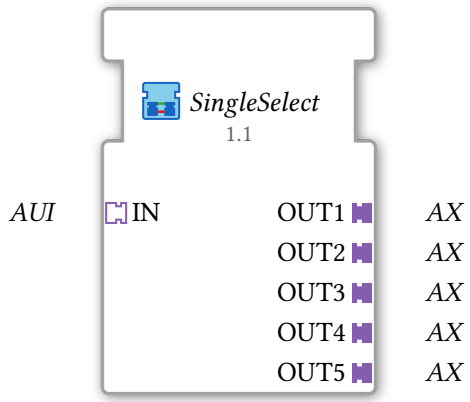


Application Scenarios

- Three-stage status display (off/ok/fault), e.g. color selection for a VT object

Summary

`Select_EnableOk_a` selects one of three parameterizable `USINT` values from enable and OK state.



SingleSelect

• – ○ • – ○ • – ○ •

Introduction

`SingleSelect` is a single selection (radio button behaviour) with five outputs: a selection index at the AUI socket `IN` activates exactly one of the five AX outputs `OUT1`..`OUT5`; the others are reset in the process. The interlocking is performed by a chain of five `ILOCK_T_FF_SR_AX`.

Interface Structure

Event Inputs

The function block has no direct event inputs.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

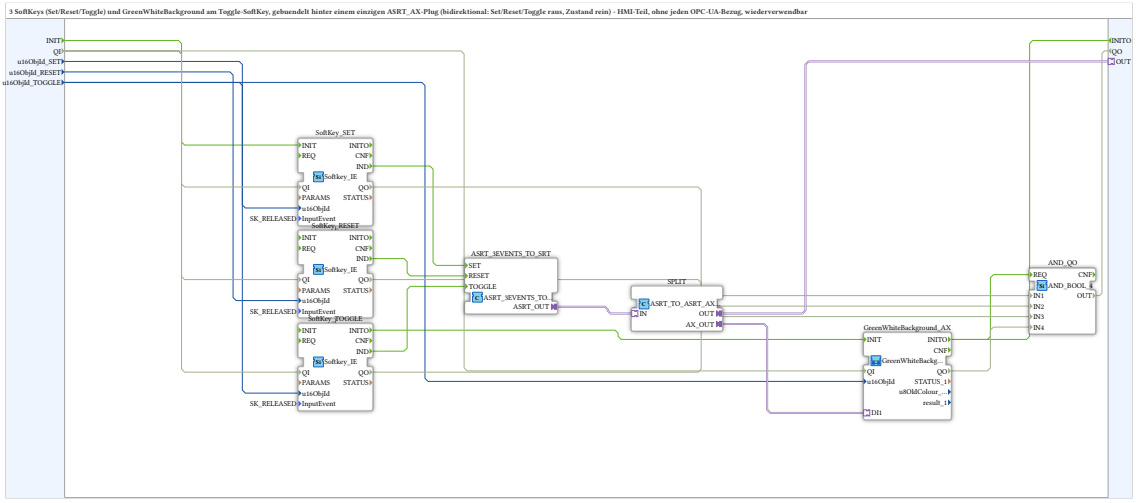
- **IN** (socket, `adapter::types::unidirectional::AUI`): selection index (UINT)
- **OUT1**..**OUT5** (plugs, `adapter::types::unidirectional::AX`): state of the five selection positions

Functionality

- `IN` ⟶ `AUI_DEMUX.K`: `AUI_DEMUX` (`adapter::events::unidirectional::AUI_DEMUX_5`) forwards the event depending on the index: `K = 0` ⟶ `EO1`, `K = 1` ⟶ `EO2`, `K = 2` ⟶ `EO3`, `K = 3` ⟶ `EO4`, `K = 4` ⟶ `EO5`.
- `AUI_DEMUX.EOn` ⟶ `ILOCK_T_FF_SR_AX_n.S` (n = 1..5): the selected flip-flop is set.
- `ILOCK_T_FF_SR_AX_n.Q` ⟶ `OUTn`: the state of each flip-flop appears at the associated output.
- `ILOCK_T_FF_SR_AX_n.ILOCK_OUT` ⟶ `ILOCK_T_FF_SR_AX_(n+1).ILOCK_IN` (n = 1..4): the five flip-flops are connected into a chain via their bidirectional `AE2` interlock adapters. When one element sets its output, it reports this through the chain and the other elements are reset (see `ILOCK_T_FF_SR_AX`).

Technical Details

- The block has no event or data ports; everything runs via adapters
- Version 1.1 tidied up the layout: `AUI_DEMUX_4` was renamed to `AUI_DEMUX` (the `_4` had no meaning)
- Valid indices are 0 to 4; the mapping between index and output is `K = n - 1` ↔ `OUTn`

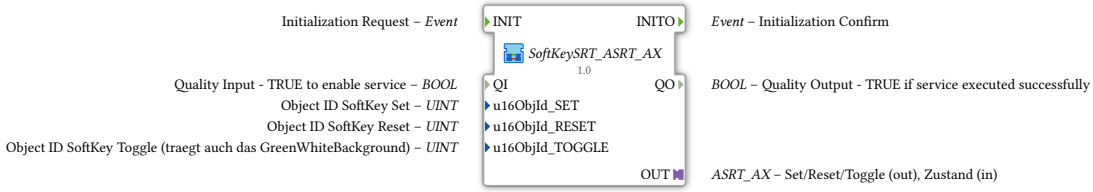


Application Scenarios

- Selection menus or operating mode selection in which only one of five options may be active at a time (e.g. via a VT selection list)

Conclusion

`SingleSelect` converts a selection index into a single selection with five AX outputs using a demultiplexer and an interlock chain of five `ILOCK_T_FF_SR_AX`.



SoftKeySRT_ASRT_AX

• – ○ • – ○ • – ○ •

Introduction

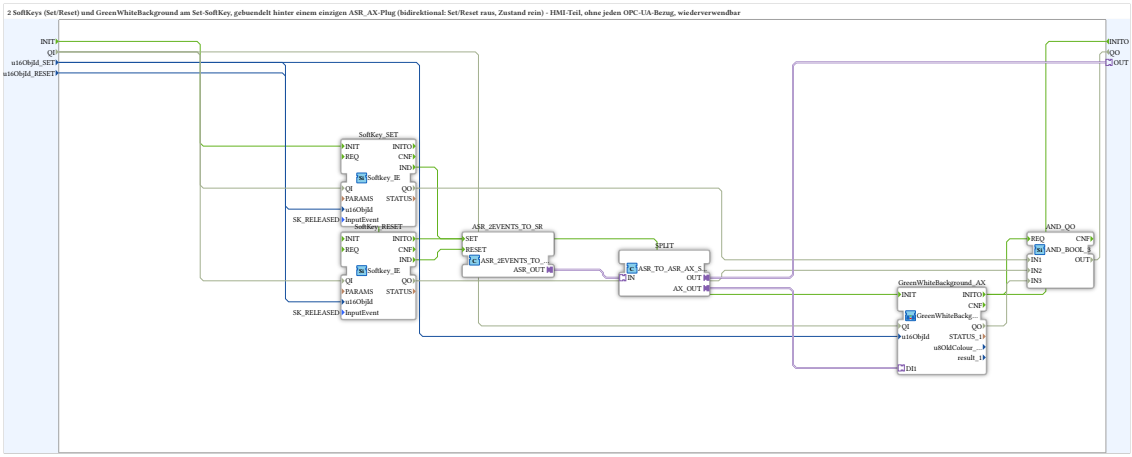
`SoftKeySRT_ASRT_AX` bundles 3 softkeys (set/reset/toggle) and a `GreenWhiteBackground1_AX` (on the toggle softkey) behind a single `ASRT_AX` plug (bidirectional: set/reset/toggle go out, state comes in). A pure HMI block with no OPC-UA involvement - the SR+toggle counterpart of `SoftKeySR_ASR_AX`.

Function blocks used

- **SoftKey_SET / SoftKey_RESET / SoftKey_TOGGLE** (`isobus::UT::io::Softkey::Softkey_IE`, `InputEvent=SK_RELEASED`): the 3 physical softkeys.
- **ASRT_3EVENTS_TO_SRT** (`adapter::conversion::unidirectional::ASRT_3EVENTS_TO_SRT`): converts the 3 softkey events into an ASRT adapter event triple.
- **SPLIT** (`adapter::events::bidirectional::ASRT_TO_ASRT_AX_SPLIT`): splits the bidirectional `ASRT_AX` traffic to `OUT` and to the background element.
- **GreenWhiteBackground_AX** (SubApp, type `MyLib::sys::GreenWhiteBackground1_AX`): status color on the toggle softkey.
- **AND_QO** (`iec61131::booleanOperators::AND_BOOL_4`): combines the `QO` outputs of the inner blocks into `QO`.

Initialization and Quality

Interface (quality pattern): event input `INIT` and event output `INITO` (each `EInit`), data input `QI` (`BOOL`, default `TRUE`) and data output `QO` (`BOOL`). Initialization: `INIT` ⟶ `SoftKey_SET.INIT`; `SoftKey_SET.INITO` ⟶ `SoftKey_RESET.INIT`; `SoftKey_RESET.INITO` ⟶ `SoftKey_TOGGLE.INIT`; `SoftKey_TOGGLE.INITO` ⟶ `GreenWhiteBackground_AX.INIT`; `GreenWhiteBackground_AX.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`. Quality: `QI` ⟶ `SoftKey_SET.QI`, `SoftKey_RESET.QI`, `SoftKey_TOGGLE.QI`, `GreenWhiteBackground_AX.QI`; `SoftKey_SET.QO`, `SoftKey_RESET.QO`, `SoftKey_TOGGLE.QO`, `GreenWhiteBackground_AX.QO` ⟶ `AND_QO.IN1` to `AND_QO.IN4` (in this order); `AND_QO.OUT` ⟶ `QO` (`AND_QO`: `iec61131::booleanOperators::AND_BOOL_4`).



Summary

Reusable set/reset/toggle-with-status block, bundled behind an `ASRT_AX` adapter - the HMI counterpart of `Uebung_010e_PC_A_OPC_Adapter`/`Uebung_010e_PC_B_OPC_Adapter`.

SoftKeySR_ASR_AX

• — ○ • — ○ • — ○ •

Introduction

`SoftKeySR_ASR_AX` bundles 2 softkeys (set/reset) and a `GreenWhiteBackground1_AX` (on the set softkey) behind a single `ASR_AX` plug (bidirectional: set/reset go out, state comes in). A pure HMI block with no OPC-UA involvement.

Interface

- **Event input**: `INIT` (`EInit`, Initialization Request)
- **Event output**: `INITO` (`EInit`, Initialization Confirm)
- **Data inputs**: `QI` (`BOOL`, default `TRUE`, Quality Input), `u16ObjId_SET`, `u16ObjId_RESET` (`UINT`, default `ID_NULL`)
- **Data output**: `QO` (`BOOL`, Quality Output)
- **Plug**: `OUT` (`adapter::types::bidirectional::ASR_AX`)

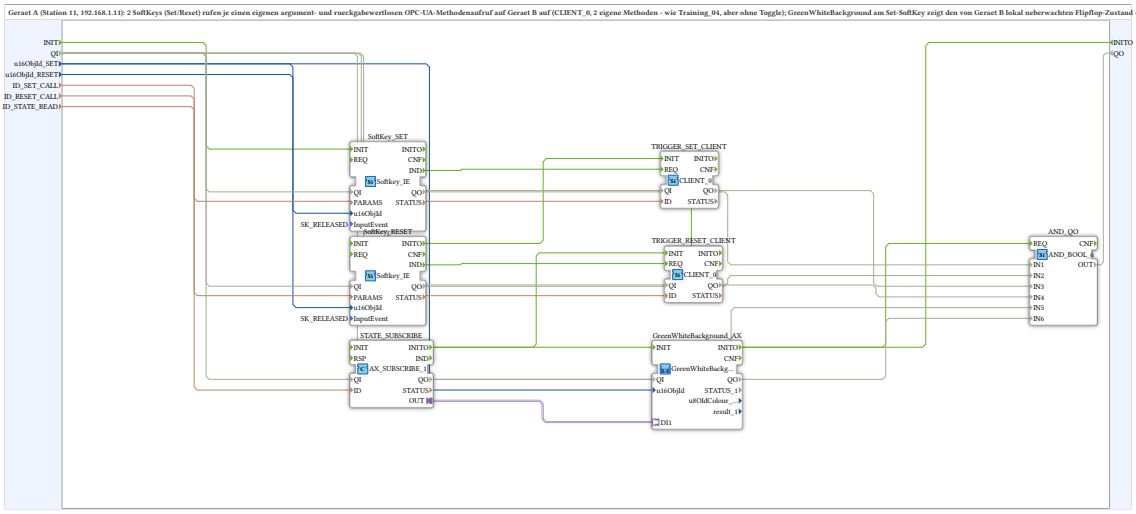
Function blocks used

- **SoftKey_SET / SoftKey_RESET** (`isobus::UT::io::Softkey::Softkey_IE`, `InputEvent=SK_RELEASED`): the two physical softkeys.
- **ASR_2EVENTS_TO_SR** (`adapter::conversion::unidirectional::ASR_2EVENTS_TO_SR`): converts the 2 softkey events into an ASR adapter event pair.
- **SPLIT** (`adapter::events::bidirectional::ASR_TO_ASR_AX_SPLIT`): splits the bidirectional `ASR_AX` traffic to `OUT` and to the background element.
- **GreenWhiteBackground_AX** (SubApp, type `MyLib::sys::GreenWhiteBackground1_AX`): status color on the set softkey.
- **AND_QO** (`iec61131::booleanOperators::AND_BOOL_3`): ANDs the `QO` outputs of `SoftKey_SET`, `SoftKey_RESET` and `GreenWhiteBackground_AX` into the block output `QO`.

Initialization and status

- Initialization chain: `INIT` ⟶ `SoftKey_SET.INIT`, `SoftKey_SET.INITO` ⟶ `SoftKey_RESET.INIT`, `SoftKey_RESET.INITO` ⟶ `GreenWhiteBackground_AX.INIT`, `GreenWhiteBackground_AX.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`
- `QI` ⟶ `SoftKey_SET.QI`, `SoftKey_RESET.QI` and `GreenWhiteBackground_AX.QI`

- `SoftKey_SET.QO` ⟶ `AND_QO.IN1`, `SoftKey_RESET.QO` ⟶ `AND_QO.IN2`, `GreenWhiteBackground_AX.QO` ⟶ `AND_QO.IN3`; `AND_QO.OUT` ⟶ `QO`

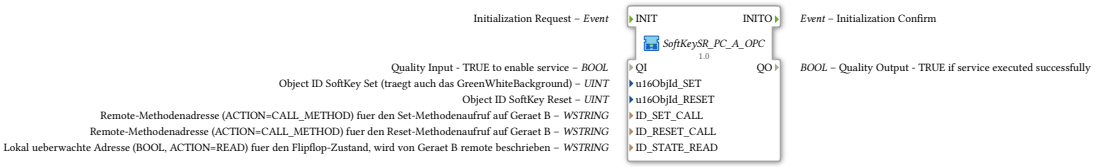


Summary

Reusable set/reset-with-status block, bundled behind an `ASR_AX` adapter - the HMI counterpart of `SoftKeySR_PC_A_OPC_Adapter`/`SoftKeySR_PC_B_OPC_Adapter`.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



SoftKeySR_PC_A_OPC

• – ○ • – ○ • – ○ •

Introduction

`SoftKeySR_PC_A_OPC` is the device-A side (station 11, 192.168.1.11) of a PC-to-PC OPC-UA set/reset pattern: 2 softkeys (set/reset) each call their own argument- and return-value-less OPC-UA method on device B (`CLIENT_0`, 2 distinct methods - like Training_04, but without toggle). `GreenWhiteBackground1_AX` on the set softkey shows the flip-flop state locally monitored from device B. “SUB style”: the protocol lives in the `MyLib::sys` composite, not in the device’s resource - counterpart: `SoftKeySR_PC_B_OPC`.

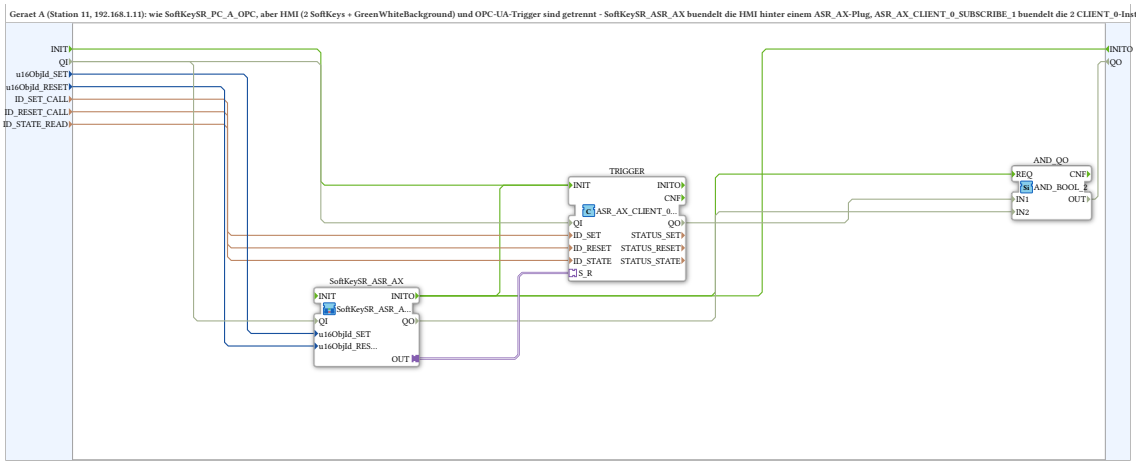
Function blocks used

- **SoftKey_SET / SoftKey_RESET** (`isobus::UT::io::Softkey::Softkey_IE`): the two physical softkeys.
- **TRIGGER_SET_CLIENT / TRIGGER_RESET_CLIENT** (`iec61499::net::CLIENT_0`): each calls its own argument-less remote method on device B (`ID_SET_CALL`/`ID_RESET_CALL`).
- **STATE_SUBSCRIBE** (`adapter::net::AX_SUBSCRIBE_1`): subscribes to the flip-flop state under `ID_STATE_READ`.
- **GreenWhiteBackground_AX** (SubApp, type `MyLib::sys::GreenWhiteBackground1_AX`): displays the state at the set softkey.
- **AND_QO** (`iec61131::booleanOperators::AND_BOOL_6`): combines the `QO` outputs of the six blocks above into the SubApp output `QO`.

Initialization and quality

- Events: `INIT` (EInit, input) and `INITO` (EInit, output, comes from `GreenWhiteBackground_AX.INITO`).

- Data input `QI` (BOOL, default `TRUE`) and data output `QO` (BOOL); the internal FBs no longer carry a fixed `QI=TRUE`.
- Initialization chain: `INIT` → `SoftKey_SET.INIT` → `SoftKey_RESET.INIT` → `TRIGGER_SET_CLIENT.INIT` → `TRIGGER_RESET_CLIENT.INIT` → `STATE_SUBSCRIBE.INIT` → `GreenWhiteBackground_AX.INIT` (each via `INITO`); `GreenWhiteBackground_AX.INITO` → `INITO` and → `AND_QO.REQ`.
- Quality: `QI` → `.QI` of all six blocks; their `QO` outputs → `AND_QO.IN1` to `IN6` (`SoftKey_SET`, `SoftKey_RESET`, `TRIGGER_SET_CLIENT`, `TRIGGER_RESET_CLIENT`, `STATE_SUBSCRIBE`, `GreenWhiteBackground_AX`); `AND_QO.OUT` → `QO`.



Summary

Device-A side of a set/reset RPC pattern with 2 distinct method calls (instead of one string parameter) and state feedback.

SoftKeySR_PC_A_OPC_Adapter

• — ○ • — ○ • — ○ •

Introduction

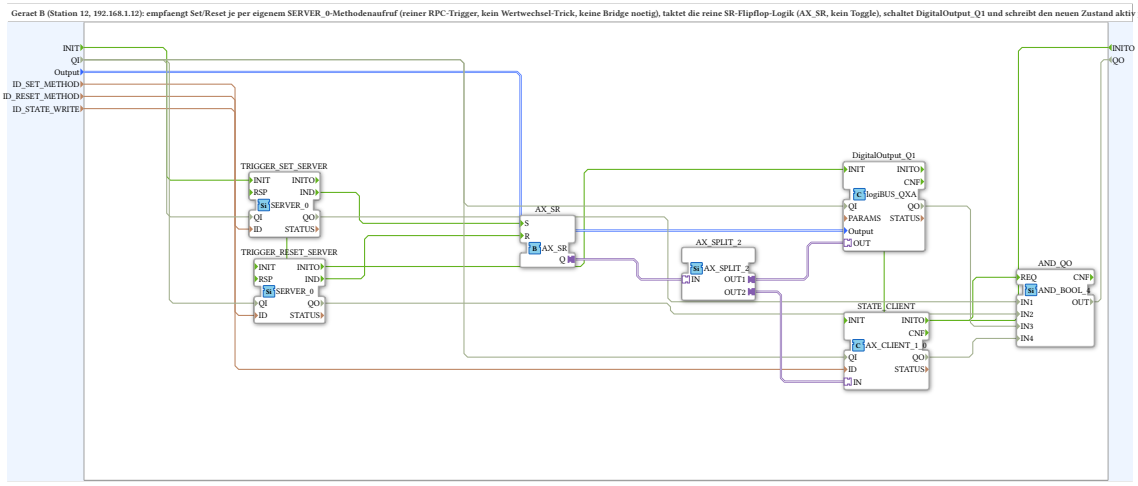
`SoftKeySR_PC_A_OPC_Adapter` is the adapter-bundled variant of `SoftKeySR_PC_A_OPC` (device A, station 11): HMI (2 softkeys + `GreenWhiteBackground`) and OPC-UA trigger are separated. `SoftKeySR_ASR_AX` bundles the HMI behind an `ASR_AX` plug; `ASR_AX_CLIENT_0_SUBSCRIBE_1` bundles the 2 `CLIENT_0` instances + `AX_SUBSCRIBE_1` behind an `ASR_AX` socket. Counterpart: `SoftKeySR_PC_B_OPC_Adapter`.

Function blocks used

- **SoftKeySR_ASR_AX** (SubApp, type `MyLib::sys::SoftKeySR_ASR_AX`): 2 softkeys + status display, bundled behind an `ASR_AX` plug.
- **TRIGGER** (`adapter::net::ASR_AX_CLIENT_0_SUBSCRIBE_1`): bundles 2 method calls (`ID_SET_CALL`/`ID_RESET_CALL`) and the state subscription (`ID_STATE_READ`) behind a single `ASR_AX` socket.
- **AND_QO** (`iec61131::booleanOperators::AND_BOOL_2`): combines `TRIGGER.QO` and `SoftKeySR_ASR_AX.QO` into the output `QO`.

Initialization and quality: The SubApp has the events `INIT`/`INITO` as well as `QI` (BOOL, initial value `TRUE`) and `QO` (BOOL). Init chain: `INIT` → `TRIGGER.INIT`, `TRIGGER.INITO` → `SoftKeySR_ASR_AX.INIT`, `SoftKeySR_ASR_AX.INITO` → `INITO` and `AND_QO.REQ`. `QI` is passed on to `TRIGGER.QI` and

`SoftKeySR_ASR_AX.QI`; `TRIGGER.QO` ⟶ `AND_QO.IN1`, `SoftKeySR_ASR_AX.QO` ⟶ `AND_QO.IN2`, `AND_QO.OUT` ⟶ `QO`.



Summary

Adapter-bundled variant of `SoftKeySR_PC_A_OPC`: HMI and network protocol cleanly separated, reusable via `SoftKeySR_ASR_AX`.

SoftKeySR_PC_B_OPC

• — ○ • — ○ • — ○ •

Introduction

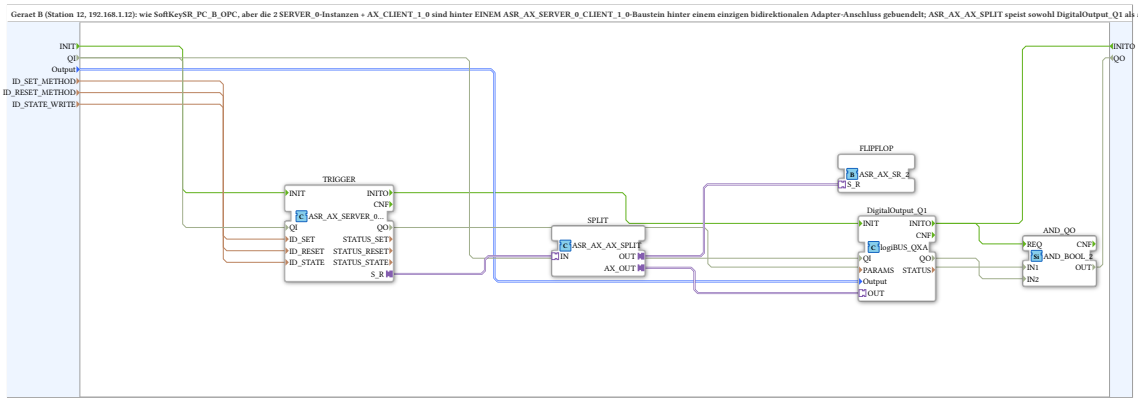
`SoftKeySR_PC_B_OPC` is the device-B side (station 12, 192.168.1.12): receives set/reset each via its own `SERVER_0` method call (a pure RPC trigger, no value-change trick, no bridge needed), clocks the pure SR flip-flop logic (`AX_SR`, no toggle), drives `DigitalOutput_Q1`, and actively writes the new state back to device A via `AX_CLIENT_1_0`. Counterpart: `SoftKeySR_PC_A_OPC`.

Function blocks used

- **TRIGGER_SET_SERVER / TRIGGER_RESET_SERVER** (`iec61499::net::SERVER_0`): each receives its own method call (`ID_SET_METHOD`/`ID_RESET_METHOD`).
- **AX_SR** (`adapter::events::unidirectional::AX_SR`): pure set/reset flip-flop logic, no toggle.
- **AX_SPLIT_2** (`adapter::events::unidirectional::AX_SPLIT_2`): splits the state to the physical output + the echo.
- **DigitalOutput_Q1** (`logiBUS::io::DQ::logiBUS_QXA`): physical output.
- **STATE_CLIENT** (`adapter::net::AX_CLIENT_1_0`): actively writes the state to device A under `ID_STATE_WRITE`.

Initialization and quality

The SubApp has the event input `INIT`, the event output `INITO` (both `EInit`), the data input `QI` (`BOOL`, default `TRUE`) and the data output `QO` (`BOOL`). Initialization runs as a chain: `INIT` ⟶ `TRIGGER_SET_SERVER.INIT`, `TRIGGER_SET_SERVER.INITO` ⟶ `TRIGGER_RESET_SERVER.INIT`, `TRIGGER_RESET_SERVER.INITO` ⟶ `DigitalOutput_Q1.INIT`, `DigitalOutput_Q1.INITO` ⟶ `STATE_CLIENT.INIT`, `STATE_CLIENT.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`). `QI` is passed to `TRIGGER_SET_SERVER`, `TRIGGER_RESET_SERVER`, `DigitalOutput_Q1` and `STATE_CLIENT`. `QO` is the output of the instance `AND_QO` (`iec61131::booleanOperators::AND_BOOL_4`), which combines the `QO` of these four instances.



Summary

Device-B side: receives set/reset via RPC, holds the pure SR flip-flop logic, and actively reports the state back.

SoftKeySR_PC_B_OPC_Adapter

• – ○ • – ○ • – ○ •

Introduction

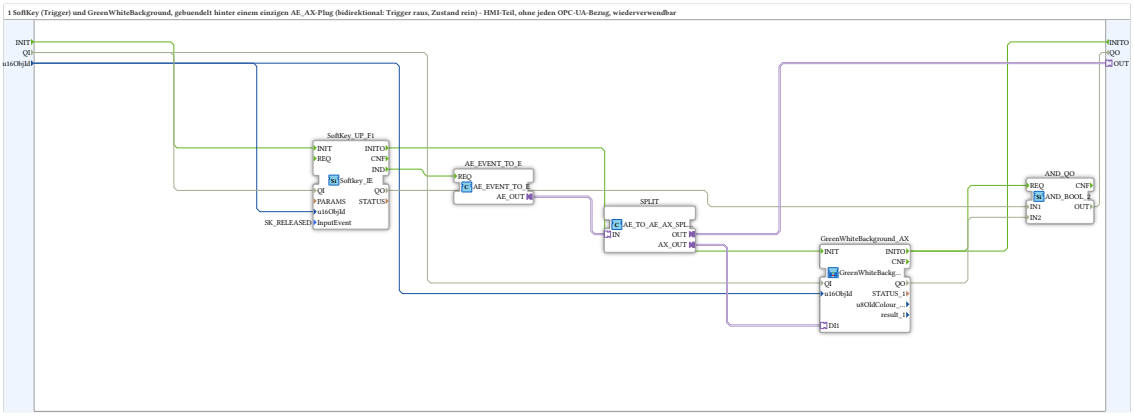
`SoftKeySR_PC_B_OPC_Adapter` is the adapter-bundled variant of `SoftKeySR_PC_B_OPC` (device B, station 12): the 2 `SERVER_0` instances + `AX_CLIENT_1_0` are bundled behind a SINGLE `ASR_AX_SERVER_0_CLIENT_1_0` block behind one bidirectional adapter connection; `ASR_AX_AX_SPLIT` feeds both `DigitalOutput_Q1` and the pure SR flip-flop logic (`ASR_AX_SR_2`, no toggle). Counterpart: `SoftKeySR_PC_A_OPC_Adapter`.

Function blocks used

- **TRIGGER** (`adapter::net::ASR_AX_SERVER_0_CLIENT_1_0`): bundles server reception (`ID_SET_METHOD`/`ID_RESET_METHOD`) and state feedback (`ID_STATE_WRITE`).
- **SPLIT** (`adapter::events::bidirectional::ASR_AX_AX_SPLIT`): splits to the physical output + the flip-flop logic.
- **FLIPFLOP** (`adapter::events::bidirectional::ASR_AX_SR_2`): pure SR flip-flop logic as an adapter block, no toggle.
- **DigitalOutput_Q1** (`logiBUS::io::DQ::logiBUS_QXA`): physical output.
- **AND_QO** (`iec61131::booleanOperators::AND_BOOL_2`): combines `TRIGGER.QO` and `DigitalOutput_Q1.QO` into the `QO` of the SubApp.

Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`): `INIT` ⟶ `TRIGGER.INIT`; `TRIGGER.INITO` ⟶ `DigitalOutput_Q1.INIT`; `DigitalOutput_Q1.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`).
- **Data input `QI`** (`BOOL`, default `TRUE`) ⟶ `TRIGGER.QI` and `DigitalOutput_Q1.QI`.
- **Data output `QO`** (`BOOL`): `TRIGGER.QO` ⟶ `AND_QO.IN1`; `DigitalOutput_Q1.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.

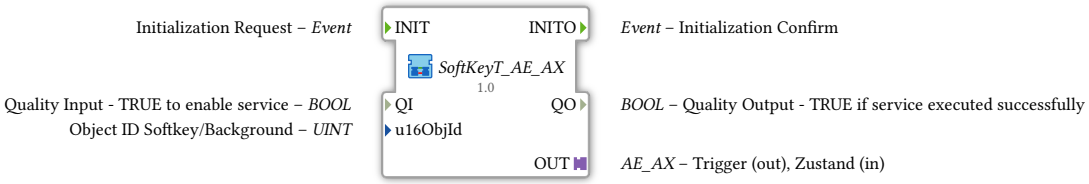


Summary

Adapter-bundled variant of `SoftKeySR_PC_B_OPC`: network protocol and SR flip-flop logic as reusable adapter blocks.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



SoftKeyT_AE_AX

• – ○ • – ○ • – ○ •

Introduction

`SoftKeyT_AE_AX` bundles 1 SoftKey (trigger) and a `GreenWhiteBackground1_AX` behind a single `AE_AX` plug (bidirectional: trigger goes out, state comes in). A pure HMI block with no OPC-UA involvement - reusable in any network that needs a single trigger softkey with a state display.

Function blocks used

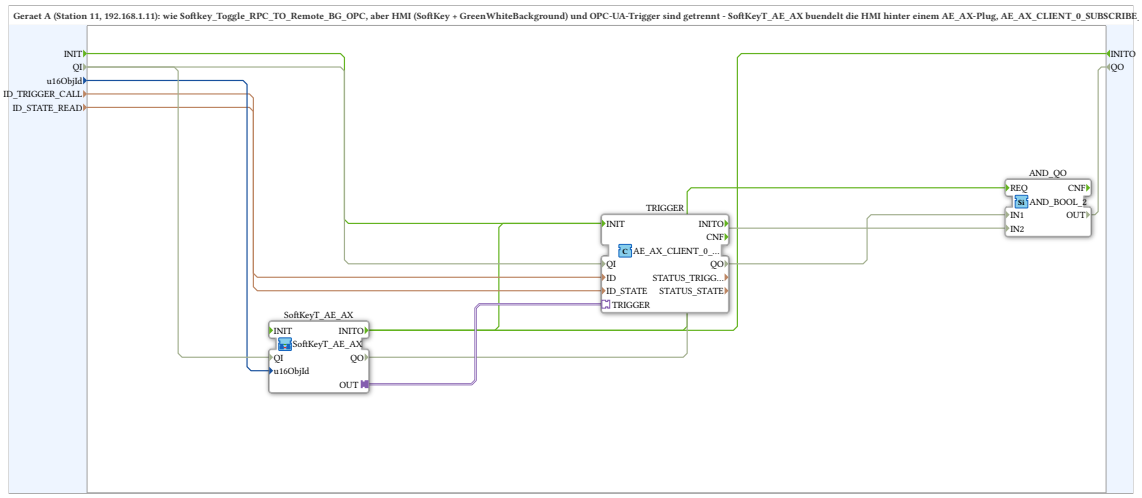
- **SoftKey_UP_F1** (`isobus::UT::io::Softkey::Softkey_IE`, `InputEvent=SK_RELEASED`): physical softkey.
- **AE_EVENT_TO_E** (`adapter::conversion::unidirectional::AE_EVENT_TO_E`): converts the softkey event into an AE adapter event.
- **GreenWhiteBackground_AX** (SubApp, type `MyLib::sys::GreenWhiteBackground1_AX`): status color on the same object.
- **SPLIT** (`adapter::events::bidirectional::AE_TO_AE_AX_SPLIT`): splits the bidirectional `AE_AX` traffic to the external plug `OUT` and internally to the background element.
- **AND_QO** (`iec61131::booleanOperators::AND_BOOL_2`): combines the `QO` outputs of the inner blocks into `QO`.

Program flow and connections

`SoftKey_UP_F1.IND -> AE_EVENT_TO_E.REQ -> SPLIT.IN -> OUT` (outward) and `SPLIT.AX_OUT -> GreenWhiteBackground_AX.DI1` (state display).

Initialization and Quality

Interface (quality pattern): event input `INIT` and event output `INITO` (each `EInit`), data input `QI` (`BOOL`, default `TRUE`) and data output `QO` (`BOOL`). Initialization: `INIT` ⟶ `SoftKey_UP_F1.INIT`; `SoftKey_UP_F1.INITO` ⟶ `GreenWhiteBackground_AX.INIT`; `GreenWhiteBackground_AX.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`. Quality: `QI` ⟶ `SoftKey_UP_F1.QI`, `GreenWhiteBackground_AX.QI`; `SoftKey_UP_F1.QO`, `GreenWhiteBackground_AX.QO` ⟶ `AND_QO.IN1` to `AND_QO.IN2` (in this order); `AND_QO.OUT` ⟶ `QO` (`AND_QO`: `iec61131::booleanOperators::AND_BOOL_2`).



Summary

Reusable single-key trigger-with-status block, bundled behind an `AE_AX` adapter - the HMI counterpart of the PC_A/PC_B OPC network blocks like `SoftKeyT_PC_A_OPC_Adapter`.

🌐 Related topic subpages on ms-muc-docs.de

SoftKeyT_PC_A_OPC_Adapter

• – ○ • – ○ • – ○ •

Introduction

`SoftKeyT_PC_A_OPC_Adapter` is the adapter-bundled variant of `Uebung_010d_PC_A_OPC` (device A, station 11): HMI (softkey + `GreenWhiteBackground`) and OPC-UA trigger are separated. `SoftKeyT_AE_AX` bundles the HMI behind an `AE_AX` plug; `AE_AX_CLIENT_0_SUBSCRIBE_1` bundles `CLIENT_0 + AX_SUBSCRIBE_1` behind an `AE_AX` socket. "SUB style": the protocol still lives in the `MyLib::sys` composite. Counterpart: `SoftKeyT_PC_B_OPC_Adapter`.

Interface

- **Event input**: `INIT` (`EInit`, Initialization Request)
- **Event output**: `INITO` (`EInit`, Initialization Confirm)
- **Data inputs**: `QI` (`BOOL`, default `TRUE`, Quality Input), `u16ObjId`, `ID_TRIGGER_CALL`, `ID_STATE_READ`
- **Data output**: `QO` (`BOOL`, Quality Output)

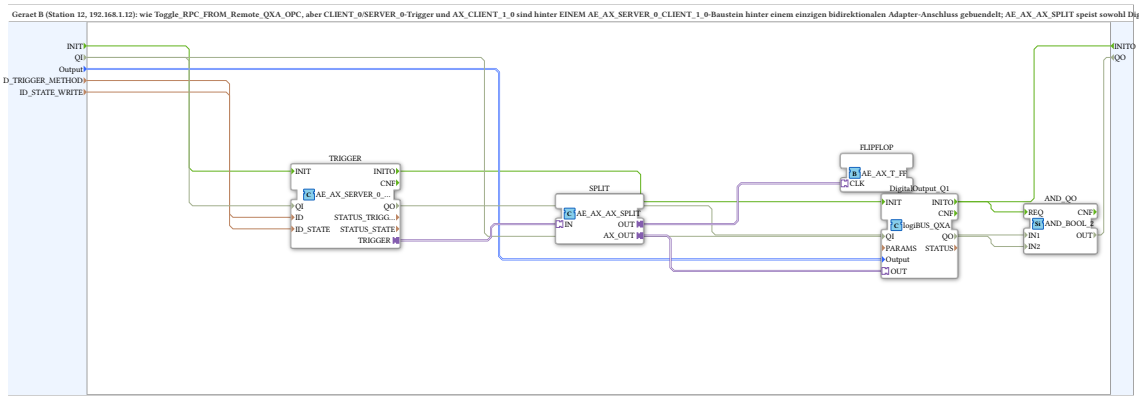
Function blocks used

- **SoftKeyT_AE_AX** (SubApp, type `MyLib::sys::SoftKeyT_AE_AX`): softkey + status display, bundled behind an `AE_AX` plug.
- **TRIGGER** (`adapter::net::AE_AX_CLIENT_0_SUBSCRIBE_1`): bundles the method call (`ID_TRIGGER_CALL`) and state subscription (`ID_STATE_READ`) behind a single `AE_AX` socket.
- **AND_QO** (`iec61131::booleanOperators::AND_BOOL_2`): ANDs `TRIGGER.QO` and `SoftKeyT_AE_AX.QO` into the block output `QO`.

Program flow and connections

`SoftKeyT_AE_AX.OUT` -> `TRIGGER.TRIGGER` (bidirectional: trigger out, state back to the HMI SubApp).

Initialization chain: `INIT` -> `TRIGGER.INIT`, `TRIGGER.INITO` -> `SoftKeyT_AE_AX.INIT`, `SoftKeyT_AE_AX.INITO` -> `INITO` and -> `AND_QO.REQ`. `QI` -> `TRIGGER.QI` and `SoftKeyT_AE_AX.QI`; `TRIGGER.QO` -> `AND_QO.IN1`, `SoftKeyT_AE_AX.QO` -> `AND_QO.IN2`, `AND_QO.OUT` -> `QO`.



Summary

Adapter-bundled variant of `Uebung_010d_PC_A_OPC`: the same function, but HMI and network protocol are cleanly separated into 2 reusable blocks instead of being wired in a single composite.

SoftKeyT_PC_B_OPC_Adapter

• – ○ • – ○ • – ○ •

Introduction

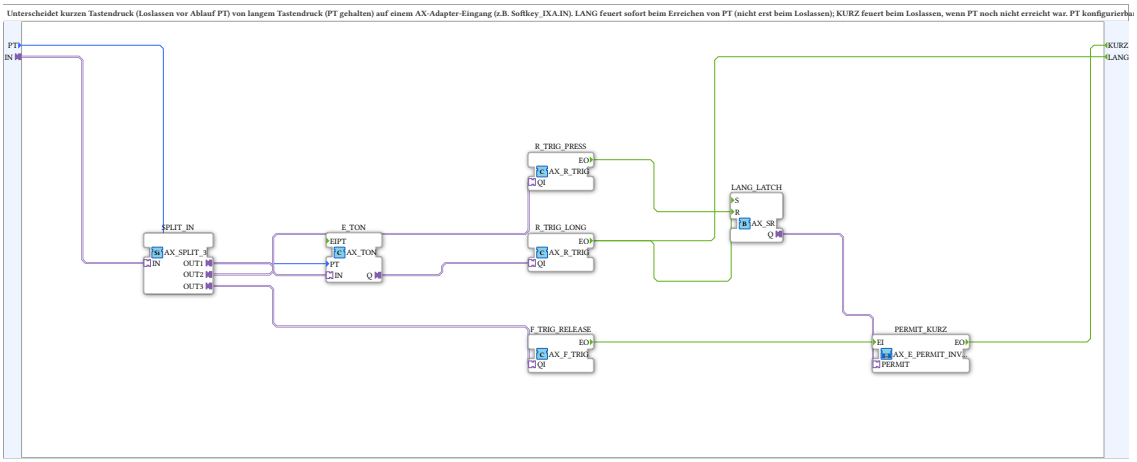
`SoftKeyT_PC_B_OPC_Adapter` is the adapter-bundled variant of `Uebung_010d_PC_B_OPC` (device B, station 12): the `CLIENT_0/SERVER_0` trigger and `AX_CLIENT_1_0` are bundled behind a SINGLE `AE_AX_SERVER_0_CLIENT_1_0` block behind one bidirectional adapter connection; `AE_AX_AX_SPLIT` feeds both `DigitalOutput_Q1` and the toggle flip-flop logic (`AE_AX_T_FF`). Counterpart: `SoftKeyT_PC_A_OPC_Adapter`.

Function blocks used

- **TRIGGER** (`adapter::net::AE_AX_SERVER_0_CLIENT_1_0`): bundles server reception (`ID_TRIGGER_METHOD`) and state feedback (`ID_STATE_WRITE`).
- **SPLIT** (`adapter::events::bidirectional::AE_AX_AX_SPLIT`): splits the trigger to the physical output + the flip-flop logic.
- **FLIPFLOP** (`adapter::events::bidirectional::AE_AX_T_FF`): toggle flip-flop logic as an adapter block.
- **DigitalOutput_Q1** (`logiBUS::io::DQ::logiBUS_QXA`): physical output.
- **AND_QO** (`iec61131::booleanOperators::AND_BOOL_2`): combines `TRIGGER.QO` and `DigitalOutput_Q1.QO` into the SubApp output `QO`.

Initialization and quality

- Events: `INIT` (EInit, input) and `INITO` (EInit, output, comes from `DigitalOutput_Q1.INITO`).
- Data input `QI` (BOOL, default `TRUE`) and data output `QO` (BOOL); `TRIGGER` and `DigitalOutput_Q1` no longer carry a fixed `QI=TRUE`.
- Initialization: `INIT` ⟶ `TRIGGER.INIT`, `TRIGGER.INITO` ⟶ `DigitalOutput_Q1.INIT`, `DigitalOutput_Q1.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`.
- Quality: `QI` ⟶ `TRIGGER.QI` and `DigitalOutput_Q1.QI`; `TRIGGER.QO` ⟶ `AND_QO.IN1`, `DigitalOutput_Q1.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.



Summary

Adapter-bundled variant of `Uebung_010d_PC_B_OPC`: network protocol and flip-flop logic as reusable adapter blocks instead of individually wired FBs.

SoftKey_Kurz_Lang

• — ○ • — ○ • — ○ •

Introduction

`SoftKey_Kurz_Lang` distinguishes a **short** key press (released before `PT` elapses) from a **long** key press (`PT` held) on an `AX` adapter input (e.g. `Softkey_IXA.IN`). `LANG` fires immediately when `PT` is reached (not only on release); `KURZ` fires on release if `PT` had not yet been reached. `PT` is configurable (default 5 s).

Interface Structure

Event Inputs

None.

Event Outputs

- **KURZ**: short press confirmed (released before `PT` elapses)
- **LANG**: long press confirmed (`PT` reached, fires immediately, not only on release)

Data Inputs

- **PT** (`TIME`): hold time for “long”, default `T#5s`

Data Outputs

None.

Adapters

- **IN** (socket, `adapter::types::unidirectional::AX`): raw key state (e.g. `Softkey_IXA.IN`)

Function Blocks (FBs) Used

- **`SPLIT_IN`** (`adapter::events::unidirectional::AX_SPLIT_3`): distributes `IN` to three targets
- **`E_TON`** (`adapter::events::unidirectional::timers::AX_TON`): on-delay with `PT`
- **`R_TRIG_LONG`** (`adapter::events::unidirectional::AX_R_TRIG`): rising edge of `E_TON.Q`
- **`R_TRIG_PRESS`** (`adapter::events::unidirectional::AX_R_TRIG`): rising edge of `IN` (start of key press)
- **`LANG_LATCH`** (`adapter::events::unidirectional::AX_SR`): remembers that `LANG` has already fired in this cycle
- **`F_TRIG_RELEASE`** (`adapter::events::unidirectional::AX_F_TRIG`): falling edge of `IN` (release)

- **PERMIT_KURZ** (SubApp `MyLib::sys::AX_E_PERMIT_INVERT_1`, AX_E_PERMIT_INVERT_1): lets the release event pass only if the permit is FALSE

Functionality

- `IN` ⟶ `SPLIT_IN.IN`; `SPLIT_IN.OUT1` ⟶ `E_TON.IN`; `PT` ⟶ `E_TON.PT`
- `SPLIT_IN.OUT2` ⟶ `R_TRIG_PRESS.QI`; `SPLIT_IN.OUT3` ⟶ `F_TRIG_RELEASE.QI`
- `E_TON.Q` ⟶ `R_TRIG_LONG.QI`
- `R_TRIG_LONG.EO` ⟶ `LANG` and `LANG_LATCH.S`
- `R_TRIG_PRESS.EO` ⟶ `LANG_LATCH.R`
- `F_TRIG_RELEASE.EO` ⟶ `PERMIT_KURZ.EI`; `LANG_LATCH.Q` ⟶ `PERMIT_KURZ.PERMIT`; `PERMIT_KURZ.EO` ⟶ `KURZ`

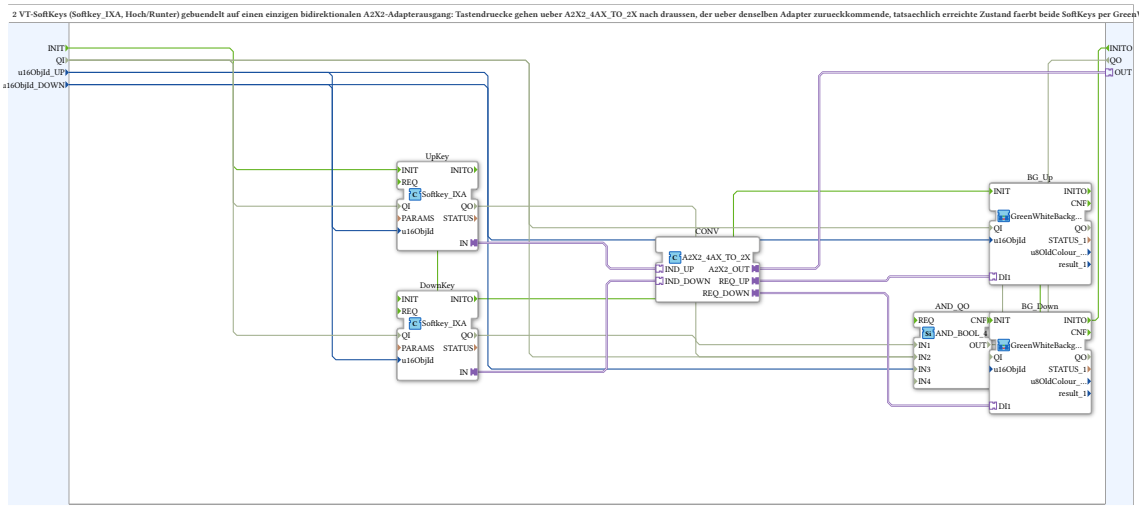
`E_TON` runs as long as `IN` is held. The rising edge of `E_TON.Q` (the moment `PT` is reached while the key is still held) triggers `LANG` immediately and sets `LANG_LATCH`. On release, `F_TRIG_RELEASE` detects the falling edge; `PERMIT_KURZ` only lets it pass if `LANG_LATCH.Q` is FALSE, i.e. `LANG` has not yet fired in this press cycle. At the start of the next key press (`R_TRIG_PRESS`) `LANG_LATCH` is reset.

Technical Details

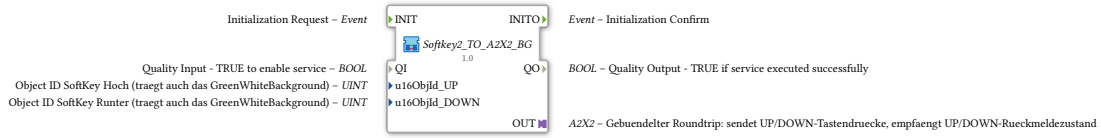
- **Bugfix compared to version 1.0:** the check must not be made directly on `E_TON.Q`. `E_TON.Q` is reset to FALSE by the same `IN` edge change (release) that also triggers `F_TRIG_RELEASE` (`AX_TON`: no `IN` ⟶ no `Q`). Since both targets are fed by the same `IN` event, the execution order between them is not guaranteed; `E_TON.Q` would practically always already be FALSE at the time of the check, and `KURZ` would additionally have fired even after `LANG` had already fired.
- `LANG_LATCH` is completely decoupled from the reset timing (set while holding, reset only at the next key press) and makes the check robust.
- `PT` is configurable as a parameter.

Application Scenarios

- Dual-function key: short press for one function, long press (e.g. 5 s) for another, together with `Softkey_Web_IXA` for keys that should also be operable via the web client



Summary



`SoftKey_Kurz_Lang` derives the separate events `KURZ` and `LANG` with a configurable hold time from an `AX` key state.

Softkey2_TO_A2X2_BG

• — ○ • — ○ • — ○ •

Introduction

`Softkey2_TO_A2X2_BG` is a composite subapplication designed to bundle two ISOagriLib softkey function blocks (one for "UP", one for "DOWN") into a single bidirectional A2X2 adapter interface. It also implements visual feedback for the softkeys by colouring them based on the actual state returned via the same adapter. This subapplication encapsulates the logic entirely within the composite, keeping the device resource simple and focused.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; starts the init chain at `UpKey.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `BG_Down.INITO`, the end of the init chain

Data Inputs

- `QI` (BOOL, initial value `TRUE`): Quality input, enables the service; passed on to `UpKey`, `DownKey`, `BG_Up` and `BG_Down`.
- `u16ObjId_UP` (UINT): Object ID for the "UP" softkey. This ID is used both by the softkey logic and by the background colouring subapplication.
- `u16ObjId_DOWN` (UINT): Object ID for the "DOWN" softkey. This ID is used both by the softkey logic and by the background colouring subapplication.

Data Outputs

- `QO` (BOOL): Quality output, AND combination (`AND_QO`, `AND_BOOL_4`) of the `QO` outputs of `UpKey`, `DownKey`, `BG_Up` and `BG_Down`.

Adapters

- `OUT` (adapter::types::bidirectional::A2X2): A bidirectional adapter that bundles the sending of UP/DOWN key press events and the reception of the actual state feedback from the remote partner (e.g. a virtual terminal).

Functionality

The subapplication internally instantiates two `Softkey_IXA` function blocks (`UpKey` and `DownKey`) to handle the ISOagriLib softkey semantics. Each softkey receives its object ID from the corresponding data input. The key press events are forwarded via adapter connections to a conversion block (`A2X2_4AX_TO_2X`), which consolidates the two separate softkey streams into a single A2X2 adapter connection.

The same A2X2 adapter also carries the returned state (e.g. which softkey is actually pressed or released at the remote terminal). This state is fed back to two `GreenWhiteBackground1_AX` subapplications (`BG_Up` and `BG_Down`), each associated with one softkey. These subapplications colour the respective softkey background green (active) or white (inactive) based on the feedback received via the adapter.

Initialization and quality: `INIT` ⟶ `UpKey.INIT`, `UpKey.INITO` ⟶ `DownKey.INIT`, `DownKey.INITO` ⟶ `BG_Up.INIT`, `BG_Up.INITO` ⟶ `BG_Down.INIT`, `BG_Down.INITO` ⟶ `INITO` and `AND_QO.REQ`. `QI` is passed on to `UpKey`, `DownKey`, `BG_Up` and `BG_Down`; their `QO` outputs go in this order to `AND_QO.IN1` to `AND_QO.IN4` (`iec61131::booleanOperators::AND_BOOL_4`), `AND_QO.OUT` ⟶ `QO`.

Thus, the entire round trip — sending key presses and receiving state — is done through the single `OUT` adapter, and the visual status is updated accordingly.

Technical Features

- **Composite bundling**: Encapsulates two independent softkey channels into one adapter interface, reducing the external connection count.

- **ISOagriLib compliance**: Uses standard `Softkey_IXA` blocks, ensuring compatibility with ISO 11783 (ISOBUS) virtual terminal implementations.
- **Bidirectional communication**: The A2X2 adapter supports both sending and receiving, enabling state feedback.
- **Background colouring**: Uses `GreenWhiteBackground1_AX` subapplications to change softkey background based on the acknowledged state.
- **Parameterisable**: Object IDs are provided as inputs, allowing reuse for different softkey identifiers without internal modification.

State Overview

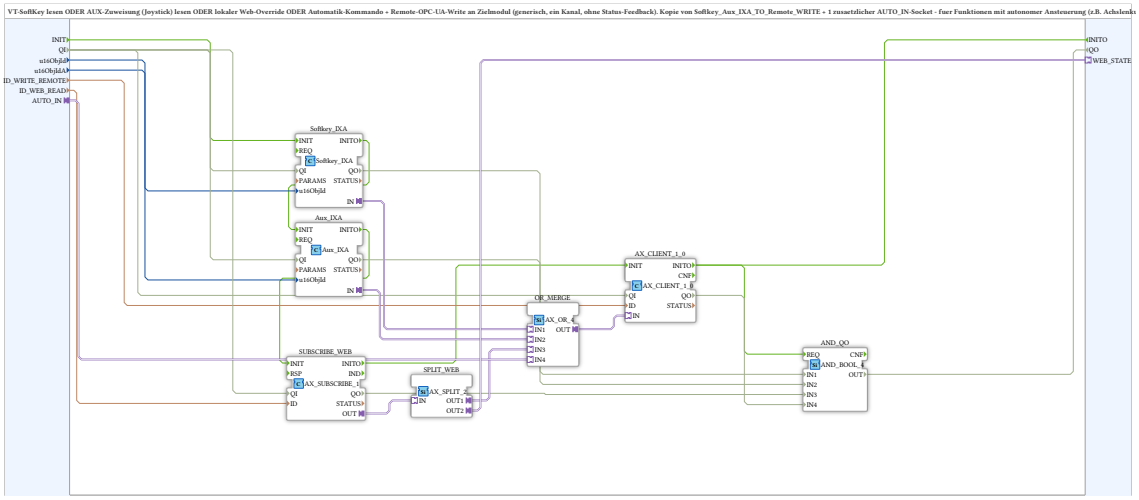
The subapplication does not maintain a finite state machine of its own. Instead, it relies on the internal `Softkey_IXA` blocks to handle the softkey state transitions (e.g. pressed, released). The `GreenWhiteBackground1_AX` subapplications react to the feedback from the adapter and colour the softkey background accordingly:

- **Green**: The softkey is currently recognised as active/pressed by the remote terminal.
- **White**: The softkey is inactive/released.

The state information flows continuously through the adapter, reflecting the latest acknowledged condition.

Application Scenarios

- **Agricultural machinery control**: A virtual terminal with multiple softkeys that must be grouped and communicated via a single A2X2 adapter for efficiency.
- **Remote terminal interaction**: When several softkeys need to be bundled into one adapter connection to reduce wiring or complexity in the device resource.
- **Status-aware softkeys**: Applications where the background colour of the softkey must match the actual operational state received from the remote partner.



Comparison with Similar Blocks

- **Individual softkey adapters**: Each softkey would require its own adapter connection. `Softkey2_TO_A2X2_BG` consolidates two into one, reducing the number of connections and simplifying the resource design.
- **Non-feedback softkeys**: Some softkey blocks only send events without receiving state. This subapplication adds bidirectional capability, enabling accurate visual feedback.
- **Hard-coded softkeys**: In contrast to blocks that hard-code object IDs, this subapplication accepts them as inputs, making it flexible for reuse in different contexts.

Conclusion

`Softkey2_TO_A2X2_BG` provides a compact, reusable solution for bundling two ISOagriLib softkeys into a single bidirectional A2X2 adapter while incorporating state-based background colouring. Its design keeps the device resource clean and reduces the number of external connections, while fully supporting the required communication and visual feedback mechanisms. This subapplication is a valuable building block for ISOBUS-compliant virtual terminals that need efficient, status-aware softkey handling.

Softkey_Aux_Auto_IXA_TO_Remote_WRITE

• — ○ • — ○ • — ○ •

Introduction

`Softkey_Aux_Auto_IXA_TO_Remote_WRITE` reads a **VT SoftKey**, an **AUX assignment (joystick)**, a **local web override** or an **automation command** and writes the result via a remote OPC-UA write to a target module (generic, one channel, without status feedback). The block is a copy of `Softkey_Aux_IXA_TO_Remote_WRITE` with an additional socket `AUTO_IN` for functions with autonomous control (e.g. axle steering centre automation).

There is still exactly **one** publisher per channel on `ID_WRITE_REMOTE`, even though four instead of three sources are merged - no self-latch risk. For status feedback/background colour see the pre-wired combination `Softkey_Aux_Auto_IXA_TO_Remote_WRITE_BG_OPC`.

Function Blocks (FBs) Used

Sub-blocks: Softkey_Aux_Auto_IXA_TO_Remote_WRITE

- **Type**: SubAppType
- **Internal FBs used**:
  - **Softkey_IXA**: `isobus::UT::io::Softkey::Softkey_IXA` - SoftKey level
  - **Aux_IXA**: `isobus::UT::io::Auxiliary::IN::Aux_IXA` - AUX level
  - **SUBSCRIBE_WEB**: `adapter::net::AX_SUBSCRIBE_1` - local subscribe for a web client
  - **SPLIT_WEB**: `adapter::events::unidirectional::AX_SPLIT_2` - distributes the web state to `OR_MERGE` and `WEB_STATE`
  - **OR_MERGE**: `adapter::booleanOperators::AX_OR_4` - OR combination of the four sources
  - **AX_CLIENT_1_0**: `adapter::net::AX_CLIENT_1_0` - remote write to the target module
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_4` - combines the `QO` of `Softkey_IXA`, `Aux_IXA`, `SUBSCRIBE_WEB` and `AX_CLIENT_1_0`
- **Import**: `ID_NULL`

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; goes to `Softkey_IXA.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirm; comes from `AX_CLIENT_1_0.INITO`, the end of the chain

The switching events themselves still travel via the adapters.

Data Inputs

- **QI** (BOOL, default TRUE): Quality Input - TRUE enables the service; goes to Softkey_IXA, Aux_IXA, SUBSCRIBE_WEB and AX_CLIENT_1_0
- **u16ObjId** (UINT, default ID_NULL): Object ID of the SoftKey (VT)
- **u16ObjIdA** (UINT, default ID_NULL): Object ID of the AuxFunction2 (VT)
- **ID_WRITE_REMOTE** (WSTRING): Remote write address to the target module (command, ACTION=WRITE, CLIENT)
- **ID_WEB_READ** (WSTRING): Local subscribe address for a web client (e.g. vt-ui-mirror) on the same module, ORed with SoftKey and AUX

Data Outputs

- **QO** (BOOL): Quality Output - TRUE if the service was executed successfully (AND of the QO of Softkey_IXA, Aux_IXA, SUBSCRIBE_WEB and AX_CLIENT_1_0)

Adapters

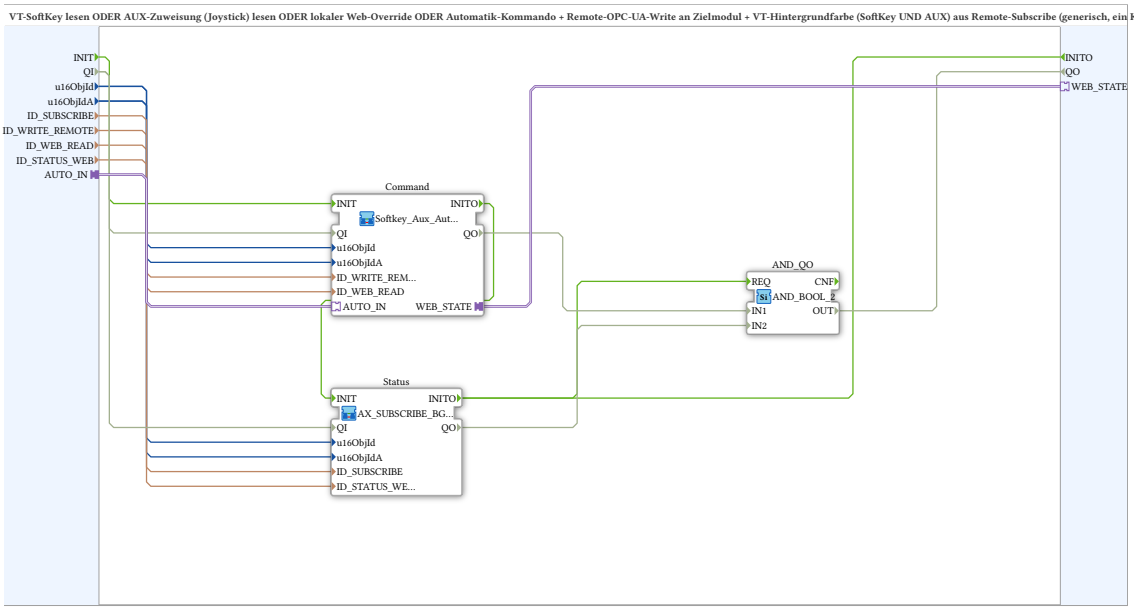
- **AUTO_IN** (socket, adapter::types::unidirectional::AX): Autonomous command (e.g. axle steering centre automation), ORed with SoftKey/Aux/web
- **WEB_STATE** (plug, adapter::types::unidirectional::AX): Web state (= SUBSCRIBE_WEB.OUT) passed on to the outside, so that other composite instances can use the same value via a data connection instead of subscribing locally again (only one local OPC-UA subscriber per node is allowed)

Program Flow and Connections

- u16ObjId ⟶ Softkey_IXA.u16ObjId; Softkey_IXA.IN ⟶ OR_MERGE.IN1
- u16ObjIdA ⟶ Aux_IXA.u16ObjId; Aux_IXA.IN ⟶ OR_MERGE.IN2
- ID_WEB_READ ⟶ SUBSCRIBE_WEB.ID; SUBSCRIBE_WEB.OUT ⟶ SPLIT_WEB.IN
- SPLIT_WEB.OUT1 ⟶ OR_MERGE.IN3; SPLIT_WEB.OUT2 ⟶ WEB_STATE
- AUTO_IN ⟶ OR_MERGE.IN4
- OR_MERGE.OUT ⟶ AX_CLIENT_1_0.IN; ID_WRITE_REMOTE ⟶ AX_CLIENT_1_0.ID
- Initialization: INIT ⟶ Softkey_IXA.INIT, Softkey_IXA.INITO ⟶ Aux_IXA.INIT, Aux_IXA.INITO ⟶ SUBSCRIBE_WEB.INIT, SUBSCRIBE_WEB.INITO ⟶ AX_CLIENT_1_0.INIT, AX_CLIENT_1_0.INITO ⟶ INITO and ⟶ AND_QO.REQ
- Quality: QI ⟶ Softkey_IXA.QI, Aux_IXA.QI, SUBSCRIBE_WEB.QI and AX_CLIENT_1_0.QI; their QO ⟶ AND_QO.IN1..IN4; AND_QO.OUT ⟶ QO

Technical Details

- Version 1.2 (2026-09-16): SPLIT_WEB (AX_SPLIT_2) inserted, since adapter plugs are strictly 1:1 (no fan-out as with data/event connections); two destinations on the same plug caused a FORTE boot error (INVALID_STATE on the second CREATE Connection)
- Version 1.1 (2026-09-16): plug WEB_STATE added; fixes the double self-subscribe on ID_WEB_READ (FORTE: “Cannot add another one”)
- Version 1.0 (2026-09-11): copy of Softkey_Aux_IXA_TO_Remote_WRITE with AX_OR_4 instead of AX_OR_3; use only for channels that need an automation, all other users remain on the original type
- No status feedback and no background colour in this block



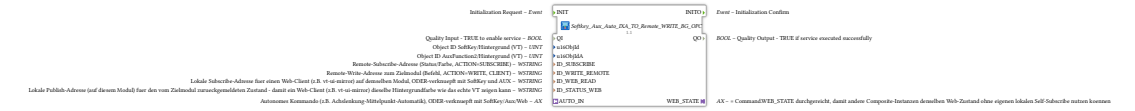
Application Scenarios

- Remote command that can be triggered simultaneously via SoftKey, joystick, web client and autonomous automation (e.g. axle steering centre automation)
- Source of WEB_STATE for Softkey_Aux_Web_IE (override detection)

Summary

Softkey_Aux_Auto_IXA_TO_Remote_WRITE ORs SoftKey, AUX, web override and automation and writes the result to the target module via exactly one publisher.

Softkey_Aux_Auto_IXA_TO_Remote_WRITE_BG_OPC



• – ○ • – ○ • – ○ •

Introduction

`Softkey_Aux_Auto_IXA_TO_Remote_WRITE_BG_OPC` is a thin wrapper (one channel) that places two Sub-Apps side by side:

- **Command** (`Softkey_Aux_Auto_IXA_TO_Remote_WRITE`): read VT softkey OR read AUX assignment (joystick) OR local web override OR automatic command → remote OPC-UA write to the target module.
- **Status** (`AX_SUBSCRIBE_BG3_WEB_OPC`): VT background color (softkey AND AUX) from a remote subscribe plus local web republish (unchanged).

The block is a copy of `Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC` that uses `Softkey_Aux_Auto_IXA_TO_Remote_WRITE` instead of `Softkey_Aux_IXA_TO_Remote_WRITE` as its command half. It is intended only for channels with an automatic requirement (currently: axle steering left/right, slope compensation left/right); for all others `Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC` remains responsible.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request

The user events still arrive via the adapter socket.

Event Outputs

- **INITO** (`EInit`): initialization confirmation (from `Status.INITO`)

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service
- **u16ObjId** (`UINT`): Object ID softkey/background (VT)
- **u16ObjIdA** (`UINT`): Object ID AuxFunction2/background (VT)
- **ID_SUBSCRIBE** (`WSTRING`): Remote subscribe address (status/color, `ACTION=SUBSCRIBE`)
- **ID_WRITE_REMOTE** (`WSTRING`): Remote write address to the target module (command, `ACTION=WRITE`, CLIENT)

- **ID_WEB_READ** (WSTRING): Local subscribe address for a web client (e.g. vt-ui-mirror) on the same module, ORed with softkey and AUX
- **ID_STATUS_WEB** (WSTRING): Local publish address (on this module) for the state reported back by the target module, so that a web client can show the same background color as the real VT

Data Outputs

- **QO** (BOOL): Quality Output - AND of Command.QO and Status.QO

Adapters

- **AUTO_IN** (socket, adapter::types::unidirectional::AX): Autonomous command (e.g. axle steering center automatic), ORed with softkey/aux/web
- **WEB_STATE** (plug, adapter::types::unidirectional::AX): Command.WEB_STATE passed through, so that other composite instances can use the same web state without their own local self-subscribe

Function Blocks (FBs) Used

- **Command**: SubApp MyLib::sys::Softkey_Aux_Auto_IXA_TO_Remote_WRITE
- **Status**: SubApp MyLib::sys::AX_SUBSCRIBE_BG3_WEB_OPC
- **AND_QO** (iec61131::booleanOperators::AND_BOOL_2): combines Command.QO and Status.QO into QO

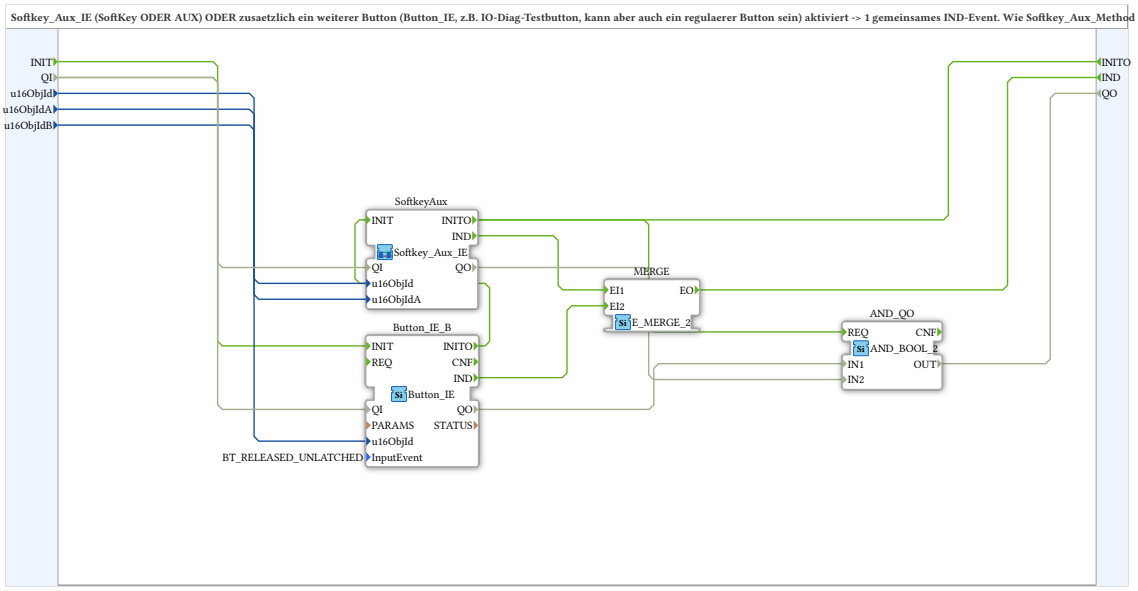
Program Flow and Connections

- u16ObjId, u16ObjIdA ⟶ Command and Status
- ID_WRITE_REMOTE, ID_WEB_READ ⟶ Command
- ID_SUBSCRIBE, ID_STATUS_WEB ⟶ Status
- AUTO_IN ⟶ Command.AUTO_IN
- Command.WEB_STATE ⟶ WEB_STATE
- INIT ⟶ Command.INIT; Command.INITO ⟶ Status.INIT; Status.INITO ⟶ INITO (and ⟶ AND_QO.REQ)
- QI ⟶ Command.QI and Status.QI
- Command.QO ⟶ AND_QO.IN1; Status.QO ⟶ AND_QO.IN2; AND_QO.OUT ⟶ QO

Command and Status are not directly connected to each other; the feedback runs via the remote subscribe.

Technical Details

- WEB_STATE (version 1.1 of Softkey_Aux_Auto_IXA_TO_Remote_WRITE) is a passed-through fan-out plug.
- Use only for channels with an automatic requirement.

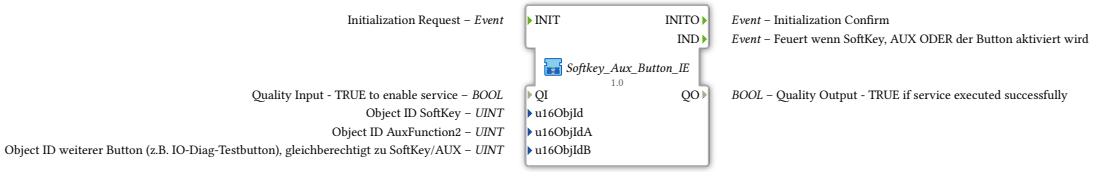


Application Scenarios

- VT key/AUX/web/automatic that writes a command via OPC-UA to a target module, with background color from the reported-back state (e.g. axle steering, slope compensation)

Summary

Softkey_Aux_Auto_IXA_TO_Remote_WRITE_BG_OPC combines command (incl. automatic) and status feedback of one channel in one SubApp.



Softkey_Aux_Button_IE

• – ○ • – ○ • – ○ •

Introduction

`Softkey_Aux_Button_IE` combines `Softkey_Aux_IE` (SoftKey OR AUX) and an additional button (`Button_IE`, e.g. the IO diagnostics test button, but it can also be a regular button) into **one** common `IND` event. It corresponds to `Softkey_Aux_Method_Button_IE` but without the local OPC-UA method and is intended for cases that only need SoftKey, AUX and button with equal rank.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirm
- **IND**: fires when the SoftKey, AUX **or** the button is activated

Data Inputs

- **QI** (`BOOL`, default `TRUE`): quality input, TRUE enables the service
- **u16ObjId** (UINT): object ID of the SoftKey
- **u16ObjIdA** (UINT): object ID of the AuxFunction2
- **u16ObjIdB** (UINT): object ID of a further button (e.g. IO diagnostics test button), equal in rank to SoftKey/AUX

Data Outputs

- **QO** (`BOOL`): quality output, AND combination (`AND_QO`) of the `QO` outputs of `Button_IE_B` and `SoftkeyAux`

Adapters

No adapters are used.

Functionality

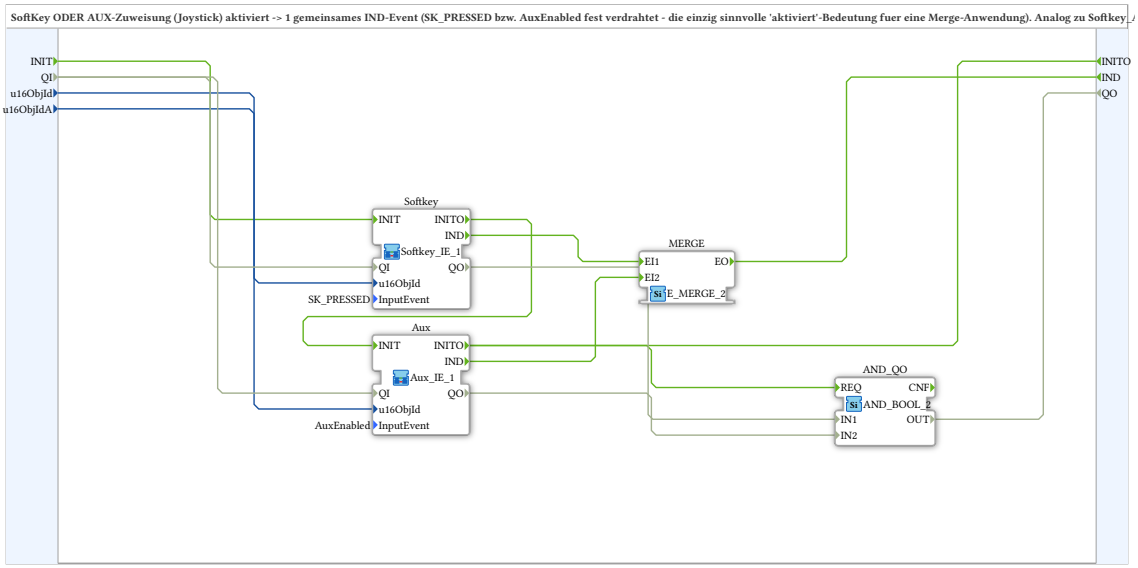
The network contains four blocks:

- SoftkeyAux (MyLib::sys::Softkey_Aux_IE): u16ObjId ⟶ SoftkeyAux.u16ObjId, u16ObjIdA ⟶ SoftkeyAux.u16ObjIdA; its IND goes to MERGE.EI1.
- Button_IE_B (isobus::UT::io::Button::Button_IE, InputEvent = BT_RELEASED_UNLATCHED): u16ObjIdB ⟶ Button_IE_B.u16ObjId; its IND goes to MERGE.EI2.
- MERGE (iec61499::events::E_MERGE_2): MERGE.EO ⟶ IND.
- AND_QO (iec61131::booleanOperators::AND_BOOL_2): combines Button_IE_B.QO (IN1) and SoftkeyAux.QO (IN2) into QO.

Initialization: INIT ⟶ Button_IE_B.INIT; Button_IE_B.INITO ⟶ SoftkeyAux.INIT; SoftkeyAux.INITO ⟶ INITO and ⟶ AND_QO.REQ. Quality: QI ⟶ Button_IE_B.QI and SoftkeyAux.QI; AND_QO.OUT ⟶ QO.

Technical Details

- The additional button triggers on release (BT_RELEASED_UNLATCHED)
- Extracted from Baender_Individual_Toggle.SUB, where the same combination (Softkey_Aux_IE + Button_IE + E_MERGE_2) was wired three times for hedgehog belt, elevator and cross belt
- Stateless

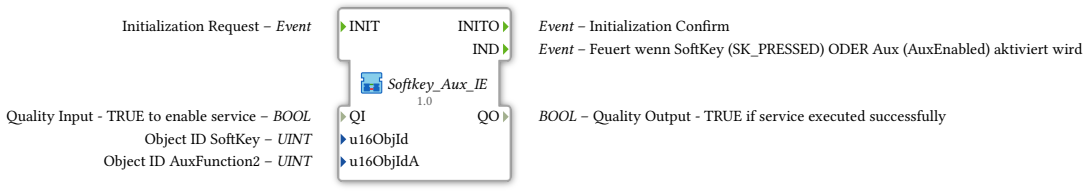


Application Scenarios

- An output that is to be triggered with equal rank by SoftKey, joystick assignment and an additional button (e.g. IO diagnostics test button)

Conclusion

Softkey_Aux_Button_IE merges SoftKey, AUX and a further button into a single IND event.



Softkey_Aux_IE

• – ○ • – ○ • – ○ •

Introduction

Softkey_Aux_IE raises a common IND event when a **SoftKey** OR an **AUX assignment (joystick)** is activated. SK_PRESSED and AuxEnabled are hard-wired, since this is the only sensible "activated" meaning for a merge application. The block is analogous to Softkey_Aux_IXA_TO_Remote_WRITE (continuous-state OR), but for the discrete event channel. It therefore does not collide with an already existing Softkey_IXA/Aux_IXA continuous-state subscription on the same object (two different subscription types).

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization Request

Event Outputs

- **INITO** (`EInit`): Initialization Confirm
- **IND**: fires when the SoftKey (`SK_PRESSED`) OR Aux (`AuxEnabled`) is activated

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE to enable the service
- **u16ObjId** (`UINT`): object ID of the SoftKey
- **u16ObjIdA** (`UINT`): object ID of the AuxFunction2

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service executed successfully (AND of `Softkey.QO` and `Aux.QO`)

Adapters

None.

Function Blocks (FBs) Used

- **`Softkey`** (SubApp `MyLib::sys::Softkey_IE_1`, Softkey_IE_1): parameter `InputEvent = SK_PRESSED`
- **`Aux`** (SubApp `MyLib::sys::Aux_IE_1`, Aux_IE_1): parameter `InputEvent = AuxEnabled`
- **`MERGE`** (`iec61499::events::E_MERGE_2`): merges both events
- **`AND_QO`** (`iec61131::booleanOperators::AND_BOOL_2`): ANDs `Softkey.QO` and `Aux.QO` into `QO`

Functionality

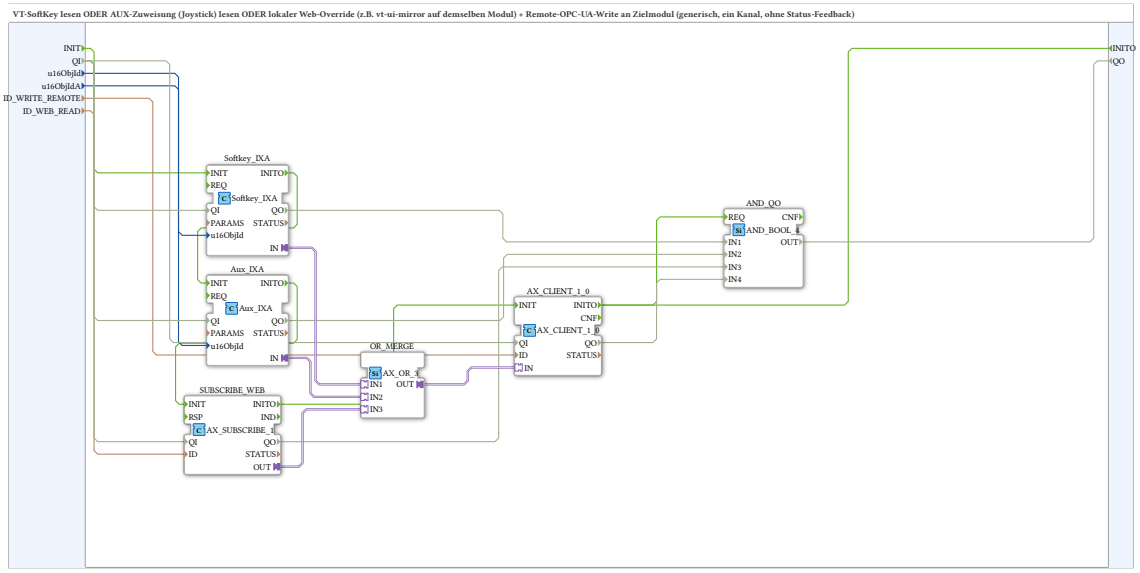
- `u16ObjId` ⟶ `Softkey.u16ObjId`; `u16ObjIdA` ⟶ `Aux.u16ObjId`
- `Softkey.IND` ⟶ `MERGE.EI1`; `Aux.IND` ⟶ `MERGE.EI2`
- `MERGE.EO` ⟶ `IND`
- Initialization chain: `INIT` ⟶ `Softkey.INIT`, `Softkey.INITO` ⟶ `Aux.INIT`, `Aux.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`
- `QI` ⟶ `Softkey.QI` and `Aux.QI`
- `Softkey.QO` ⟶ `AND_QO.IN1`, `Aux.QO` ⟶ `AND_QO.IN2`, `AND_QO.OUT` ⟶ `QO`

Technical Details

- Imports `isobus::UT::io::Softkey::SoftKeyActivationCode::SK_PRESSED` and `isobus::UT::io::Auxiliary::IN::AuxiliaryState::AuxEnabled`
- Works via the discrete event channel, not via the continuous state

Application Scenarios

- One event from SoftKey or joystick assignment, e.g. for toggle or trigger functions



Summary

`Softkey_Aux_IE` combines SoftKey and AUX activation into one common `IND` event.

Softkey_Aux_IXA_TO_Remote_WRITE

• – ○ • – ○ • – ○ •

Introduction

`Softkey_Aux_IXA_TO_Remote_WRITE` is the command half of `Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC`, extracted as an independent component: VT SoftKey, AUX assignment (joystick), and a local web override (e.g., vt-ui-mirror on the same module) are combined using an OR operator and written to a target module via remote write—without status feedback.

Function Blocks (FBs) Used

Sub-Blocks: Softkey_Aux_IXA_TO_Remote_WRITE

- **Type**: SubAppType
- **Internal FBs Used**:
- **Softkey_IXA**: `isobus::UT::io::Softkey::Softkey_IXA` — VT SoftKey Adapter (`u16ObjId`).
- **Aux_IXA**: `isobus::UT::io::Auxiliary::IN::Aux_IXA` — AUX Assignment/Joystick Adapter (`u16ObjIdA`).
- **SUBSCRIBE_WEB**: `adapter::net::AX_SUBSCRIBE_1` — Local web subscribe (`ID_WEB_READ`), e.g., from a vt-ui-mirror on the same module.
- **OR_MERGE**: `adapter::booleanOperators::AX_OR_3` — Combines SoftKey, Aux, and Web Override using OR.
- **AX_CLIENT_1_0**: `adapter::net::AX_CLIENT_1_0` — Writes the combined signal to the target module using remote write (`ID_WRITE_REMOTE`).
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_4` — Combines the `QO` outputs of `Softkey_IXA`, `Aux_IXA`, `SUBSCRIBE_WEB` and `AX_CLIENT_1_0` into the SubApp output `QO`.
- **Interface**: event input `INIT`, event output `INITO`, data input `QI` (default `TRUE`, passed on to the four FBs), data output `QO`.
- **How it Works**: Three independent command sources (SoftKey, Aux, local web override) are combined using `AX_OR_3` and transmitted to the target module as a single remote write command.

Program Flow and Connections

1. `u16ObjId` ⟶ `Softkey_IXA.u16ObjId`; `u16ObjIdA` ⟶ `Aux_IXA.u16ObjId`; `ID_WEB_READ` ⟶ `SUBSCRIBE_WEB.ID`; `ID_WRITE_REMOTE` ⟶ `AX_CLIENT_1_0.ID` (Data connections, hidden).
2. `Softkey_IXA.IN` ⟶ `OR_MERGE.IN1`; `Aux_IXA.IN` ⟶ `OR_MERGE.IN2`; `SUBSCRIBE_WEB.OUT` ⟶ `OR_MERGE.IN3`.
3. `OR_MERGE.OUT` ⟶ `AX_CLIENT_1_0.IN`.
4. Initialization: `INIT` ⟶ `Softkey_IXA.INIT`; `Softkey_IXA.INITO` ⟶ `Aux_IXA.INIT`; `Aux_IXA.INITO` ⟶ `SUBSCRIBE_WEB.INIT`; `SUBSCRIBE_WEB.INITO` ⟶ `AX_CLIENT_1_0.INIT`; `AX_CLIENT_1_0.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`.
5. Quality: `QI` ⟶ `Softkey_IXA.QI`, `Aux_IXA.QI`, `SUBSCRIBE_WEB.QI` and `AX_CLIENT_1_0.QI`; their `QO` outputs ⟶ `AND_QO.IN1` to `IN4`; `AND_QO.OUT` ⟶ `QO`.

Technical Features

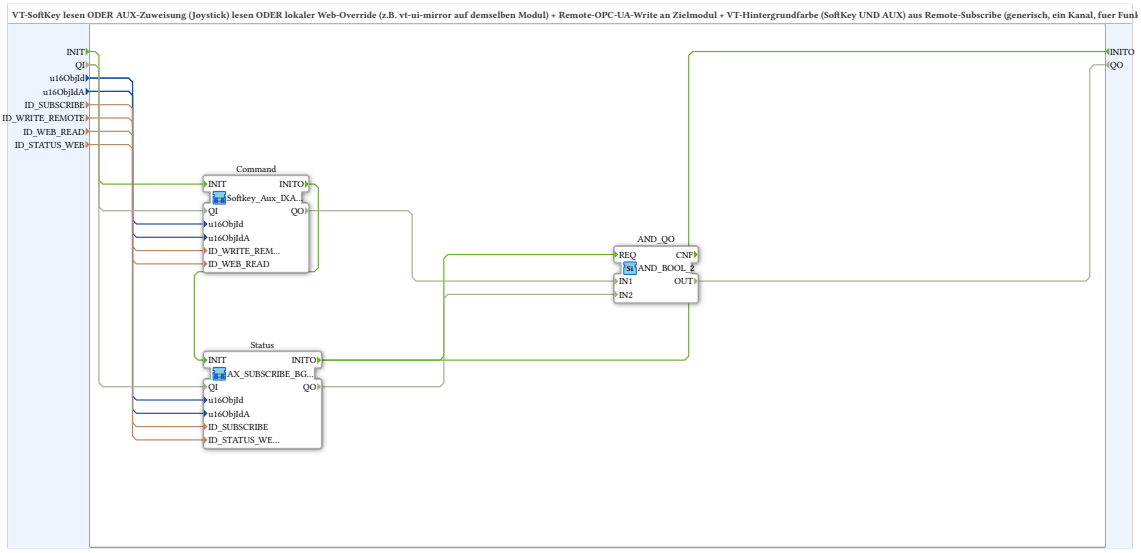
- **Three Equal Command Sources**: SoftKey, AUX Assignment, and Local Web Override function equally via the OR operator—any of the three sources can trigger the command.
- **No Status Feedback**: Unlike `Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC`, this block does not contain any feedback/background color; For this purpose, `AX_SUBSCRIBE_BG3_WEB_OPC` should be placed alongside it with the same values as `u16ObjId`/`u16ObjIdA`. Important for this manual pairing: `ID_WEB_READ` (here) and `ID_STATUS_WEB` (in `AX_SUBSCRIBE_BG3_WEB_OPC`) must be different local OPC UA nodes, otherwise the same feedback-loop risk arises as described for `Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC`. `ID_WRITE_REMOTE` (here) and `ID_SUBSCRIBE` (there), by contrast, both target the remote module and may reference the same remote node.

Application Scenarios

- Remote control of a target module via soft key, AUX joystick assignment, or a local web client, without requiring a status display on the same module.

Comparison with Similar Modules

For the complete, pre-wired combination of both sides (command + status), `Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC` should still be used, which contains this module as a command sub-module.



Summary

`Softkey_Aux_IXA_TO_Remote_WRITE` encapsulates the pure command side of a remote channel: three OR-linked sources (soft key, aux, local web override), written to a target module via remote write.

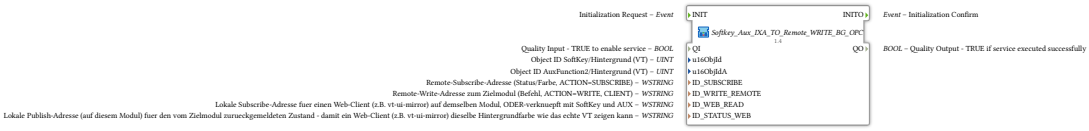
Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC



• — ○ • — ○ • — ○ •

Introduction

`Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC` reads a VT softkey OR an AUX assignment (joystick) OR a local web override and writes the result to a target module via remote OPC UA write. Additionally, the VT background color (softkey AND AUX) is set using a remote subscribe from the target module. This is intended for functions without a local physical output, where the control interface is located on one module (e.g., STG1), but the actuator is on a different module without its own VT connection.

`Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC` reads a VT softkey OR an AUX assignment (joystick) OR a local web override and writes the result to a target module via remote OPC UA write. Since version 1.2, the function block is a thin-walled wrapper that places two independently reusable sub-blocks side by side: `Softkey_Aux_IXA_TO_Remote_WRITE` (command) and `AX_SUBSCRIBE_BG3_WEB_OPC` (status). The external interface initially remained unchanged; the wrapper has since gained the events `INIT`/`INITO` as well as `QI` (BOOL, initial value `TRUE`) and `QO` (BOOL).

Function Blocks (FBs) Used

Sub-blocks: Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC

- **Type**: SubAppType
- **Internal FBs Used**:
- **Command** (SubApp, `MyLib::sys::Softkey_Aux_IXA_TO_Remote_WRITE`): SoftKey OR Aux OR local web override ⟶ Remote write to the target module.
- **Status** (SubApp, `MyLib::sys::AX_SUBSCRIBE_BG3_WEB_OPC`): Remote Subscribe ⟶ Background color on SoftKey AND Aux + local web republish.
- **AND_QO** (`iec61131::booleanOperators::AND_BOOL_2`): combines `Command.QO` and `Status.QO` into the output `QO`.
- **Functionality**: Both sub-components run independently as far as data is concerned (only the init chain and the quality combination connect them); they only share the same `u16ObjId`/`u16ObjIdA` values so that the command and status display operate on the same VT object.

Program Flow and Connections

1. `u16ObjId` ⟶ `Command.u16ObjId` and `Status.u16ObjId`; `u16ObjIdA` ⟶ `Command.u16ObjIdA` and `Status.u16ObjIdA` (data connections, hidden).

2. ID_WRITE_REMOTE ⟶ Command.ID_WRITE_REMOTE; ID_WEB_READ ⟶ Command.ID_WEB_READ.
3. ID_SUBSCRIBE ⟶ Status.ID_SUBSCRIBE; ID_STATUS_WEB ⟶ Status.ID_STATUS_WEB.
4. Apart from the init chain (item 5), there is no direct SubApp connection between Command and Status —both sub-apps are completely independent and communicate only indirectly via the target module (commands write to it, status updates are subscribed to from it). Locally, their paths can still become connected if ID_WEB_READ and ID_STATUS_WEB are accidentally configured to alias the same OPC UA node (see the feedback-loop note below).
5. Initialization: INIT ⟶ Command.INIT; Command.INITO ⟶ Status.INIT; Status.INITO ⟶ INITO and AND_QO.REQ.
6. Quality: QI ⟶ Command.QI and Status.QI; Command.QO ⟶ AND_QO.IN1; Status.QO ⟶ AND_QO.IN2; AND_QO.OUT ⟶ QO.

Technical Features

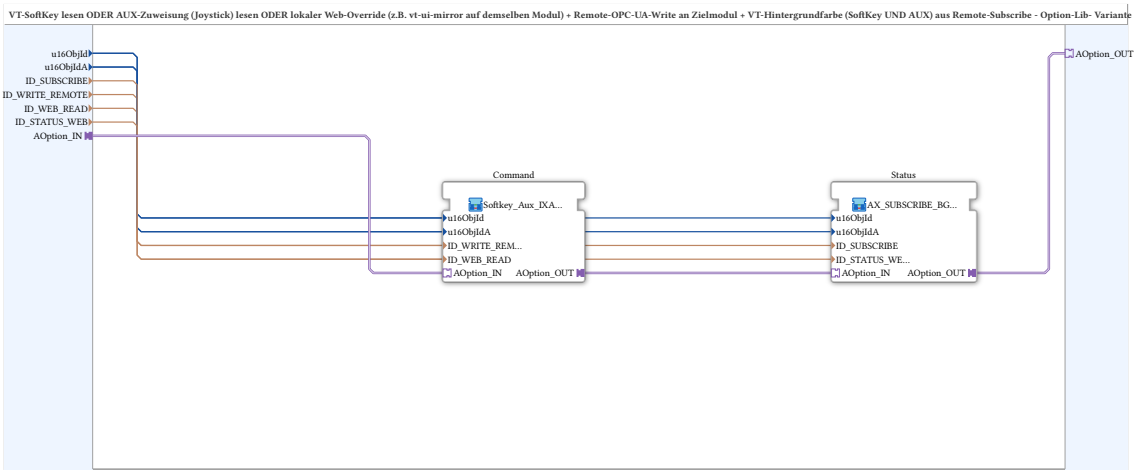
- **Pure wrapper since version 1.2**: The splitting into Command/Status does not change the behavior, but allows the independent reuse of both halves (e.g., AX_SUBSCRIBE_BG3_WEB_OPC solely for status displays).
- **No local physical output**: The actuator is located on a separate module; this block only maps operation and status feedback to the operator module.
- **Separate local nodes for web override and web status**: ID_WRITE_REMOTE (write) and ID_SUBSCRIBE (read) both point at the remote target module and may legitimately reference the same remote node there — write and subscribe are different OPC UA operations, so this poses no feedback risk on this module. The actual feedback-loop risk lies with the two *local* nodes on this module: ID_WEB_READ (read by Command via AX_SUBSCRIBE_1 and merged into the command OR) and ID_STATUS_WEB (written by Status via AX_PUBLISH_1 with the state echoed back from the target module) must be different local OPC UA nodes — otherwise Command would read the state republished by Status as if it were a manual web override and write it straight back to the target module as a new command.

Application Scenarios

- Control stations without their own physical output, where both the SoftKey and AUX joystick assignment are intended to control a remote actuator, and the control screen must additionally display its status using color.

Comparison with Similar Modules

If only a SoftKey without AUX is required, use Softkey_IXA_TO_Remote_WRITE_BG_OPC. For command or status alone (without the other half), the sub-modules Softkey_Aux_IXA_TO_Remote_WRITE and AX_SUBSCRIBE_BG3_WEB_OPC, respectively, can be used directly.



Summary

Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC combines the command and status pages of a remote channel with softkey and auxiliary controls behind a stable, well-known interface—since version 1.2, it's a pure wrapper around two independent components.

Softkey_Aux_IXA_TO_Remote_WRITE_BG_Option_OPC

• — ○ • — ○ • — ○ •

Introduction

`Softkey_Aux_IXA_TO_Remote_WRITE_BG_Option_OPC` is the option-lib variant of `Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC`: read a VT SoftKey OR an AUX assignment (joystick) OR a local web override, remote OPC-UA write to a target module, and VT background colour (SoftKey and AUX) from a remote subscribe. If the option is not selected, both the command side and the status side are inactive (real `INIT_REQ`/`INIT_CNF`, no VT object binding). The block is a thin wrapper around two sub-blocks that are chained sequentially via the `AOption` adapter.

Interface Structure

Event Inputs

None (initialization runs via the adapter `AOption_IN`).

Event Outputs

None.

Data Inputs

Variable	Type	Default	Comment
`u16ObjId`	UINT		Object ID SoftKey/background (VT).
`u16ObjIdA`	UINT		Object ID AuxFunction2/background (VT).
`ID_SUBSCRIBE`	WSTRING		Remote subscribe address (status/colour, `ACTION=SUBSCRIBE`).
`ID_WRITE_REMOTE`	WSTRING		Remote write address to the target module (command, `ACTION=WRITE`, CLIENT).
`ID_WEB_READ`	WSTRING		Local subscribe address for a web client on the same module, ORed with SoftKey and AUX.
`ID_STATUS_WEB`	WSTRING		Local publish address for the state reported back by the target module.

Data Outputs

None.

Adapters

Adapter	Type	Direction	Comment
AOption_IN	Option::AOption	Socket	Drives INIT/QI of Command AND Status sequentially; connect e.g. to AOption_AUI_DEMUX_N.OUTx or the AOption_OUT of an upstream instance.
AOption_OUT	Option::AOption	Plug	Passes the activation on to a downstream instance (daisy chain, e.g. a second instance sharing the same option); leave unused if nothing follows.

Function Blocks (FBs) Used

Sub-blocks: Softkey_Aux_IXA_TO_Remote_WRITE_BG_Option_OPC

- **Type**: SubAppType
- **Internal FBs used**:
  - **Command** (SubApp, MyLib::sys::Softkey_Aux_IXA_TO_Remote_WRITE_Option): SoftKey OR Aux OR web override -> remote write; see Softkey_Aux_IXA_TO_Remote_WRITE_Option.
  - **Status** (SubApp, MyLib::sys::AX_SUBSCRIBE_BG3_WEB_Option_OPC): remote subscribe -> background colour on SoftKey and Aux plus local web republish; see AX_SUBSCRIBE_BG3_WEB_Option_OPC.

Program Flow and Connections

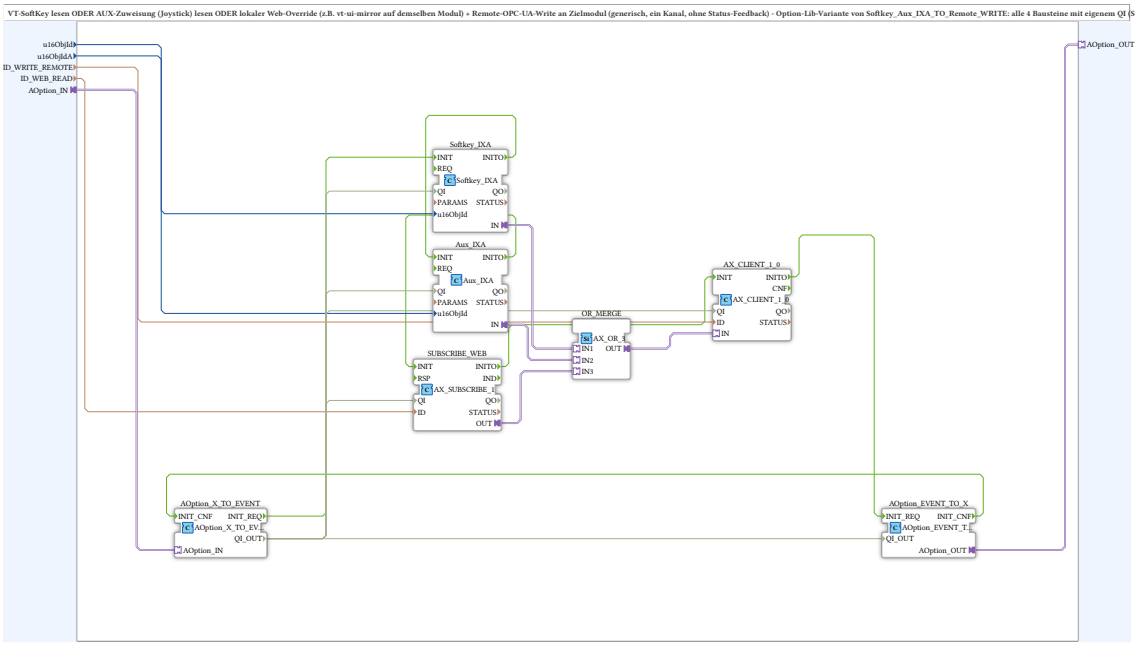
1. Adapter chain: AOption_IN -> Command.AOption_IN; Command.AOption_OUT -> Status.AOption_IN; Status.AOption_OUT -> AOption_OUT. The option thus activates the command side first, then the status side, then a downstream instance.
2. u16ObjId -> Command.u16ObjId and Status.u16ObjId; u16ObjIdA -> Command.u16ObjIdA and Status.u16ObjIdA.
3. ID_WRITE_REMOTE -> Command.ID_WRITE_REMOTE; ID_WEB_READ -> Command.ID_WEB_READ; ID_SUBSCRIBE -> Status.ID_SUBSCRIBE; ID_STATUS_WEB -> Status.ID_STATUS_WEB.
4. The block has no event or QI/QO connections of its own; activation and acknowledgment run exclusively via the adapters AOption_IN/AOption_OUT.

Technical Features

- **Command and Status are both option-gated:** All blocks with a real QI can be switched off via the AOption socket.
- **Sequential chain instead of socket split:** Command.AOption_OUT -> Status.AOption_IN (strictly 1:1), analogous to the daisy-chain style of OptionalGroup_001a. The block's own AOption_OUT passes the chain on to further instances sharing the same option.
- As in the original: ID_WEB_READ (from Command) and ID_STATUS_WEB (from Status) must point to different local OPC-UA nodes, otherwise feedback arises (see Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC).

Application Scenarios

- Optional operator station with SoftKey and Aux assignment for a remote actuator including coloured status display, active only when the option is selected.
- Several instances sharing the same option, chained via AOption_OUT.



Summary

Softkey_Aux_IXA_TO_Remote_WRITE_BG_Option_OPC bundles the command and status sides of a remote channel behind a shared AOption socket and passes the activation on via AOption_OUT.

Softkey_Aux_IXA_TO_Remote_WRITE_Option

• — ○ • — ○ • — ○ •

Introduction

`Softkey_Aux_IXA_TO_Remote_WRITE_Option` reads a VT SoftKey OR an AUX assignment (joystick) OR a local web override (e.g. `vt-ui-mirror` on the same module) and writes the result via remote OPC-UA write to a target module (generic, one channel, without status feedback). It is the option-lib variant of `Softkey_Aux_IXA_TO_Remote_WRITE`: all four blocks with their own `QI` (`Softkey_IXA`, `Aux_IXA`, `SUBSCRIBE_WEB`, `AX_CLIENT_1_0`) are initialized and gated sequentially by a single `Option::AOption` socket. The plug `AOption_OUT` passes the activation on to a downstream group (daisy chain).

Interface Structure

Event Inputs / Outputs

None (initialization runs via the adapter `AOption_IN`).

Data Inputs

Variable	Type	Default	Comment
`u16ObjId`	UINT	`ID_NULL`	Object ID SoftKey (VT).
`u16ObjIdA`	UINT	`ID_NULL`	Object ID AuxFunction2 (VT).
`ID_WRITE_REMOTE`	WSTRING		Remote write address to the target module (command, `ACTION=WRITE`, CLIENT).
`ID_WEB_READ`	WSTRING		Local subscribe address for a web client (e.g. `vt-ui-mirror`) on the same module, ORed with SoftKey and AUX.

Data Outputs

None.

Adapters

Adapter	Type	Direction	Comment
AOption_IN	Option::AOption	Socket	Drives INIT/QI of Softkey_IXA, Aux_IXA, SUBSCRIBE_WEB and AX_CLIENT_1_0; connect e.g. to AOption_AUI_DEMUX_N.OUTx.
AOption_OUT	Option::AOption	Plug	Passes the activation on to a downstream group (daisy chain); leave unused if nothing follows.

Function Blocks (FBs) Used

Sub-blocks: Softkey_Aux_IXA_TO_Remote_WRITE_Option

- **Type**: SubAppType
- **Internal FBs used**:
  - **AOption_X_TO_EVENT** (Option::conversion::AOption_X_TO_EVENT): converts the socket AOption_IN into INIT_REQ/QI_OUT, see AOption_X_TO_EVENT.
  - **Softkey_IXA** (isobus::UT::io::Softkey::Softkey_IXA): reads the SoftKey (u16ObjId).
  - **Aux_IXA** (isobus::UT::io::Auxiliary::IN::Aux_IXA): reads the AUX assignment (u16ObjIdA).
  - **SUBSCRIBE_WEB** (adapter::net::AX_SUBSCRIBE_1): reads the local web override (ID_WEB_READ).
  - **OR_MERGE** (adapter::booleanOperators::AX_OR_3): OR of the three sources.
  - **AX_CLIENT_1_0** (adapter::net::AX_CLIENT_1_0): remote write to ID_WRITE_REMOTE.
  - **AOption_EVENT_TO_X** (Option::conversion::AOption_EVENT_TO_X): passes the activation on to AOption_OUT.

Program Flow and Connections

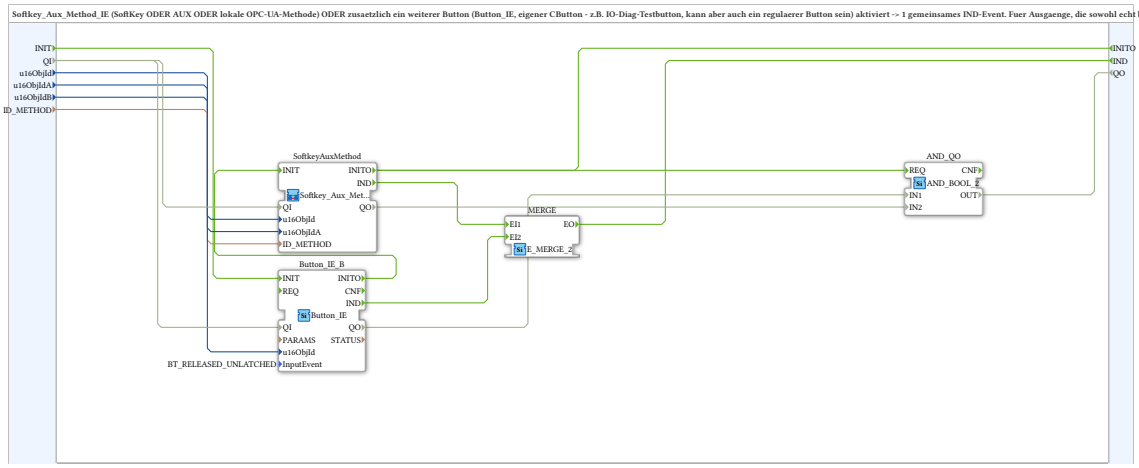
1. Sequential initialization: AOption_X_TO_EVENT.INIT_REQ -> Softkey_IXA.INIT; Softkey_IXA.INITO -> Aux_IXA.INIT; Aux_IXA.INITO -> SUBSCRIBE_WEB.INIT; SUBSCRIBE_WEB.INITO -> AX_CLIENT_1_0.INIT; AX_CLIENT_1_0.INITO -> AOption_EVENT_TO_X.INIT_REQ; AOption_EVENT_TO_X.INIT_CNF -> AOption_X_TO_EVENT.INIT_CNF.
2. AOption_X_TO_EVENT.QI_OUT -> QI of Softkey_IXA, Aux_IXA, SUBSCRIBE_WEB, AX_CLIENT_1_0 and AOption_EVENT_TO_X.QI_OUT.
3. Data: Softkey_IXA.IN -> OR_MERGE.IN1; Aux_IXA.IN -> OR_MERGE.IN2; SUBSCRIBE_WEB.OUT -> OR_MERGE.IN3; OR_MERGE.OUT -> AX_CLIENT_1_0.IN.
4. Parameters: u16ObjId -> Softkey_IXA.u16ObjId; u16ObjIdA -> Aux_IXA.u16ObjId; ID_WEB_READ -> SUBSCRIBE_WEB.ID; ID_WRITE_REMOTE -> AX_CLIENT_1_0.ID.
5. Adapters: AOption_IN -> AOption_X_TO_EVENT.AOption_IN; AOption_EVENT_TO_X.AOption_OUT -> AOption_OUT.

Technical Features

- **Real INIT_REQ/INIT_CNF instead of just a QI bool:** If the option is not selected, all four blocks stay inactive.
- **Sequential instead of parallel:** Initialization runs as a daisy chain (Softkey_IXA -> Aux_IXA -> SUBSCRIBE_WEB -> AX_CLIENT_1_0); AOption_OUT allows further instances sharing the same option to be attached (e.g. a second SoftKey instance) or, as in Softkey_Aux_IXA_TO_Remote_WRITE_BG_Option_OPC, the status half.
- The counterpart without option is Softkey_Aux_IXA_TO_Remote_WRITE.

Application Scenarios

- Optional operating function that reads SoftKey, Aux and web override only when the option is selected and writes to a target module via remote write.
- Several SoftKeys sharing the same option, chained via AOption_OUT.



Summary

Softkey_Aux_IXA_TO_Remote_WRITE_Option is the option-gated variant of the remote-write command with SoftKey, Aux and web override; its four QI blocks are activated via an AOption socket and it passes the activation on via AOption_OUT.

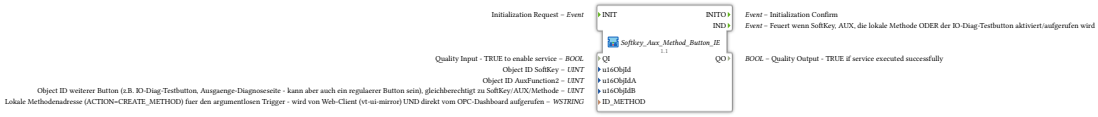
Softkey_Aux_Method_Button_IE



• – ○ • – ○ • – ○ •

Introduction

`Softkey_Aux_Method_Button_IE` extends `Softkey_Aux_Method_IE` (SoftKey OR AUX OR local OPC-UA method) by **one further button** (`Button_IE`, its own `CButton` - e.g. an IO-diag test button, but it can also be a regular button). If any of these sources is activated, a common `IND` event is produced.

The block serves outputs that are both operated for real (SoftKey/AUX/web/dashboard) and triggered equally via an additional button. The button background is fed separately by the caller from the resulting state; `u16ObjIdB` therefore remains available to the caller.

Function Blocks (FBs) Used

Sub-blocks: Softkey_Aux_Method_Button_IE

- **Type**: SubAppType
- **Internal blocks used**:
  - **SoftkeyAuxMethod**: SubApp `MyLib::sys::Softkey_Aux_Method_IE` - SoftKey, AUX or local method
  - **Button_IE_B**: `isobus::UT::io::Button::Button_IE` (`InputEvent=BT_RELEASED_UNLATCHED`) - further button
  - **MERGE**: `iec61499::events::E_MERGE_2` - merges both `IND` events
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` - combines the `QO` of `Button_IE_B` and `SoftkeyAuxMethod`
- **Imports**: `ID_NULL`, `BT_RELEASED_UNLATCHED`

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; goes to `Button_IE_B.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirm; comes from `SoftkeyAuxMethod.INITO`
- **IND**: Fires when the SoftKey, AUX, the local method or the additional button is activated/called

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service; goes to `Button_IE_B` and `SoftkeyAuxMethod`
- **u16ObjId** (`UINT`): Object ID of the SoftKey
- **u16ObjIdA** (`UINT`): Object ID of the `AuxFunction2`
- **u16ObjIdB** (`UINT`, default `ID_NULL`): Object ID of a further button (e.g. IO-diag test button on the outputs diagnostic page; can also be a regular button), equal to SoftKey/AUX/method
- **ID_METHOD** (`WSTRING`): Local method address (`ACTION=CREATE_METHOD`) for the argument-less trigger - called by the web client (`vt-ui-mirror`) and directly by the OPC dashboard

Data Outputs

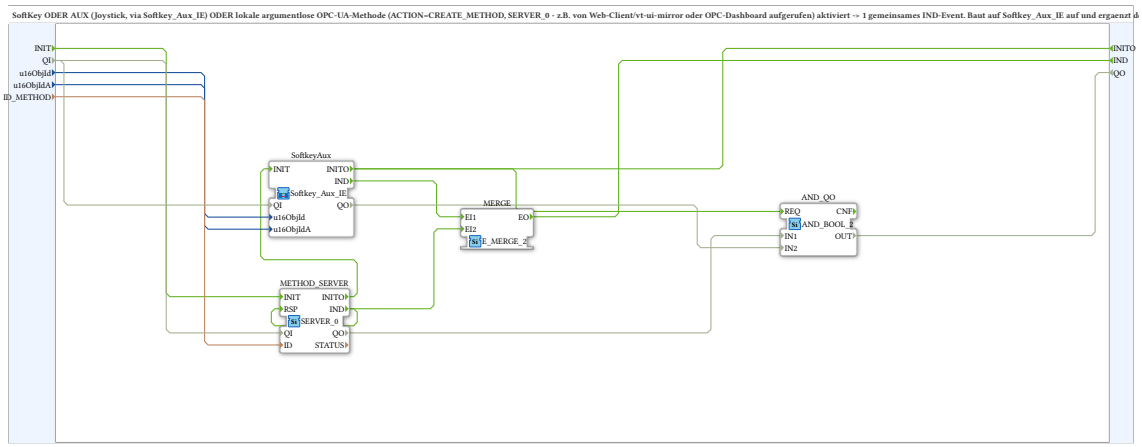
- **QO** (`BOOL`): Quality Output - TRUE if the service was executed successfully (AND of the `QO` of `Button_IE_B` and `SoftkeyAuxMethod`)

Program Flow and Connections

- `u16ObjId`, `u16ObjIdA`, `ID_METHOD` ⟶ `SoftkeyAuxMethod`
- `u16ObjIdB` ⟶ `Button_IE_B.u16ObjId`
- `SoftkeyAuxMethod.IND` ⟶ `MERGE.EI1`; `Button_IE_B.IND` ⟶ `MERGE.EI2`
- `MERGE.EO` ⟶ `IND`
- Initialization: `INIT` ⟶ `Button_IE_B.INIT`, `Button_IE_B.INITO` ⟶ `SoftkeyAuxMethod.INIT`, `SoftkeyAuxMethod.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`
- Quality: `QI` ⟶ `Button_IE_B.QI` and `SoftkeyAuxMethod.QI`; `Button_IE_B.QO` ⟶ `AND_QO.IN1`, `SoftkeyAuxMethod.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`

Technical Details

- Version 1.1 (2026-09-15): `u16ObjId_TEST` renamed to `u16ObjIdB` (`Button_IE_TEST` ⟶ `Button_IE_B`), since the additional button is not always an IO-diag test button
- Used, among others, by `AX_SoftkeyToggle_RS_TO_AX` for the toggle branch



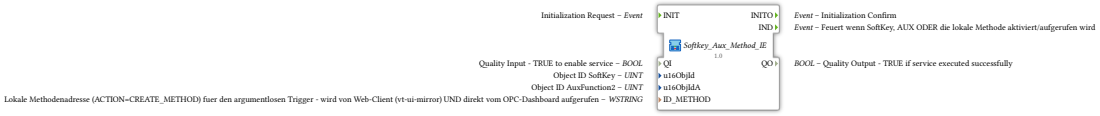
Application Scenarios

- Toggle output that is to be operated equally via SoftKey, joystick, web/dashboard and an additional diagnostic button

Summary

`Softkey_Aux_Method_Button_IE` supplements `Softkey_Aux_Method_IE` with one more button and provides a common `IND` event.

Softkey_Aux_Method_IE



• – ○ • – ○ • – ○ •

Introduction

`Softkey_Aux_Method_IE` merges three triggers into **one common `IND` event**: a VT softkey, an AUX function (joystick, via `Softkey_Aux_IE`) or a **local argument-less OPC-UA method** (`ACTION=CREATE_METHOD`, `SERVER_0`) that is called e.g. by the web client (`vt-ui-mirror`) or by

the OPC dashboard. The block builds on `Softkey_Aux_IE` and adds the method channel. Unlike `Softkey_Aux_Web_IE` (web via `SUBSCRIBE_R_TRIG` on a written variable), the web/dashboard trigger here is a genuine RPC method call without a shared variable.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirmation
- **IND**: Fires when the softkey, AUX or the local method is activated/called

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service
- **u16ObjId** (`UINT`): Object ID of the softkey
- **u16ObjIdA** (`UINT`): Object ID of the AuxFunction2
- **ID_METHOD** (`WSTRING`): Local method address (`ACTION=CREATE_METHOD`) for the argument-less trigger; called by the web client (`vt-ui-mirror`) and directly by the OPC dashboard

Data Outputs

- **QO** (`BOOL`): Quality Output - AND of `METHOD_SERVER.QO` and `SoftkeyAux.QO`

Adapters

This function block uses no adapters.

Function Blocks (FBs) Used

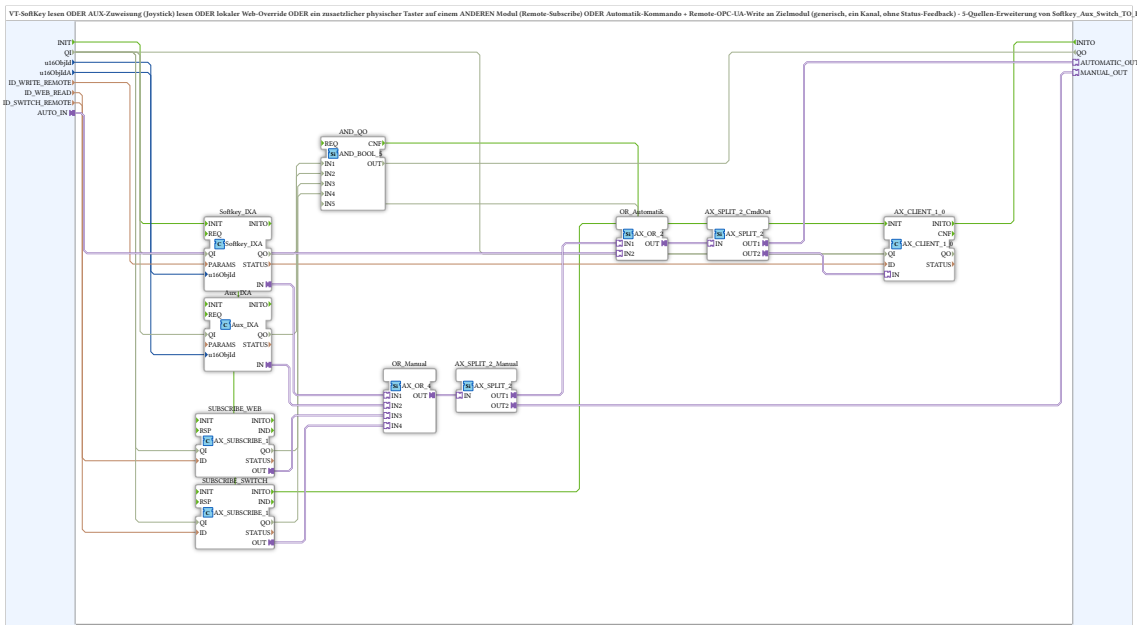
- **SoftkeyAux**: SubApp `MyLib::sys::Softkey_Aux_IE` - softkey or AUX
- **METHOD_SERVER**: `iec61499::net::SERVER_0` - local method
- **MERGE**: `iec61499::events::E_MERGE_2` - merges the two triggers
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` - combines `METHOD_SERVER.QO` and `SoftkeyAux.QO` into `QO`

Program Flow and Connections

- `SoftkeyAux.IND` ⟶ `MERGE.EI1`
- `METHOD_SERVER.IND` ⟶ `MERGE.EI2`
- `METHOD_SERVER.IND` ⟶ `METHOD_SERVER.RSP` (feedback wiring)
- `MERGE.EO` ⟶ `IND`
- `u16ObjId`, `u16ObjIdA` ⟶ `SoftkeyAux`; `ID_METHOD` ⟶ `METHOD_SERVER.ID`
- `INIT` ⟶ `METHOD_SERVER.INIT`; `METHOD_SERVER.INITO` ⟶ `SoftkeyAux.INIT`; `SoftkeyAux.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`)
- `QI` ⟶ `METHOD_SERVER.QI` and `SoftkeyAux.QI`
- `METHOD_SERVER.QO` ⟶ `AND_QO.IN1`; `SoftkeyAux.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`

Technical Details

- **`RSP` must be wired back to `IND`.** The trigger is argument-less and needs no processing; without this connection, FORTE's `onServerMethodCall` blocks the OPC-UA server thread for up to 4 s while holding open62541's global `serviceMutex`, which every `AX_PUBLISH_1` on another FORTE thread also needs (see `Ventilsteuerung/OPC_UA_VERNETZUNG.md`, item 12).



Application Scenarios

- Key, joystick assignment and web/dashboard call that trigger the same action (e.g. "All off")

Summary

`Softkey_Aux_Method_IE` combines softkey, AUX and an OPC-UA method call into one common `IND` event.

Softkey_Aux_Switch_Auto_TO_Remote_WRITE

• – ○ • – ○ • – ○ •

Introduction

`Softkey_Aux_Switch_Auto_TO_Remote_WRITE` combines, by OR, five sources of a command: the VT SoftKey, the AUX assignment (joystick), a local web override, an additional physical button on another module (remote subscribe) and an autonomous automation command (`AUTO_IN`). The result is written to a target module via remote OPC-UA write (generic, one channel, without status feedback). The block is the 5-source extension of `Softkey_Aux_Switch_TO_Remote_WRITE` by the additional socket `AUTO_IN` (e.g. automatic filling hysteresis driving the same filling belt raise line as SoftKey/AUX/web/physical button).

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirm

Data Inputs

- **QI** (`BOOL`, default `TRUE`): quality input, TRUE enables the service
- **u16ObjId** (UINT): object ID of the SoftKey (VT), default `ID_NULL`
- **u16ObjIdA** (UINT): object ID of the AuxFunction2 (VT), default `ID_NULL`
- **ID_WRITE_REMOTE** (WSTRING): remote write address to the target module (command, `ACTION=WRITE`, CLIENT)
- **ID_WEB_READ** (WSTRING): local subscribe address for a web client (e.g. vt-ui-mirror) on the same module, ORed with SoftKey and AUX
- **ID_SWITCH_REMOTE** (WSTRING): remote subscribe address of an additional physical button on another module, ORed with SoftKey/AUX/web/automation

Data Outputs

- **QO** (`BOOL`): quality output, AND combination (`AND_QO`, `AND_BOOL_5`) of the `QO` outputs of `Softkey_IXA`, `Aux_IXA`, `SUBSCRIBE_WEB`, `SUBSCRIBE_SWITCH` and `AX_CLIENT_1_0`

Adapters

- **AUTO_IN** (socket, AX): autonomous command (e.g. automatic filling hysteresis), ORed with SoftKey/AUX/web/physical button
- **AUTOMATIC_OUT** (plug, AX): optional; locally merged raw command (SoftKey OR AUX OR web OR switch OR automation) before the remote write. Leave unwired if not needed
- **MANUAL_OUT** (plug, AX): optional; only the manual sources (SoftKey OR AUX OR web OR switch), **without** AUTO_IN. This allows, for example, an automation to be switched off when the operator intervenes manually, without the automation switching itself off through its own command. Leave unwired if not needed

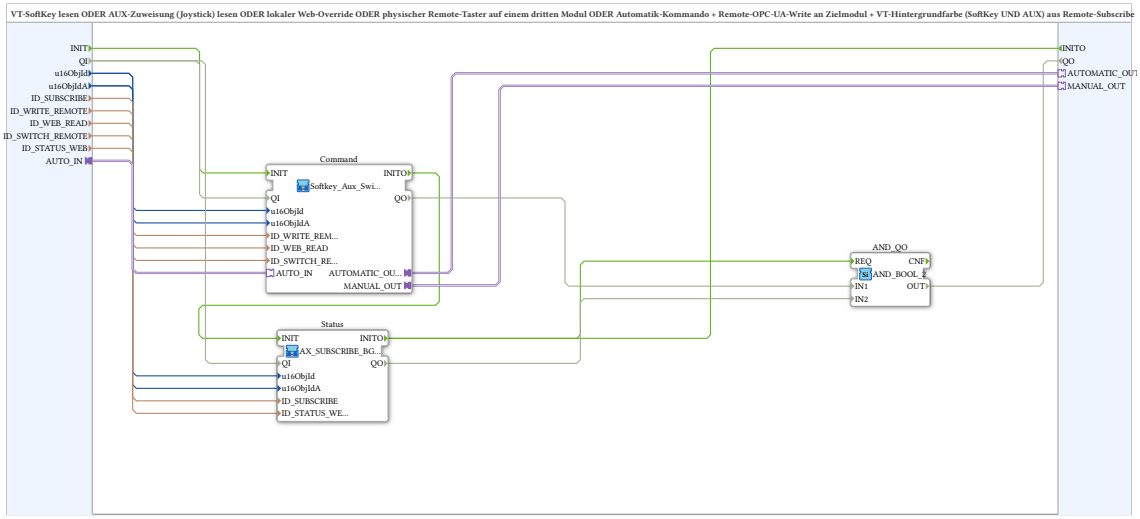
Functionality

The network works in two OR stages:

1. **Manual sources**: Softkey_IXA (isobus::UT::io::Softkey::Softkey_IXA, u16ObjId) → OR_Manual.IN1, Aux_IXA (isobus::UT::io::Auxiliary::IN::Aux_IXA, u16ObjIdA) → OR_Manual.IN2, SUBSCRIBE_WEB (AX_SUBSCRIBE_1, address ID_WEB_READ) → OR_Manual.IN3, SUBSCRIBE_SWITCH (AX_SUBSCRIBE_1, address ID_SWITCH_REMOTE) → OR_Manual.IN4. OR_Manual is an AX_OR_4.
2. OR_Manual.OUT → AX_SPLIT_2_Manual: OUT1 → OR_Automatik.IN1, OUT2 → MANUAL_OUT.
3. **Automation**: AUTO_IN → OR_Automatik.IN2. OR_Automatik is an AX_OR_2.
4. OR_Automatik.OUT → AX_SPLIT_2_CmdOut: OUT1 → AUTOMATIC_OUT, OUT2 → AX_CLIENT_1_0.IN.
5. AX_CLIENT_1_0 (adapter::net::AX_CLIENT_1_0) writes the command via OPC-UA to the address ID_WRITE_REMOTE.
6. AND_QO (iec61131::booleanOperators::AND_BOOL_5) combines the QO outputs of Softkey_IXA (IN1), Aux_IXA (IN2), SUBSCRIBE_WEB (IN3), SUBSCRIBE_SWITCH (IN4) and AX_CLIENT_1_0 (IN5) into QO.
7. Initialization: INIT → Softkey_IXA.INIT → Aux_IXA.INIT → SUBSCRIBE_WEB.INIT → SUBSCRIBE_SWITCH.INIT → AX_CLIENT_1_0.INIT; AX_CLIENT_1_0.INITO → INITO and → AND_QO.REQ. QI is distributed to all five blocks.

Technical Details

- The former AX_OR_5 was split into OR_Manual (AX_OR_4) and OR_Automatik (AX_OR_2) so that MANUAL_OUT is available without the automation part; the overall behaviour for AUTOMATIC_OUT and the remote write remained unchanged
- MANUAL_OUT prevents self-shutdown: if the automation used its own command for switching off, it would switch itself off through it
- Every adapter is branched only through AX_SPLIT_2



Application Scenarios

- Filling belt raise: the command can come from the operator (SoftKey/AUX/web/physical button S08) or from the automatic filling hysteresis and is written to the target module
- Automation that switches off as soon as the operator intervenes manually (via MANUAL_OUT)

Conclusion

Softkey_Aux_Switch_Auto_TO_Remote_WRITE merges five command sources by OR, writes the result to a target module via OPC-UA and optionally provides two intermediate states via AUTOMATIC_OUT and MANUAL_OUT.

Softkey_Aux_Switch_Auto_TO_Remote_WRITE_BG_OPC

• – ○ • – ○ • – ○ •

Introduction

`Softkey_Aux_Switch_Auto_TO_Remote_WRITE_BG_OPC` combines, for a command to a target module: reading the VT **SoftKey** OR reading the **AUX assignment** (joystick) OR a local **web override** OR a physical **remote switch** on a third module OR an **automatic command**, plus a **remote OPC-UA write** to the target module and the **VT background colour** (SoftKey and AUX) from a remote subscribe. It is the 5-source variant of `Softkey_Aux_Switch_TO_Remote_WRITE_BG_OPC` with an additional `AUTO_IN` socket, e.g. filling conveyor raise: SoftKey/AUX/web/physical switch S08 AND automatic filling hysteresis.

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization Request

Event Outputs

- **INITO** (`EInit`): Initialization Confirm

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE to enable the service
- **u16ObjId** (`UINT`): object ID of SoftKey/background (VT)
- **u16ObjIdA** (`UINT`): object ID of AuxFunction2/background (VT)
- **ID_SUBSCRIBE** (`WSTRING`): remote subscribe address (status/colour, `ACTION=SUBSCRIBE`)
- **ID_WRITE_REMOTE** (`WSTRING`): remote write address to the target module (command, `ACTION=WRITE`, CLIENT)
- **ID_WEB_READ** (`WSTRING`): local subscribe address for a web client (e.g. vt-ui-mirror) on the same module, OR-ed with SoftKey and AUX
- **ID_SWITCH_REMOTE** (`WSTRING`): remote subscribe address of an additional physical switch on another module, OR-ed with SoftKey/AUX/web/automatic
- **ID_STATUS_WEB** (`WSTRING`): local publish address (on this module) for the state reported back by the target module, so that a web client can show the same background colour as the real VT

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service executed successfully (AND of `Command.QO` and `Status.QO`)

Adapters

All adapters are of type `adapter::types::unidirectional::AX`.

- **AUTO_IN** (socket): autonomous command (e.g. automatic filling hysteresis), OR-ed with SoftKey/Aux/web/physical switch
- **AUTOMATIC_OUT** (plug): optional, locally merged raw command, passed through from `Command.AUTOMATIC_OUT`; leave unwired if not needed
- **MANUAL_OUT** (plug): optional, only the manual sources (SoftKey/AUX/web/switch) without the automatic part, passed through from `Command.MANUAL_OUT`; leave unwired if not needed

Function Blocks (FBs) Used

- **`Command`** (SubApp `MyLib::sys::Softkey_Aux_Switch_Auto_TO_Remote_WRITE`, Softkey_Aux_Switch_Auto_TO_Remote_WRITE): forms the command from all sources and writes it remotely
- **`Status`** (SubApp `MyLib::sys::AX_SUBSCRIBE_BG3_WEB_OPC`, AX_SUBSCRIBE_BG3_WEB_OPC): subscribes to the state, colours the background and publishes it for the web client
- **`AND_QO`** (`iec61131::booleanOperators::AND_BOOL_2`): ANDs `Command.QO` and `Status.QO` into `QO`

Functionality

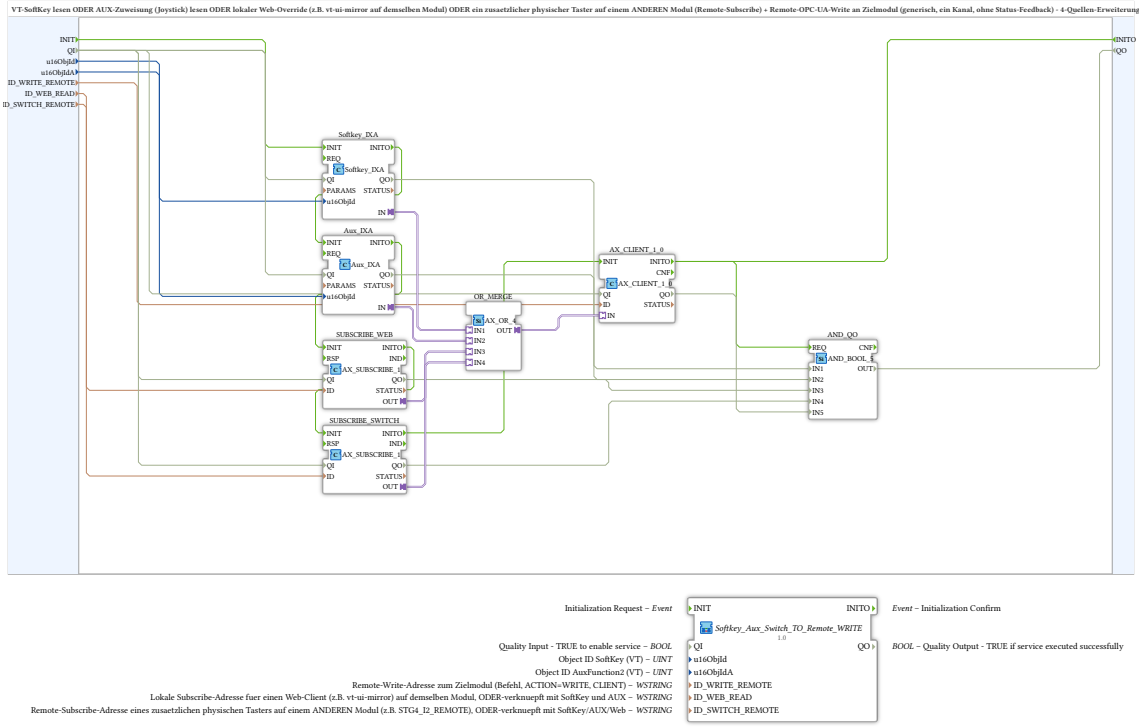
- `u16ObjId`, `u16ObjIdA`, `ID_WRITE_REMOTE`, `ID_WEB_READ`, `ID_SWITCH_REMOTE` ⟶ the like-named inputs of `Command`
- `AUTO_IN` ⟶ `Command.AUTO_IN`
- `Command.AUTOMATIC_OUT` ⟶ `AUTOMATIC_OUT`; `Command.MANUAL_OUT` ⟶ `MANUAL_OUT`
- `u16ObjId`, `u16ObjIdA`, `ID_SUBSCRIBE`, `ID_STATUS_WEB` ⟶ the like-named inputs of `Status`
- Initialization chain: `INIT` ⟶ `Command.INIT`, `Command.INITO` ⟶ `Status.INIT`, `Status.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`
- `QI` ⟶ `Command.QI` and `Status.QI`
- `Command.QO` ⟶ `AND_QO.IN1`, `Status.QO` ⟶ `AND_QO.IN2`, `AND_QO.OUT` ⟶ `QO`

Technical Details

- Command path (`Command`) and status path (`Status`) are separate: the command goes to the target module via remote write, the background colour comes from the state reported back by the target module
- Optional outputs `AUTOMATIC_OUT`/`MANUAL_OUT` allow local reuse of the merged command or of the manual part only

Application Scenarios

- A mixed manual/automatic operating point, e.g. filling conveyor raise (SoftKey, AUX, web, physical switch S08 and automatic filling)



Summary

The SubApp bundles five command sources, a remote write to the target module and the reported VT background colour.

Softkey_Aux_Switch_TO_Remote_WRITE

• — ○ • — ○ • — ○ •

Introduction

The `Softkey_Aux_Switch_TO_Remote_WRITE` subapplication is a 4-source extension of the `Softkey_Aux_IXA_TO_Remote_WRITE` function block. It merges four independent command sources into a single OPC-UA write request that is sent to a remote target module. The four sources are:

1. **SoftKey** – an ISO-bus VT SoftKey (identified by `u16ObjId`).
2. **Auxiliary function** – an ISO-bus Auxiliary Function 2 (identified by `u16ObjIdA`).
3. **Local Web override** – a subscription to a web client (e.g., `vt-ui-mirror`) on the same module (`ID_WEB_READ`).
4. **Remote physical switch** – an additional physical button on a different module, obtained via a remote subscription (`ID_SWITCH_REMOTE`).

All four sources are combined using an OR-logic into a single command, which is then written to the target module via a generic one-channel OPC-UA client (`AX_CLIENT_1_0`) that uses the address provided in `ID_WRITE_REMOTE`. The subapplication is designed for scenarios such as cutting-height adjustment, where a SoftKey on STG1, a physical button on STG4, and a web override must all trigger the same actuator on STG2 – without relying on multiple independent writers that could cause race conditions or last-write-wins errors.

This block does **not** provide status feedback or background colour highlighting; for that purpose, a separate block (e.g., `AX_SUBSCRIBE_BG3_WEB_OPC`) can be placed alongside, reusing the same object IDs.

Interface Structure

The subapplication has the event input `INIT`, the event output `INITO`, six data inputs (`QI` plus the five described below) and the data output `QO`. It exposes no adapters.

Event Inputs

- **INIT** (`EInit`): initialization request; starts the chain `Softkey_IXA` ⟶ `Aux_IXA` ⟶ `SUBSCRIBE_WEB` ⟶ `SUBSCRIBE_SWITCH` ⟶ `AX_CLIENT_1_0`.

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `AX_CLIENT_1_0.INITO`.

Data Inputs

Name	Type	Initial Value	Description
QI	BOOL	TRUE	Quality input, service enable; passed on to all five internal FBs
u16ObjId	UINT	ID_NULL	Object ID of the SoftKey (VT)
u16ObjIdA	UINT	ID_NULL	Object ID of the AuxFunction2 (VT)
ID_WRITE_REMOTE	WSTRING	–	OPC-UA address of the remote target module for the write command (ACTION=WRITE, CLIENT)
ID_WEB_READ	WSTRING	–	Local subscribe address for a web client (e.g., vt-ui-mirror) on the same module, OR-combined with SoftKey and AUX
ID_SWITCH_REMOTE	WSTRING	–	Remote subscribe address of an additional physical button on a different module (e.g., STG4_I2_REMOTE), OR-combined with the other sources

Data Outputs

Name	Type	Description
QO	BOOL	Quality output, AND of the QO outputs of Softkey_IXA, Aux_IXA, SUBSCRIBE_WEB, SUBSCRIBE_SWITCH and AX_CLIENT_1_0 (via AND_QO, AND_BOOL_5)

Adapters

None (all adapter connections are internal to the subapplication).

Functionality

The subapplication implements a logical OR of four boolean command sources, followed by a single OPC-UA write to a remote target. Internally, it uses the following function blocks:

- Softkey_IXA – reads the SoftKey state via an ISO-bus adapter and outputs a boolean.
- Aux_IXA – reads the Auxiliary Function 2 state and outputs a boolean.
- SUBSCRIBE_WEB – subscribes to the ID_WEB_READ address to receive a boolean from a web client.
- SUBSCRIBE_SWITCH – subscribes to the ID_SWITCH_REMOTE address to receive a boolean from a remote physical button.
- OR_MERGE (type AX_OR_4) – combines the four boolean inputs into a single output.
- AX_CLIENT_1_0 – writes the merged boolean to the remote target using the ID_WRITE_REMOTE address.

The data flow is as follows:

1. The four sources are read continuously via their respective adapters/subscriptions.
2. The four boolean signals are fed into AX_OR_4, which produces a TRUE if any of the four is active.
3. The OR result is passed to AX_CLIENT_1_0, which sends an OPC-UA write request to the configured remote address.

Initialization and quality: INIT → Softkey_IXA.INIT, Softkey_IXA.INITO → Aux_IXA.INIT, Aux_IXA.INITO → SUBSCRIBE_WEB.INIT, SUBSCRIBE_WEB.INITO → SUBSCRIBE_SWITCH.INIT, SUBSCRIBE_SWITCH.INITO → AX_CLIENT_1_0.INIT, AX_CLIENT_1_0.INITO → INITO and → AND_QO.REQ. QI goes to all five FBs; their QO outputs feed AND_QO.IN1 to IN5, and AND_QO.OUT drives QO.

This design ensures that all commands from different inputs are combined into a single write operation, avoiding multiple writers that might conflict with each other. The subapplication is intended for use cases where a command must be triggered from multiple physical or logical locations but only one data point is written to the target.

Technical Features

- **Generic OPC-UA Client** – Uses a single AX_CLIENT_1_0 adapter to write a boolean value to a remote node. The node address is provided via ID_WRITE_REMOTE.

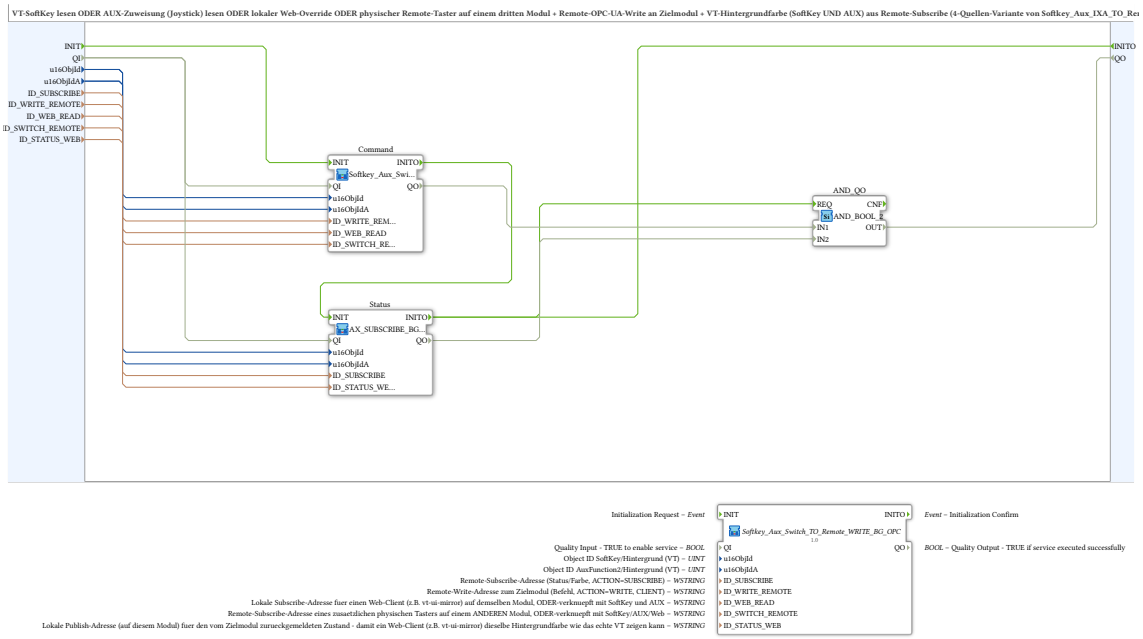
- **Four-input OR Combination** – Internal `AX_OR_4` merges SoftKey, AuxFunction, Web override, and remote switch signals.
- **Remote Subscription** – Uses `AX_SUBSCRIBE_1` adapters for both the web override and the remote switch, enabling cross-module communication.
- **No Status Feedback** – The subapplication only sends commands; it does not receive or process status information from the target. For feedback, a separate subscription block must be used.
- **Configurable Object IDs** – Both VT object IDs (`u16ObjId` and `u16ObjIdA`) are passed through to the internal SoftKey and Aux blocks, allowing flexible mapping to ISO-bus objects.
- **Initialisation** – The internal FB instances are no longer fixed to `QI = TRUE`; they receive the subapplication input `QI` (initial value `TRUE`) and are initialised sequentially via `INIT`/`INITO`.

State Overview

The subapplication does not implement an explicit state machine. Its behaviour is purely combinatorial: the logic continuously evaluates the four input sources and writes the OR result to the remote target. No internal states are stored, and no sequence or timing logic is applied. This makes it suitable for simple command-forwarding tasks where immediate response is required.

Application Scenarios

- **Cutting-Height Adjustment** – A SoftKey on module STG1, a physical push-button S06/S07 on module STG4, and a web override (via `vt-ui-mirror`) on STG1 all control an actuator on STG2. The subapplication combines these inputs and sends a single write command to STG2.
- **Multi-Location Emergency Stop** – When a stop command can be issued from a panel, a remote button, or a web interface, this block forwards the first activated command to a safety-relevant controller.
- **Generic Command Forwarding** – Any scenario where a boolean command must be generated from multiple sources and sent to a remote node with exactly one OPC-UA write per transition.



Comparison with Similar Blocks

- **vs. `Softkey_Aux_IXA_TO_Remote_WRITE`** – The present block adds a fourth input (`ID_SWITCH_REMOTE`), allowing a physical button on a third module to be included. The internal logic is identical except for the extended OR gate (4 inputs instead of 3).
- **vs. a network of separate `AX_CLIENT_1_0` blocks** – Using multiple writers to the same target would create race conditions and last-write-wins issues. This subapplication aggregates all sources into a single client, guaranteeing deterministic behaviour.
- **vs. blocks with status feedback** – This block is deliberately simple and does not provide feedback; a companion block (e.g., `AX_SUBSCRIBE_BG3_WEB_OPC`) must be used if status highlighting is required.

Conclusion

`Softkey_Aux_Switch_TO_Remote_WRITE` provides a clean, robust solution for merging four command sources into one remote OPC-UA write. Its architecture avoids common pitfalls of distributed control systems, such as conflicting writes, and keeps the interface minimal – only the necessary object IDs and communication addresses are exposed. It is well-suited for applications where multiple physical or virtual controls must trigger a single actuator or function on a remote module, especially in agricultural and industrial machinery. The block is intentionally simple, offering no status feedback and requiring an external subscription block for full UI integration.

Softkey_Aux_Switch_TO_Remote_WRITE_BG_OPC

• — ○ • — ○ • — ○ •

Introduction

The **Softkey_Aux_Switch_TO_Remote_WRITE_BG_OPC** subapplication is a thin wrapper that combines two existing subapplications into a complete OPC UA remote control and status visualization solution. It reads up to four independent input sources — a VT softkey, an AUX joystick assignment, a local web override, and a physical remote button located on a third module — OR-combines them, and writes the resulting command to a target module via OPC UA. Simultaneously, it subscribes to the target module's status and updates the background color of both the softkey and AUX elements, while republishing the status locally for web clients.

This is the 4-source variant of `Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC`, intended for functions that include an additional permanently installed button on a third module, such as blade adjustment (Schnittverstellung).

Interface Structure

The subapplication exposes the events `INIT`/`INITO`, the data `QI`/`QO` and seven further data inputs, but no adapters. Internally, it connects these inputs to two child subapplications: `Command` (type `MyLib::sys::Softkey_Aux_Switch_TO_Remote_WRITE`) and `Status` (type `MyLib::sys::AX_SUBSCRIBE_BG3_WEB_OPC`).

Event Inputs

- **INIT** (`EInit`): initialization request; starts the init chain at `Command.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `Status.INITO`, the end of the init chain

Data Inputs

Name	Type	Description
`QI`	BOOL	Quality input, initial value `TRUE`; passed on to `Command.QI` and `Status.QI`.
`u16ObjId`	UINT	Object ID of the SoftKey/background element on the VT.
`u16ObjIdA`	UINT	Object ID of the AuxFunction2/background element on the VT.

ID_SUBSCRIBE	WSTRING	Remote subscribe address for status/color data (ACTION=SUBSCRIBE).
ID_WRITE_REMOTE	WSTRING	Remote write address on the target module for command data (ACTION=WRITE, CLIENT).
ID_WEB_READ	WSTRING	Local subscribe address for a web client (e.g., vt-ui-mirror) on the same module; OR-combined with SoftKey and AUX.
ID_SWITCH_REMOTE	WSTRING	Remote subscribe address for an additional physical button on another module; OR-combined with SoftKey/AUX/Web.
ID_STATUS_WEB	WSTRING	Local publish address (on this module) for the state reported back from the target module, enabling a web client to display the same background color as the real VT.

Data Outputs

- **QO** (BOOL): quality output, AND combination (AND_QO, AND_BOOL_2) of Command.QO and Status.QO

Adapters

None.

Functionality

Initialization and quality: INIT → Command.INIT, Command.INITO → Status.INIT, Status.INITO → INITO and AND_QO.REQ. QI is passed on to Command.QI and Status.QI; Command.QO → AND_QO.IN1, Status.QO → AND_QO.IN2, AND_QO.OUT → QO.

The subapplication operates in two parallel paths (with respect to data; they are connected only by the init chain and the AND combination of the quality outputs):

1. **Command path (Write):** The internal Command subapplication reads the four input sources:
   - u16ObjId — SoftKey state at the VT.
   - u16ObjIdA — AUX joystick assignment state at the VT.
   - ID_WEB_READ — local web override.
   - ID_SWITCH_REMOTE — physical button on a third module.

   These sources are OR-combined (any active source triggers the command), and the result is written to the target module via OPC UA using the address from ID_WRITE_REMOTE.
2. **Status path (Read):** The internal Status subapplication subscribes to the target module's status using ID_SUBSCRIBE. It updates the background color for both u16ObjId (SoftKey) and u16ObjIdA (AUX), and republishes the status locally via ID_STATUS_WEB so web clients can mirror the same background color.

Technical Features

- **OPC UA Integration:** Uses ACTION=WRITE (CLIENT) for commands and ACTION=SUBSCRIBE for status updates.
- **OR Logic:** Four independent input sources are logically OR-combined, providing high flexibility in control and redundancy.
- **Status Feedback Loop:** The target module's reported state is subscribed to and used for visual feedback (background color) on both the VT and connected web clients.
- **Reusable Internal Blocks:** Composed of two well-established subapplications (Softkey_Aux_Switch_TO_Remote_WRITE and AX_SUBSCRIBE_BG3_WEB_OPC), ensuring reliability and maintainability.
- **Standard Compliance:** Implements IEC 61499-2 and is licensed under the Eclipse Public License 2.0.

State Overview

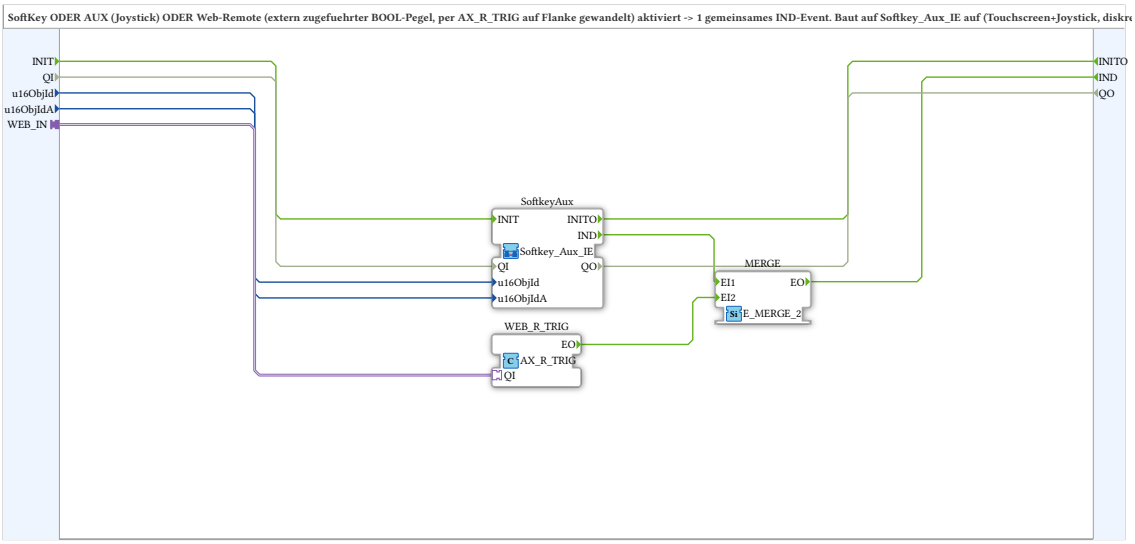
The subapplication does not define an explicit state machine at its own level. The internal Command subapplication handles the OR-combination of the input sources and the remote write operation, while the internal Status subapplication handles subscription and background-color update logic. Both operate continuously, driven by the OPC UA communication events.

Application Scenarios

Typical use cases include:

- **Machine tool control panels (e.g., blade adjustment):** A physical button on a third module, combined with VT softkeys, AUX joystick assignments, and web overrides, can trigger the same function on a target module.
- **Remote visualization:** Web clients (e.g., vt-ui-mirror) can display the same background color as the physical VT, providing consistent user feedback.
- **Multi-source control:** When a function must be controllable from multiple independent locations — HMI panel, joystick, web interface, and a remote hardware button.

Comparison with Similar Blocks

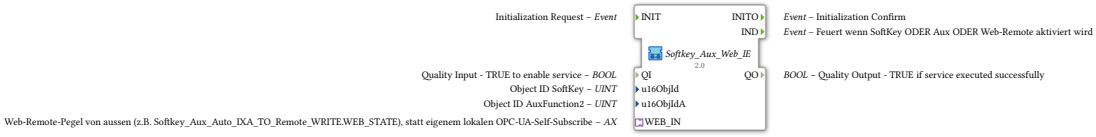


Feature	Softkey_Aux_Switch_TO_Remote_WRITE_BG_OPC (this block)	Softkey_Aux_TO_Remote_WRITE_BG_OPC (3-source variant)
Sources	4 (SoftKey, AUX, Web, Remote Switch)	3 (SoftKey, AUX, Web)
Remote hardware button on third module	Yes	No
Target module write	Yes	Yes
Status subscription / background color	Yes	Yes
Web republish	Yes	Yes

The primary difference is the additional `ID_SWITCH_REMOTE` input, which enables the integration of a physical button located on a separate module.

Conclusion

Softkey_Aux_Switch_TO_Remote_WRITE_BG_OPC is a flexible, reusable subapplication for OPC UA-based remote control with visual status feedback. By combining four independent input sources and providing both command write and status subscribe capabilities, it addresses complex control scenarios requiring input from multiple physical and virtual locations. For standard 3-source applications without an additional remote button, the 3-source variant remains the recommended choice.



Softkey_Aux_Web_IE

• – ○ • – ○ • – ○ •

Introduction

`Softkey_Aux_Web_IE` raises a common `IND` event when **SoftKey OR AUX (joystick) OR web remote** is activated. The web channel is an externally supplied `BOOL` level (`AX`) that is converted into an edge via `AX_R_TRIG`. The block builds on `Softkey_Aux_IE` (touchscreen + joystick, discrete event channel) and additionally merges the web channel - a pattern for "activated from whatever source, one result event", e.g. for override detection.

Function Blocks (FBs) Used

Sub-blocks: Softkey_Aux_Web_IE

- **Type**: SubAppType
- **Internal blocks used**:
  - **SoftkeyAux**: SubApp `MyLib::sys::Softkey_Aux_IE` - SoftKey or AUX
  - **WEB_R_TRIG**: `adapter::events::unidirectional::AX_R_TRIG` - converts the web level into a rising edge (`EO`)
  - **MERGE**: `iec61499::events::E_MERGE_2` - merges both events

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; goes to `SoftkeyAux.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirm; comes from `SoftkeyAux.INITO`
- **IND**: Fires when SoftKey, Aux or web remote is activated

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service; goes to `SoftkeyAux.QI`
- **u16ObjId** (`UINT`): Object ID of the SoftKey
- **u16ObjIdA** (`UINT`): Object ID of the `AuxFunction2`

Data Outputs

- **QO** (`BOOL`): Quality Output - TRUE if the service was executed successfully; comes from `SoftkeyAux.QO`

Adapters

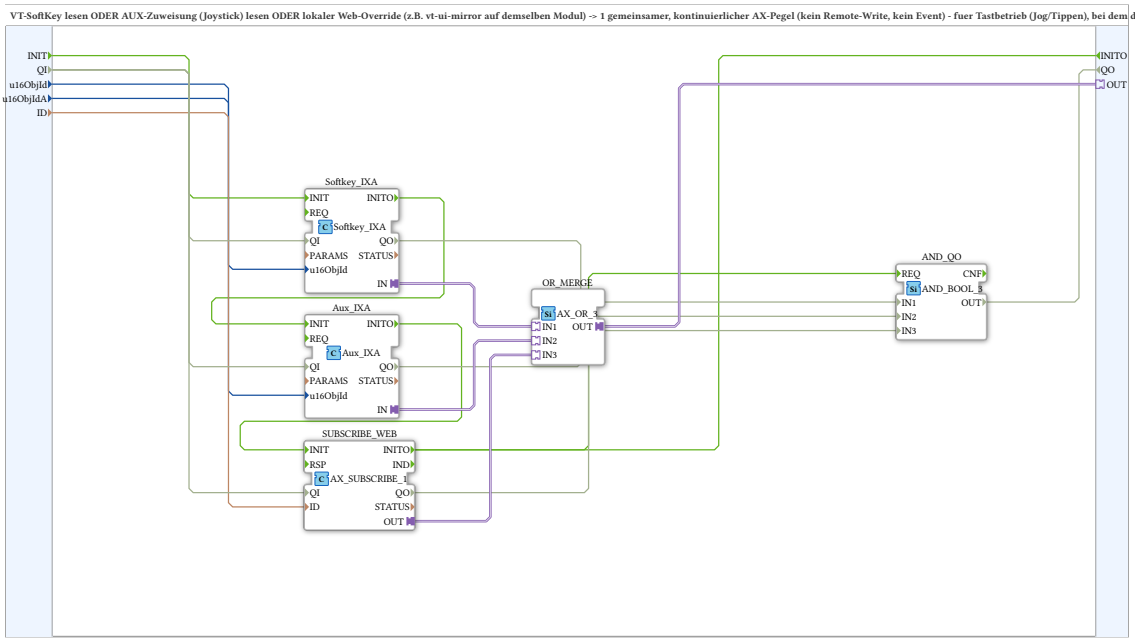
- **WEB_IN** (socket, `adapter::types::unidirectional::AX`): Web remote level from outside (e.g. `Softkey_Aux_Auto_IXA_TO_Remote_WRITE.WEB_STATE`) instead of its own local OPC-UA self-subscribe

Program Flow and Connections

- `u16ObjId` ⟶ `SoftkeyAux.u16ObjId`; `u16ObjIdA` ⟶ `SoftkeyAux.u16ObjIdA`
- `SoftkeyAux.IND` ⟶ `MERGE.EI1`
- `WEB_IN` ⟶ `WEB_R_TRIG.QI`; `WEB_R_TRIG.EO` ⟶ `MERGE.EI2`
- `MERGE.EO` ⟶ `IND`
- Initialization: `INIT` ⟶ `SoftkeyAux.INIT`; `SoftkeyAux.INITO` ⟶ `INITO`
- Quality: `QI` ⟶ `SoftkeyAux.QI`; `SoftkeyAux.QO` ⟶ `QO`

Technical Details

- Version 2.0 (2026-09-16): ID parameter and internal self-subscribe (`SUBSCRIBE_R_TRIG`) removed, replaced by the socket `WEB_IN` plus `AX_R_TRIG`. This fixes the double self-subscribe (FORTE: "Cannot add another one"), because the web node is already subscribed by the command side (`Softkey_Aux_Auto_IXA_TO_Remote_WRITE.WEB_STATE`)
- Only the rising edge of the web level is evaluated
- Version 1.0 (2026-09-11): initial implementation



Application Scenarios

- Override detection: event as soon as the operator intervenes via SoftKey, joystick or web
- Interplay with `Softkey_Aux_Auto_IXA_TO_Remote_WRITE` (`WEB_STATE`)

Summary

`Softkey_Aux_Web_IE` bundles SoftKey, AUX and an externally supplied web level into a single `IND` event.

Softkey_Aux_Web_IXA

• — ○ • — ○ • — ○ •

Introduction

`Softkey_Aux_Web_IXA` merges a VT softkey, an AUX assignment (joystick) and a local web override (e.g. `vt-ui-mirror` on the same module) into **one common, continuous AX level** - without a remote write and without an event. It is intended for jog operation, where the level itself (not an edge) is to be processed further, e.g. as the `G` input of an `AX_AX_SEL_AR` or as `DI1` of a GreenWhiteBackground feedback. It corresponds to the command half of `Softkey_Aux_IXA_TO_Remote_WRITE`, but provides `OUT` instead of a remote write.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirmation

Apart from `INITO` there are no event outputs - user events run via the adapter plug.

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the service
- **u16ObjId** (`UINT`, default `ID_NULL`): Object ID of the softkey (VT)
- **u16ObjIdA** (`UINT`, default `ID_NULL`): Object ID of the AuxFunction2 (VT)

- **ID** (`WSTRING`): Local subscribe address for a web client (e.g. `vt-ui-mirror`) on the same module, ORed with softkey and AUX

Data Outputs

- **QO** (`BOOL`): Quality Output - AND of `Softkey_IXA.QO`, `Aux_IXA.QO` and `SUBSCRIBE_WEB.QO`

Adapters

- **OUT** (plug, `adapter::types::unidirectional::AX`): Softkey OR aux OR web override, continuous level (`TRUE` as long as held/active)

Function Blocks (FBs) Used

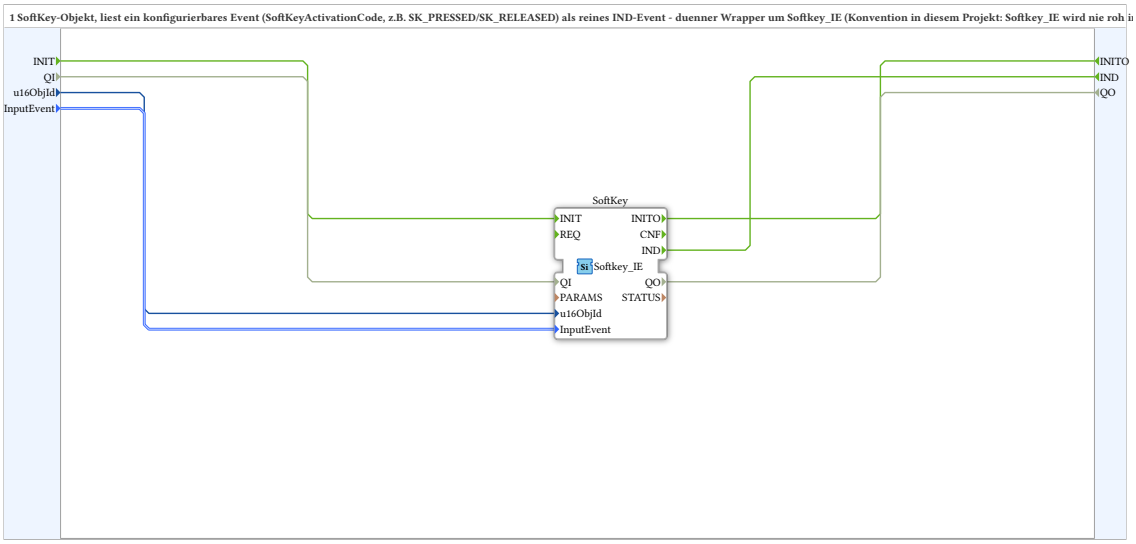
- **Softkey_IXA**: `isobus::UT::io::Softkey::Softkey_IXA`
- **Aux_IXA**: `isobus::UT::io::Auxiliary::IN::Aux_IXA`
- **SUBSCRIBE_WEB**: `adapter::net::AX_SUBSCRIBE_1`
- **OR_MERGE**: `adapter::booleanOperators::AX_OR_3`
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_3`

Program Flow and Connections

- `u16ObjId` ⟶ `Softkey_IXA.u16ObjId`; `u16ObjIdA` ⟶ `Aux_IXA.u16ObjId`; `ID` ⟶ `SUBSCRIBE_WEB.ID`
- `Softkey_IXA.IN` ⟶ `OR_MERGE.IN1`
- `Aux_IXA.IN` ⟶ `OR_MERGE.IN2`
- `SUBSCRIBE_WEB.OUT` ⟶ `OR_MERGE.IN3`
- `OR_MERGE.OUT` ⟶ `OUT`
- `INIT` ⟶ `Softkey_IXA.INIT`; `Softkey_IXA.INITO` ⟶ `Aux_IXA.INIT`; `Aux_IXA.INITO` ⟶ `SUBSCRIBE_WEB.INIT`; `SUBSCRIBE_WEB.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`)
- `QI` ⟶ `Softkey_IXA.QI`, `Aux_IXA.QI` and `SUBSCRIBE_WEB.QI`
- `Softkey_IXA.QO` ⟶ `AND_QO.IN1`; `Aux_IXA.QO` ⟶ `AND_QO.IN2`; `SUBSCRIBE_WEB.QO` ⟶ `AND_QO.IN3`; `AND_QO.OUT` ⟶ `QO`

Technical Details

- Continuous level instead of an edge: `OUT` stays `TRUE` as long as at least one source is active.
- No remote write and no user event output (only `INITO`).

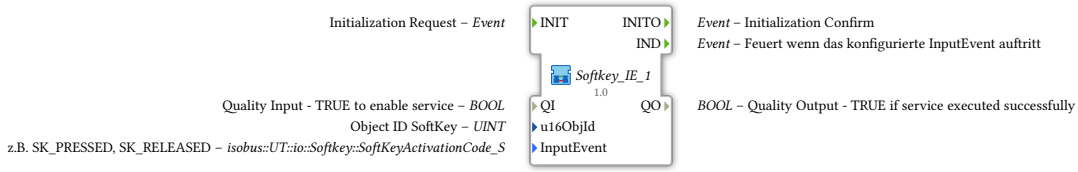


Application Scenarios

- Jog operation where the level is to go to a selector or a background color feedback

Summary

`Softkey_Aux_Web_IXA` ORs softkey, aux and web override into one AX level.



Softkey_IE_1

• – ◦ • – ◦ • – ◦ •

Introduction

`Softkey_IE_1` reads a SoftKey object and outputs a configurable event (`SoftKeyActivationCode`, e.g. `SK_PRESSED`/`SK_RELEASED`) as a pure `IND` event. The block is a thin wrapper around `isobus::UT::io::Softkey::Softkey_IE`, analogous to `Aux_IE_1` and `Button_IE_1`. Convention in this project: `Softkey_IE` is never used raw inline but always wrapped.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirm
- **IND**: fires when the configured `InputEvent` occurs

Data Inputs

- **QI** (`BOOL`, default `TRUE`): quality input, TRUE enables the service
- **u16ObjId** (UINT): object ID of the SoftKey (default `ID_NULL`)
- **InputEvent** (`isobus::UT::io::Softkey::SoftKeyActivationCode_S`): e.g. `SK_PRESSED`, `SK_RELEASED` (default `Invalid`)

Data Outputs

- **QO** (`BOOL`): quality output, taken directly from `SoftKey.QO`

Adapters

No adapters are used.

Functionality

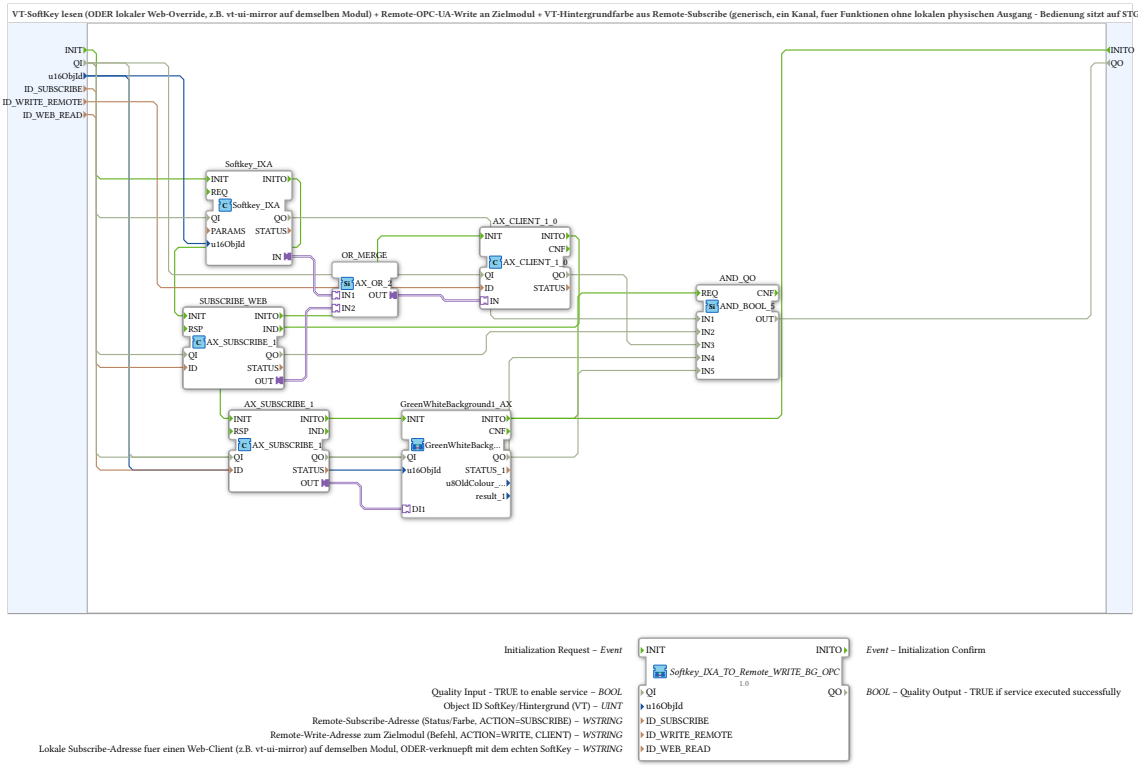
The network contains exactly one instance `SoftKey` of type `isobus::UT::io::Softkey::Softkey_IE` (`QI` comes from the subapp input `QI`). `u16ObjId` and `InputEvent` are routed unchanged to the like-named inputs of the instance, and its event `IND` is output directly as the `IND` of the SubApp.

Technical Details

- Pure pass-through without logic or state of its own
- `QI` is exposed as an input (default `TRUE`) and `QO` comes directly from `SoftKey.QO`; left unwired, the block is therefore active
- Because `InputEvent` is a parameter, the same SubApp can be used for different kinds of events (e.g. pressing or releasing)

Application Scenarios

- Reading a single VT operation as an event without using the raw IE block directly in the network



⚖️ Comparison with Similar Blocks

Equivalent wrappers are `Aux_IE_1` and `Button_IE_1` they differ only in the VT object type and in the enumeration type of `InputEvent`.

Conclusion

`Softkey_IE_1` is a minimal wrapper that provides a configurable SoftKey event as `IND`.

Softkey_IXA_TO_Remote_WRITE_BG_OPC

• — ○ • — ○ • — ○ •

Introduction

This subapplication is designed for scenarios where the operator interface is located on a VT (Virtual Terminal) device (STG1), but the actual actuator resides on a different module that does not have direct VT access. The subapplication reads a local softkey, optionally merges it with a web-based override, sends the resulting command to the remote module via OPC UA, and then receives the actual state back from the remote module to update the softkey background colour accordingly. This creates a closed-loop feedback mechanism that keeps the operator informed of the real actuator status.

Interface Structure

The subapplication exposes the initialization events `INIT`/`INITO`, the status ports `QI`/`QO` and data inputs. It has no adapter interfaces at the subapplication level.

Event Inputs

- **INIT** (`EInit`): Initialization Request

Event Outputs

- **INITO** (`EInit`): Initialization Confirm

Data Inputs

Name	Type	Initial Value	Comment
`QI`	`BOOL`	`TRUE`	Quality Input - TRUE enables the service.
`u16ObjId`	`UINT`	`ID_NULL`	Object ID of the softkey / background (VT).
`ID_SUBSCRIBE`	`WSTRING`	–	Remote subscribe address (status/colour, `ACTION=SUBSCRIBE`).
`ID_WRITE_REMOTE`	`WSTRING`	–	Remote write address to the target module (command, `ACTION=WRITE`, `CLIENT`).

ID_WEB_READ	WSTRING	–	Local subscribe address for a web client (e.g. vt-ui-mirror) on the same module, OR-combined with the real softkey.

Data Outputs

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if the service executed successfully (AND of Softkey_IXA, SUBSCRIBE_WEB, AX_CLIENT_1_0, AX_SUBSCRIBE_1 and GreenWhiteBackground1_AX).

Adapters

None.

Functionality

The internal logic of the subapplication consists of seven blocks:

1. Softkey_IXA – reads the local softkey state based on the configured u16ObjId.
2. SUBSCRIBE_WEB – subscribes to a local web-based input (e.g. a mirror of the VT display) using the ID_WEB_READ address.
3. OR_MERGE – an AX_OR_2 boolean operator that combines the softkey signal and the web override signal using a logical OR.
4. AX_CLIENT_1_0 – an OPC UA client that writes the merged signal to the remote device via the ID_WRITE_REMOTE endpoint.
5. AX_SUBSCRIBE_1 – an OPC UA subscriber that receives the actual state from the remote device via ID_SUBSCRIBE.
6. GreenWhiteBackground1_AX – a subapplication that issues a Q_BackgroundColour command to change the softkey background colour based on the received state (green for active, white for inactive).
7. AND_QO – an iec61131::booleanOperators::AND_BOOL_5 block that ANDs the QO outputs of Softkey_IXA, SUBSCRIBE_WEB, AX_CLIENT_1_0, AX_SUBSCRIBE_1 and GreenWhiteBackground1_AX into the subapplication output QO.

Initialization and status: INIT ⟶ Softkey_IXA.INIT, Softkey_IXA.INITO ⟶ SUBSCRIBE_WEB.INIT, SUBSCRIBE_WEB.INITO ⟶ AX_CLIENT_1_0.INIT, AX_CLIENT_1_0.INITO ⟶ AX_SUBSCRIBE_1.INIT, AX_SUBSCRIBE_1.INITO ⟶ GreenWhiteBackground1_AX.INIT, GreenWhiteBackground1_AX.INITO ⟶ INITO and ⟶ AND_QO.REQ. QI ⟶ Softkey_IXA.QI, SUBSCRIBE_WEB.QI, AX_CLIENT_1_0.QI, AX_SUBSCRIBE_1.QI and GreenWhiteBackground1_AX.QI; their QO outputs ⟶ AND_QO.IN1..IN5; AND_QO.OUT ⟶ QO.

The overall data flow is:

- The local softkey and the optional web override are OR-merged.
- The merged signal is written to the remote module via OPC UA.
- The remote module's actual state is read back via OPC UA subscription.
- The state is used to set the background colour of the softkey, giving immediate visual feedback.

Technical Features

- ✅ OPC UA client and subscriber functionality built in.
- ✅ Local softkey reading via Softkey_IXA.
- ✅ Optional integration with web-based UI mirroring (vt-ui-mirror).
- ✅ OR logic for merging multiple input sources.
- ✅ Remote state feedback with background colour update.
- ✅ Only the initialization handshake (INIT/INITO) and the aggregated status QO are exposed – the subapplication acts as a self-contained control unit.
- ✅ Configurable via the address/object-ID inputs plus QI.

State Overview

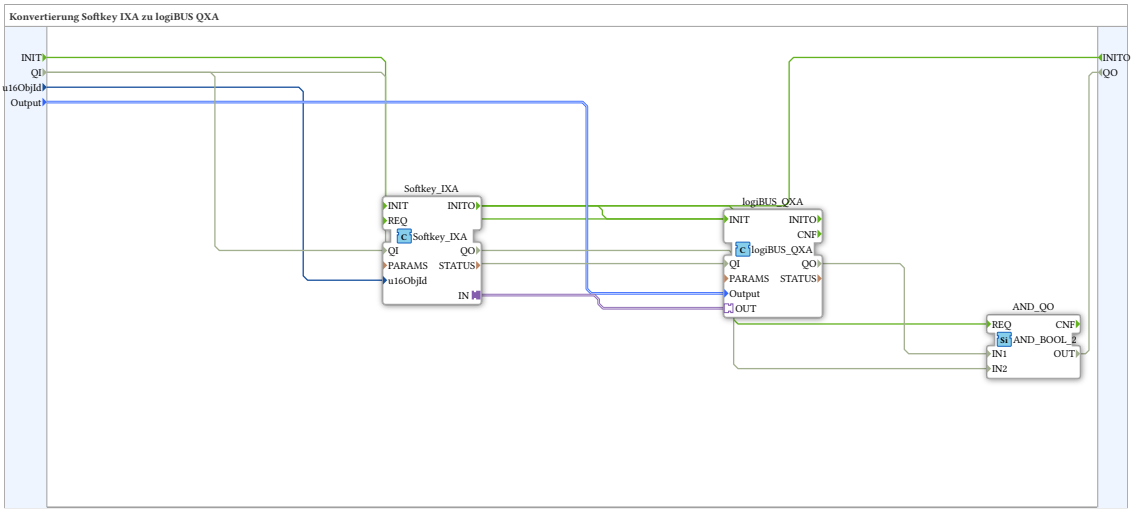
The subapplication does not contain an explicit state machine. It operates purely combinatorially – the current input values determine the output behaviour. The only internal states are those of the individual

function blocks (e.g. connection states of the OPC UA client and subscriber), but these are managed internally and are not exposed to the user. The dynamic behaviour is that of a closed-loop control: the displayed colour always reflects the most recent remote state.

Application Scenarios

- **Remote actuator control from a VT** – when the operator interface is on STG1 (VT), but the actuator is on another module without VT capabilities.
- **Softkey with web-override** – when operators may also use a local web-based mirror to trigger the same function.
- **Visual status feedback** – the softkey background changes to green/white to indicate the actual actuator state, not just the pressed command.
- **Generic single-channel usage** – suitable for any function that does not have a physical output on the VT itself but requires remote actuation and feedback.

Comparison with Similar Blocks

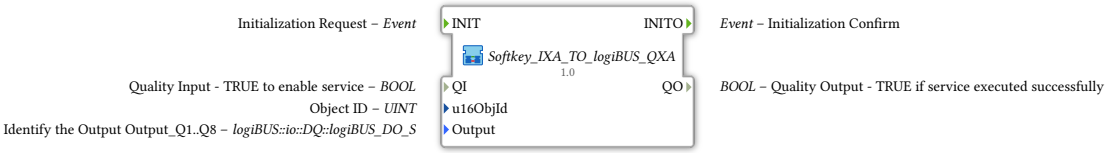


- **`Softkey_Aux_IXA_TO_Remote_WRITE_BG_OPC`** – extends this subapplication with a third input source (e.g. an auxiliary function object like a joystick) and uses `GreenWhiteBackground3_AX` instead of `1_AX` for a three-state background.
- **`Button_IXA_TO_Remote_WRITE_BG_OPC`** – identical functionality but for a VT button instead of a softkey.
- **`Softkey_IXA_TO_Remote_WRITE_BG_OPC`** – the single-channel version described here, optimised for functions with exactly one operator-initiated source (plus optional web override).

These variants share the same core architecture but differ in input multiplicity and background colour handling.

Conclusion

`Softkey_IXA_TO_Remote_WRITE_BG_OPC` provides a robust and reusable solution for bridging VT-based operator inputs to remote actuators over OPC UA. Its integration of local softkey reading, web override, OR logic, remote write, and remote state subscription ensures reliable operation with clear visual feedback. The simple interface and configurable addresses make it easy to adapt to various modules and use cases, while the underlying design supports extensibility to more complex scenarios.



Softkey_IXA_TO_logiBUS_QXA

• – ○ • – ○ • – ○ •

Introduction

`Softkey_IXA_TO_logiBUS_QXA` connects a VT softkey (`Softkey_IXA`) directly to a physical digital output (`logiBUS_QXA`) — functionally identical to `Button_IXA_TO_logiBUS_QXA`, but for softkeys instead of buttons.

Function Blocks (FBs) Used

Sub-blocks: Softkey_IXA_TO_logiBUS_QXA

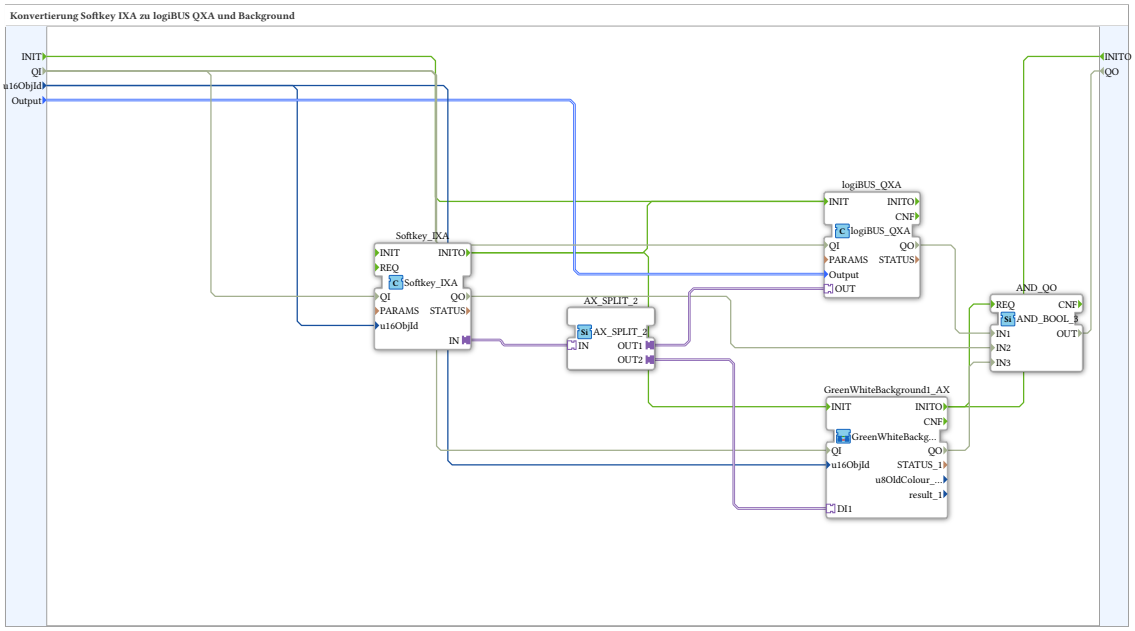
- **Type**: SubAppType
- **Internal FBs used**:
  - **Softkey_IXA**: `isobus::UT::io::Softkey::Softkey_IXA` — VT softkey adapter.
  - **logiBUS_QXA**: `logiBUS::io::DQ::logiBUS_QXA` — physical digital output.
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` — combines `logiBUS_QXA.QO` and `Softkey_IXA.QO` into the SubApp output `QO`.
- **Interface**: event input `INIT`, event output `INITO`, data input `QI` (default `TRUE`, passed on to both FBs), data output `QO`.
- **Functionality**: Direct adapter connection `Softkey_IXA.IN` ⟶ `logiBUS_QXA.OUT`, no intermediate logic (apart from the `AND_QO` combination of the quality signals).

Program Flow and Connections

1. `u16ObjId` ⟶ `Softkey_IXA.u16ObjId`; `Output` ⟶ `logiBUS_QXA.Output`.
2. `Softkey_IXA.IN` ⟶ `logiBUS_QXA.OUT`.
3. Initialization: `INIT` ⟶ `logiBUS_QXA.INIT`; `logiBUS_QXA.INITO` ⟶ `Softkey_IXA.INIT`; `Softkey_IXA.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`.
4. Quality: `QI` ⟶ `logiBUS_QXA.QI` and `Softkey_IXA.QI`; `logiBUS_QXA.QO` ⟶ `AND_QO.IN1`, `Softkey_IXA.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.

Application Scenarios

- Minimal softkey-to-output block with no status display or remote control.

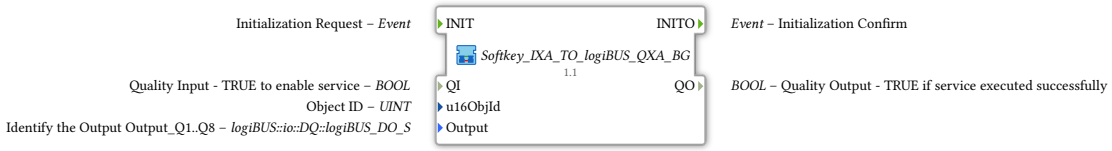


Summary

Softkey counterpart to `Button_IXA_TO_logiBUS_QXA` — identical pattern, different control type.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



Softkey_IXA_TO_logiBUS_QXA_BG

• – ○ • – ○ • – ○ •

Introduction

`Softkey_IXA_TO_logiBUS_QXA_BG` extends `Softkey_IXA_TO_logiBUS_QXA` with a VT status color — the softkey counterpart to `Button_IXA_TO_logiBUS_QXA_BG`.

Function Blocks (FBs) Used

Sub-blocks: Softkey_IXA_TO_logiBUS_QXA_BG

- **Type**: SubAppType
- **Internal FBs used**:
  - **Softkey_IXA**: `isobus::UT::io::Softkey::Softkey_IXA` — VT softkey adapter.
  - **logiBUS_QXA**: `logiBUS::io::DQ::logiBUS_QXA` — physical digital output.
  - **AX_SPLIT_2**: `adapter::events::unidirectional::AX_SPLIT_2` — splits the softkey signal.
  - **GreenWhiteBackground1_AX** (SubApp, `MyLib::sys`): sets the VT status color (see Background Color Blocks).
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_3` — combines `logiBUS_QXA.QO`, `Softkey_IXA.QO` and `GreenWhiteBackground1_AX.QO` into the output `QO`.
- **Functionality**: `Softkey_IXA.IN` is distributed via `AX_SPLIT_2` to both `logiBUS_QXA.OUT` and `GreenWhiteBackground1_AX.DI1`. The SubApp interface additionally has the events `INIT`/`INITO` as well as `QI` (BOOL, initial value `TRUE`) and `QO` (BOOL).

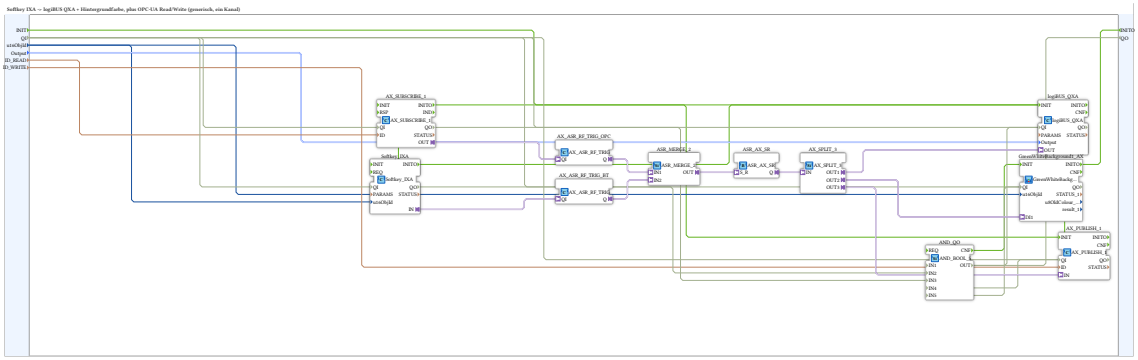
Program Flow and Connections

1. `u16ObjId` ⟶ `Softkey_IXA.u16ObjId` and `GreenWhiteBackground1_AX.u16ObjId`; `Output` ⟶ `logiBUS_QXA.Output`.
2. `Softkey_IXA.IN` ⟶ `AX_SPLIT_2.IN` ⟶ `AX_SPLIT_2.OUT1` ⟶ `logiBUS_QXA.OUT`, `AX_SPLIT_2.OUT2` ⟶ `GreenWhiteBackground1_AX.DI1`.
3. Initialization chain: `INIT` ⟶ `logiBUS_QXA.INIT`, `logiBUS_QXA.INITO` ⟶ `Softkey_IXA.INIT`, `Softkey_IXA.INITO` ⟶ `GreenWhiteBackground1_AX.INIT`, `GreenWhiteBackground1_AX.INITO` ⟶ `INITO` and `AND_QO.REQ`.

4. Quality: `QI` ⟶ `logiBUS_QXA.QI`, `Softkey_IXA.QI` and `GreenWhiteBackground1_AX.QI`; their `QO` outputs ⟶ `AND_QO.IN1` to `AND_QO.IN3` (in this order); `AND_QO.OUT` ⟶ `QO`.

Application Scenarios

- VT softkey with direct visual feedback, without OPC-UA.

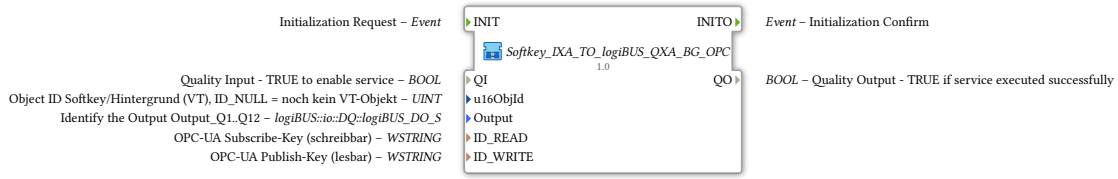


Summary

Softkey counterpart to `Button_IXA_TO_logiBUS_QXA_BG` — identical pattern, different control type.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



Softkey_IXA_TO_logiBUS_QXA_BG_OPC

• — ○ • — ○ • — ○ •

Introduction

`Softkey_IXA_TO_logiBUS_QXA_BG_OPC` is the SoftKey counterpart to `Button_IXA_TO_logiBUS_QXA_BG_OPC_LATCHING`: A VT SoftKey and an OPC UA remote command are each converted into set/reset events via edge detection and combined in a common latch. This is **not** a true click-toggle: pressing triggers `SET`, releasing triggers `RESET` — with only one source active, that's purely momentary behavior. The difference from a simple OR gate only shows up once the SoftKey and the OPC UA command overlap in time: whichever edge arrives last always wins, regardless of source (last-wins), instead of the output staying ON as long as either source is active.

Function Blocks (FBs) Used

Sub-Blocks: Softkey_IXA_TO_logiBUS_QXA_BG_OPC

- **Type**: SubAppType
- **Internal FBs Used**:
- **Softkey_IXA**: `isobus::UT::io::Softkey::Softkey_IXA` — VT SoftKey, `u16ObjId` identifies the SoftKey.
- **AX_ASR_RF_TRIG_BT** / **AX_ASR_RF_TRIG_OPC**: each `adapter::events::unidirectional::AX_ASR_RF_TRIG` — convert the rising/falling edge of the SoftKey or the OPC UA Subscribe value into a Set/Reset event pair (ASR).
- **ASR_MERGE_2**: `adapter::events::unidirectional::ASR_MERGE_2` — combines the two ASR sources (SoftKey, OPC UA).

- **ASR_AX_SR**: `adapter::events::unidirectional::ASR_AX_SR` — Set/Reset Latch, creates the latched output state from the combined ASR signal.
- **AX_SPLIT_3**: `adapter::events::unidirectional::AX_SPLIT_3` — distributes the latch output to three destinations.
- **logiBUS_QXA**: `logiBUS::io::DQ::logiBUS_QXA` — physical digital output.
- **GreenWhiteBackground1_AX** (SubApp, `MyLib::sys`): VT background color matching the output state.
- **AX_SUBSCRIBE_1** / **AX_PUBLISH_1**: each `adapter::net::AX_SUBSCRIBE_1/AX_PUBLISH_1` — OPC UA read/write access.
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_5` — combines the `QO` of `logiBUS_QXA`, `Softkey_IXA`, `AX_SUBSCRIBE_1`, `AX_PUBLISH_1` and `GreenWhiteBackground1_AX`.
- **Functionality**: Identical to the latching structure of `Button_IXA_TO_logiBUS_QXA_BG_OPC_LATCHING`, but with `Softkey_IXA` instead of `Button_IXA` as the local input source.

Program Flow and Connections

1. `Softkey_IXA.IN` (adapter) ⟶ `AX_ASR_RF_TRIG_BT.QI` ⟶ `AX_ASR_RF_TRIG_BT.Q` ⟶ `ASR_MERGE_2.IN2`.
2. `AX_SUBSCRIBE_1.OUT` ⟶ `AX_ASR_RF_TRIG_OPC.QI` ⟶ `AX_ASR_RF_TRIG_OPC.Q` ⟶ `ASR_MERGE_2.IN1`.
3. `ASR_MERGE_2.OUT` ⟶ `ASR_AX_SR.S_R`.
4. `ASR_AX_SR.Q` ⟶ `AX_SPLIT_3.IN` ⟶ `AX_SPLIT_3.OUT1` ⟶ `logiBUS_QXA.OUT`, `AX_SPLIT_3.OUT2` ⟶ `GreenWhiteBackground1_AX.DI1`, `AX_SPLIT_3.OUT3` ⟶ `AX_PUBLISH_1.IN`.
5. Initialization: event input `INIT` ⟶ `logiBUS_QXA.INIT`, `logiBUS_QXA.INITO` ⟶ `Softkey_IXA.INIT`, `Softkey_IXA.INITO` ⟶ `AX_SUBSCRIBE_1.INIT`, `AX_SUBSCRIBE_1.INITO` ⟶ `AX_PUBLISH_1.INIT` (hidden connection), `AX_PUBLISH_1.INITO` ⟶ `GreenWhiteBackground1_AX.INIT`, `GreenWhiteBackground1_AX.INITO` ⟶ event output `INITO` and ⟶ `AND_QO.REQ`.
6. Parameters: `u16ObjId` ⟶ `Softkey_IXA.u16ObjId` and `GreenWhiteBackground1_AX.u16ObjId`; `Output` ⟶ `logiBUS_QXA.Output`; `ID_READ` ⟶ `AX_SUBSCRIBE_1.ID`; `ID_WRITE` ⟶ `AX_PUBLISH_1.ID`.
7. Quality: data input `QI` (`BOOL`, default `TRUE`) ⟶ `logiBUS_QXA.QI`, `Softkey_IXA.QI`, `AX_SUBSCRIBE_1.QI`, `AX_PUBLISH_1.QI` and `GreenWhiteBackground1_AX.QI`; their `QO` ⟶ `AND_QO.IN1`..`IN5`; `AND_QO.OUT` ⟶ data output `QO`.

Technical Features

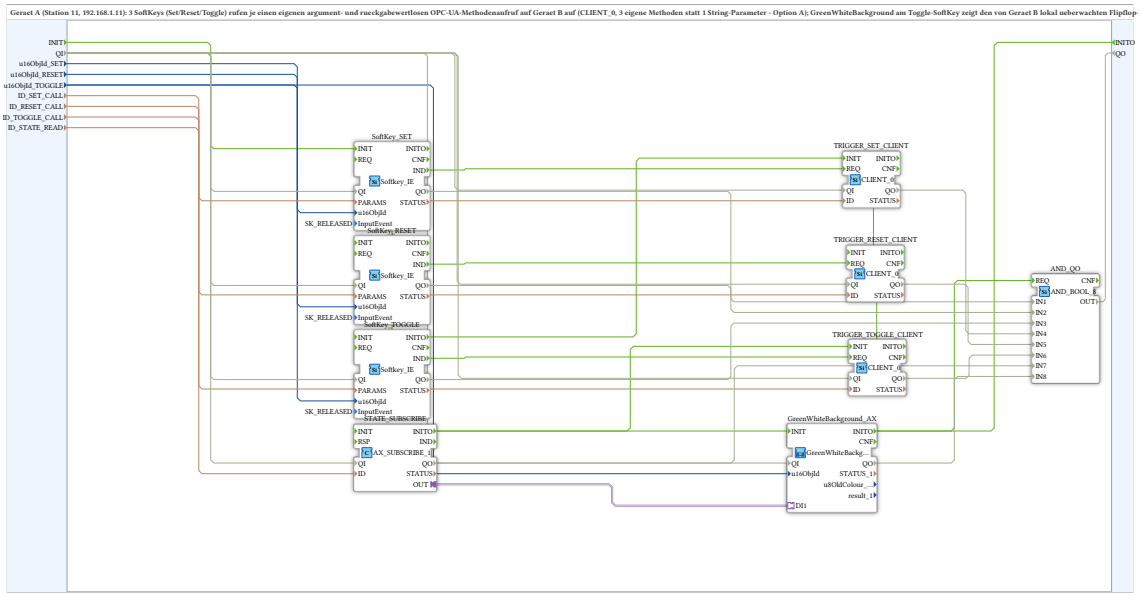
- **Last-wins via ASR latch, not a real toggle**: As with `Button_IXA_TO_logiBUS_QXA_BG_OPC_LATCHING`, the behavior is purely momentary with only one source active (ON only while held). The difference from a momentary OR gate only shows up once both sources overlap: whichever edge (set or reset, from either source) arrives last determines the state.
- **Two independent last-wins sources**: A soft key and an OPC UA command each independently deliver set/reset events; `ASR_MERGE_2` combines both into a common latch input without prioritizing either source.

Application Scenarios

- Digital outputs with two independent switching sources (soft key AND remote OPC UA command) where whichever action arrives last should win, instead of one permanently active source blocking the other, with VT status display and OPC UA feedback.

Comparison with Similar Modules

Structurally identical to `Button_IXA_TO_logiBUS_QXA_BG_OPC_LATCHING`, except that `Softkey_IXA` is used instead of `Button_IXA` as the local control source — including the same last-wins characteristic (not click-toggle). Compared to the simpler `Softkey_IXA_TO_logiBUS_QXA_BG` (only local softkey, no OPC UA connection, no latch logic), this module includes the complete edge detection/merge/latch chain as well as OPC UA subscribe/publish functionality.



Summary

`Softkey_IXA_TO_logiBUS_QXA_BG_OPC` switches a digital logiBUS output via a soft key and/or a remote OPC UA command, including VT status color and OPC UA echo. With only one source active the behavior is purely momentary; when both sources overlap, last-wins applies instead of a true OR gate.

Softkey_SRT_RPC_TO_Remote_BG_OPC

• — ○ • — ○ • — ○ •

Introduction

The **Softkey_SRT_RPC_TO_Remote_BG_OPC** subapplication is a composite type designed for a two-device OPC-UA automation scenario. It runs on **Device A** (Station 11, 192.168.1.11) and controls three softkeys – **Set**, **Reset**, and **Toggle** – each of which triggers its own argument-free, return-value-free OPC-UA method call on a remote **Device B**. Instead of passing a string parameter to a single generic method, this design (Option A) uses three distinct remote method addresses, providing clearer semantics and easier maintenance. Additionally, a **GreenWhiteBackground** indication on the Toggle softkey reflects a flip-flop state that is locally monitored on Device B and made available to Device A via an OPC-UA variable subscription. The entire protocol logic is encapsulated inside the `MyLib::sys` composite, keeping the device resource simple and reusable.

Interface Structure

The subapplication exposes only data inputs at its interface. All event handling and adapter logic are internal to the composite.

Event Inputs

- **INIT** (`EInit`): initialization request. Apart from that, the subapplication does not expose any event inputs. Activation is performed internally by the softkey function blocks, which react to hardware events.

Event Outputs

- **INITO** (EInit): initialization confirmation (from GreenWhiteBackground_AX.INITO). No other events are propagated to the outside world.

Data Inputs

Name	Type	Description
QI	BOOL	Quality Input, TRUE enables the service (default TRUE).
u16ObjId_SET	UINT	Object ID of the **Set** softkey. Initial value: ID_NULL.
u16ObjId_RESET	UINT	Object ID of the **Reset** softkey. Initial value: ID_NULL.
u16ObjId_TOGGLE	UINT	Object ID of the **Toggle** softkey (also carries the GreenWhiteBackground indication). Initial value: ID_NULL.
ID_SET_CALL	WSTRING	Remote method address (ACTION=CALL_METHOD) for the **Set** method call on Device B.
ID_RESET_CALL	WSTRING	Remote method address (ACTION=CALL_METHOD) for the **Reset** method call on Device B.
ID_TOGGLE_CALL	WSTRING	Remote method address (ACTION=CALL_METHOD) for the **Toggle** method call on Device B.
ID_STATE_READ	WSTRING	Locally monitored OPC-UA address (BOOL, ACTION=READ) for the flip-flop state that is remotely written by Device B.

Data Outputs

- **QO** (BOOL): Quality Output, AND (AND_QO, iec61131::booleanOperators::AND_BOOL_8) of the QO outputs of all eight internal blocks (3 × Softkey_IE, 3 × CLIENT_0, STATE_SUBSCRIBE, GreenWhiteBackground_AX).

Adapters

None at the interface level. Internally, an AX_SUBSCRIBE_1 adapter is used to establish the subscription for the state variable.

Functionality

The subapplication implements the following end-to-end behavior:

1. **Softkey Detection** – Three isobus::UT::io::Softkey::Softkey_IE instances (SoftKey_SET, SoftKey_RESET, SoftKey_TOGGLE) are configured with InputEvent = SK_RELEASED (activation on key release); their QI comes from the QI input of the subapplication. Each instance is associated with a distinct Object ID supplied via the u16ObjId_* inputs.
2. **Remote Method Invocation** – When a softkey is pressed, the corresponding IND event is routed to the REQ input of a dedicated iec61499::net::CLIENT_0 function block (TRIGGER_SET_CLIENT, TRIGGER_RESET_CLIENT, TRIGGER_TOGGLE_CLIENT). Each client is enabled via the QI input of the subapplication and holds the remote method address in its ID input, which is wired from the corresponding ID_*_CALL data input.
3. **State Subscription** – An adapter::net::AX_SUBSCRIBE_1 block (STATE_SUBSCRIBE) continuously subscribes to the OPC-UA variable specified in ID_STATE_READ. Its output (an adapter interface) is connected to the DI1 adapter socket of a MyLib::sys::GreenWhiteBackground1_AX subapplication.
4. **Initialization and Quality** – INIT runs through a chain SoftKey_SET → SoftKey_RESET → SoftKey_TOGGLE → TRIGGER_SET_CLIENT → TRIGGER_RESET_CLIENT → TRIGGER_TOGGLE_CLIENT → STATE_SUBSCRIBE → GreenWhiteBackground_AX (each INITO → next INIT); GreenWhiteBackground_AX.INITO → INITO (and → AND_QO.REQ). QI is distributed to .QI of all eight blocks; their QO outputs feed AND_QO.IN1..IN8, and AND_QO.OUT → QO.
5. **Visual Indication** – The GreenWhiteBackground1_AX subapplication, fed with u16ObjId_TOGGLE and the subscribed state value, renders either a green or a white background on the Toggle softkey, reflecting the current flip-flop state maintained on Device B.

Technical Features

- **Fully composite design** – The protocol logic is contained within a `MyLib::sys` composite, keeping the device resource lean and making the subapplication portable across different resources or devices.
- **Dedicated OPC-UA method clients** – Three separate `CLIENT_0` instances, one per softkey, allow independent configuration and fault isolation for each remote call.
- **No parameter passing** – The remote methods are intentionally argument-free, simplifying the OPC-UA server implementation on Device B and avoiding string-parsing overhead.
- **Event-driven activation** – Softkey events are captured on release (`SK_RELEASED`), providing deterministic triggering.
- **Subscription-based state feedback** – The flip-flop state is obtained via OPC-UA subscription (not polling), ensuring timely and bandwidth-efficient updates.
- **Configurable identifiers** – Object IDs and remote addresses are injected at instantiation time, allowing the same subapplication to be reused with different hardware layouts or OPC-UA server configurations.
- **EPL-2.0 licensing** – The subapplication is published under the Eclipse Public License 2.0.

State Overview

The subapplication itself does not contain an explicit state machine. However, its constituent elements exhibit the following state-oriented behavior:

- **Softkey FBs** – Each `Softkey_IE` is in an *idle* state until a hardware-level key-release event occurs. Upon detection, the FB generates an `IND` event and returns to the idle state.
- **Client FBs** – Each `CLIENT_0` transitions through *request sent* → *response received* → *idle* for every triggered call. While `QI` is TRUE, the clients remain operationally ready.
- **State variable (remote)** – The flip-flop state on Device B is a single BOOL (binary) value. It transitions between `0` (white background) and `1` (green background) each time the Toggle method is invoked. The `STATE_SUBSCRIBE` adapter continuously tracks changes and forwards them to the background rendering component.

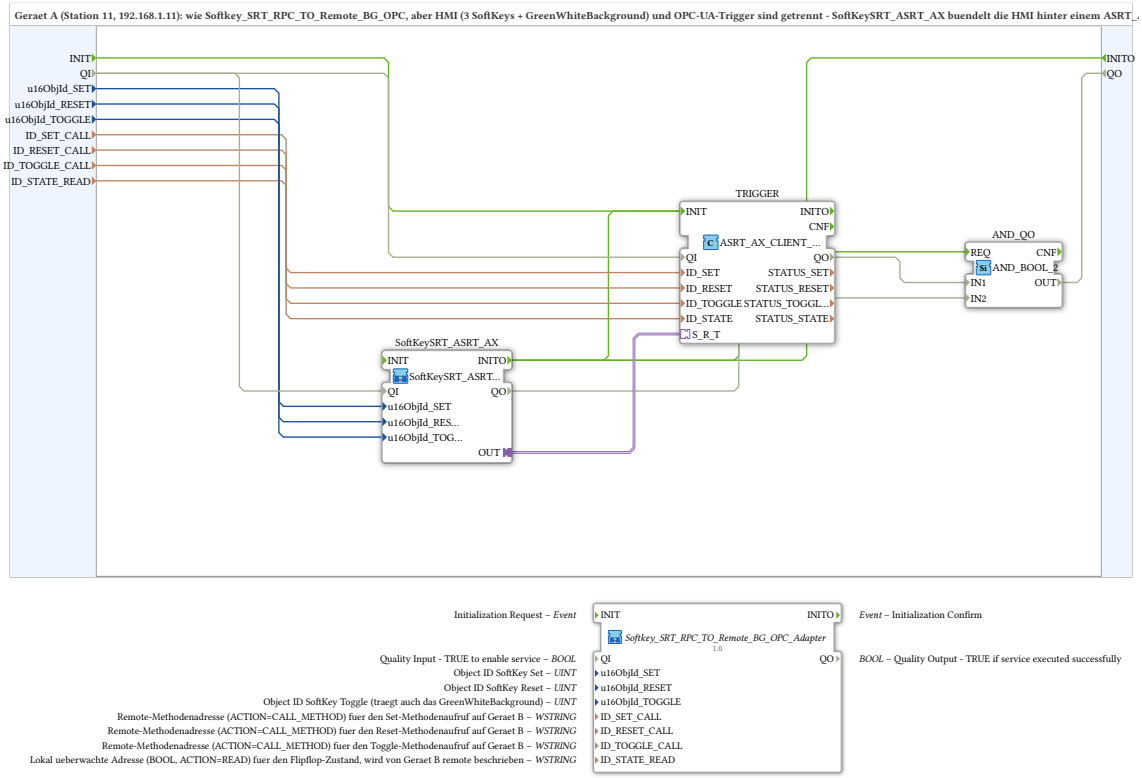
The overall system thus implements a classic **set / reset / toggle** control paradigm with visual feedback, where the state source of truth resides on Device B.

Application Scenarios

This subapplication is well suited for:

- **Industrial control panels** – Physical or virtual softkeys on a local operator panel (Device A) that remotely operate actuators, valves, or machine functions on a PLC or controller (Device B).
- **Multi-device OPC-UA architectures** – Where one device needs to invoke discrete, side-effect-free methods on another device, and the current state must be displayed locally.
- **Toggle-with-feedback user interfaces** – For example, enabling/disabling a production line parameter, where the background color of the key gives the operator an immediate visual confirmation of the actual remote state.
- **Modular and portable HMI components** – Because all protocol logic is embedded in the composite, the same subapplication can be dropped into different 4diac projects without modifying the resource.

Comparison with Similar Blocks



Feature / Aspect	**Softkey_SRT_RPC_TO_Remote_BG** (Option A)	Remote_Softkey_Single-Method-With-String-Parameter (Option B)	Generic OPC-UA Client FB (non-dedicated)
Remote method granularity	Three dedicated methods (Set / Reset / Toggle)	One method that accepts a string parameter to select the action	User must supply address and parameters per call
Parameter handling	No arguments; minimal server complexity	Server must parse the string, incurring overhead and error risk	Flexible but requires manual mapping
State feedback	Built-in subscription and GreenWhiteBackground visualization	Typically requires an additional subscription block	Not included – must be added externally

Error isolation	High – failure of one method call does not affect the others	Lower – a parsing error in the string affects all calls	Depends on configuration, often shared
Configuration effort	Moderate – three addresses must be provided	Low – only one address, but the string must be constructed	High – full OPC-UA node configuration required
Clarity / maintainability	Excellent – each call is explicit and self-documenting	Acceptable – but string contracts are error-prone	Depends on the engineer's discipline
Suitability for industrial HMI	Very high – designed for operator panels with visual feedback	Medium – more suited for ad-hoc remote calls	Medium – versatile but not tailored to softkey use cases

Conclusion

The **Softkey_SRT_RPC_TO_Remote_BG_OPC** subapplication provides a clean, reusable, and industrially oriented solution for controlling three softkey-driven remote method invocations over OPC-UA, combined with live state visualization. Its dedicated-method approach (Option A) eliminates string-parsing pitfalls and improves failure isolation, while the subscription-based GreenWhiteBackground feedback gives operators immediate and reliable confirmation of the remote flip-flop state. By encapsulating all protocol details within a `MyLib::sys` composite, the subapplication promotes modularity, portability, and maintainability across different 4diac projects. This makes it an excellent building block for modern HMI and SCADA-style applications built on the Eclipse 4diac framework.

Softkey_SRT_RPC_TO_Remote_BG_OPC_Adapter

• – ○ • – ○ • – ○ •

Introduction

The **Softkey_SRT_RPC_TO_Remote_BG_OPC_Adapter** is a composite subapplication designed for distributed automation scenarios, specifically for Device A (Station 11, IP 192.168.1.11). It realizes a remote

control architecture where three SoftKeys (Set, Reset, Toggle) and a GreenWhiteBackground indicator are operated via an HMI on Device A, while the actual flip-flop logic is executed on a remote Device B.

This subapplication separates the HMI interaction from the OPC-UA trigger mechanism: the `SoftKeySRT_ASRT_AX` subapplication bundles the HMI logic behind an ASRT_AX plug, while the `ASRT_AX_CLIENT_0_SUBSCRIBE_1` FB bundles three CLIENT_0 instances plus an AX_SUBSCRIBE_1 behind an ASRT_AX socket. The communication protocol is implemented inside the `MyLib::sys` composite, not in the device resource, following the "SUB style" architectural pattern.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirm

Data Inputs

Name	Type	Initial Value	Comment
`QI`	BOOL	`TRUE`	Quality input - TRUE enables the service.
`u16ObjId_SET`	UINT	`ID_NULL`	Object ID for the SoftKey Set function.
`u16ObjId_RESET`	UINT	`ID_NULL`	Object ID for the SoftKey Reset function.
`u16ObjId_TOGGLE`	UINT	`ID_NULL`	Object ID for the SoftKey Toggle function (also carries the GreenWhiteBackground state).
`ID_SET_CALL`	WSTRING	–	Remote method address (`ACTION=CALL_METHOD`) for the Set method call on Device B.
`ID_RESET_CALL`	WSTRING	–	Remote method address (`ACTION=CALL_METHOD`) for the Reset method call on Device B.
`ID_TOGGLE_CALL`	WSTRING	–	Remote method address (`ACTION=CALL_METHOD`) for the Toggle method call on Device B.
`ID_STATE_READ`	WSTRING	–	Locally monitored address (`BOOL`, `ACTION=READ`) for the flip-flop state, written remotely by Device B.

Data Outputs

- **QO** (`BOOL`): quality output, AND combination (`AND_QO`, `AND_BOOL_2`) of the `QO` outputs of `TRIGGER` and `SoftKeySRT_ASRT_AX`

Adapters

The subapplication contains two internal components connected via an adapter link:

- **SoftKeySRT_ASRT_AX** (type `MyLib::sys::SoftKeySRT_ASRT_AX`) – provides the HMI/SoftKey logic and exposes a plug.
- **TRIGGER** (type `adapter::net::ASRT_AX_CLIENT_0_SUBSCRIBE_1`) – provides the OPC-UA client/subscription functionality and exposes a socket.

The adapter connection is established between `SoftKeySRT_ASRT_AX.OUT` (plug) and `TRIGGER.S_R_T` (socket).

Functionality

The subapplication implements a remote SoftKey control loop with the following data flows:

1. **HMI Signal Acquisition** – The three SoftKey object IDs (`u16ObjId_SET`, `u16ObjId_RESET`, `u16ObjId_TOGGLE`) are forwarded to the `SoftKeySRT_ASRT_AX` subapplication, which interprets HMI input and maintains the GreenWhiteBackground state.

2. **Remote Method Invocation** – The remote method addresses (`ID_SET_CALL`, `ID_RESET_CALL`, `ID_TOGGLE_CALL`) are passed to the `TRIGGER` FB. This FB uses OPC-UA `CALL_METHOD` actions to invoke the corresponding methods on Device B.
3. **State Monitoring** – The `ID_STATE_READ` address is monitored via an OPC-UA `READ` action to obtain the flip-flop state, which is written remotely by Device B.
4. **Adapter Coupling** – The `SoftKeySRT_ASRT_AX` output is connected to the `TRIGGER` socket through an ASRT_AX adapter, decoupling the HMI logic from the OPC-UA transport details.

Technical Features

- **Modular architecture** – Separation of HMI handling (SoftKeySRT_ASRT_AX) and OPC-UA communication (TRIGGER) improves reusability and testability.
- **Protocol encapsulation** – The communication protocol resides within the `MyLib::sys` composite library, not in the device resource, enabling easier maintenance and versioning.
- **Parameterized addresses** – All remote end-points are configured via WSTRING inputs, allowing flexible deployment without modifying the internal network.
- **Initialization support** – Object IDs are initialized to `ID_NULL` (imported from `isobus::UT::Q::const::IDs`), ensuring a well-defined startup state.
- **Quality wiring** – `QI` (default `TRUE`) is passed to the `TRIGGER` FB and to `SoftKeySRT_ASRT_AX` (there is no hard-wired `QI` parameter any more); the `QO` outputs of both are combined by `AND_QO` (`AND_BOOL_2`) into `QO`. Initialization runs as `INIT` ⟶ `TRIGGER.INIT`; `TRIGGER.INITO` ⟶ `SoftKeySRT_ASRT_AX.INIT`; `SoftKeySRT_ASRT_AX.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`.

State Overview

The subapplication itself does not maintain an explicit state machine; the state logic is contained in the embedded `SoftKeySRT_ASRT_AX` subapplication. The overall system reflects three operational states:

- **Idle** – No SoftKey pressed, flip-flop state unknown/initial.
- **Set / Reset** – Corresponding remote method called on Device B, state updated via `ID_STATE_READ`.
- **Toggle** – Remote toggle method executed; the GreenWhiteBackground indicator reflects the new flip-flop state.

The flip-flop state is continuously readable via the locally monitored `ID_STATE_READ` address.

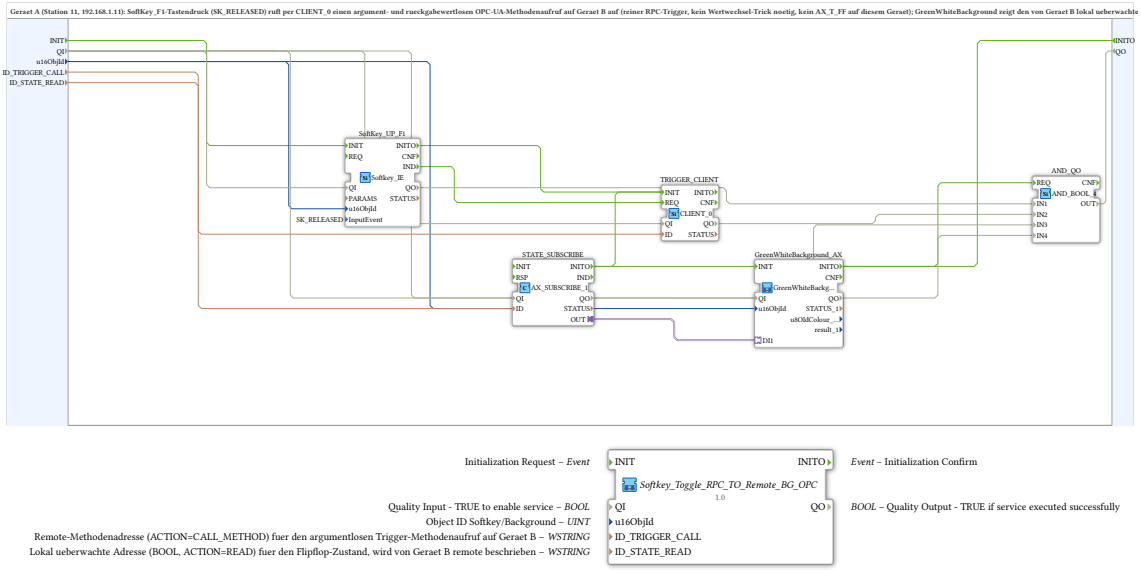
Application Scenarios

This subapplication is suited for:

- **Distributed HMI panels** – Controlling remote actuators or logic from a central operator station.
- **OPC-UA based machine control** – When the actual SoftKey logic resides on a different device than the HMI.
- **Reusable SoftKey libraries** – Where the same HMI pattern is applied to multiple remote targets by changing the object IDs and method addresses.
- **Complex automation cells** – Such as station-based production lines where station 11 (Device A) supervises station functions on Device B.

Comparison with Similar Blocks

Compared to the simpler `Softkey_SRT_RPC_TO_Remote_BG_OPC` (where HMI and OPC-UA trigger are combined), this adapter variant:



- **Separates concerns** – HMI processing and OPC-UA subscription are individually replaceable.
- **Reduces resource footprint** – Bundles three CLIENT_0 instances and one AX_SUBSCRIBE_1 into a single ASRT_AX socket, simplifying wiring.
- **Improves maintainability** – The protocol logic lives in the `MyLib::sys` composite, making it easier to update without touching device resources.
- **Enables plug-and-play** – The ASRT_AX adapter pattern allows rapid exchange of either the HMI or the communication layer.

Conclusion

The `Softkey_SRT_RPC_TO_Remote_BG_OPC_Adapter` is a well-structured subapplication that cleanly separates HMI SoftKey handling from OPC-UA based remote method invocation and state monitoring. By leveraging adapter-based design and encapsulating the protocol in a library composite, it provides a flexible, scalable, and maintainable solution for distributed automation scenarios. Its parameterized inter-

face makes it adaptable to various object IDs and remote addresses without code changes, significantly reducing engineering effort in multi-station systems.

Softkey_Toggle_RPC_TO_Remote_BG_OPC

• — ○ • — ○ • — ○ •

Introduction

Softkey_Toggle_RPC_TO_Remote_BG_OPC is a composite subapplication used on device A, e.g. Station 11 at IP address 192.168.1.11. It combines a softkey input, an OPC UA client request, and a state-monitoring adapter to provide a remote toggle control with visual feedback.

When the F1 softkey is released, represented by `SK_RELEASED`, the subapplication sends an argumentless and return-value-less OPC UA method call to a remote device B through a `CLIENT_0` function block. This is a pure remote procedure call trigger. No value-change trick and no additional flip-flop block is required on device A. The actual flip-flop state is monitored on device B and displayed locally by a `GreenWhiteBackground` composite, which shows either green or white depending on the remote state.

The protocol logic is encapsulated inside the `MyLib::sys` composite subapplication, not directly in the device resource.

Interface Structure

The subapplication exposes the initialization events `INIT`/`INITO`, the status ports `QI`/`QO` and data inputs. It has no externally visible adapter interfaces.

Event Inputs

Name	Type	Description
`INIT`	`EInit`	Initialization Request

All other event generation is handled internally by the softkey input block.

Event Outputs

Name	Type	Description
`INITO`	`EInit`	Initialization Confirm

Data Inputs

Name	Type	Initial Value	Description
`QI`	`BOOL`	`TRUE`	Quality Input - TRUE enables the service.

u16ObjId	UINT	ID_NULL	Object ID used for the softkey and the background element.
ID_TRIGGER_CALL	WSTRING	–	Remote OPC UA method address with ACTION=CALL_METHOD. Used for the argument-less trigger method call on device B.
ID_STATE_READ	WSTRING	–	Locally monitored OPC UA address for the flip-flop state. The address is of type BOOL and uses ACTION=READ. It is written remotely by device B.

Data Outputs

Name	Type	Description
QO	BOOL	Quality Output - TRUE if the service executed successfully (AND of SoftKey_UP_F1, TRIGGER_CLIENT, STATE_SUBSCRIBE and GreenWhiteBackground_AX).

Adapters

None in the external interface.
Internally, the adapter output STATE_SUBSCRIBE.OUT is connected to the adapter input GreenWhiteBackground_AX.DI1.

Functionality

The subapplication performs two main tasks, triggering a remote OPC UA method call and visualizing the remote flip-flop state, plus the initialization and status wiring.

1. SoftKey_UP_F1, an instance of isobus::UT::io::Softkey::Softkey_IE, is configured with InputEvent = SK_RELEASED and receives QI from the subapplication's QI input.
2. When the F1 softkey is released, the internal event output IND of SoftKey_UP_F1 is emitted.
3. This event is connected to the REQ input of TRIGGER_CLIENT, an instance of iec61499::net::CLIENT_0.
4. TRIGGER_CLIENT uses the ID_TRIGGER_CALL address to execute the remote OPC UA method on device B. The method has no arguments and no return value, so a single event-triggered request is sufficient.
5. In parallel, STATE_SUBSCRIBE, an instance of adapter::net::AX_SUBSCRIBE_1, monitors the ID_STATE_READ address and provides the current flip-flop state through its adapter output OUT.
6. This adapter output is connected to GreenWhiteBackground_AX.DI1.
7. GreenWhiteBackground_AX uses u16ObjId to address the correct background element and displays the state as green or white.
8. Initialization and status: INIT → SoftKey_UP_F1.INIT, SoftKey_UP_F1.INITO → TRIGGER_CLIENT.INIT, TRIGGER_CLIENT.INITO → STATE_SUBSCRIBE.INIT, STATE_SUBSCRIBE.INITO → GreenWhiteBackground_AX.INIT, GreenWhiteBackground_AX.INITO → INITO and → AND_QO.REQ. QI is forwarded to SoftKey_UP_F1, TRIGGER_CLIENT, STATE_SUBSCRIBE and GreenWhiteBackground_AX; their QO outputs are ANDed by the AND_QO block (type iec61131::booleanOperators::AND_BOOL_4) into QO.

The result is a clean remote toggle operation: the user presses F1, device B toggles its internal flip-flop, and device A displays the new state.

Technical Features

- Composite subapplication type belonging to the MyLib::sys package.
- Uses isobus::UT::io::Softkey::Softkey_IE for softkey event detection.
- Uses iec61499::net::CLIENT_0 for the OPC UA remote method call.
- Uses adapter::net::AX_SUBSCRIBE_1 for adapter-based state subscription.
- Uses MyLib::sys::GreenWhiteBackground1_AX for green/white state visualization.
- Configuration is done through data inputs; apart from the optional INIT/INITO chain no external event wiring is necessary.
- No internal state machine is required.

- All internal blocks receive `QI` from the subapplication's `QI` input (default `TRUE`).
- The remote method call is a pure RPC trigger and does not require writing alternating values to a tag.
- The protocol and communication details are contained inside the composite subapplication, making it reusable across resources.

State Overview

The subapplication does not contain an explicit ECC state machine. Its behavior is event-driven and dataflow-oriented.

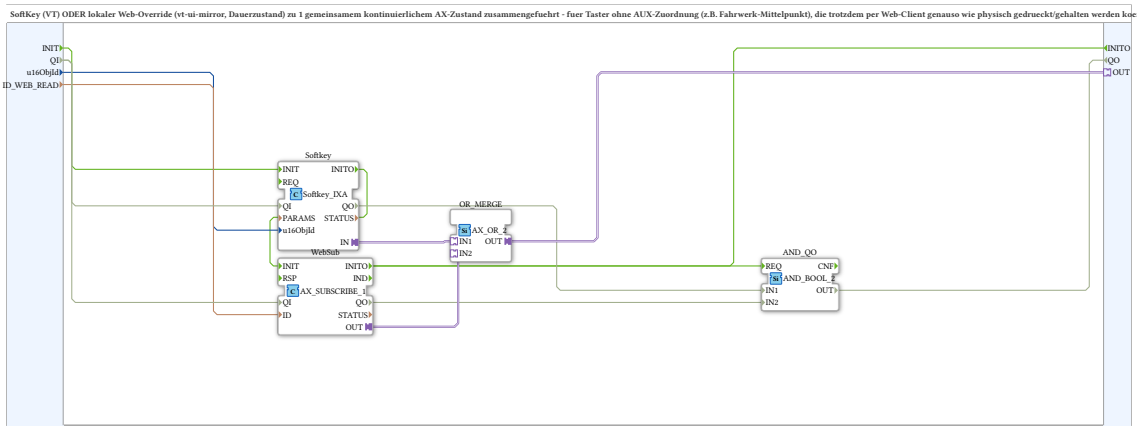
Conceptually, the following states can be identified:

State	Description
Waiting for F1 release	The softkey block is armed and waits for `SK_RELEASED`. The background displays the current remote state.
Issuing remote call	On `SK_RELEASED`, the event is forwarded to `CLIENT_0`, which sends the OPC UA method call to device B.
Monitoring and visualization	`STATE_SUBSCRIBE` reads the remote BOOL state and updates `GreenWhiteBackground_AX`.

No flip-flop state is stored locally on device A. The authoritative state remains on device B.

Application Scenarios

- **Remote operator panel**: Device A acts as an operator interface for device B. Pressing F1 triggers a remote action on device B.
- **RPC-based toggle**: Device B contains a flip-flop that toggles as side effect of an OPC UA method call. Device A only sends the trigger and does not need to simulate a value change.
- **Visual state feedback**: The green/white background gives the operator immediate feedback about the remote flip-flop state.
- **Reusable protocol encapsulation**: The complete OPC UA trigger and state-read logic is bundled in a library composite, so the resource on device A remains simple and maintainable.

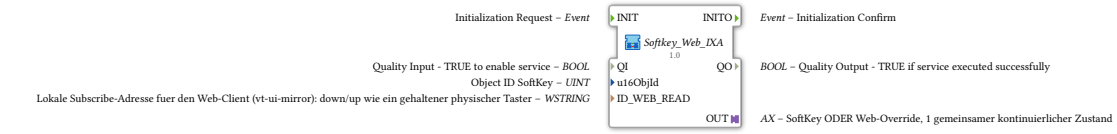


Comparison with Similar Blocks

Approach	Characteristics
Direct softkey to local output	Simple, but cannot trigger remote OPC UA methods.
Raw `CLIENT_0` in the resource	Requires manual event and data wiring in every resource. No integrated state visualization.
Value-change trigger with `AX_T_FF`	Requires an extra flip-flop or alternating write values on device A and can produce unnecessary network traffic.
This subapplication	Uses an explicit OPC UA `CALL_METHOD` trigger and an adapter-based state subscription. The complete protocol logic is encapsulated in the composite subapplication.

Conclusion

Softkey_Toggle_RPC_TO_Remote_BG_OPC provides a compact and reusable solution for remote OPC UA triggering with local visual feedback. By combining a softkey event source, a `CLIENT_0` RPC trigger, an adapter-based state subscription, and a green/white background display, it achieves a clean separation between HMI input, communication logic, and visualization. The design follows a "subapplication style" where the complexity of the remote protocol is hidden inside the composite, making it suitable for reusable library-based automation components.



Softkey_Web_IXA

• — ○ • — ○ • — ○ •

Introduction

`Softkey_Web_IXA` merges a **SoftKey (VT)** OR a local **web override** (vt-ui-mirror, continuous state) into **one** common continuous `AX` state. It is intended for keys without an AUX assignment (e.g. undercarriage centre point) that should nevertheless be pressable or holdable via the web client just like physically. Analogous to `Softkey_Aux_IXA_TO_Remote_WRITE`, which additionally has AUX and remote write; here only the pure merge without AUX and without writing anywhere. The caller processes the merged state further itself (e.g. with `SoftKey_Kurz_Lang`).

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; starts the chain `Softkey` ⟶ `WebSub`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `WebSub.INITO`

Data Inputs

- **QI** (`BOOL`, default `TRUE`): quality input, service enable; passed on to `Softkey` and `WebSub`
- **u16ObjId** (`UINT`): object ID of the SoftKey
- **ID_WEB_READ** (`WSTRING`): local subscribe address for the web client (vt-ui-mirror): down/up like a held physical key

Data Outputs

- **QO** (`BOOL`): quality output, `AND` of the `QO` outputs of `Softkey` and `WebSub` (via `AND_QO`)

Adapters

- **OUT** (plug, `adapter::types::unidirectional::AX`): SoftKey OR web override as one common continuous state

Function Blocks (FBs) Used

- **`Softkey`** (`isobus::UT::io::Softkey::Softkey_IXA`): reads the SoftKey state
- **`WebSub`** (`adapter::net::AX_SUBSCRIBE_1`): subscribes to the web override
- **`OR_MERGE`** (`adapter::booleanOperators::AX_OR_2`): OR combination of both states
- **`AND_QO`** (`iec61131::booleanOperators::AND_BOOL_2`): combines `Softkey.QO` and `WebSub.QO` into the SubApp output `QO`

Functionality

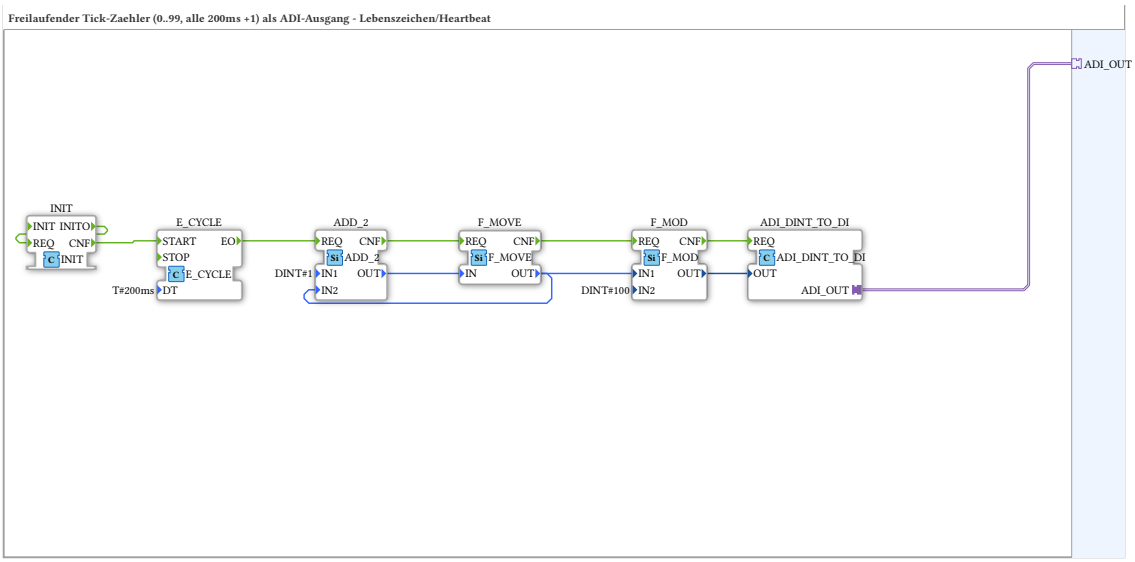
- `u16ObjId` ⟶ `Softkey.u16ObjId`; `ID_WEB_READ` ⟶ `WebSub.ID`
- `Softkey.IN` ⟶ `OR_MERGE.IN1`; `WebSub.OUT` ⟶ `OR_MERGE.IN2`
- `OR_MERGE.OUT` ⟶ `OUT`
- Initialization: `INIT` ⟶ `Softkey.INIT`; `Softkey.INITO` ⟶ `WebSub.INIT`; `WebSub.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`
- Quality: `QI` ⟶ `Softkey.QI` and `WebSub.QI`; `Softkey.QO` ⟶ `AND_QO.IN1`, `WebSub.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`

Technical Details

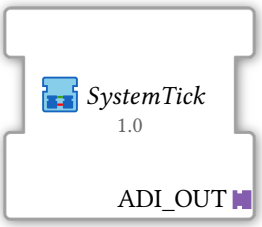
- Continuous state (not an event): the web client can hold the key like a physical one
- No AUX, no remote write

Application Scenarios

- Keys without AUX assignment that should also be operable via the web client and whose state is processed further e.g. by `SoftKey_Kurz_Lang`



Summary



`Softkey_Web_IXA` ORs SoftKey and web override into one continuous `AX` state.

SystemTick

ADI – Aktueller Tick-Zaehlerstand (0..99), aendert sich alle 200ms

• – ○ • – ○ • – ○ •

Introduction

The **SystemTick** subapplication is a free-running tick counter designed to serve as a heartbeat indicator for industrial control systems. It independently increments a counter value every 200 milliseconds, cycling back to zero after reaching 100 (i.e., a full cycle lasts 20 seconds). The current counter value is provided via

an adapter output, making it easy to monitor the health of the system that hosts this subapplication. As long as the output value keeps changing, the system is alive — regardless of whether the value is displayed locally or distributed via OPC-UA to other modules.

Interface Structure

This subapplication provides a single adapter output and no direct event or data interfaces. All internal logic is encapsulated within the embedded function block network.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Name	Type	Description
`ADI_OUT`	`adapter::types::unidirectional::ADI`	Current tick counter value (0–99), updated every 200 ms.

Functionality

The subapplication implements a cyclic counter using the following internal function blocks:

- **INIT** – Performs initialization and starts the cycle generation.
- **E_CYCLE** – Generates a periodic event every 200 ms (configured via its `DT` parameter).
- **ADD_2** – Adds 1 to the current counter value on each cycle.
- **F_MOVE** – Stores the current counter value and forwards it to the arithmetic operations.
- **F_MOD** – Applies modulo 100 when returning the visible value to ensure the range 0–99.
- **ADI_DINT_TO_DI** – Converts the internal DINT counter value into the `ADI` adapter format for the `ADI_OUT` plug.

Working sequence:

1. The `INIT` function block starts `E_CYCLE` after initialization.
2. Each cycle, `E_CYCLE` triggers `ADD_2`, which increments the counter by 1.
3. The incremented value is stored in `F_MOVE` and also fed to `F_MOD` for modulo 100.
4. `F_MOD` outputs a value between 0 and 99 and passes it to `ADI_DINT_TO_DI`.
5. `ADI_DINT_TO_DI` packages the value and sends it via the `ADI_OUT` adapter output.

Technical Features

- **Periodicity:** 200 ms (configurable via the `DT` parameter of the `E_CYCLE` block).
- **Value range:** 0 to 99 (modulo 100).
- **Cycle duration:** 20 seconds for a complete wrap-around.
- **Output type:** Unidirectional `ADI` adapter, carrying one event and one 32-bit integer (DINT).
- **Initialization:** Automatic start via the `INIT` block; no external trigger required.
- **Encapsulation:** All logic is self-contained; no direct I/O or interface connections except the adapter output.

State Overview

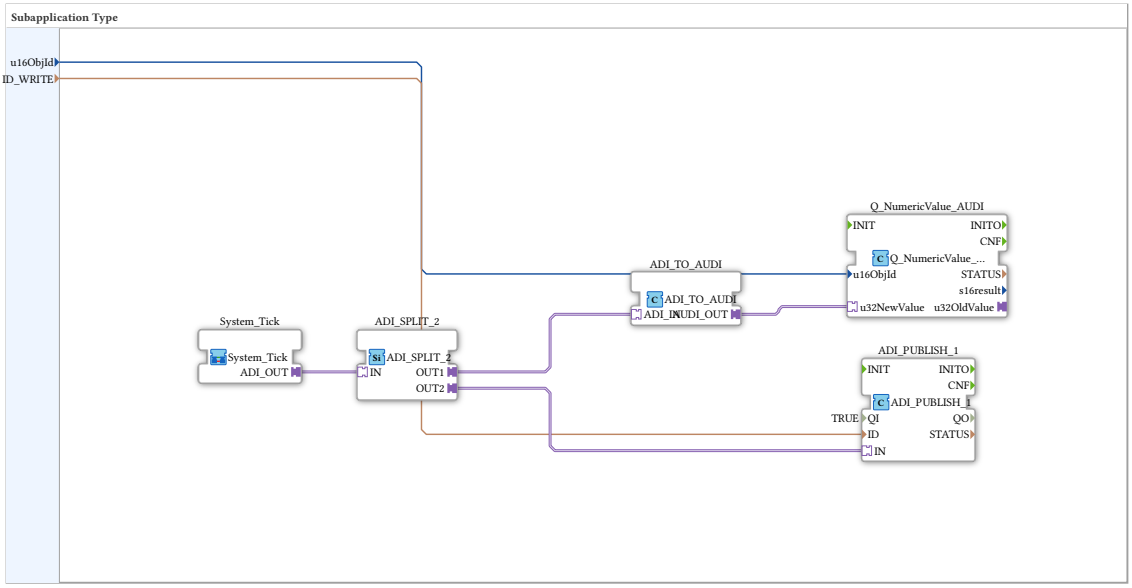
The subapplication does not expose an explicit state machine to the outside. Internally, the counter value is held in the `F_MOVE`/`ADD_2` loop, which behaves as a simple infinite cycle:

1. **Startup:** `INIT` runs and starts `E_CYCLE`.
2. **Counting:** Each cycle increments the counter by 1.
3. **Wrap:** When the value reaches 100, `F_MOD` resets it to 0.

4. **Output:** The current value is continuously reflected on `ADI_OUT`.

Application Scenarios

- **Heartbeat monitoring:** Use the periodic updating counter as a "system alive" signal in distributed control systems.
- **Operational indication:** Display the tick value on a visualization (HMI) to show that the underlying logic is still executing.
- **OPC-UA distribution:** Feed the adapter output to an OPC-UA server (e.g., a gateway) to make the heartbeat available to remote clients.
- **Watchdog functionality:** Detect loss of signal when the output stops changing, indicating a malfunction or offline state.

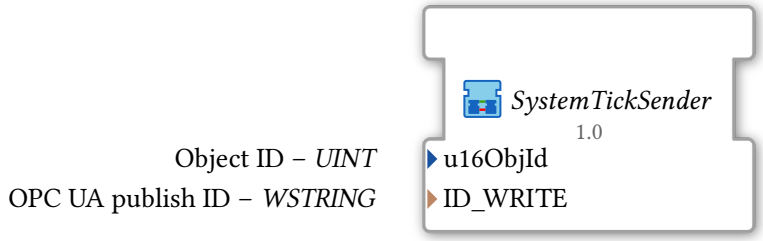


Comparison with Similar Blocks

- **SystemTick vs. simple E_CYCLE with counter:** Unlike a raw periodic event, SystemTick provides a standardized adapter output that encapsulates both an event and a value, making it easier to reuse and integrate with other adapters.
- **SystemTick vs. PLC timer blocks:** Traditional IEC 61131 timers require explicit reset and hold logic; SystemTick runs autonomously and includes modulo scaling.
- **SystemTick vs. heartbeat FBs with fixed periods:** The period is adjustable (via `DT`) and the value range can be easily modified by changing the modulo constant, offering flexibility.

Conclusion

The **SystemTick** subapplication is a compact, self-contained heartbeat generator well suited for monitoring the health of automation systems. Its simple interface (single adapter output) and clear internal structure make it easy to integrate into larger 4diac projects. The periodic, bounded counter provides a reliable liveliness signal that can be consumed locally or remotely, fulfilling a fundamental requirement in distributed control environments.



SystemTickSender

• — ○ • — ○ • — ○ •

Introduction

`SystemTickSender` provides a cyclically incrementing "heartbeat" for the VT and web client — a simple, immediately visible confirmation that the controller is running and processing events. The block is used in several training examples in this system, including `InputOutputTesterButton_DIDO_OPC_UA` and `InputOutputTesterButton_PWM_OPC_UA`.

Function Blocks (FBs) Used

Sub-blocks: SystemTickSender

- **Type**: SubAppType
- **Internal FBs used**:
  - **System_Tick** (SubApp, `MyLib::sys`): provides a cyclically incrementing value as an `ADI` adapter (DINT).
  - **ADI_SPLIT_2**: `adapter::events::unidirectional::ADI_SPLIT_2` — splits the counter adapter into two directions.
  - **ADI_TO_AUDI**: `adapter::conversion::unidirectional::ADI_TO_AUDI` — converts a DINT adapter to a UDINT adapter (numerically correct, see Numeric vs. bitwise: `ANY_INT`⟶`ANY_INT` is a safe cast).
  - **Q_NumericValue_AUDI**: `isobus::UT::Q::Q_NumericValue_AUDI` — writes the counter value into a VT number field.
  - **ADI_PUBLISH_1**: `adapter::net::ADI_PUBLISH_1` — OPC-UA publish of the raw DINT counter value to the web client.
- **Functionality**: The internally generated counter is used once for the VT display (via a UDINT intermediate step, since `Q_NumericValue_AUDI` expects that type) and once raw as DINT for OPC-UA publish.

Program Flow and Connections

1. `System_Tick.ADI_OUT` ⟶ `ADI_SPLIT_2.IN`.
2. `ADI_SPLIT_2.OUT1` ⟶ `ADI_TO_AUDI.ADI_IN` ⟶ `ADI_TO_AUDI.AUDI_OUT` ⟶ `Q_NumericValue_AUDI.u32NewValue` (VT display).
3. `ADI_SPLIT_2.OUT2` ⟶ `ADI_PUBLISH_1.IN` (OPC-UA publish).
4. Parameters: `u16ObjId` ⟶ `Q_NumericValue_AUDI.u16ObjId`; `ID_WRITE` ⟶ `ADI_PUBLISH_1.ID`.

Technical Details

- **Two parallel uses of the same counter**: VT display (via `ADI_TO_AUDI`, since `Q_NumericValue_AUDI` expects a UDINT adapter) and OPC-UA publish (directly as DINT) run independently via `ADI_SPLIT_2`.
- **Numerically correct conversion**: `ADI_TO_AUDI` (DINT⟶UDINT) is an `ANY_INT`⟶`ANY_INT` cast, not a bit-reinterpretation trap like e.g. `AD_TO_AR`.

Application Scenarios

- "Heartbeat" display on the VT and web UI to show at a glance that the controller is active and hasn't crashed or frozen.

Summary

`SystemTickSender` is a simple but widely reused block across almost every training example in this system, distributing a cyclic counter value in parallel to a VT number field and an OPC-UA web client — a minimal but effective heartbeat for the controller.

SystemTickSender_ISO

• — ○ • — ○ • — ○ •

Introduction

`SystemTickSender_ISO` displays the heartbeat locally on a VT numeric output field, without OPC UA. The running tick counter is written directly to a VT numeric field, so it's immediately clear on the screen whether the controller is still active (the value must change every 200 ms).

Function Blocks (FBs) Used

Sub-Blocks: SystemTickSender_ISO

- **Type**: SubAppType
- **Internal FBs Used**:
- **System_Tick** (SubApp, `MyLib::sys`): returns the counter reading as a `ADI` adapter (DINT).
- **ADI_TO_AUDI**: `adapter::conversion::unidirectional::ADI_TO_AUDI` — converts the DINT value to `AUDI` (UDINT) because `Q_NumericValue_AUDI` expects an unsigned value.
- **Q_NumericValue_AUDI**: `isobus::UT::Q::Q_NumericValue_AUDI` — VT command "Change numeric value" (Part 6 – F.22), writes the value to the numeric output field `u16ObjId`.
- **Functionality**: `System_Tick` returns the counter value, `ADI_TO_AUDI` converts it to the data type expected by `Q_NumericValue_AUDI`.

Program Flow and Connections

1. `u16ObjId` ⟶ `Q_NumericValue_AUDI.u16ObjId` (data connection, hidden).
2. `System_Tick.ADI_OUT` ⟶ `ADI_TO_AUDI.ADI_IN` ⟶ `ADI_TO_AUDI.AUDI_OUT` ⟶ `Q_NumericValue_AUDI.u32NewValue`.
3. `INIT` ⟶ `Q_NumericValue_AUDI.INIT`; `Q_NumericValue_AUDI.INITO` ⟶ `INITO` (new event input `INIT` / event output `INITO`, both `EInit`).
4. `QI` (`BOOL`, default `TRUE`) ⟶ `Q_NumericValue_AUDI.QI`; `Q_NumericValue_AUDI.QO` ⟶ `QO` (`BOOL`, Quality Output - `TRUE` if the VT write succeeded).

Technical Features

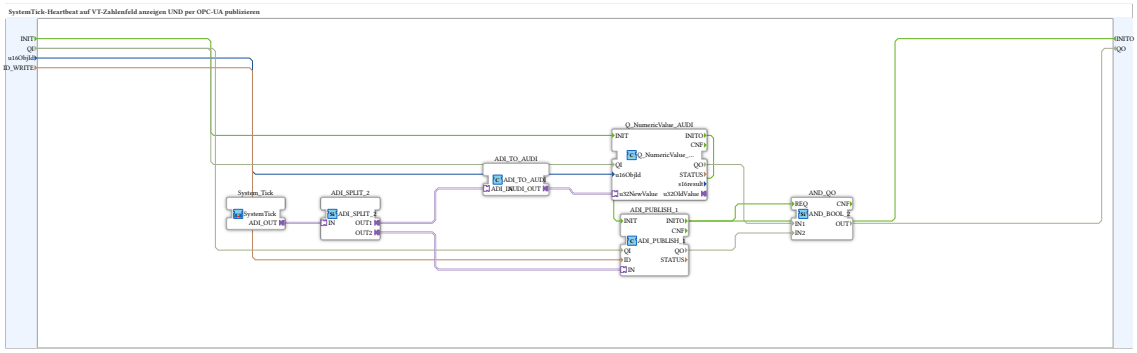
- **Purely local, no OPC UA**: Unlike `SystemTickSender_ISO_OPC`, this module does not have a `ADI_PUBLISH_1` adapter.

Application Scenarios

- Modules with their own VT connection that only need to make the heartbeat visible locally, without remote monitoring.

Comparison with Similar Modules

For additional remote distribution, use `SystemTickSender_ISO_OPC` for a module without its own VT connection (OPC UA only), use `SystemTickSender_OPC`. Compared to `SystemTickSender` (VT + OPC UA, older example with `ADI_SPLIT_2`), this module is the pure VT-only variant without split/publish functionality.



Summary

`SystemTickSender_ISO` displays the system tick heartbeat exclusively on a local VT numeric field—the most streamlined option for modules with their own VT connection without remote monitoring.

SystemTickSender_ISO_OPC

• – ○ • – ○ • – ○ •

Introduction

`SystemTickSender_ISO_OPC` combines `SystemTickSender_ISO` (display on a local VT number field) with `SystemTickSender_OPC` (remote publishing via OPC UA) so that the same status indicator is visible both on the local screen and can be monitored by other modules via remote subscribe.

Function Blocks (FBs) Used

Sub-Blocks: SystemTickSender_ISO_OPC

- **Type**: SubAppType
- **Internal FBs Used**:
- **System_Tick** (SubApp, `MyLib::sys`): Returns the counter reading as a `ADI` adapter (DINT).
- **ADI_SPLIT_2**: `adapter::events::unidirectional::ADI_SPLIT_2` — Fans `System_Tick.ADI_OUT` out to two destinations, as an adapter socket can only accept one source: one output feeds the VT display (via `ADI_TO_AUDI`), the other feeds `ADI_PUBLISH_1` for OPC UA publishing.
- **ADI_TO_AUDI**: `adapter::conversion::unidirectional::ADI_TO_AUDI` — Converts DINT to UDINT for VT display.
- **Q_NumericValue_AUDI**: `isobus::UT::Q::Q_NumericValue_AUDI` — displays the value locally on the VT (`u16ObjId`).

- **ADI_PUBLISH_1**: `adapter::net::ADI_PUBLISH_1` (`QI` comes from the input `QI`) — publishes the same counter value via OPC UA (`ID_WRITE`).
- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` — combines `Q_NumericValue_AUDI.QO` and `ADI_PUBLISH_1.QO` into the output `QO`.
- **Functionality**: The counter value from `System_Tick` is branched via `ADI_SPLIT_2`: one branch goes to the VT display via `ADI_TO_AUDI`, as with `SystemTickSender_ISO`, the other goes directly to `ADI_PUBLISH_1` for OPC UA publishing — as with `SystemTickSender_OPC`.

Program Flow and Connections

1. `System_Tick.ADI_OUT` ⟶ `ADI_SPLIT_2.IN`.
2. `ADI_SPLIT_2.OUT1` ⟶ `ADI_TO_AUDI.ADI_IN` ⟶ `ADI_TO_AUDI.AUDI_OUT` ⟶ `Q_NumericValue_AUDI.u32NewValue` (VT display).
3. `ADI_SPLIT_2.OUT2` ⟶ `ADI_PUBLISH_1.IN` (OPC UA publish).
4. Parameters: `u16ObjId` ⟶ `Q_NumericValue_AUDI.u16ObjId`; `ID_WRITE` ⟶ `ADI_PUBLISH_1.ID`.
5. Initialization chain (event input `INIT` / event output `INITO`, both `EInit`): `INIT` ⟶ `Q_NumericValue_AUDI.INIT`; `Q_NumericValue_AUDI.INITO` ⟶ `ADI_PUBLISH_1.INIT`; `ADI_PUBLISH_1.INITO` ⟶ `INITO` and `AND_QO.REQ`.
6. Quality: `QI` (`BOOL`, default `TRUE`) ⟶ `Q_NumericValue_AUDI.QI` and `ADI_PUBLISH_1.QI`; `Q_NumericValue_AUDI.QO` ⟶ `AND_QO.IN1`; `ADI_PUBLISH_1.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO` (`BOOL`, Quality Output - `TRUE` if the VT write and the OPC UA publish succeeded).

Technical Features

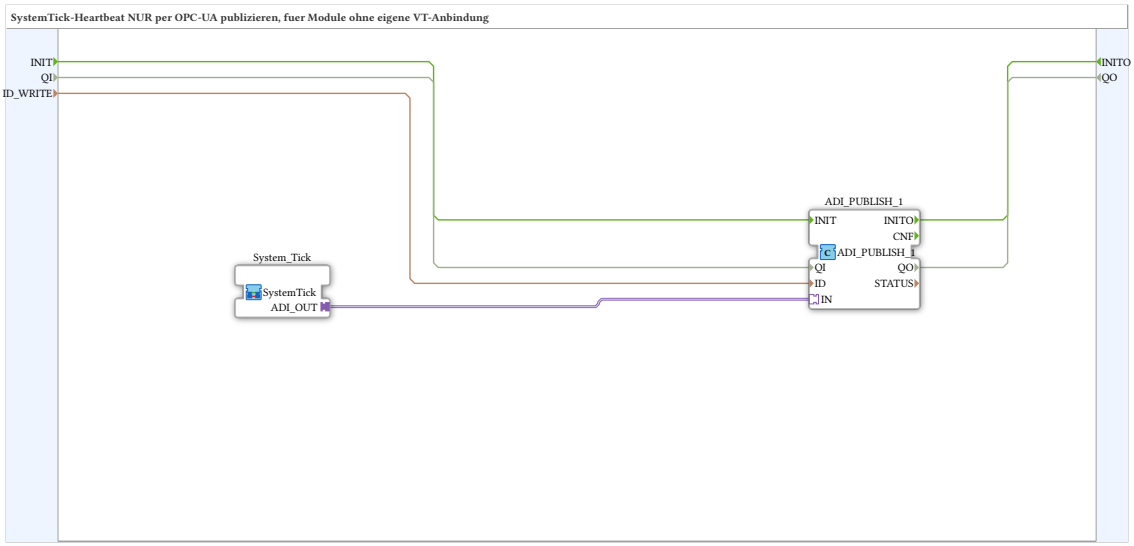
- **One counter, two uses**: `ADI_SPLIT_2` allows the parallel use of the same `System_Tick` counter for VT display and OPC UA publishing without duplicating the counter.

Application Scenarios

- Modules with their own VT connection whose heartbeat should also be monitored by other modules via remote subscribe.

Comparison with similar function blocks

If only one of the two outputs is needed, the simpler `SystemTickSender_ISO` (VT only) or `SystemTickSender_OPC` (OPC UA only) should be used. This pattern (Split ⟶ VT Display + OPC UA Publish) is structurally equivalent to the older `SystemTickSender`.



Summary

`SystemTickSender_ISO_OPC` displays the SystemTick Heartbeat simultaneously locally on the VT and remotely via OPC UA by combining the two leaner individual variants into a single component.

SystemTickSender_OPC

• – ○ • – ○ • – ○ •

Introduction

`SystemTickSender_OPC` is the most streamlined SystemTick variant for modules without their own VT connection: The running tick counter from `System_Tick` is published directly via OPC UA, without a local VT display. Another module with VT can subscribe to and display this value via remote subscribe to monitor the module's activity.

Function Blocks (FBs) Used

Sub-Blocks: SystemTickSender_OPC

- **Type**: SubAppType
- **Internal FBs Used**:
- **System_Tick** (SubApp, `MyLib::sys`): returns the counter reading as a `ADI` adapter (DINT).
- **ADI_PUBLISH_1**: `adapter::net::ADI_PUBLISH_1` — publishes the counter reading directly via OPC UA (`ID_WRITE`).
- **Functionality**: The counter reading from `System_Tick` is passed directly to `ADI_PUBLISH_1` without conversion.

Program Flow and Connections

1. `ID_WRITE` ⟶ `ADI_PUBLISH_1.ID` (Data connection, hidden).
2. `System_Tick.ADI_OUT` ⟶ `ADI_PUBLISH_1.IN`.
3. Initialization: event input `INIT` ⟶ `ADI_PUBLISH_1.INIT`; `ADI_PUBLISH_1.INITO` ⟶ event output `INITO`.
4. Quality: data input `QI` (`BOOL`, default `TRUE`) ⟶ `ADI_PUBLISH_1.QI`; `ADI_PUBLISH_1.QO` ⟶ data output `QO`.

Technical Features

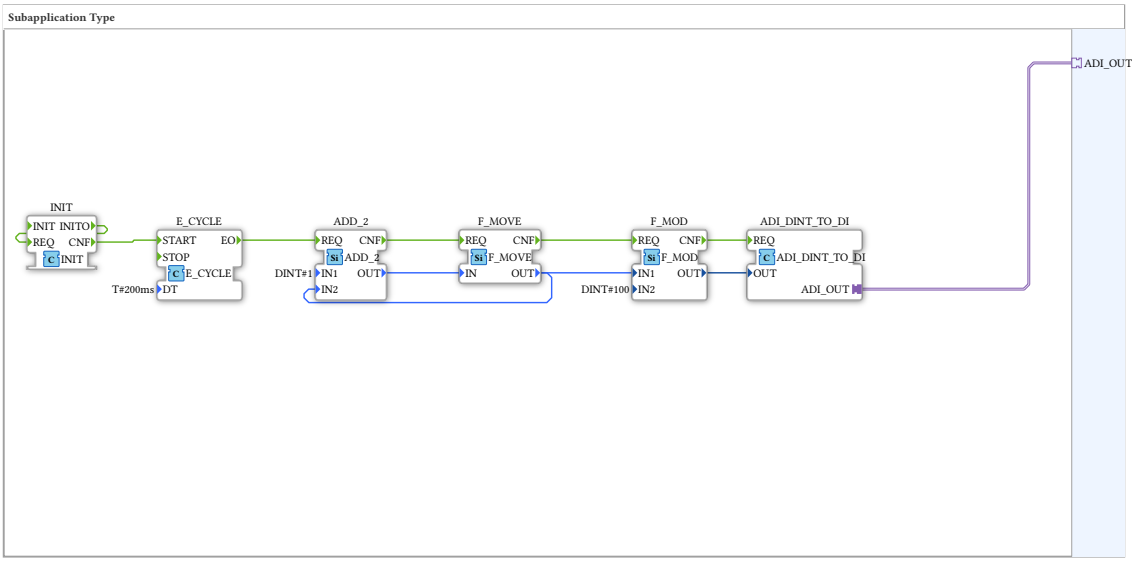
- **No type conversion required**: Since no VT display is involved, the `ADI_TO_AUDI` conversion is omitted —the raw DINT value is published directly.

Application Scenarios

- Modules without their own VT connection (e.g., pure I/O/field modules) whose liveness is to be monitored by another module with VT.

Comparison with Similar Modules

If a local VT display is also required, use `SystemTickSender_ISO_OPC` (VT + OPC UA) or `SystemTickSender_ISO` (VT only).



Summary

`SystemTickSender_OPC` publishes the SystemTick heartbeat exclusively via OPC UA — the minimal option for modules without their own VT connection.

System_Tick

• – ○ • – ○ • – ○ •

Introduction

`System_Tick` generates a continuous, cyclically incrementing DINT counter (200 ms tick, value range 0..99, wrapping via modulo) and exposes it through an `ADI` adapter (DINT) for other blocks to consume — a simple heartbeat counter.

Function Blocks Used

Sub-blocks: System_Tick

- **Type**: SubAppType
- **Internal FBs used**:
  - **INIT**: `iec61131::booleanOperators::INIT` — fires once at startup (`INITO` fed back to `REQ`) and starts the cycle timer.

  - **E_CYCLE**: `iec61499::events::E_CYCLE` — cyclic event, `DT=T#200ms`, started via `INIT.CNF`.
  - **ADD_2**: `iec61131::arithmetic::ADD_2` — adds `IN1=DINT#1` to the current counter value (`IN2`, fed back from `F_MOVE.OUT`).
  - **F_MOVE**: `iec61131::selection::F_MOVE` (`DataType=DINT`) — holds/passes the current counter value, acting as the feedback loop's intermediate storage.
  - **F_MOD**: `iec61131::arithmetic::F_MOD` — modulo operation with `IN2=DINT#100`, limiting the value range to 0..99.
  - **ADI_DINT_TO_DI**: `adapter::conversion::unidirectional::ADI_DINT_TO_DI` — converts the DINT value onto the `ADI_OUT` adapter for external use.
- **Operation**: `INIT` starts the `E_CYCLE` timer; each cycle increments the counter via `ADD_2`/`F_MOVE` by 1, `F_MOD` keeps it within 0..99, and `ADI_DINT_TO_DI` places the result onto the output adapter.

Program Flow and Connections

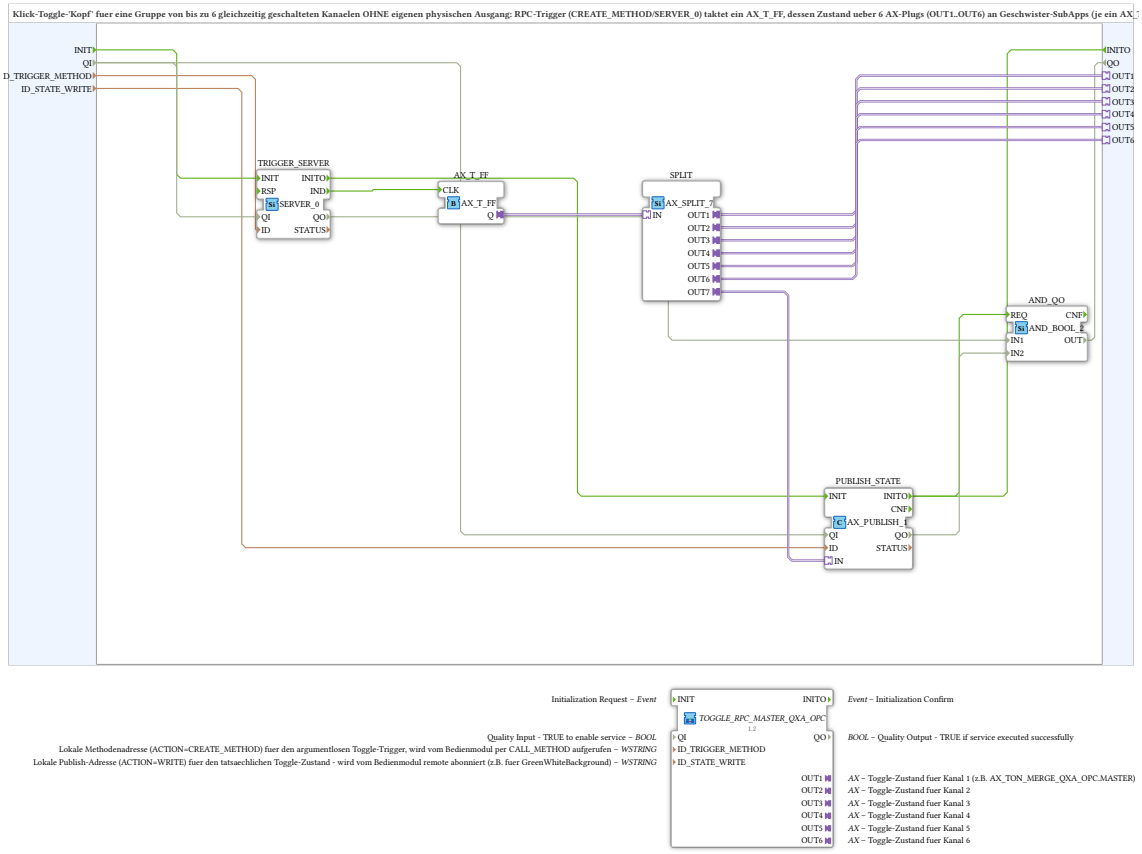
1. `INIT.INITO` ⟶ `INIT.REQ` (self-trigger at startup); `INIT.CNF` ⟶ `E_CYCLE.START`.
2. `E_CYCLE.EO` ⟶ `ADD_2.REQ` (every 200 ms).
3. `F_MOVE.OUT` ⟶ `ADD_2.IN2` (feedback of the current value); `ADD_2.OUT` ⟶ `F_MOVE.IN`.
4. `ADD_2.CNF` ⟶ `F_MOVE.REQ` ⟶ `F_MOD.REQ` (event chain); `F_MOVE.OUT` ⟶ `F_MOD.IN1`.
5. `F_MOD.CNF` ⟶ `ADI_DINT_TO_DI.REQ`; `F_MOD.OUT` ⟶ `ADI_DINT_TO_DI.OUT`.
6. `ADI_DINT_TO_DI.ADI_OUT` (adapter) ⟶ `ADI_OUT` (SubApp interface).

Technical Details

- The counter runs purely internally within the block (no external data inputs) — it is an autonomous clock that triggers itself via `INIT`.
- The modulo bound `DINT#100` yields a value range of 0..99, not 1..100 as one might assume at first glance — the value implicitly starts at 0 after `INIT`, and `ADD_2` counts up by 1 each cycle from there.

Application Scenarios

- Heartbeat/liveness signal for diagnostic purposes, e.g. to show on the VT or via OPC-UA that the controller is actively cycling.
- Simple substitute for a one-second tick (5 cycles of 200 ms ≈ 1 s) for test purposes, without configuring a dedicated timer block.



Summary

Autonomous, self-triggering 200 ms counter with modulo limiting, exposed via a DINT adapter — a simple heartbeat block.

TOGGLE_RPC_MASTER_QXA_OPC

• — ○ • — ○ • — ○ •

Introduction

The `TOGGLE_RPC_MASTER_QXA_OPC` is a subapplication that implements a remote-controlled toggle "head" for a group of up to six simultaneously switched channels without having its own physical output. It is intended for OPC UA based operator panels: a remote client triggers a toggle operation by calling a local OPC UA method, and the resulting state is distributed through six adapter plugs to sibling subapplications. The same state is also published locally so that an operator panel can display it, for example as a background colour.

This subapplication is designed for multi-channel use cases where one softkey should toggle several outputs at the same time, but each physical channel may still have its own delayed start behaviour.

Interface Structure

The subapplication exposes the data input `QI`, two WSTRING data inputs, the data output `QO` and six unidirectional AX adapter plugs. Apart from `INIT`/`INITO` it has no event inputs or outputs and no sockets.

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirmation (from `PUBLISH_STATE.INITO`)

Data Inputs

Name	Type	Description
`QI`	BOOL	Quality Input, TRUE enables the service (default `TRUE`); distributed to `TRIGGER_SERVER.QI` and `PUBLISH_STATE.QI`.

ID_TRIGGER_METHOD	WSTRING	Local OPC UA method address (ACTION=CREATE_METHOD) used as the argumentless toggle trigger. It is called remotely by the operator panel via CALL_METHOD.
ID_STATE_WRITE	WSTRING	Local OPC UA publish address (ACTION=WRITE) for the actual toggle state. It can be subscribed by remote operator panels, e.g. for a GreenWhite background indication.

Data Outputs

- **QO** (BOOL): Quality Output, AND of TRIGGER_SERVER.QO and PUBLISH_STATE.QO (AND_QO, iec61131::booleanOperators::AND_BOOL_2)

Adapters

Name	Type	Direction / Kind	Description
OUT1	adapter::types::unidirectional::AX	Plug	Toggle state for channel 1, typically connected to an AX_TON_MERGE_QXA_OPC.MASTER.
OUT2	adapter::types::unidirectional::AX	Plug	Toggle state for channel 2.
OUT3	adapter::types::unidirectional::AX	Plug	Toggle state for channel 3.
OUT4	adapter::types::unidirectional::AX	Plug	Toggle state for channel 4.
OUT5	adapter::types::unidirectional::AX	Plug	Toggle state for channel 5.
OUT6	adapter::types::unidirectional::AX	Plug	Toggle state for channel 6.

Unused OUTn plugs can simply remain unconnected.

Functionality

The subapplication provides a click-toggle behaviour:

1. The internal OPC UA server FB TRIGGER_SERVER receives an incoming method call or event at its IND input.
2. The same event clocks the internal AX_T_FF flip-flop.
3. The flip-flop output Q toggles between FALSE and TRUE on every trigger.
4. The state is forwarded to the AX_SPLIT_7 block, which distributes it to seven branches.
5. Six of the branches are connected to the OUT1 .. OUT6 adapter plugs and can be wired to sibling subapplications.
6. The seventh branch is connected to PUBLISH_STATE, which publishes the state under the configured OPC UA address ID_STATE_WRITE.
7. TRIGGER_SERVER.IND is directly connected to TRIGGER_SERVER.RSP, ensuring that the OPC UA server response is sent immediately and that the server thread is not blocked.
8. Initialization and quality: INIT → TRIGGER_SERVER.INIT; TRIGGER_SERVER.INITO → PUBLISH_STATE.INIT; PUBLISH_STATE.INITO → INITO (and → AND_QO.REQ). QI → TRIGGER_SERVER.QI and PUBLISH_STATE.QI; TRIGGER_SERVER.QO → AND_QO.IN1, PUBLISH_STATE.QO → AND_QO.IN2, AND_QO.OUT → QO.

This allows the toggle state to be used both locally in the automation network and remotely for HMI display purposes.

Technical Features

- Uses iec61499::net::SERVER_0 as the OPC UA method and event server.
- Uses adapter::events::unidirectional::AX_T_FF as the central toggle flip-flop.
- Uses adapter::events::unidirectional::AX_SPLIT_7 to distribute one toggle state to seven outputs.
- Uses adapter::net::AX_PUBLISH_1 to publish the current toggle state to OPC UA.
- Uses iec61131::booleanOperators::AND_BOOL_2 (AND_QO) to combine the QO outputs of the server and the publisher.
- TRIGGER_SERVER.IND is wired directly to TRIGGER_SERVER.RSP to avoid blocking the OPC UA server thread.

- Supports up to six 1:1 adapter connections to sibling subapplications.
- The data input connections are marked as not visible in the internal network to keep the design compact.
- Licensed under the Eclipse Public License 2.0.

State Overview

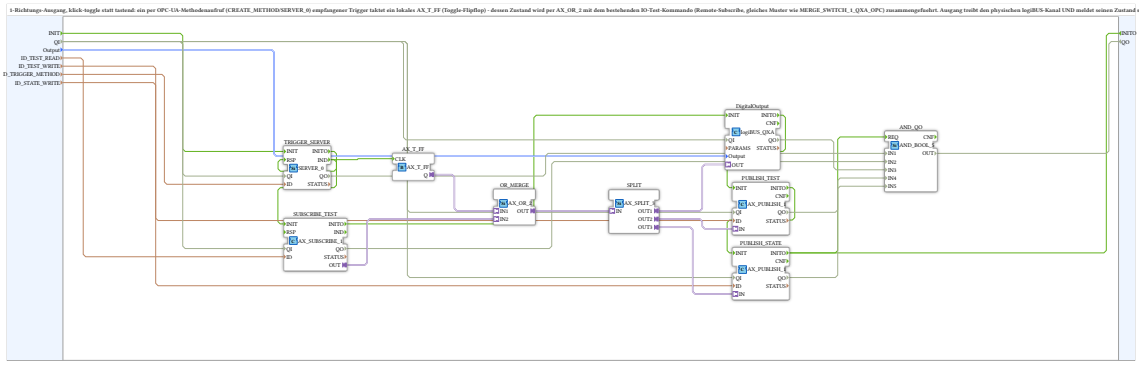
The central state is the boolean output `Q` of the internal `AX_T_FF` block. It toggles on every rising edge of the trigger event from `TRIGGER_SERVER.IND`.

State	Meaning
`FALSE`	Toggle state is off. All connected `OUTn` adapter values and the published OPC UA state are `FALSE`.
`TRUE`	Toggle state is on. All connected `OUTn` adapter values and the published OPC UA state are `TRUE`.
Transition	A trigger event is received, `Q` is inverted, and the new state is distributed to all branches.

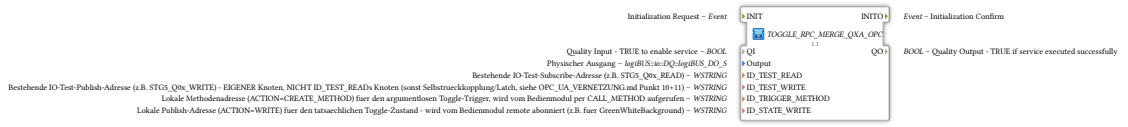
There is no additional internal state machine; the behaviour is that of a simple T flip-flop.

Application Scenarios

- **Lighting groups**: A bank of six spotlights can be switched with a single softkey while each channel starts with its own delay to avoid capacitive inrush current peaks.
- **Multi-channel remote control**: An operator panel calls one OPC UA method to toggle a group of drives, valves, or light channels.
- **HMI background indication**: The published state is subscribed by the operator panel and used for colour feedback, e.g. Green/White background.
- **Distributed systems**: The `OUTn` plugs can be connected to sibling subapplications such as `AX_TON_MERGE_QXA_OPC`, one per physical channel, allowing shared toggle control with individual channel timing.



Comparison with Similar Blocks



- `TOGGLE_RPC_MASTER_QXA_OPC` has no physical output of its own. Instead, it provides six adapter plugs to distribute the toggle state to multiple sibling subapplications.
- `TOGGLE_RPC_MERGE_QXA_OPC` is the single-output variant. It includes the physical output path and is recommended when only one output is required.
- Other softkey/RPC toggle blocks may support remote background toggling, but they do not provide the same multi-channel fan-out through six separate plugs.

Conclusion

`TOGGLE_RPC_MASTER_QXA_OPC` is a flexible solution for remote click-toggle control of up to six channels via OPC UA. It combines a method-triggered flip-flop, local adapter-based fan-out, and OPC UA state publication. The direct `IND` to `RSP` connection keeps the OPC UA server responsive, and unused outputs can be left unconnected, making the subapplication suitable for both small and medium-sized multi-channel HMI-controlled applications.

TOGGLE_RPC_MERGE_QXA_OPC

• — ○ • — ○ • — ○ •

Introduction

TOGGLE_RPC_MERGE_QXA_OPC is a composite subapplication designed for single-action (click-toggle) output control. It combines an RPC-based trigger with an existing IO-test command to drive a physical binary output. The RPC trigger is received via OPC-UA method calls (CREATE_METHOD/SERVER_0) and toggles a local flip-flop. The resulting state is merged with the standard IO-test signal and then split to provide both a physical output and two separate feedback channels – one for IO diagnostics and one for the actual functional state (e.g., for background colour indication on a softkey). The design ensures full consistency with the project's other similar blocks, avoiding self-latch by using distinct publish nodes for commands and feedback.

Interface Structure

The subapplication exposes data inputs plus the quality/initialization ports (`QI`, `QO`, `INIT`, `INITO`); no adapters are present at the subapp level. All other event and adapter connections are internal.

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirm

Data Inputs

Name	Type	Description
`QI`	`BOOL`	Quality input - TRUE enables the service (initial value: `TRUE`)
`Output`	`logiBUS::io::DQ::logiBUS_DO_S`	Physical output value to be applied (initialized to `logiBUS_DO::Invalid`). Internal connection to the physical output FB.
`ID_TEST_READ`	`WSTRING`	Subscription address for the existing IO-test command (e.g., `STG5_Q0x_READ`).
`ID_TEST_WRITE`	`WSTRING`	Publish address for the IO-test feedback. Must be a separate node from `ID_TEST_READ` to avoid self-feedback/latch.
`ID_TRIGGER_METHOD`	`WSTRING`	Local method address (ACTION=CREATE_METHOD) for the argumentless toggle trigger, invoked by the operation panel via CALL_METHOD.
`ID_STATE_WRITE`	`WSTRING`	Local publish address (ACTION=WRITE) for the actual toggle state – subscribed remotely by the operation panel (e.g., for GreenWhiteBackground).

Data Outputs

- **QO** (`BOOL`): quality output, AND combination (`AND_QO`, `AND_BOOL_5`) of the `QO` outputs of `TRIGGER_SERVER`, `SUBSCRIBE_TEST`, `DigitalOutput`, `PUBLISH_TEST` and `PUBLISH_STATE`. The actual results are still delivered through the internal OPC-UA publish blocks.

Adapters

None at the subapp interface. Internally, the following adapters/FBs are used:

- `TRIGGER_SERVER` (iec61499::net::SERVER_0) – receives the RPC method call.
- `AX_T_FF` (adapter::events::unidirectional::AX_T_FF) – toggle flip-flop.
- `SUBSCRIBE_TEST` (adapter::net::AX_SUBSCRIBE_1) – subscribes to the IO-test command.
- `OR_MERGE` (adapter::booleanOperators::AX_OR_2) – merges flip-flop state and IO-test signal.
- `SPLIT` (adapter::events::unidirectional::AX_SPLIT_3) – distributes the merged result.
- `DigitalOutput` (logiBUS::io::DQ::logiBUS_QXA) – physical output.
- `PUBLISH_TEST` (adapter::net::AX_PUBLISH_1) – publishes feedback to IO-test node.
- `PUBLISH_STATE` (adapter::net::AX_PUBLISH_1) – publishes the functional state to the dedicated feedback node.

Functionality

The subapplication implements a **click-toggle** behaviour:

- A single press of a softkey (or any RPC client) issues an **argument-free method call** on the `ID_TRIGGER_METHOD` node.
- `TRIGGER_SERVER` receives this call and its `IND` event toggles the `AX_T_FF` flip-flop (`CLK` input).
- The flip-flop output (`Q`) is combined via `OR_MERGE` with the signal coming from the IO-test subscription (`SUBSCRIBE_TEST`). This way the IO-test command can still force the output regardless of the toggle state.
- The combined result is passed to `SPLIT`, which feeds three destinations:
  1. `DigitalOutput` – drives the physical logiBUS channel.
  2. `PUBLISH_TEST` – writes to the IO-test feedback node (address from `ID_TEST_WRITE`).
  3. `PUBLISH_STATE` – writes to the functional feedback node (address from `ID_STATE_WRITE`).

Initialization and quality: `INIT` → `TRIGGER_SERVER.INIT` → `SUBSCRIBE_TEST.INIT` → `DigitalOutput.INIT` → `PUBLISH_TEST.INIT` → `PUBLISH_STATE.INIT`; `PUBLISH_STATE.INITO` → `INITO` and → `AND_QO.REQ`. `QI` is distributed to all five blocks (no hard-wired `QI` parameter any more); their `QO` outputs feed `AND_QO.IN1` to `AND_QO.IN5` in this order, `AND_QO.OUT` → `QO`.

The use of **separate write nodes** for feedback avoids the self-latch problem that would occur if the same OPC-UA node were used for both command and feedback. The toggle state is **not actively written back** to the panel via a client; instead, it is locally published and remotely subscribed – a pattern consistent with all other functions in the project.

Technical Features

- **RPC Trigger without Polling**: The trigger is delivered as a method call (`CREATE_METHOD/SERVER_0`), eliminating any value-change tricks or polling overhead.
- **Toggle Flip-Flop**: The `AX_T_FF` changes its output on each rising edge of the input event, providing a bistable state.
- **Merging with IO-Test**: The `AX_OR_2` ensures that the IO-test command can override the toggle state, keeping the diagnostic capability intact.
- **Deterministic Feedback**: Two separate publish adapters (`PUBLISH_TEST` and `PUBLISH_STATE`) guarantee that IO diagnostics and functional state are reported independently.
- **No Active Client-Write**: The feedback is published locally and subscribed remotely, consistent with the project's distributed architecture (e.g., softkey background updates).
- **Unique Publish Nodes**: `ID_TEST_WRITE` and `ID_STATE_WRITE` must be distinct from each other and from the corresponding command nodes to prevent feedback loops.

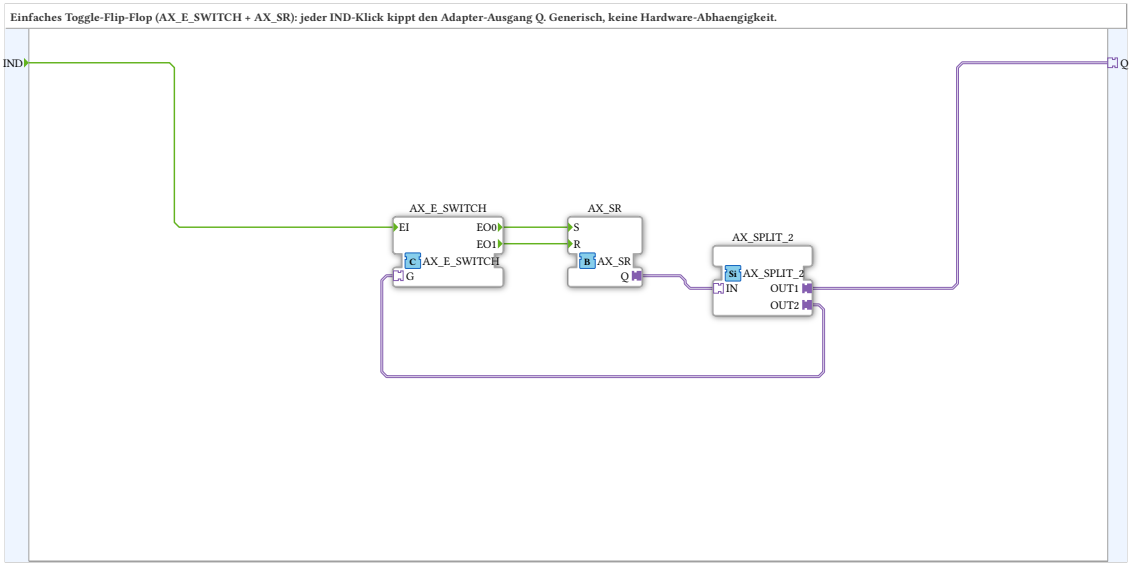
State Overview

The internal `AX_T_FF` flip-flop maintains a single Boolean state (`Q`). This state toggles on every `CLK` pulse, which is generated by the RPC method call. The flip-flop is **not** reset by any external signal; it only changes when a new trigger arrives. The output of the OR gate follows either the flip-flop state or the IO-test signal, whichever is currently TRUE. Since the IO-test signal is typically FALSE during normal operation, the output normally mirrors the flip-flop state.

Application Scenarios

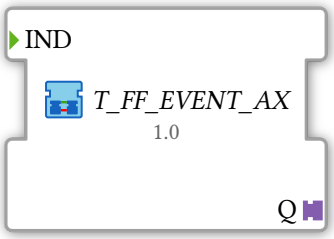
- **Flash Light Control**: A single press turns the light ON, another press turns it OFF – no need to hold the button.
- **Any Toggle-Type Output**: Suitable for functions where a momentary switch action must produce a sustained state (e.g., latching relays, mode toggles).

- **Integration with IO-Testing**: The block preserves the ability to force the output via the IO-test system without interfering with the toggle logic.
- **Softkey Interaction**: The functional state is made available to the operation panel via a dedicated publish node, enabling dynamic visual feedback (e.g., green/white background) as seen in other project functions.



Comparison with Similar Blocks

- **MERGE_SWITCH_1_QXA_OPC**: Uses a level-based subscription (value change) as the command source instead of an RPC trigger. TOGGLE_RPC_MERGE_QXA_OPC additionally toggles the state via a flip-flop, making it a true click-toggle rather than a momentary switch.
- **ILOCK_SWITCH_2_QXA_OPC**: Also follows the pattern of separate feedback nodes, but its command source is different. TOGGLE_RPC_MERGE_QXA_OPC adds the toggle functionality while maintaining the same robust feedback architecture.
- **Toggle_RPC_FROM_Remote_QXA_OPC (original exercise)**: The original actively wrote back to the panel via a client. This block instead publishes locally and subscribes remotely, which is more consistent with the project's distributed design and avoids unnecessary OPC-UA client writes.



Conclusion

TOGGLE_RPC_MERGE_QXA_OPC provides a clean, reusable solution for click-toggle outputs in a distributed automation environment. By combining an RPC-based trigger with a local flip-flop, merging it with the IO-test command, and publishing separate feedback channels, it achieves reliable operation without feedback loops. Its design is fully aligned with the project's established patterns, making it ideal for functions that require a single press to toggle a binary state.

T_FF_EVENT_AX

Event Input (Clock / Click) – *Event*

AX – Adapter Output Q

• – ◦ • – ◦ • – ◦ •

Introduction

T_FF_EVENT_AX is a generic toggle flip-flop (T-FF) subapplication that implements a toggling latch behavior based on an event-driven input and an adapter-based output. Every incoming `IND` event toggles

the logical state of the output adapter Q. The subapplication is built entirely from standard event adapter blocks (AX_E_SWITCH, AX_SR, AX_SPLIT_2) and is completely hardware-independent.

Interface Structure

Event Inputs

Name	Type	Comment
IND	Event	Event input (Clock / Click) – triggers the toggling

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Name	Type	Direction	Comment
Q	adapter::types::unidirectional::AX	Output (Plug)	Adapter output holding the current toggled state

Functionality

The subapplication implements a classic toggle (T) flip-flop behavior entirely through event and adapter connections:

1. An IND event triggers the internal AX_E_SWITCH block.
2. AX_E_SWITCH evaluates its gating input G and activates exactly one of its two event outputs:
   - EO0 if the gate is inactive (state FALSE),
   - EO1 if the gate is active (state TRUE).
3. If EO0 fires, the internal AX_SR is **Set** (Q becomes TRUE).
   If EO1 fires, the internal AX_SR is **Reset** (Q becomes FALSE).
4. The current state from AX_SR.Q is passed to AX_SPLIT_2.
5. AX_SPLIT_2.OUT1 drives the external adapter output Q; AX_SPLIT_2.OUT2 is fed back to the gating input G of AX_E_SWITCH.
6. This feedback loop ensures that on the next IND event the gate has switched state, so the opposite branch is triggered – producing the alternating toggle effect.

Technical Features

- **Pure event-driven design**: no cyclic data scanning, no level-triggered polling.
- **Generic adapter interface**: no hardware-specific dependencies, fully reusable in distributed IEC 61499 systems.
- Built from three reusable adapter-pattern blocks:
  - AX_E_SWITCH – gated event router with two complementary outputs.
  - AX_SR – Set/Reset flip-flop that stores the state.
  - AX_SPLIT_2 – fan-out adapter splitting the state signal to the external plug and the internal feedback path.
- **Internal feedback loop** provides the memory/toggling effect without additional logic.
- Implemented as a subapplication, encapsulating the logic for easy reuse and readability.

State Overview

State	Description
Q = FALSE	Internal AX_SR is Reset. On the next IND event, EO0 fires and Q becomes TRUE.

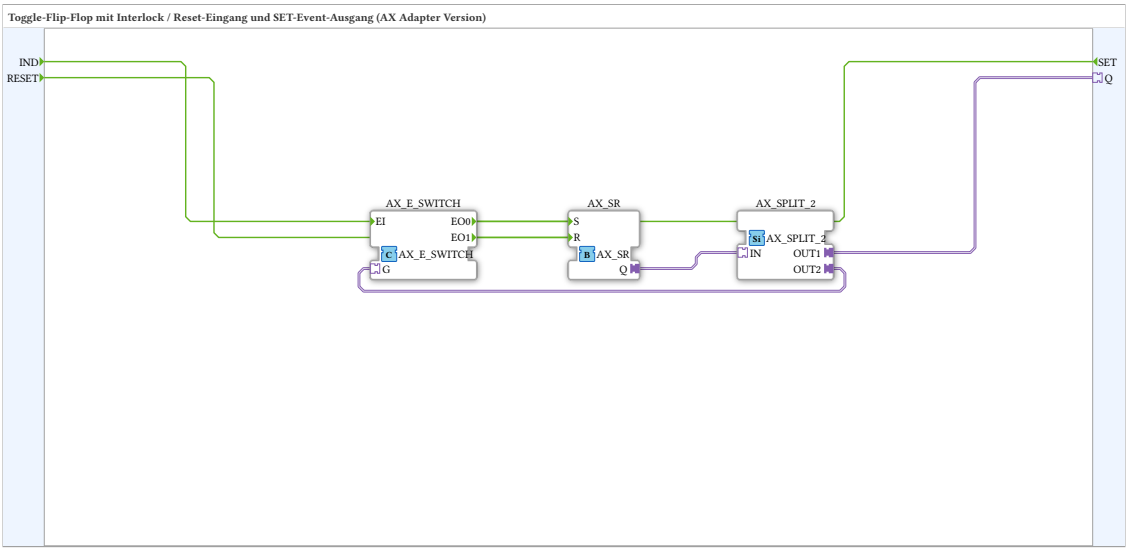
Q = TRUE	Internal AX_SR is Set. On the next IND event, EO1 fires and Q becomes FALSE.

The system alternates between these two states on every IND event, regardless of the duration or timing of the input pulse.

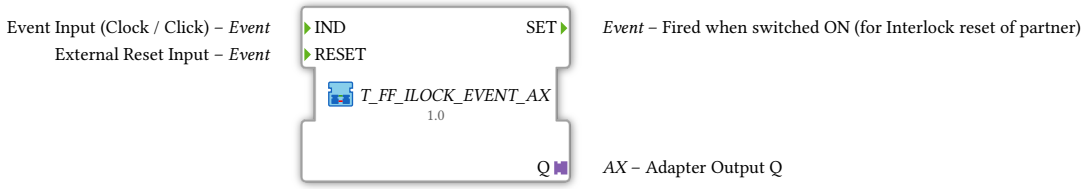
Application Scenarios

- **Push-button toggles**: e.g., start/stop of a motor, light ON/OFF control in HMI panels.
- **Mode switching**: toggling between two operating modes in a control application.
- **Edge-triggered state toggling**: event-driven state changes in distributed automation systems.
- **Generic event-based logic**: wherever a single event should invert a Boolean/state output, without requiring a level-based data input.

Comparison with Similar Blocks



Block	Behavior
AX_SR	Level-triggered Set/Reset – the output depends on which input (S or R) was activated last, not on toggling.
D flip-flop	Copies the data input on a clock edge, does not toggle.
Hardware T-FF	Toggles on a clock edge – similar behavior, but uses binary level inputs/outputs.
T_FF_EVENT_AX	Event-driven toggle flip-flop with an AX adapter output – toggles on every IND event, hardware-independent.



The main distinction of T_FF_EVENT_AX is its **event-driven nature** and **adapter-type interface**, making it ideal for IEC 61499 event-based processing rather than cyclic scanning.

Conclusion

T_FF_EVENT_AX is a compact, reusable, and generic subapplication implementing a toggle flip-flop with a purely event-driven design. Its adapter-based output and internal feedback loop make it a flexible building block for IEC 61499 applications where state toggling on a single event is required. Since it relies only on standard event adapters and no hardware-specific resources, it can be deployed across different platforms and runtime environments without modification.

T_FF_ILOCK_EVENT_AX

• – ◦ • – ◦ • – ◦ •

Introduction

T_FF_ILOCK_EVENT_AX is a subapplication-based function block that implements a **Toggle Flip-Flop with Interlock** functionality. It provides a clock/toggle input (`IND`), an unconditional reset input (`RESET`), a state output via an AX adapter (`Q`), and a dedicated `SET` event output that is used to coordinate interlocking with a partner block.

This component is realized entirely with event-driven adapter connections (unidirectional AX type), making it suitable for modular and distributed control applications where event-based data exchange between function blocks is preferred over cyclic data transmission. The block is primarily designed for scenarios where **mutual exclusion** between two devices must be guaranteed — for example, two actuators that may never be active at the same time.

Interface Structure

Event Inputs

Name	Description
`IND`	Event input acting as clock / toggle trigger. Each event toggles the state.
`RESET`	External reset input. Forces the output `Q` to inactive (OFF) unconditionally.

Event Outputs

Name	Description
`SET`	Fired when the block switches from OFF to ON. Used to reset the interlock partner.

Data Inputs

No data inputs are used. The block is purely event-driven.

Data Outputs

No data outputs are used. The current state is provided through the `Q` adapter plug.

Adapters

Name	Type	Description
`Q`	`adapter::types::unidirectional::AX`	Output adapter carrying the current state (ON / OFF) of the flip-flop.

Functionality

The subapplication contains three internal function blocks that are connected to realize the toggle-with-interlock behavior:

- **`AX_E_SWITCH`** — routes the incoming `IND` event depending on the gate signal `G`.
- **`AX_SR`** — a Set/Reset flip-flop that stores the actual state.
- **`AX_SPLIT_2`** — duplicates the state signal for the external output and the feedback path.

Internal event flow:

1. When an event arrives at `IND`, it is forwarded to the `EI` input of `AX_E_SWITCH`.
2. The `AX_E_SWITCH` block evaluates the gate adapter `G`, which receives the current state `Q` via the feedback loop:

- **If `Q` is inactive (OFF):** the event is routed to output `EO0`.
  - `EO0` triggers the **Set** input of `AX_SR`, driving the state to ON.
  - Simultaneously, the **`SET`** event output is fired, signalling the interlock partner that this block has been activated.
- **If `Q` is active (ON):** the event is routed to output `EO1`.
  - `EO1` triggers the **Reset** input of `AX_SR`, driving the state back to OFF.

3. The `AX_SR` block maintains the current state; its adapter output `Q` is fed into `AX_SPLIT_2`.
4. `AX_SPLIT_2` duplicates the state:
   - **`OUT1`** is connected to the external `Q` adapter plug of the subapplication.
   - **`OUT2`** is fed back to the gate `G` of `AX_E_SWITCH`, closing the control loop.

The external `RESET` event is connected directly to the **Reset** input of the `AX_SR` flip-flop, forcing the state to OFF at any time — regardless of the current state.

Technical Features

- **Pure event-driven design:** No data inputs or outputs; all state exchange uses AX adapter types.
- **Unidirectional AX adapters:** All internal and external adapter connections are of the unidirectional AX type, providing a lightweight and defined data flow direction.
- **State-dependent event routing:** The `AX_E_SWITCH` uses the feedback of the output state to decide whether an `IND` event turns the flip-flop ON or OFF.
- **Interlock support:** A dedicated `SET` event output is fired on every OFF→ON transition, allowing a partner block to be reset. This ensures that two mutually exclusive devices cannot be activated simultaneously.
- **Unconditional reset:** The `RESET` event bypasses any state evaluation and forces the output to OFF.
- **Low resource footprint:** The implementation uses only three internal function blocks and requires no internal variables or state machines from the user's perspective.

State Overview

The following table summarizes the behavior of the flip-flop:

Current State (`Q`)	Input Event	Next State (`Q`)	`SET` Output fired?
OFF	`IND`	ON	**Yes**
ON	`IND`	OFF	No
OFF or ON	`RESET`	OFF	No

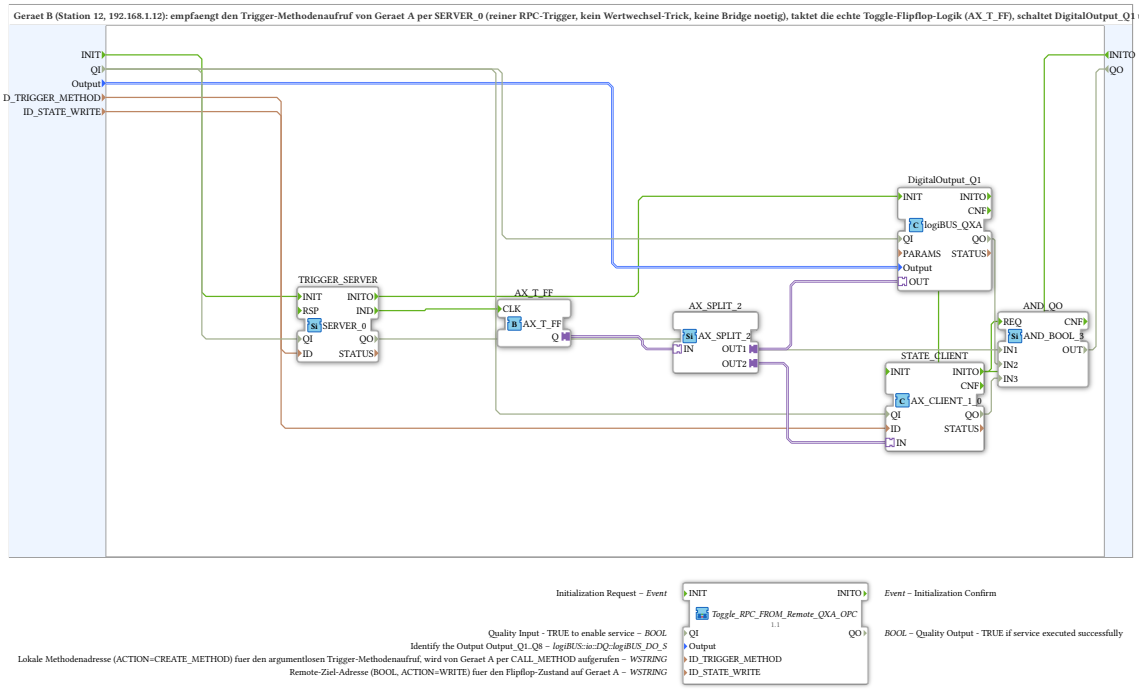
This state diagram shows a classic toggle operation with the added interlock pulse on the rising edge (OFF→ON).

Application Scenarios

- **Interlocked actuators:** Two motors, valves, or conveyors sharing a common output station where only one may run at a time. Pressing the start button on one unit activates it and automatically resets the other via the `SET` event.
- **Mutual exclusion for control panels:** Two push-buttons for alternative operating modes; the active mode is toggled and the partner mode is locked out.
- **Alternating control with safety interlock:** In production lines where two stations work alternately, this block ensures that a handover of the active state occurs cleanly and without overlap.
- **Event-driven distributed systems:** Because the block uses AX adapters, it can be embedded in systems where separate applications communicate via adapter sockets and plugs.

Comparison with Similar Blocks

Block / Approach	Difference
Standard T_FF (toggle)	Provides only a simple toggle output without interlock coordination or reset event capability.
SR flip-flop	Is level/event driven by Set and Reset inputs but does not toggle on a single clock and cannot signal an interlock partner.



E_SWITCH based latch	A latch can hold a state but lacks the automatic toggle behavior and the SET synchronisation output.
Counter / step chain	Counters provide numeric step sequences but are not intended for simple two-state interlocking.

The key advantage of T_FF_ILOCK_EVENT_AX is the combination of toggle functionality, unconditional reset, and the interlock SET output in a single compact event-driven component.

Conclusion

T_FF_ILOCK_EVENT_AX is a compact, event-driven subapplication that implements a toggle flip-flop with interlock capabilities. Its internal architecture uses adapter-based event switching and a set/reset flip-flop with feedback, resulting in a reliable mutual-exclusion mechanism for control applications. The dedicated SET event output and the reset input make it especially suitable for systems where two or more participants must never be active at the same time. Because it is implemented entirely with AX adapters and events, it integrates cleanly into modern distributed control platforms such as Eclipse 4diac.

Toggle_RPC_FROM_Remote_QXA_OPC

• — ○ • — ○ • — ○ •

Introduction

Toggle_RPC_FROM_Remote_QXA_OPC is a composite SubApplication designed for a distributed OPC UA control scenario. It runs on Device B and waits for a pure RPC trigger method call coming from Device A. Each received trigger toggles a real flip-flop logic block, updates a local digital output, and actively writes the new state back to Device A. The communication protocol is encapsulated in the composite itself, so the device resource does not need any protocol-specific wiring.

Interface Structure

The SubApplication exposes the initialization events INIT/INITO, the status ports QI/QO and no adapter plugs/sockets. All other external information enters through three data inputs.

Event Inputs

- INIT (EInit): Initialization Request

Event Outputs

- INITO (EInit): Initialization Confirm

Data Inputs

Name	Type	Initial Value	Description
QI	BOOL	TRUE	Quality Input - TRUE enables the service.
Output	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Selects the digital output channel, e.g. Q1..Q8, that shall be toggled.
ID_TRIGGER_METHOD	WSTRING		Local method address for the argumentless RPC trigger. Device A calls this method using CALL_METHOD.
ID_STATE_WRITE	WSTRING		Remote address on Device A where the new flip-flop state is written back as a BOOL.

Data Outputs

- QO (BOOL): Quality Output - TRUE if the service executed successfully (AND of TRIGGER_SERVER.QO, DigitalOutput_Q1.QO and STATE_CLIENT.QO).

Adapters

No adapter sockets or plugs are exposed on the SubApplication boundary. Internally, adapter connections are used to forward the toggle event and state to the digital output and to the write-back client.

Functionality

The SubApplication implements a remote toggle request/response cycle:

1. Device A invokes the configured OPC UA method.
2. TRIGGER_SERVER, an instance of iec61499::net::SERVER_0, receives the request and raises its IND event.
3. The IND event directly clocks the toggle flip-flop AX_T_FF.
4. The same IND event is immediately connected back to TRIGGER_SERVER.RSP, releasing the OPC UA server thread and avoiding blocking delays.
5. The flip-flop output Q is fed into AX_SPLIT_2, which duplicates the adapter event/data stream.
6. The first split output drives DigitalOutput_Q1, a logiBUS::io::DQ::logiBUS_QXA instance, to set or clear the selected physical digital output.
7. The second split output feeds STATE_CLIENT, an adapter::net::AX_CLIENT_1_0 instance, which writes the new state back to Device A using the address given by ID_STATE_WRITE.
8. Initialization and status: INIT → TRIGGER_SERVER.INIT, TRIGGER_SERVER.INITO → DigitalOutput_Q1.INIT, DigitalOutput_Q1.INITO → STATE_CLIENT.INIT, STATE_CLIENT.INITO → INITO and → AND_QO.REQ. QI is forwarded to TRIGGER_SERVER, DigitalOutput_Q1 and STATE_CLIENT; their QO outputs go to AND_QO.IN1..IN3 (block AND_QO, type iec61131::booleanOperators::AND_BOOL_3), and AND_QO.OUT → QO.

The result is a complete remote toggle operation: Device A triggers, Device B toggles, Device B updates its output, and Device A receives the new state.

Technical Features

- Pure RPC trigger mechanism using SERVER_0; no value-change trick or intermediate bridge is required.
- TRIGGER_SERVER.IND is wired directly to TRIGGER_SERVER.RSP, preventing the OPC UA server thread from being held and avoiding project-wide communication delays.
- Real toggle logic is implemented with the AX_T_FF flip-flop adapter.
- AX_SPLIT_2 distributes the same adapter event/data stream to two consumers.

- Digital output handling is done with `logiBUS_QXA`, supporting channel selection via the `Output` data input.
- Active state write-back is performed by `AX_CLIENT_1_0`.
- The whole protocol stack lives inside the `MyLib::sys` composite, keeping the device resource clean.

State Overview

The SubApplication does not contain an explicit ECC state machine. Its stateful behavior is fully encapsulated in the internal `AX_T_FF` flip-flop:

- On each `CLK` event, the internal state toggles.
- The current state is available on the `Q` adapter output.
- The toggled state is then propagated to the digital output and to the write-back client.

Because the toggle logic is a true flip-flop, every remote method call changes the output state alternately between true and false.

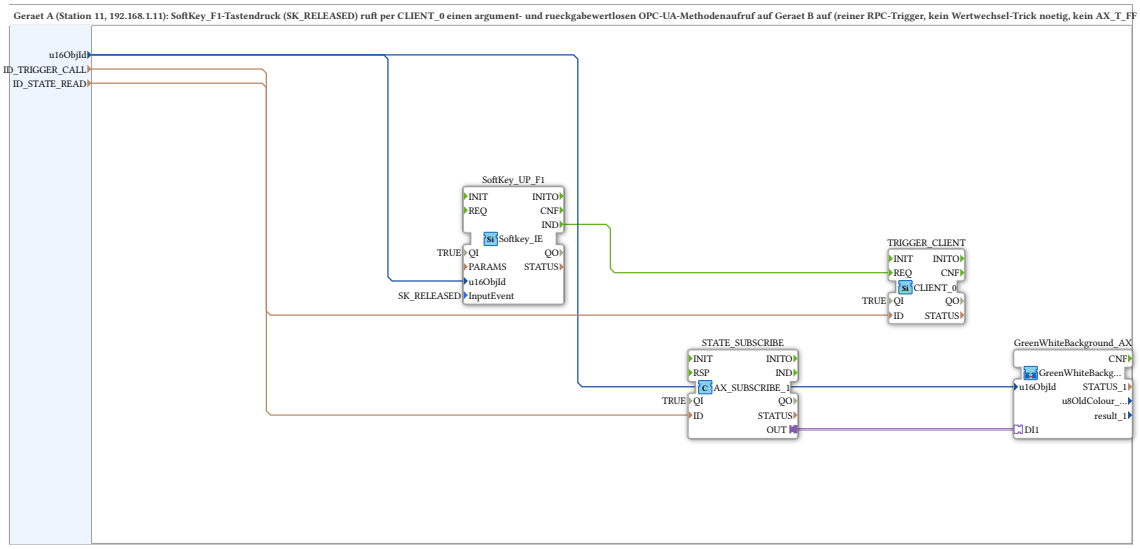
Application Scenarios

This SubApplication is useful in distributed automation systems where one controller must remotely toggle an output on another controller and keep both devices synchronized. A typical scenario is:

- Device A acts as the master or HMI/SCADA gateway.
- Device B is a remote station, e.g. Station 12 at IP `192.168.1.12`.
- Device A sends an OPC UA method call to Device B.
- Device B toggles its local digital output.
- Device B writes the new output state back to Device A for consistent visualization or further logic.

This pattern is especially valuable when no continuous cyclic data exchange is required and a simple event-driven RPC is preferred.

Comparison with Similar Blocks

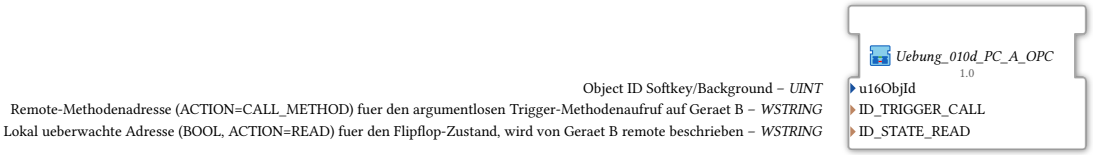


Compared to simpler or alternative implementations:

- **Plain `SERVER_0` without `RSP` wiring**: Can block the OPC UA server thread and delay unrelated OPC UA requests. This SubApplication avoids that by directly connecting `IND` to `RSP`.
- **Value-change trick**: Many implementations use a data value change instead of a real method call. This SubApplication uses a real RPC method trigger, which is cleaner and avoids unintended triggers.
- **Bridge-based communication**: Some architectures require a separate bridge block in the device resource. This SubApplication encapsulates the bridge/protocol logic inside the composite, so the resource remains simple and reusable.
- **FB with internal ECC**: A basic function block would implement the toggle in an ECC; this composite uses a dedicated `AX_T_FF` adapter, making the logic explicit and reusable.

Conclusion

`Toggle_RPC_FROM_Remote_QXA_OPC` provides a robust, self-contained way to implement remote toggling over OPC UA. It combines a responsive RPC server, true flip-flop behavior, digital output control, and active state write-back in one composite SubApplication. The direct `IND` to `RSP` wiring ensures that the OPC UA stack remains responsive, while the clean separation of protocol and resource logic makes the SubApplication easy to reuse and maintain.



Uebung_010d_PC_A_OPC

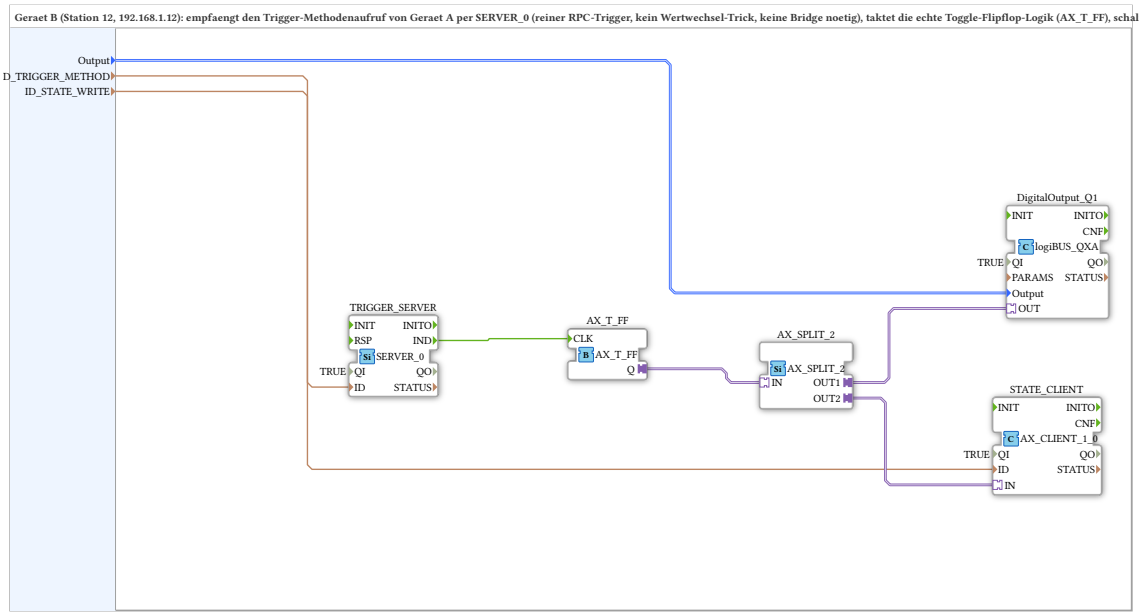
• – ○ • – ○ • – ○ •

Introduction

`Uebung_010d_PC_A_OPC` is the device-A side (station 11, 192.168.1.11) of the PC-to-PC OPC-UA variant of exercise 010d (toggle flip-flop via softkey): a softkey press calls an argument- and return-value-less OPC-UA method on device B via `CLIENT_0` (a pure RPC trigger, no value-change trick needed, no toggle logic on this device). `GreenWhiteBackground1_AX` shows the flip-flop state locally monitored from device B. "SUB style": the protocol lives in the `MyLib::sys` composite, not in the device's resource - counterpart: `Uebung_010d_PC_B_OPC`.

Function blocks used

- **SoftKey_UP_F1** (`isobus::UT::io::Softkey::Softkey_IE`): physical softkey (F1), `InputEvent=SK_RELEASED`.
- **TRIGGER_CLIENT** (`iec61499::net::CLIENT_0`): calls the argument-less remote method under `ID_TRIGGER_CALL`.
- **STATE_SUBSCRIBE** (`adapter::net::AX_SUBSCRIBE_1`): subscribes to the flip-flop state written by device B, under `ID_STATE_READ`.
- **GreenWhiteBackground_AX** (SubApp, type `MyLib::sys::GreenWhiteBackground1_AX`): displays the subscribed state at the softkey.



Summary

Device-A side of a PC-to-PC toggle trigger: the softkey calls a remote method, the actual flip-flop state is reported back from device B.

Uebung_010d_PC_B_OPC

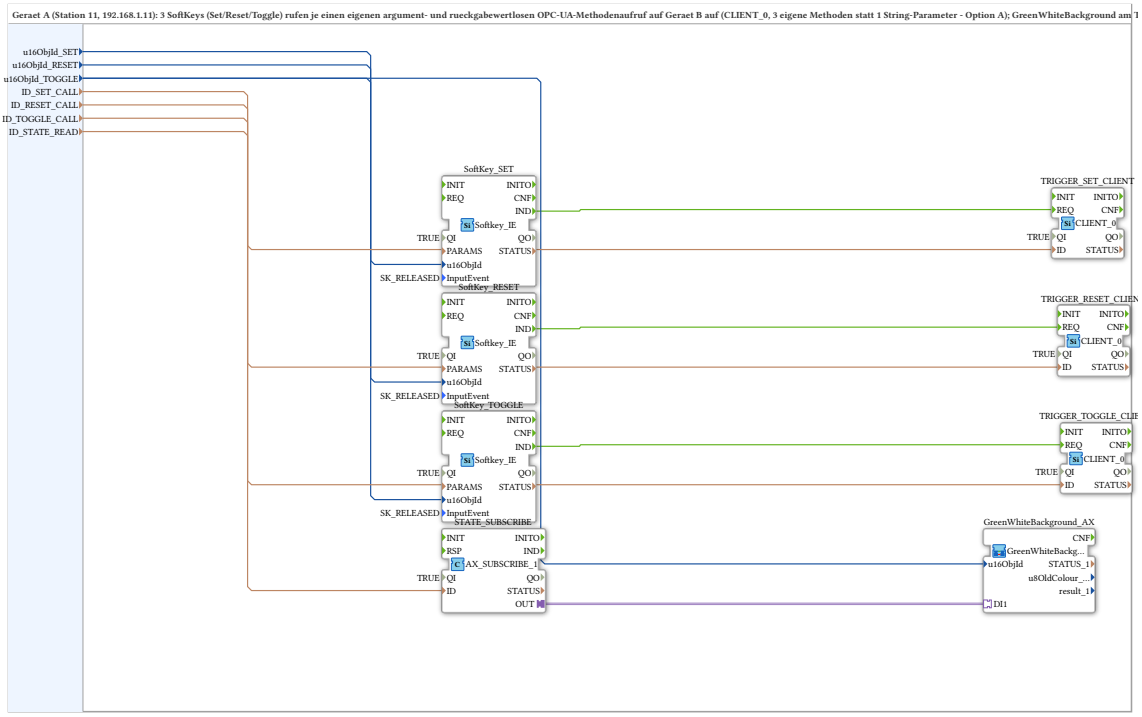
• – ○ • – ○ • – ○ •

Introduction

`Uebung_010d_PC_B_OPC` is the device-B side (station 12, 192.168.1.12) of the PC-to-PC OPC-UA variant of exercise 010d: receives the trigger method call from device A via `SERVER_0` (a pure RPC trigger, no value-change trick, no bridge needed), clocks the actual toggle flip-flop logic (`AX_T_FF`), drives `DigitalOutput_Q1`, and actively writes the new state back to device A via `AX_CLIENT_1_0`. Counterpart: `Uebung_010d_PC_A_OPC`.

Function blocks used

- **TRIGGER_SERVER** (`iec61499::net::SERVER_0`): receives the method call under `ID_TRIGGER_METHOD`.
- **AX_T_FF** (`adapter::events::unidirectional::AX_T_FF`): toggle flip-flop, clocked by `TRIGGER_SERVER.IND`.
- **AX_SPLIT_2** (`adapter::events::unidirectional::AX_SPLIT_2`): splits the flip-flop state to the physical output + the echo.
- **DigitalOutput_Q1** (`logiBUS::io::DQ::logiBUS_QXA`): physical output (`Output` selects `Output_Q1..Q8`).
- **STATE_CLIENT** (`adapter::net::AX_CLIENT_1_0`): actively writes the new state to device A under `ID_STATE_WRITE`.



Summary

Device-B side: receives the trigger via RPC, holds the actual toggle logic, and actively reports the state back to device A.

Uebung_010e_PC_A_OPC

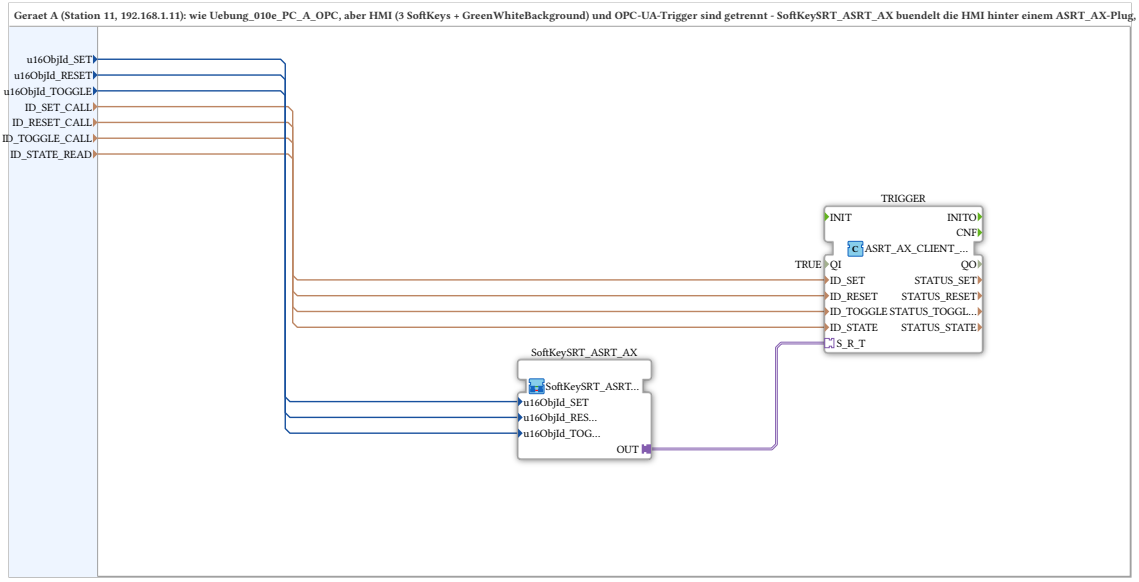
• – ○ • – ○ • – ○ •

Introduction

`Uebung_010e_PC_A_OPC` is the device-A side (station 11, 192.168.1.11) of the PC-to-PC OPC-UA variant of exercise 010e (SR+toggle flip-flop via 3 softkeys): 3 softkeys (set/reset/toggle) each call their own argument- and return-value-less OPC-UA method on device B (`CLIENT_0`, 3 distinct methods instead of 1 string parameter - option A). `GreenWhiteBackground1_AX` on the toggle softkey shows the flip-flop state locally monitored from device B. Counterpart: `Uebung_010e_PC_B_OPC`.

Function blocks used

- **SoftKey_SET / SoftKey_RESET / SoftKey_TOGGLE** (`isobus::UT::io::Softkey::Softkey_IE`): the 3 physical softkeys.
- **TRIGGER_SET_CLIENT / TRIGGER_RESET_CLIENT / TRIGGER_TOGGLE_CLIENT** (`iec61499::net::CLIENT_0`): each its own remote method (`ID_SET_CALL`/`ID_RESET_CALL`/`ID_TOGGLE_CALL`).
- **STATE_SUBSCRIBE** (`adapter::net::AX_SUBSCRIBE_1`): subscribes to the flip-flop state under `ID_STATE_READ`.
- **GreenWhiteBackground_AX** (SubApp, type `MyLib::sys::GreenWhiteBackground1_AX`): displays the state at the toggle softkey.



Summary

Device-A side of a set/reset/toggle RPC pattern with 3 distinct method calls and state feedback.

Uebung_010e_PC_A_OPC_Adapter

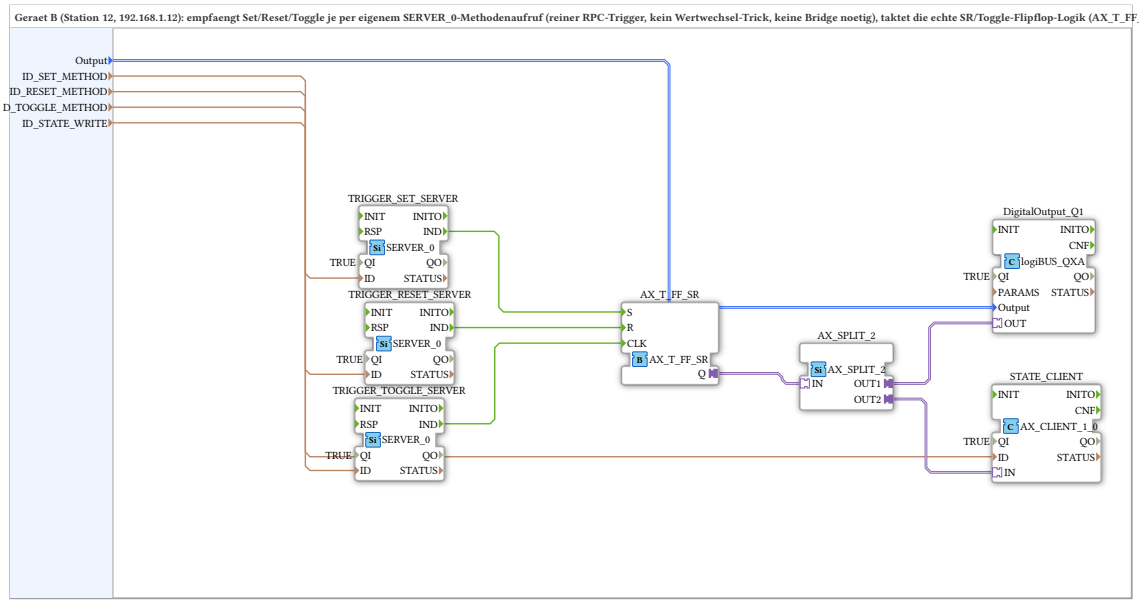
• — ○ • — ○ • — ○ •

Introduction

`Uebung_010e_PC_A_OPC_Adapter` is the adapter-bundled variant of `Uebung_010e_PC_A_OPC` (device A, station 11): HMI (3 softkeys + `GreenWhiteBackground`) and OPC-UA trigger are separated. `SoftKeySRT_ASRT_AX` bundles the HMI behind an `ASRT_AX` plug; `ASRT_AX_CLIENT_0_SUBSCRIBE_1` bundles the 3 `CLIENT_0` instances + `AX_SUBSCRIBE_1` behind an `ASRT_AX` socket. Counterpart: `Uebung_010e_PC_B_OPC_Adapter`.

Function blocks used

- **SoftKeySRT_ASRT_AX** (SubApp, type `MyLib::sys::SoftKeySRT_ASRT_AX`): 3 softkeys + status display, bundled behind an `ASRT_AX` plug.
- **TRIGGER** (`adapter::net::ASRT_AX_CLIENT_0_SUBSCRIBE_1`): bundles 3 method calls (`ID_SET_CALL`/`ID_RESET_CALL`/`ID_TOGGLE_CALL`) and the state subscription (`ID_STATE_READ`) behind a single `ASRT_AX` socket.



Summary

Adapter-bundled variant of `Uebung_010e_PC_A_OPC`: HMI and network protocol cleanly separated, reusable via `SoftKeySRT_ASRT_AX`.

Uebung_010e_PC_B_OPC

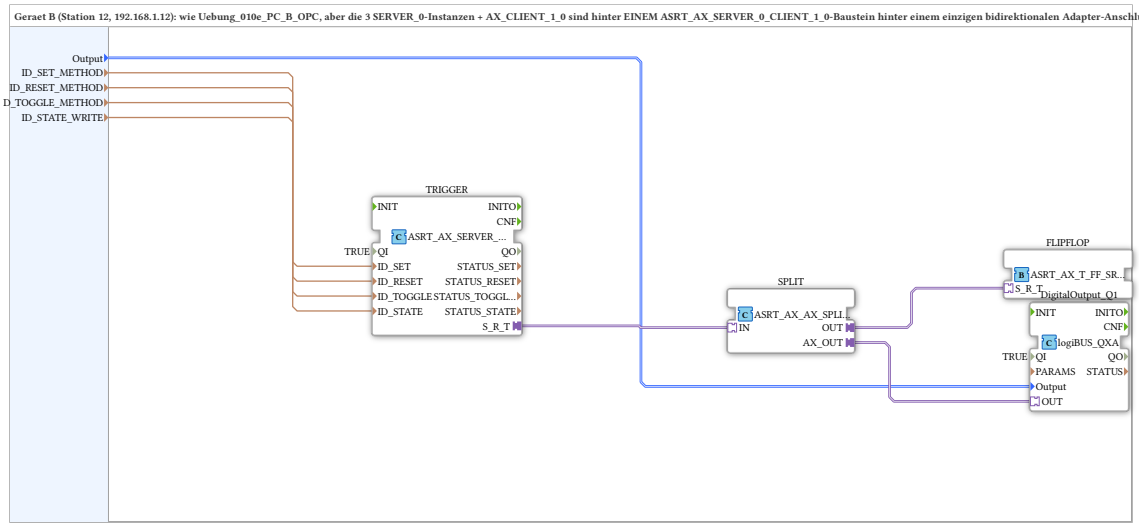
• – ○ • – ○ • – ○ •

Introduction

`Uebung_010e_PC_B_OPC` is the device-B side (station 12, 192.168.1.12): receives set/reset/toggle each via its own `SERVER_0` method call (a pure RPC trigger, no value-change trick, no bridge needed), clocks the actual SR/toggle flip-flop logic (`AX_T_FF_SR`), drives `DigitalOutput_Q1`, and actively writes the new state back to device A via `AX_CLIENT_1_0`. Counterpart: `Uebung_010e_PC_A_OPC`.

Function blocks used

- **TRIGGER_SET_SERVER / TRIGGER_RESET_SERVER / TRIGGER_TOGGLE_SERVER** (`iec61499::net::SERVER_0`): each receives its own method call.
- **AX_T_FF_SR** (`adapter::events::unidirectional::AX_T_FF_SR`): combined set/reset/toggle flip-flop logic.
- **AX_SPLIT_2** (`adapter::events::unidirectional::AX_SPLIT_2`): splits the state to the physical output + the echo.
- **DigitalOutput_Q1** (`logiBUS::io::DQ::logiBUS_QXA`): physical output.
- **STATE_CLIENT** (`adapter::net::AX_CLIENT_1_0`): actively writes the state to device A under `ID_STATE_WRITE`.



Summary

Device-B side: receives set/reset/toggle via RPC, holds the combined SR/toggle flip-flop logic, and actively reports the state back.

Uebung_010e_PC_B_OPC_Adapter

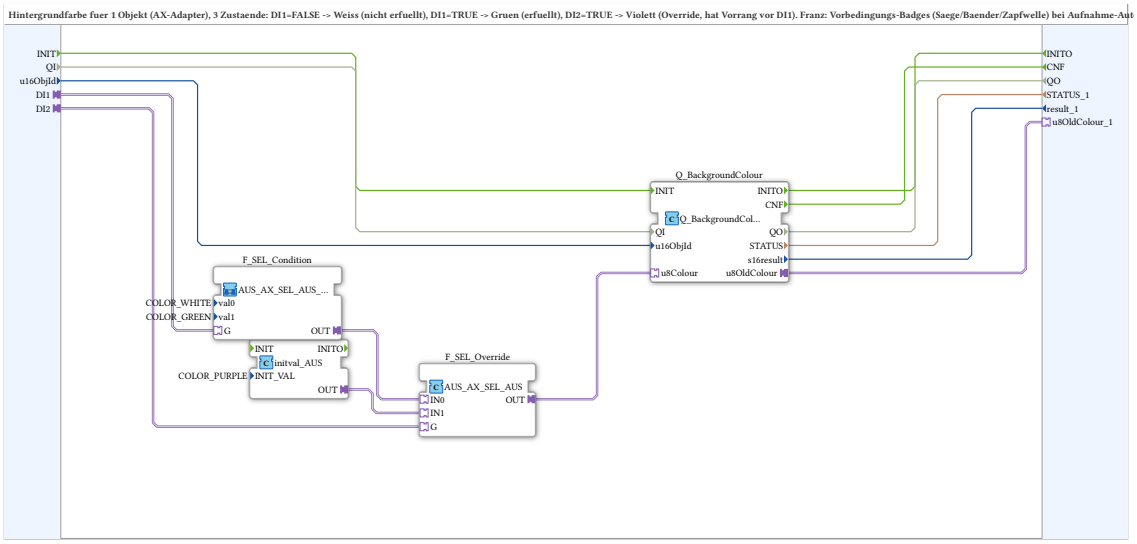
• — ○ • — ○ • — ○ •

Introduction

`Uebung_010e_PC_B_OPC_Adapter` is the adapter-bundled variant of `Uebung_010e_PC_B_OPC` (device B, station 12): the 3 `SERVER_0` instances + `AX_CLIENT_1_0` are bundled behind a SINGLE `ASRT_AX_SERVER_0_CLIENT_1_0` block behind one bidirectional adapter connection; `ASRT_AX_AX_SPLIT` feeds both `DigitalOutput_Q1` and the SR/toggle flip-flop logic (`ASRT_AX_T_FF_SR_2`). Counterpart: `Uebung_010e_PC_A_OPC_Adapter`.

Function blocks used

- **TRIGGER** (`adapter::net::ASRT_AX_SERVER_0_CLIENT_1_0`): bundles server reception (`ID_SET_METHOD`/`ID_RESET_METHOD`/`ID_TOGGLE_METHOD`) and state feedback (`ID_STATE_WRITE`).
- **SPLIT** (`adapter::events::bidirectional::ASRT_AX_AX_SPLIT`): splits to the physical output + the flip-flop logic.
- **FLIPFLOP** (`adapter::events::bidirectional::ASRT_AX_T_FF_SR_2`): combined SR/toggle flip-flop logic as an adapter block.
- **DigitalOutput_Q1** (`logiBUS::io::DQ::logiBUS_QXA`): physical output.



Summary

Adapter-bundled variant of `Uebung_010e_PC_B_OPC`: network protocol and SR/toggle flip-flop logic as reusable adapter blocks.

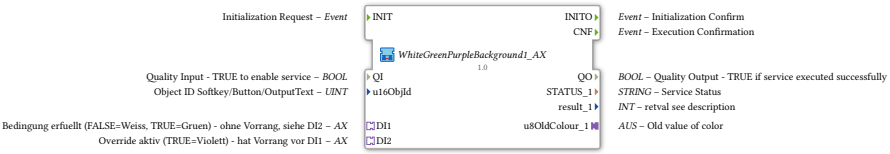
WhiteGreenPurpleBackground1_AX



• – ○ • – ○ • – ○ •

Introduction

`WhiteGreenPurpleBackground1_AX` sets the background colour for **one object** (`AX` adapter) with three states:

- `DI1=FALSE` ⟶ **white** (not fulfilled)
- `DI1=TRUE` ⟶ **green** (fulfilled)
- `DI2=TRUE` ⟶ **purple** (override, takes precedence over `DI1`)

It is used, for example, for precondition badges (saw/belts/PTO) of the pick-up automation. The block is built analogously to `GreenWhiteBackground1_AX`.

Function Blocks (FBs) Used

Sub-blocks: WhiteGreenPurpleBackground1_AX

- **Type**: SubAppType
- **Internal blocks used**:
  - **F_SEL_Condition**: SubApp `MyLib::sys::AUS_AX_SEL_AUS_2_VAL` with `val0=COLOR_WHITE`, `val1=COLOR_GREEN` - selects white or green based on `DI1`
  - **F_SEL_Override**: `adapter::iec61131::selection::AUS_AX_SEL_AUS` - selects between the condition result (`IN0`) and purple (`IN1`) based on `DI2`
  - **initval_AUS**: `adapter::types::unidirectional::AUS::initval::initval_AUS` with `INIT_VAL=COLOR_PURPLE`
  - **Q_BackgroundColour**: `isobus::UT::Q::Q_BackgroundColour_AUS` - writes the colour to the VT object `u16ObjId`
- **Imports**: `ID_NULL`, `COLOR_GREEN`, `COLOR_WHITE`, `COLOR_PURPLE`

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization request (⟶ `Q_BackgroundColour.INIT`)

Further events arrive via the adapters `DI1` and `DI2`.

Event Outputs

- **INITO** (EInit): Initialization confirmation (from Q_BackgroundColour.INITO)
- **CNF**: Execution confirmation (from Q_BackgroundColour.CNF)

Data Inputs

- **QI** (BOOL, default TRUE): Quality Input - TRUE enables the service (⟶ Q_BackgroundColour.QI)
- **u16ObjId** (UINT, default ID_NULL): Object ID of softkey/button/output text

Data Outputs

- **QO** (BOOL): Quality Output - TRUE if the service executed successfully (from Q_BackgroundColour.QO)
- **STATUS_1** (STRING): Service status (from Q_BackgroundColour.STATUS)
- **result_1** (INT): Return value (from Q_BackgroundColour.s16result)

Adapters

- **DI1** (socket, adapter::types::unidirectional::AX): Condition fulfilled (FALSE = white, TRUE = green), without precedence, see DI2
- **DI2** (socket, adapter::types::unidirectional::AX): Override active (TRUE = purple), takes precedence over DI1
- **u8OldColour_1** (plug, adapter::types::unidirectional::AUS): Old colour value

Program Flow and Connections

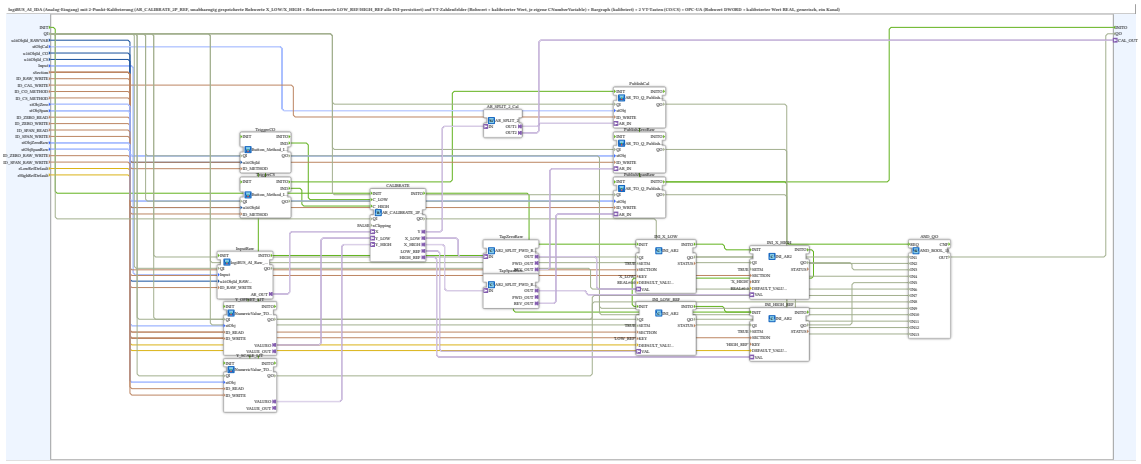
- DI1 ⟶ F_SEL_Condition.G
- DI2 ⟶ F_SEL_Override.G
- F_SEL_Condition.OUT ⟶ F_SEL_Override.IN0; initval_AUS.OUT ⟶ F_SEL_Override.IN1
- F_SEL_Override.OUT ⟶ Q_BackgroundColour.u8Colour
- u16ObjId ⟶ Q_BackgroundColour.u16ObjId
- INIT ⟶ Q_BackgroundColour.INIT; Q_BackgroundColour.INITO ⟶ INITO
- QI ⟶ Q_BackgroundColour.QI; Q_BackgroundColour.QO ⟶ QO
- Q_BackgroundColour.u8OldColour ⟶ u8OldColour_1; .STATUS ⟶ STATUS_1; .s16result ⟶ result_1; .CNF ⟶ CNF

Technical Details

- Two nested selectors (not a single AX_SEL), since a single AX_SEL re-evaluates only when its **own** G changes and the second stage would otherwise not follow up on a change of DI1
- Both selectors are re-evaluated in series via a common trigger (E_MERGE_2 from DI1.E1/DI2.E1), so that a change of DI1 **or** DI2 always yields the complete, correct colour
- Version 1.0 (2026-10-01)

State Overview

DI1	DI2	Colour
FALSE	FALSE	White (COLOR_WHITE)
TRUE	FALSE	Green (COLOR_GREEN)
any	TRUE	Purple (COLOR_PURPLE)



Application Scenarios

- Precondition badges (saw, belts, PTO) of a pick-up automation with override indication

Summary

WhiteGreenPurpleBackground1_AX colours a VT object white, green or purple, where the override DI2 takes precedence over the condition DI1.

logiBUS_AI_Calibrate_2P_IDA_OPC

• – ○ • – ○ • – ○ •

Introduction

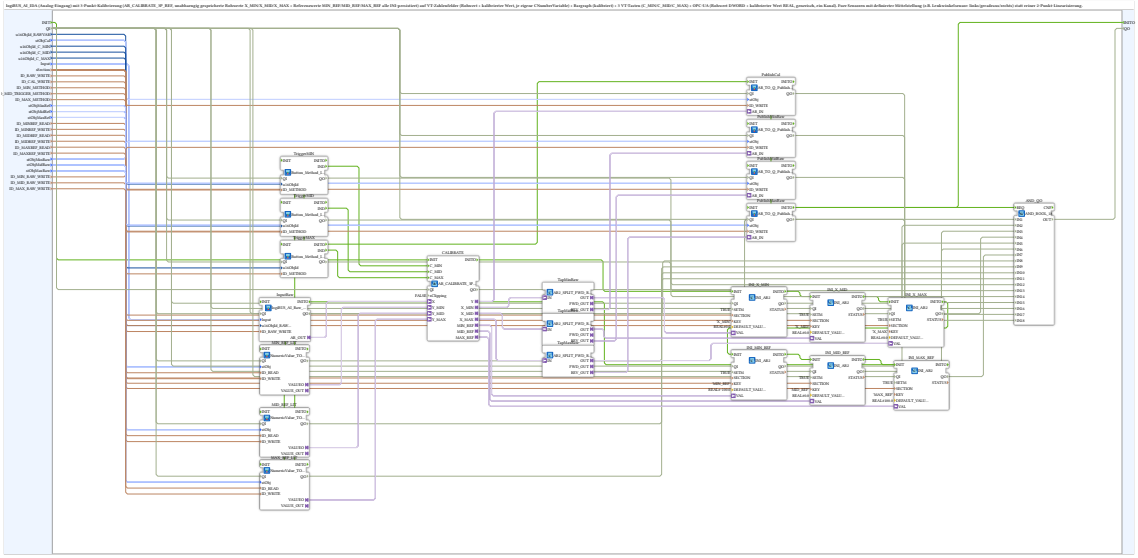
`logiBUS_AI_Calibrate_2P_IDA_OPC` connects a physical analog input (`logiBUS_AI_IDA`) to a full VT- and OPC-UA-backed 2-point calibration (`AR_CALIBRATE_2P_REF`) — used by the AI_Calibrate_2P training sample. The input's raw value is converted into a physically scaled value through the 2-point calibration chain; zero point (`Zero`) and span (`Span`) as well as their measured raw values (`ZeroRaw`/`SpanRaw`) are adjustable and readable via both VT and OPC-UA, and are persisted in an INI file. In partial calibration (only one point calibrated), a clean fallback logic immediately utilizes the available reference value.

Function blocks used

- **logiBUS_AI_IDA** (`logiBUS::io::AI::logiBUS_AI_IDA`): physical analog input, provides the raw value as an adapter.
- **AR_CALIBRATE_2P_REF** (adapter composite): 2-point calibration (zero/span) with raw value diagnostics (`ZeroRaw`/`SpanRaw`), partial calibration fallback logic, and configurable clipping (`xClipping`).
- **VT and OPC-UA bridges** (analogous to `NumericValue_TO_AR2_OPC`/`OPC_TO_AR2` and `INI_IN_AND_STORE_AR2`): expose `Zero`/`Span` and `ZeroRaw`/`SpanRaw` both via VT input fields/displays and via OPC-UA, and persist calibration values in an INI file.

Initialization and quality

- Events: `INIT` (EInit, input) and `INITO` (EInit, output, comes from `PublishSpanRaw.INITO`).
- Data input `QI` (BOOL, default `TRUE`) and data output `QO` (BOOL); the internal FBs (`CALIBRATE`, `INI_X_LOW`, `INI_X_HIGH`, `INI_LOW_REF`, `INI_HIGH_REF`) no longer carry a fixed `QI=TRUE`.
- Initialization chain (each `INITO` ⟶ `INIT` of the next): `INIT` ⟶ `CALIBRATE` ⟶ `INI_X_LOW` ⟶ `INI_X_HIGH` ⟶ `INI_LOW_REF` ⟶ `INI_HIGH_REF` ⟶ `InputRaw` ⟶ `Y_OFFSET_LIT` ⟶ `Y_SCALE_LIT` ⟶ `TriggerCO` ⟶ `TriggerCS` ⟶ `PublishCal` ⟶ `PublishZeroRaw` ⟶ `PublishSpanRaw`; `PublishSpanRaw.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`.
- Quality: `QI` is passed on to all 13 instances of this chain; their `QO` outputs feed `AND_QO.IN1` to `IN13` in exactly this order (a single `iec61131::booleanOperators::AND_BOOL_13`; the former cascade of `AND_QO_A` (`AND_BOOL_5`) and `AND_QO` (`AND_BOOL_9`) is replaced, version 1.12); `AND_QO.OUT` ⟶ `QO`.



Summary

Complete 2-point calibration block for a physical analog input: raw-value acquisition, 2-point calibration with raw-value diagnostics, immediate partial calibration fallback, VT display/input, and OPC-UA connectivity in one composite.

logiBUS_AI_Calibrate_3P_IDA_OPC

• — ○ • — ○ • — ○ •

Introduction

`logiBUS_AI_Calibrate_3P_IDA_OPC` reads a logiBUS analog input (`logiBUS_AI_IDA`) and calibrates it with a **3-point calibration** (`AR_CALIBRATE_3P_REF`): the three raw values `X_MIN/X_MID/X_MAX` and the three reference values `MIN_REF/MID_REF/MAX_REF` are stored independently of each other and all persisted in an INI file. The raw and the calibrated value are output to VT number fields (each its own `CNumberVariable`), three VT keys (`C_MIN/C_MID/C_MAX`) trigger the calibration, and the values are published via OPC-UA (raw value `DWORD`, calibrated value `REAL`; generic, one channel). The block is intended for sensors with a defined center position (e.g. steering angle sensor: left/straight/right) instead of a pure 2-point linearization.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; starts the init chain at `CALIBRATE.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `PublishMaxRaw.INITO`, the end of the init chain

Data Inputs

General:

- **QI** (`BOOL`, default `TRUE`): Quality input, enables the service; passed on to all 18 service instances (see `AND_QO`)

Input and display:

- **Input** (logiBUS::io::AI::logiBUS_AI_S, default logiBUS_AI::Invalid): Identifies the analog input AnalogInput_I1..I8
- **u16ObjId_RAWVAR** (UINT, default ID_NULL): Object ID of the CNumberVariable for the uncalibrated raw value (0-4095, pure diagnostic display)
- **stObjCal** (NumericObjectPool_S): Object ID + scale/offset/decimals of the CNumberVariable for the calibrated value (own, independent variable)
- **sSection** (STRING): INI section name for the persistence of X_MIN/X_MID/X_MAX/MIN_REF/MID_REF/MAX_REF; unique per channel, otherwise the channels collide in settings.ini

VT keys and methods:

- **u16ObjId_C_MIN**, **u16ObjId_C_MID**, **u16ObjId_C_MAX** (UINT, default ID_NULL): Object IDs of the keys C_MIN (approach min position, then press), C_MID (center position) and C_MAX (max position)
- **ID_MIN_METHOD**, **ID_MID_TRIGGER_METHOD**, **ID_MAX_METHOD** (WSTRING): Method addresses (ACTION=CREATE_METHOD) for the argument-less triggers; equivalent to the local VT key, callable from the OPC-UA dashboard and via CLIENT_0 from another station

Reference values (VT input field + OPC-UA):

- **stObjMinRef**, **stObjMidRef**, **stObjMaxRef** (NumericObjectPool_S): Input fields for MIN_REF/MID_REF/MAX_REF
- **ID_MINREF_READ**, **ID_MIDREF_READ**, **ID_MAXREF_READ** (WSTRING): Remote subscribe addresses of the reference values (REAL, ACTION=SUBSCRIBE)
- **ID_MINREF_WRITE**, **ID_MIDREF_WRITE**, **ID_MAXREF_WRITE** (WSTRING): Remote echo addresses of the reference values (REAL, ACTION=PUBLISH)

Raw values at the calibration points (pure diagnostic display):

- **stObjMinRaw**, **stObjMidRaw**, **stObjMaxRaw** (NumericObjectPool_S): Display fields for the raw value at the MIN/MID/MAX calibration point
- **ID_MIN_RAW_WRITE**, **ID_MID_RAW_WRITE**, **ID_MAX_RAW_WRITE** (WSTRING): Publish addresses (REAL, ACTION=PUBLISH)

OPC-UA outputs:

- **ID_RAW_WRITE** (WSTRING): Raw value feedback address (DWORD 0-4095, ACTION=PUBLISH)
- **ID_CAL_WRITE** (WSTRING): Feedback address of the calibrated value (REAL, ACTION=PUBLISH)

Data Outputs

- **QO** (BOOL): Quality output, AND combination of all 18 QO sources in a single AND_QO block (iec61131::booleanOperators::AND_BOOL_18)

Adapters

This function block has no adapters at its interface; AR adapters are used internally.

Function Blocks (FBs) Used

- **InputRaw**: SubApp MyLib::sys::logiBUS_AI_Raw_VT_AR_OPC - reads the analog input, displays the raw value and publishes it
- **CALIBRATE**: adapter::Engineering::measurements::AR_CALIBRATE_3P_REF (xClipping=FALSE, QI comes from the input QI) - 3-point calibration
- **MIN_REF_LIT**, **MID_REF_LIT**, **MAX_REF_LIT**: SubApp MyLib::sys::NumericValue_TO_AR2_OPC - reference values from VT input field or OPC-UA
- **TriggerMIN**, **TriggerMID**, **TriggerMAX**: SubApp MyLib::sys::Button_Method_IE - key OR local method → IND
- **INI_X_MIN**, **INI_X_MID**, **INI_X_MAX**: eclipse4diac::storage::INI_AR2 (keys X_MIN/X_MID/X_MAX, default 0.0)
- **INI_MIN_REF**, **INI_MID_REF**, **INI_MAX_REF**: INI_AR2 (keys MIN_REF/MID_REF/MAX_REF, defaults -100.0/0.0/100.0)
- **TapMinRaw**, **TapMidRaw**, **TapMaxRaw**: adapter::events::bidirectional::AR2_SPLIT_FWD_REV
- **PublishCal**, **PublishMinRaw**, **PublishMidRaw**, **PublishMaxRaw**: SubApp MyLib::sys::AR_TO_Q_Publish_OPC - VT display and OPC-UA publish

- **AND_QO**: `iec61131::booleanOperators::AND_BOOL_18` - combines the `QO` outputs of all 18 service instances (`CALIBRATE`, 6× `INI_AR2`, `InputRaw`, 3× `*_REF_LIT`, 3× `Trigger*`, `PublishCal`, 3× `Publish*Raw`) into the output `QO` (formerly a cascade of several smaller AND blocks)

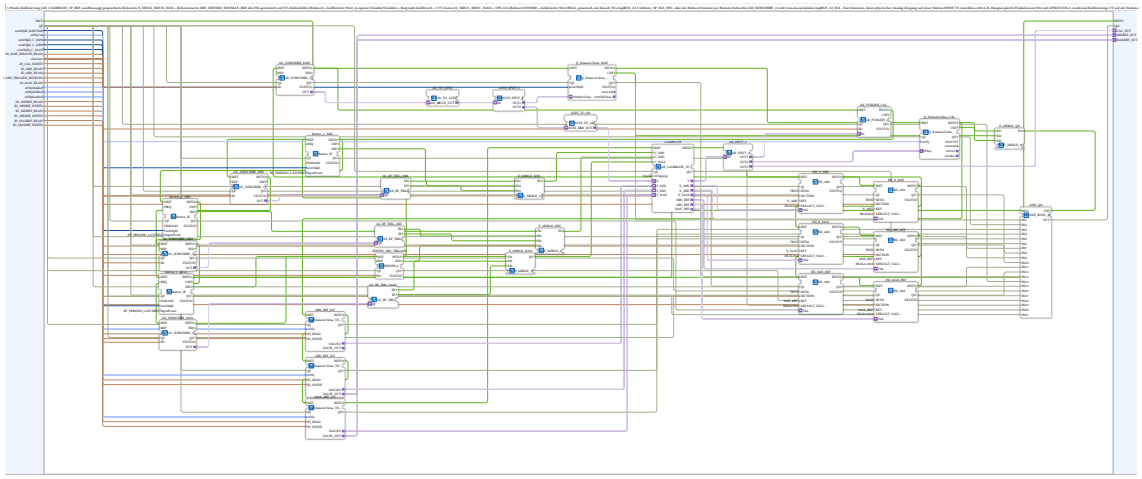
All `INI_AR2` use `SETM=TRUE`; their `QI` comes from the input `QI`; `sSection` is their common `SECTION`.

Program Flow and Connections

1. `InputRaw.AR_OUT` ⟶ `CALIBRATE.X` (raw value).
2. `TriggerMIN.IND/TriggerMID.IND/TriggerMAX.IND` ⟶ `CALIBRATE.C_MIN/C_MID/C_MAX`.
3. Reference values: `MIN_REF_LIT.VALUEO/MID_REF_LIT.VALUEO/MAX_REF_LIT.VALUEO` ⟶ `CALIBRATE.Y_MIN/Y_MID/Y_MAX`.
4. Stored raw values: `CALIBRATE.X_MIN/X_MID/X_MAX` ⟶ `TapMinRaw.IN/TapMidRaw.IN/TapMaxRaw.IN`; their `OUT` ⟶ `INI_X_MIN.VAL/INI_X_MID.VAL/INI_X_MAX.VAL`; `REV_OUT` ⟶ `PublishMinRaw/PublishMidRaw/PublishMaxRaw.AR_IN`.
5. Reference values (persistence): `CALIBRATE.MIN_REF/MID_REF/MAX_REF` ⟶ `INI_MIN_REF.VAL/INI_MID_REF.VAL/INI_MAX_REF.VAL`.
6. Calibrated value: `CALIBRATE.Y` ⟶ `PublishCal.AR_IN`.
7. Initialization chain: `INIT` ⟶ `CALIBRATE` ⟶ `INI_X_MIN` ⟶ `INI_X_MID` ⟶ `INI_X_MAX` ⟶ `INI_MIN_REF` ⟶ `INI_MID_REF` ⟶ `INI_MAX_REF` ⟶ `InputRaw` ⟶ `MIN_REF_LIT` ⟶ `MID_REF_LIT` ⟶ `MAX_REF_LIT` ⟶ `TriggerMIN` ⟶ `TriggerMID` ⟶ `TriggerMAX` ⟶ `PublishCal` ⟶ `PublishMinRaw` ⟶ `PublishMidRaw` ⟶ `PublishMaxRaw` (each `INITO` ⟶ next `INIT`); `PublishMaxRaw.INITO` ⟶ `INITO` and `AND_QO.REQ`.
8. Quality: `QI` ⟶ `.QI` of all 18 instances; `CALIBRATE.QO` ⟶ `AND_QO.IN1`; `INI_X_MIN/INI_X_MID/INI_X_MAX.QO` ⟶ `IN2/IN3/IN4`; `INI_MIN_REF/INI_MID_REF/INI_MAX_REF.QO` ⟶ `IN5/IN6/IN7`; `InputRaw.QO` ⟶ `IN8`; `MIN_REF_LIT/MID_REF_LIT/MAX_REF_LIT.QO` ⟶ `IN9/IN10/IN11`; `TriggerMIN/TriggerMID/TriggerMAX.QO` ⟶ `IN12/IN13/IN14`; `PublishCal.QO` ⟶ `IN15`; `PublishMinRaw/PublishMidRaw/PublishMaxRaw.QO` ⟶ `IN16/IN17/IN18`; `AND_QO.OUT` ⟶ `QO`.

Technical Details

- All six calibration corner values (three raw values, three reference values) are INI-persisted independently of each other via one `INI_AR2` each.
- `xClipping=FALSE`: the calibrated value is not clamped.
- `sSection` must be unique per channel.

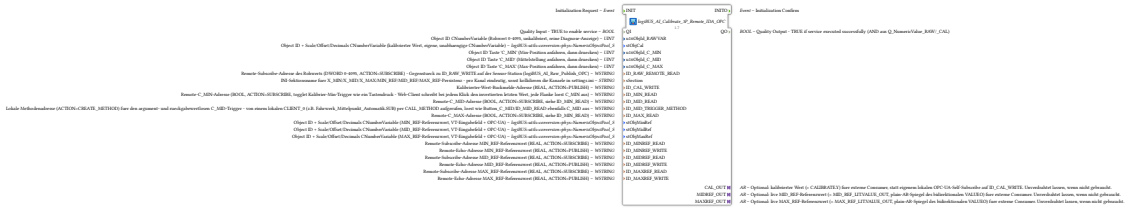


Application Scenarios

- Sensors with a defined center position, e.g. steering angle sensor (left/straight/right)
- Calibration via VT key, OPC-UA dashboard or remote call from another station

Summary

`logiBUS_AI_Calibrate_3P_IDA_OPC` bundles analog input, 3-point calibration, INI persistence, VT display and OPC-UA connection of one channel in one SubApp.



logiBUS_AI_Calibrate_3P_Remote_IDA_OPC

• – ◦ • – ◦ • – ◦ •

Introduction

`logiBUS_AI_Calibrate_3P_Remote_IDA_OPC` performs a **3-point calibration** (`AR_CALIBRATE_3P_REF`) for an analog raw value. The raw values `X_MIN`/`X_MID`/`X_MAX` and the reference values `MIN_REF`/`MID_REF`/`MAX_REF` are stored independently and all INI-persisted. The results appear on VT number fields (raw value and calibrated value, each with its own CNumberVariable), three VT buttons (`C_MIN`/`C_MID`/`C_MAX`) trigger the calibration points, and the raw value (DWORD) and the calibrated value (REAL) are provided generically for one channel via OPC-UA. In contrast to `logiBUS_AI_Calibrate_3P_IDA_OPC`, the raw value comes **via remote subscribe** (`AD_SUBSCRIBE_1`) instead of from a local `logiBUS_AI_IDA`; this allows sensors on a station without a VT connection to be calibrated (e.g. slope compensation angle sensor B14 on STG3) while calibration and VT run on the station with the VT connection. The raw value is published there by `logiBUS_AI_Raw_Publish_OPC`.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; starts the initialization chain (first link `Q_NumericValue_RAW.INIT`)

Event Outputs

- **INITO** (`EInit`): initialization confirm; comes from `Button_C_MAX.INITO`, the end of the chain

Data Inputs

- **QI** (BOOL): quality input - TRUE enables the service (default `TRUE`); distributed to all 21 inner instances
- **u16ObjId_RAWVAR** (UINT): object ID of the CNumberVariable for the raw value (0-4095, uncalibrated, pure diagnostic display)
- **stObjCal** (`NumericObjectPool_S`): object ID + scale/offset/decimals of the CNumberVariable for the calibrated value (own, independent variable)
- **u16ObjId_C_MIN**, **u16ObjId_C_MID**, **u16ObjId_C_MAX** (UINT): object IDs of the buttons `C_MIN`, `C_MID`, `C_MAX` (move to the position, then press)
- **ID_RAW_REMOTE_READ** (WSTRING): remote subscribe address of the raw value (DWORD 0-4095, `ACTION=SUBSCRIBE`); counterpart to `ID_RAW_WRITE` on the sensor station
- **sSection** (STRING): INI section name for the persistence of `X_MIN`/`X_MID`/`X_MAX`/`MIN_REF`/`MID_REF`/`MAX_REF`; unique per channel, otherwise the channels collide in `settings.ini`
- **ID_CAL_WRITE** (WSTRING): feedback address of the calibrated value (REAL, `ACTION=PUBLISH`)
- **ID_MIN_READ**, **ID_MID_READ**, **ID_MAX_READ** (WSTRING): remote addresses (BOOL, `ACTION=SUBSCRIBE`) for `C_MIN`/`C_MID`/`C_MAX`; every edge (the web client writes the inverted last value on each click) triggers the calibration point like a button press
- **ID_MID_TRIGGER_METHOD** (WSTRING): local method address (`ACTION=CREATE_METHOD`) for the argument-less and return-value-less `C_MID` trigger; called by a local `CLIENT_0` (e.g. `Fahrwerk_Mittelpunkt_Automatik.SUB`) via `CALL_METHOD` and triggers `C_MID` like `Button_C_MID`/`ID_MID_READ`
- **stObjMinRef**, **stObjMidRef**, **stObjMaxRef** (`NumericObjectPool_S`): object ID + scale/offset/decimals of the reference values `MIN_REF`/`MID_REF`/`MAX_REF` (VT input field + OPC-UA)
- **ID_MINREF_READ**, **ID_MIDREF_READ**, **ID_MAXREF_READ** (WSTRING): remote subscribe addresses of the reference values (REAL, `ACTION=SUBSCRIBE`)
- **ID_MINREF_WRITE**, **ID_MIDREF_WRITE**, **ID_MAXREF_WRITE** (WSTRING): remote echo addresses of the reference values (REAL, `ACTION=PUBLISH`)

Data Outputs

- **QO** (BOOL): quality output - TRUE if the service was executed successfully (AND of the `QO` of all 21 inner instances, see section Functionality)

Adapters

- **CAL_OUT** (plug, AR): optional; calibrated value (CALIBRATE.Y) for external consumers instead of an own local OPC-UA self-subscribe on ID_CAL_WRITE
- **MIDREF_OUT** (plug, AR): optional; live MID_REF reference value (MID_REF_LIT.VALUE_OUT, plain AR mirror of the bidirectional VALUEO) for external consumers
- **MAXREF_OUT** (plug, AR): optional; live MAX_REF reference value (MAX_REF_LIT.VALUE_OUT) for external consumers

Functionality

Raw value: AD_SUBSCRIBE_RAW (adapter::net::AD_SUBSCRIBE_1, QI from outside, address ID_RAW_REMOTE_READ) ⟶ AD_TO_AUDI ⟶ AUDI_SPLIT_2. OUT1 ⟶ Q_NumericValue_RAW.u32NewValue (Q_NumericValue_AUDI, raw value display on u16ObjId_RAWVAR); OUT2 ⟶ AUDI_TO_AR ⟶ CALIBRATE.X.

Calibration: CALIBRATE (adapter::Engineering::measurements::AR_CALIBRATE_3P_REF, xClipping = FALSE, QI from outside) maps the raw value X via the three points to Y. Y_MIN/Y_MID/Y_MAX come from MIN_REF_LIT/MID_REF_LIT/MAX_REF_LIT (each MyLib::sys::NumericValue_TO_AR2_OPC VT input field and OPC-UA, last writer wins).

Result: CALIBRATE.Y ⟶ AR_SPLIT_2 (AR_SPLIT_3): OUT1 ⟶ AR_PUBLISH_CAL (AR_PUBLISH_1, address ID_CAL_WRITE), OUT2 ⟶ Q_NumericValue_CAL.rPhys (Q_NumericValue_PHYSA, display with stObjCal), OUT3 ⟶ CAL_OUT. MID_REF_LIT.VALUE_OUT ⟶ MIDREF_OUT and MAX_REF_LIT.VALUE_OUT ⟶ MAXREF_OUT.

Triggers: every calibration point has its own event merge. C_MIN: Button_C_MIN.IND (Button_IE, BT_PRESSED_LATCHED), AX_RF_TRIG_MIN.ER and .EF (both edges of the remote subscribe AX_SUBSCRIBE_MIN, address ID_MIN_READ) ⟶ E_MERGE_MIN (E_MERGE_3) ⟶ CALIBRATE.C_MIN. C_MAX analogously via Button_C_MAX, AX_SUBSCRIBE_MAX, AX_RF_TRIG_MAX, E_MERGE_MAX (E_MERGE_3). C_MID additionally with SERVER_MID_TRIGGER (iec61499::net::SERVER_0, method ID_MID_TRIGGER_METHOD) ⟶ E_MERGE_MID (E_MERGE_4) ⟶ CALIBRATE.C_MID.

Persistence: CALIBRATE.X_MIN/X_MID/X_MAX and MIN_REF/MID_REF/MAX_REF each go to one INI_AR2 instance (INI_X_MIN, INI_X_MID, INI_X_MAX, INI_MIN_REF, INI_MID_REF, INI_MAX_REF; SETM = TRUE, SECTION from sSection, KEY = name). The defaults are X_MIN/X_MID/X_MAX = REAL#0.0 as well as MIN_REF = REAL#-100.0, MID_REF = REAL#50.0, MAX_REF = REAL#100.0.

Initialisation: INIT runs as one single chain (each INITO ⟶ next INIT) through Q_NumericValue_RAW ⟶ Q_NumericValue_CAL ⟶ MIN_REF_LIT ⟶ MID_REF_LIT ⟶ MAX_REF_LIT ⟶ CALIBRATE ⟶ INI_X_MIN ⟶ INI_X_MID ⟶ INI_X_MAX ⟶ INI_MIN_REF ⟶ INI_MID_REF ⟶ INI_MAX_REF ⟶ AD_SUBSCRIBE_RAW ⟶ AR_PUBLISH_CAL ⟶ AX_SUBSCRIBE_MIN ⟶ AX_SUBSCRIBE_MID ⟶ AX_SUBSCRIBE_MAX ⟶ SERVER_MID_TRIGGER ⟶ Button_C_MIN ⟶ Button_C_MID ⟶ Button_C_MAX; Button_C_MAX.INITO goes to the event output INITO and to AND_QO.REQ.

Quality: QI is passed to all 21 instances of the chain. QO is the output of the instance AND_QO (iec61131::booleanOperators::AND_BOOL_21), which combines the QO of these 21 instances in a single block (IN1..IN21: Q_NumericValue_RAW, Q_NumericValue_CAL, MIN_REF_LIT, MID_REF_LIT, MAX_REF_LIT, CALIBRATE, INI_X_MIN, INI_X_MID, INI_X_MAX, INI_MIN_REF, INI_MID_REF, INI_MAX_REF, AD_SUBSCRIBE_RAW, AR_PUBLISH_CAL, AX_SUBSCRIBE_MIN, AX_SUBSCRIBE_MID, AX_SUBSCRIBE_MAX, SERVER_MID_TRIGGER, Button_C_MIN, Button_C_MID, Button_C_MAX). In addition there is E_MERGE_QO (E_MERGE_3), which merges Q_NumericValue_CAL.INITO and the CNF events of Q_NumericValue_RAW and Q_NumericValue_CAL; its output EO triggers AND_QO.REQ, so QO is re-evaluated on every new Q_NumericValue_RAW/Q_NumericValue_CAL value (CNF) (up to v1.6 EO was not connected).

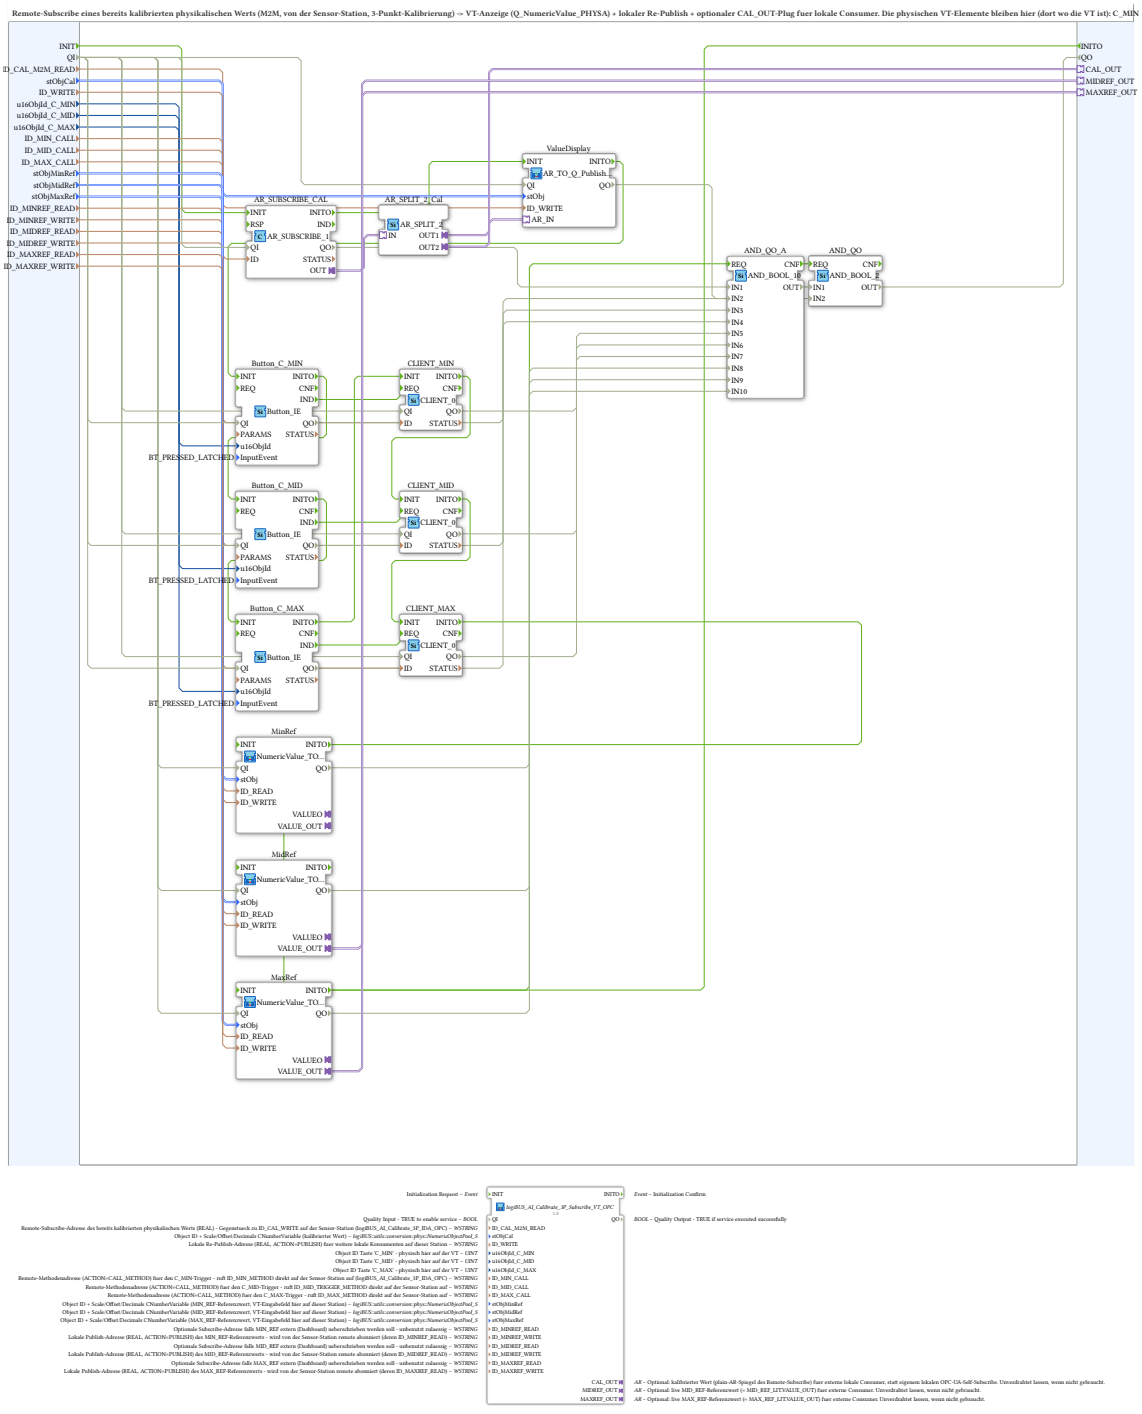
Technical Details

- The defaults of X_MID/X_MAX are deliberately 0.0: with 0.5/1.0 the calibrated flags xMidCal/xMaxCal of AR_CALIBRATE_3P_REF latched to TRUE at every restart although MID/MAX were never calibrated (fix in version 1.6)
- CALIBRATE has an INIT/QI/QO enable pattern; without QI = TRUE the block stays in state START and REQ never runs (version 1.5); here QI comes from the SubApp input QI (default TRUE) instead of a fixed parameter
- MIDREF_OUT/MAXREF_OUT are fed from VALUE_OUT, not from the bidirectional VALUEO: an AR_SPLIT_2 directly on an AR2 plug would be a type error (version 1.2)
- The optional plugs CAL_OUT/MIDREF_OUT/MAXREF_OUT allow external consumers to read the already calibrated value via adapter instead of subscribing to the same OPC-UA node locally again (FORTE: 'Cannot add another one'); leave unwired if not needed (e.g. slope compensation channel)

- The merge chains for `C_MIN`/`C_MID`/`C_MAX` are a single `E_MERGE_3`/`E_MERGE_4` each instead of several `E_MERGE_2` (OR is associative, functionally identical); `C_MIN`/`C_MID`/`C_MAX` of `CALIBRATE` are pure event inputs
- Remote triggers fire on **every** edge (rising and falling), since the web client writes the inverted last value on each click

Application Scenarios

- Calibration of an angle or position sensor (e.g. slope compensation) whose analog input sits on a different station than the VT
- Three-point calibration with min, centre and max position including adjustable reference values and persisted raw values



⚖️ Comparison with Similar Blocks

`logiBUS_AI_Calibrate_3P_IDA_OPC` reads the raw value locally from a `logiBUS_AI_IDA`; this remote variant replaces its `logiBUS_AI_IDA` + `AD_SPLIT_2` + `AD_PUBLISH_RAW` with an `AD_SUBSCRIBE_1`. The chain of calibration and VT connection is unchanged. The sensor side is `logiBUS_AI_Raw_Publish_OPC`.

Conclusion

`logiBUS_AI_Calibrate_3P_Remote_IDA_OPC` calibrates a remotely subscribed analog raw value via three points, persists all calibration data, shows raw and calibrated value on the VT and provides them via OPC-UA.

logiBUS_AI_Calibrate_3P_Subscribe_VT_OPC

• — ○ • — ○ • — ○ •

Introduction

`logiBUS_AI_Calibrate_3P_Subscribe_VT_OPC` is the VT-side counterpart to the sensor station `logiBUS_AI_Calibrate_3P_IDA_OPC`: the SubApp subscribes via OPC-UA (M2M) to the **already calibrated** physical value of the 3-point calibration, shows it in the VT, re-publishes it locally and optionally provides it on the plug `CAL_OUT` for local consumers. The physical VT elements stay here (where the VT is): the keys `C_MIN`/`C_MID`/`C_MAX` call the corresponding methods on the sensor station directly via `CLIENT_0` (a genuine event-to-event method call, no toggle/publish/subscribe detour). The three reference value input fields `MIN_REF`/`MID_REF`/`MAX_REF` (`NumericValue_TO_AR2_OPC`) are still published **locally** and subscribed remotely by the sensor station; `MID_REF` and `MAX_REF` are additionally re-

exposed as plain AR plugs (MIDREF_OUT/MAXREF_OUT). Used by the 3-point calibration training sample InputOutputTesterButton_AI_Calibrate_3P_OPC_UA.

Interface Structure

Event Inputs

- **INIT** (EInit): initialization request

Event Outputs

- **INITO** (EInit): initialization confirmation (from MaxRef.INITO)

Data Inputs

- **QI** (BOOL, default TRUE): Quality Input - TRUE enables the services
- **ID_CAL_M2M_READ** (WSTRING): remote subscribe address of the already calibrated physical value (REAL), counterpart of ID_CAL_WRITE on the sensor station
- **stObjCal** (NumericObjectPool_S): object ID + scale/offset/decimals of the CNumberVariable for the calibrated value
- **ID_WRITE** (WSTRING): local re-publish address (REAL, ACTION=PUBLISH) for further local consumers
- **u16ObjId_C_MIN**, **u16ObjId_C_MID**, **u16ObjId_C_MAX** (UINT, default ID_NULL): object IDs of the keys C_MIN/C_MID/C_MAX on the VT
- **ID_MIN_CALL**, **ID_MID_CALL**, **ID_MAX_CALL** (WSTRING): remote method addresses (ACTION=CALL_METHOD) for the three calibration triggers on the sensor station
- **stObjMinRef**, **stObjMidRef**, **stObjMaxRef** (NumericObjectPool_S): object ID + scale/offset/decimals of the reference value input fields on this station
- **ID_MINREF_READ**, **ID_MIDREF_READ**, **ID_MAXREF_READ** (WSTRING): optional subscribe addresses if the reference value is to be overridden externally (dashboard); may be left unused
- **ID_MINREF_WRITE**, **ID_MIDREF_WRITE**, **ID_MAXREF_WRITE** (WSTRING): local publish addresses (REAL, ACTION=PUBLISH) of the reference values, subscribed remotely by the sensor station

Data Outputs

- **QO** (BOOL): Quality Output - TRUE if all services succeeded (AND of AND_QO_A.OUT and ValueDisplay.QO)

Adapters

- **CAL_OUT** (plug, adapter::types::unidirectional::AR): optional, calibrated value (plain AR mirror of the remote subscribe) for external local consumers; leave unwired if not needed
- **MIDREF_OUT** (plug, adapter::types::unidirectional::AR): optional, live MID_REF reference value
- **MAXREF_OUT** (plug, adapter::types::unidirectional::AR): optional, live MAX_REF reference value

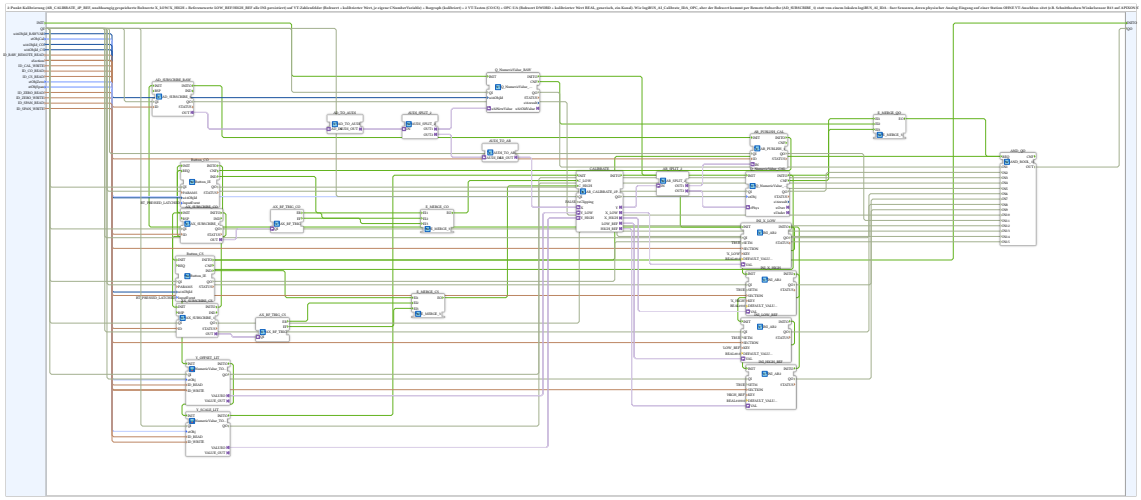
Function blocks used

- **AR_SUBSCRIBE_CAL** (adapter::net::AR_SUBSCRIBE_1): subscribes to the calibrated value from the sensor station (ID_CAL_M2M_READ).
- **AR_SPLIT_2_Cal** (adapter::events::unidirectional::AR_SPLIT_2): distributes the value to ValueDisplay and CAL_OUT.
- **ValueDisplay** (SubApp AR_TO_Q_Publish_OPC): VT display and local re-publish (stObjCal, ID_WRITE).
- **Button_C_MIN**, **Button_C_MID**, **Button_C_MAX** (isobus::UT::io::Button::Button_IE, InputEvent = BT_PRESSED_LATCHED): read the three VT keys.
- **CLIENT_MIN**, **CLIENT_MID**, **CLIENT_MAX** (iec61499::net::CLIENT_0): call the methods on the sensor station (ID_MIN_CALL/ID_MID_CALL/ID_MAX_CALL).
- **MinRef**, **MidRef**, **MaxRef** (SubApp NumericValue_TO_AR2_OPC): VT input fields of the reference values, published locally.
- **AND_QO_A** (iec61131::booleanOperators::AND_BOOL_10) and **AND_QO** (iec61131::booleanOperators::AND_BOOL_2): combine the QO outputs of all sub-blocks into the QO of the SubApp.

Functionality

- **Calibrated value:** AR_SUBSCRIBE_CAL.OUT → AR_SPLIT_2_Cal.IN; AR_SPLIT_2_Cal.OUT1 → ValueDisplay.AR_IN; AR_SPLIT_2_Cal.OUT2 → CAL_OUT.

- **Calibration keys:** `Button_C_MIN.IND` ⟶ `CLIENT_MIN.REQ`, `Button_C_MID.IND` ⟶ `CLIENT_MID.REQ`, `Button_C_MAX.IND` ⟶ `CLIENT_MAX.REQ`.
- **Reference values:** `MinRef/MidRef/MaxRef` receive `stObjMinRef/stObjMidRef/stObjMaxRef`, `ID_*REF_READ` and `ID_*REF_WRITE`; `MidRef.VALUE_OUT` ⟶ `MIDREF_OUT`, `MaxRef.VALUE_OUT` ⟶ `MAXREF_OUT`.
- **Initialization chain:** `INIT` ⟶ `AR_SUBSCRIBE_CAL` ⟶ `ValueDisplay` ⟶ `Button_C_MIN` ⟶ `Button_C_MID` ⟶ `Button_C_MAX` ⟶ `CLIENT_MIN` ⟶ `CLIENT_MID` ⟶ `CLIENT_MAX` ⟶ `MinRef` ⟶ `MidRef` ⟶ `MaxRef` (each `INITO` ⟶ next `INIT`); `MaxRef.INITO` ⟶ `INITO` and ⟶ `AND_QO_A.REQ`; `AND_QO_A.CNF` ⟶ `AND_QO.REQ`.
- **Quality:** `QI` ⟶ `.QI` of `AR_SUBSCRIBE_CAL`, `Button_C_MIN/_MID/_MAX`, `CLIENT_MIN/_MID/_MAX`, `MinRef`, `MidRef`, `MaxRef` and `ValueDisplay`. `AR_SUBSCRIBE_CAL.QO`, the three `Button_C_*.QO`, the three `CLIENT_*.QO` and `MinRef.QO/MidRef.QO/MaxRef.QO` ⟶ `AND_QO_A.IN1..IN10`; `AND_QO_A.OUT` ⟶ `AND_QO.IN1`, `ValueDisplay.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.



Summary

Remote display block for an already calibrated 3-point value: subscribe of the calibrated value, VT display with local re-publish, calibration keys as method calls to the sensor station, and locally published reference value input fields in one composite.

logiBUS_AI_Calibrate_Remote_IDA_OPC

• – ○ • – ○ • – ○ •

Introduction

`logiBUS_AI_Calibrate_Remote_IDA_OPC` is a 2-point calibration (`AR_CALIBRATE_2P_REF`, independently stored raw values `X_LOW/X_HIGH` and reference values `LOW_REF/HIGH_REF`, all INI-persisted) with VT number fields (raw value and calibrated value, each its own `CNumberVariable`), two VT buttons (CO/CS) and OPC-UA (raw value `DWORD`, calibrated value `REAL`, generic, one channel). It corresponds to `logiBUS_AI_Calibrate_2P_IDA_OPC`, but the raw value arrives via **remote subscribe** (`AD_SUBSCRIBE_1`) instead of from a local `logiBUS_AI_IDA`. This is intended for sensors whose physical analog input sits on a station **without a VT connection** (e.g. cutting-height angle sensor B13 on APIXON STG3, while calibration and VT run on the station with the VT connection). The raw value is published there via `logiBUS_AI_Raw_Publish_OPC`.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirm

Data Inputs

- **QI** (`BOOL`, default `TRUE`): quality input, TRUE enables the service
- **u16ObjId_RAWVAR** (`UINT`): object ID of the `CNumberVariable` (raw value 0..4095, uncalibrated, pure diagnostic display), default `ID_NULL`
- **stObjCal** (`NumericObjectPool_S`): object ID plus scale/offset/decimals of the `CNumberVariable` for the calibrated value (its own, independent variable)
- **u16ObjId_CO** (`UINT`): object ID of button "CO" (calibration zero point: apply reference 1, then press)
- **u16ObjId_CS** (`UINT`): object ID of button "CS" (calibration span: apply reference 2, then press; only possible after CO)
- **ID_RAW_REMOTE_READ** (`WSTRING`): remote subscribe address of the raw value (`DWORD` 0..4095, `ACTION=SUBSCRIBE`), counterpart of `ID_RAW_WRITE` on the sensor station
- **sSection** (`STRING`): INI section name for the persistence of `X_LOW`/`X_HIGH`/`LOW_REF`/`HIGH_REF`; unique per channel, otherwise the channels collide in `settings.ini`
- **ID_CAL_WRITE** (`WSTRING`): feedback address of the calibrated value (`REAL`, `ACTION=PUBLISH`)
- **ID_CO_READ** (`WSTRING`): remote CO address (`BOOL`, `ACTION=SUBSCRIBE`): toggles the calibration zero point trigger like a button press; the web client writes the inverted last value on every click, every edge (rising or falling) triggers CO
- **ID_CS_READ** (`WSTRING`): remote CS address (`BOOL`, `ACTION=SUBSCRIBE`): toggles the calibration span trigger, see `ID_CO_READ`
- **stObjZero** (`NumericObjectPool_S`): `CNumberVariable` of the ZERO reference value (VT input field + OPC-UA)
- **stObjSpan** (`NumericObjectPool_S`): `CNumberVariable` of the SPAN reference value (VT input field + OPC-UA)
- **ID_ZERO_READ** (`WSTRING`): remote subscribe address ZERO reference value (`REAL`, `ACTION=SUBSCRIBE`)
- **ID_ZERO_WRITE** (`WSTRING`): remote echo address ZERO reference value (`REAL`, `ACTION=PUBLISH`)
- **ID_SPAN_READ** (`WSTRING`): remote subscribe address SPAN reference value (`REAL`, `ACTION=SUBSCRIBE`)
- **ID_SPAN_WRITE** (`WSTRING`): remote echo address SPAN reference value (`REAL`, `ACTION=PUBLISH`)

Data Outputs

- **QO** (`BOOL`): quality output, AND combination (`AND_QO`, a single `AND_BOOL_15`) of the `QO` outputs of all 15 inner blocks with `QO`: `Q_NumericValue_RAW`, `Q_NumericValue_CAL`, `Y_OFFSET_LIT`, `Y_SCALE_LIT`, `CALIBRATE`, `INI_X_LOW`, `INI_X_HIGH`, `INI_LOW_REF`, `INI_HIGH_REF`, `AD_SUBSCRIBE_RAW`, `AR_PUBLISH_CAL`, `AX_SUBSCRIBE_CO`, `AX_SUBSCRIBE_CS`, `Button_CO`, `Button_CS`

Adapters

None.

Function Blocks (FBs) Used

- **`AD_SUBSCRIBE_RAW`** (`adapter::net::AD_SUBSCRIBE_1`): subscribes to the remote raw value
- **`AD_TO_AUDI`**, **`AUDI_SPLIT_2`**, **`AUDI_TO_AR`**: conversion and splitting of the raw value
- **`Q_NumericValue_RAW`** (`isobus::UT::Q::Q_NumericValue_AUDI`): VT raw value display
- **`CALIBRATE`** (`adapter::Engineering::measurements::AR_CALIBRATE_2P_REF`, `xClipping = FALSE`): 2-point calibration
- **`Y_OFFSET_LIT`**, **`Y_SCALE_LIT`** (SubApp `MyLib::sys::NumericValue_TO_AR2_OPC`, NumericValue_TO_AR2_OPC): ZERO/SPAN reference values as `AR2`
- **`Button_CO`**, **`Button_CS`** (`isobus::UT::io::Button::Button_IE`, `InputEvent = BT_PRESSED_LATCHED`): VT buttons
- **`AX_SUBSCRIBE_CO`**, **`AX_SUBSCRIBE_CS`** (`adapter::net::AX_SUBSCRIBE_1`): remote triggers

- **AX_RF_TRIG_CO**, **AX_RF_TRIG_CS** (adapter::events::unidirectional::AX_RF_TRIG): detect rising and falling edge
- **E_MERGE_CO**, **E_MERGE_CS** (iec61499::events::E_MERGE_3): merge button, rising and falling edge
- **INI_X_LOW**, **INI_X_HIGH**, **INI_LOW_REF**, **INI_HIGH_REF** (eclipse4diac::storage::INI_AR2, SETM = TRUE): persistence; keys X_LOW/X_HIGH/LOW_REF/HIGH_REF, defaults 0.0/0.0/0.0/100.0
- **AND_QO** (iec61131::booleanOperators::AND_BOOL_15, since v1.5): replaces the former cascade AND_QO_A (AND_BOOL_4) + AND_QO_B (AND_BOOL_10) + AND_QO (AND_BOOL_3) with a single block for all 15 QO sources
- **AR_SPLIT_2** (adapter::events::unidirectional::AR_SPLIT_2), **AR_PUBLISH_CAL** (adapter::net::AR_PUBLISH_1), **Q_NumericValue_CAL** (isobus::UT::Q::Q_NumericValue_PHYSA): output of the calibrated value

Functionality

- Raw value path: AD_SUBSCRIBE_RAW.OUT → AD_TO_AUDI.AD_IN → AUDI_SPLIT_2.IN; AUDI_SPLIT_2.OUT1 → Q_NumericValue_RAW.u32NewValue (VT display); AUDI_SPLIT_2.OUT2 → AUDI_TO_AR.AUDI_IN → CALIBRATE.X
- Persistence: CALIBRATE.X_LOW/X_HIGH/LOW_REF/HIGH_REF ↔ INI_X_LOW/INI_X_HIGH/INI_LOW_REF/INI_HIGH_REF.VAL; sSection → SECTION of all four
- References: Y_OFFSET_LIT.VALUEO → CALIBRATE.Y_LOW; Y_SCALE_LIT.VALUEO → CALIBRATE.Y_HIGH
- Calibrated value: CALIBRATE.Y → AR_SPLIT_2.IN; OUT1 → AR_PUBLISH_CAL.IN; OUT2 → Q_NumericValue_CAL.rPhys
- CO trigger: Button_CO.IND → E_MERGE_CO.EI1; AX_SUBSCRIBE_CO.OUT → AX_RF_TRIG_CO.QI; AX_RF_TRIG_CO.ER → E_MERGE_CO.EI2, AX_RF_TRIG_CO.EF → E_MERGE_CO.EI3; E_MERGE_CO.EO → CALIBRATE.C_LOW
- CS trigger: analogous with Button_CS, AX_SUBSCRIBE_CS, AX_RF_TRIG_CS, E_MERGE_CS → CALIBRATE.C_HIGH
- Initialisation chain: INIT → Q_NumericValue_RAW.INIT → Q_NumericValue_CAL.INIT → Y_OFFSET_LIT.INIT → Y_SCALE_LIT.INIT → CALIBRATE.INIT → INI_X_LOW.INIT → INI_X_HIGH.INIT → INI_LOW_REF.INIT → INI_HIGH_REF.INIT → AD_SUBSCRIBE_RAW.INIT → AR_PUBLISH_CAL.INIT → AX_SUBSCRIBE_CO.INIT → AX_SUBSCRIBE_CS.INIT → Button_CO.INIT → Button_CS.INIT; Button_CS.INITO → INITO and → AND_QO.REQ. In addition E_MERGE_QO (E_MERGE_3) merges Q_NumericValue_CAL.INITO and the CNF events of Q_NumericValue_RAW and Q_NumericValue_CAL; its output EO triggers AND_QO.REQ, so QO is re-evaluated on every new value (from v1.6; previously EO was not connected). QI is distributed to all inner blocks; their QO outputs feed AND_QO.IN1 to AND_QO.IN15 in the order of the chain, AND_QO.OUT → QO. (The former partial chain AD_SUBSCRIBE_RAW.INITO → AR_PUBLISH_CAL.INIT → AX_SUBSCRIBE_CO.INIT → AX_SUBSCRIBE_CS.INIT is part of this chain.)

Technical Details

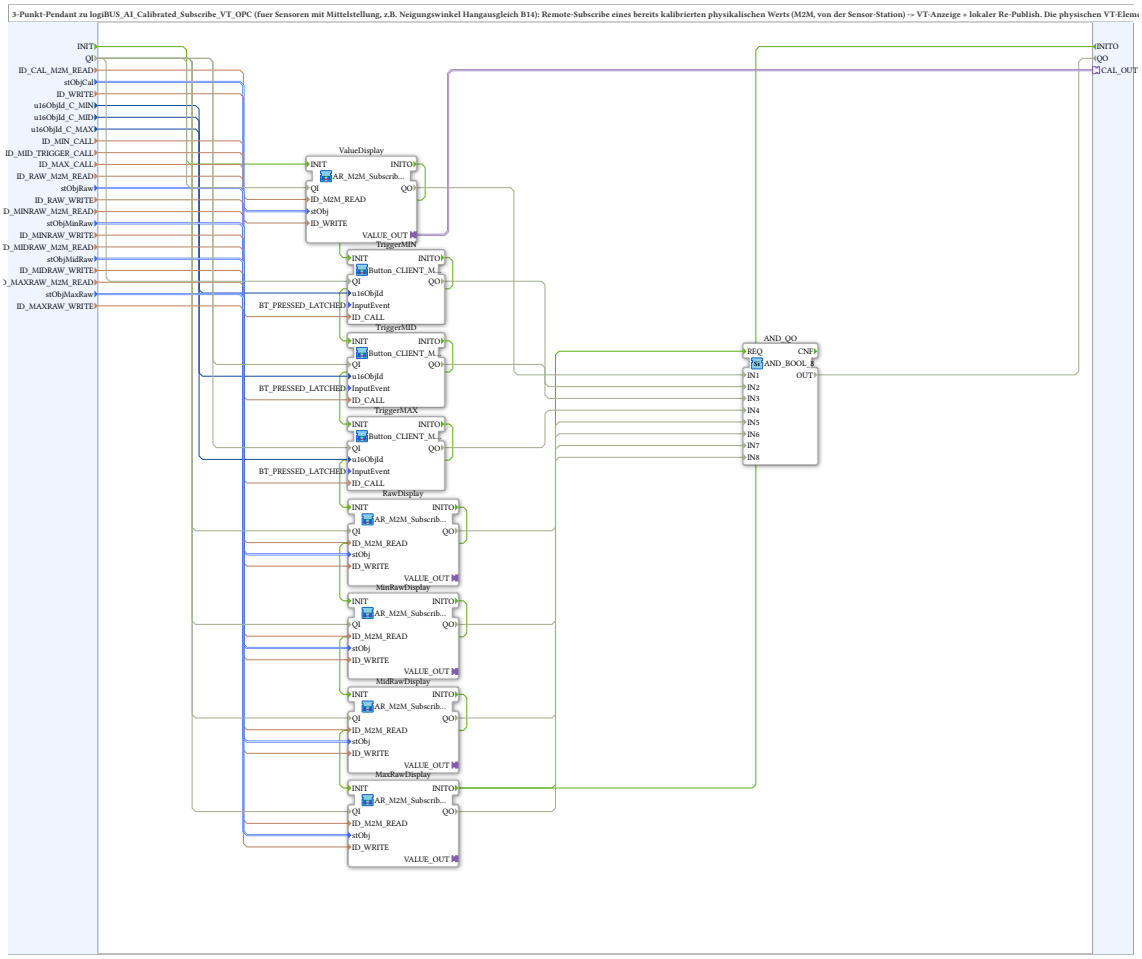
- **Raw value via remote subscribe:** logiBUS_AI_IDA, AD_SPLIT_2 and AD_PUBLISH_RAW of the local variant are replaced by AD_SUBSCRIBE_1, the rest of the calibration and VT chain is unchanged.
- **CO/CS without AX sockets:** since v1.1 C_LOW/C_HIGH of AR_CALIBRATE_2P_REF are pure event inputs; the E_MERGE_3 blocks connect directly via event connections (v1.2: one E_MERGE_3 instead of two E_MERGE_2 in series, functionally identical).
- **QI on CALIBRATE:** since v1.3 AR_CALIBRATE_2P_REF has an INIT/QI/QO enable pattern; without QI = TRUE the block would stay in state START and REQ would never run. The QI of all inner blocks now comes from the subapp input QI (default TRUE) instead of fixed parameters.
- **Bugfix v1.4 (code review PR #260):** INI_X_HIGH.DEFAULT_VALUE was REAL#1.0 instead of 0.0; as a result the calibrated flag xHighCal latched TRUE immediately at every boot although HIGH was never calibrated. Affects cutting height, oil temperature and pressure.
- **Web trigger:** CO/CS are triggered by every edge (rising or falling), because the web client writes the inverted last value on every click.
- This type is being superseded by logiBUS_AI_Calibrated_Subscribe_VT_OPC (local analog processing); the adjustments keep the file compilable.

Application Scenarios

- Calibrating a sensor whose analog input sits on a station without a VT connection, with VT operation on another station

⚖️ Comparison with Similar Building Blocks

- `logiBUS_AI_Calibrate_2P_IDA_OPC`: raw value from a local `logiBUS_AI_IDA`
- `logiBUS_AI_Calibrate_3P_Remote_IDA_OPC`: three-point variant with remote raw value



Summary

`logiBUS_AI_Calibrate_Remote_IDA_OPC` calibrates a remotely published analog raw value in two points, shows raw and calibrated value on the VT and publishes the calibrated value via OPC-UA.

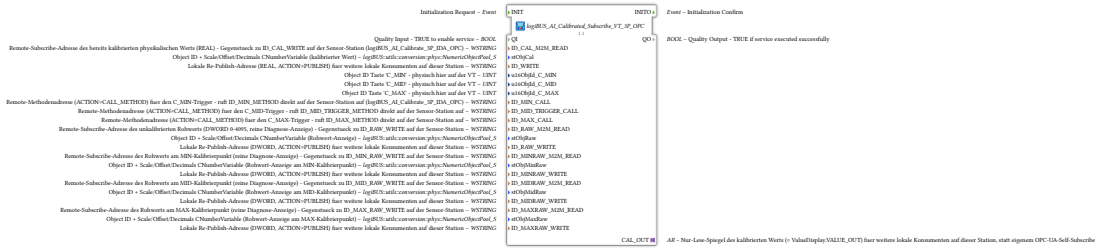
logiBUS_AI_Calibrated_Subscribe_VT_3P_OPC



• — ○ • — ○ • — ○ •

Introduction

`logiBUS_AI_Calibrated_Subscribe_VT_3P_OPC` is the **3-point counterpart** of `logiBUS_AI_Calibrated_Subscribe_VT_OPC` for sensors with a centre position (e.g. slope compensation tilt angle B14). Via remote subscribe (M2M, from the sensor station) it subscribes to an **already calibrated physical value**, shows it on the VT and re-publishes it locally.

The physical VT elements stay where the VT is: the keys **C_MIN/C_MID/C_MAX** call the methods `ID_MIN_METHOD/ID_MID_TRIGGER_METHOD/ID_MAX_METHOD` directly on the sensor station via `CLIENT_0` (`logiBUS_AI_Calibrate_3P_IDA_OPC`) - a true event-to-event method call, no toggle/publish/subscribe detour (see `OPC_UA_VERNETZUNG.md`, item 14). The reference value input fields `MIN_REF/MID_REF/MAX_REF` deliberately stay outside this SubApp (separate `NumericValue_TO_CLIENT_1_0_OPC` instances per caller).

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization Request

Event Outputs

- **INITO** (`EInit`): Initialization Confirm

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE to enable the service

Calibrated value:

- **ID_CAL_M2M_READ** (`WSTRING`): Remote subscribe address of the already calibrated physical value (`REAL`); counterpart of `ID_CAL_WRITE` on the sensor station (`logiBUS_AI_Calibrate_3P_IDA_OPC`)
- **stObjCal** (`NumericObjectPool_S`, default `u16ObjId := ID_NULL, r32Scale := 1.0, i32Offset := 0, u8Decimals := 1`): Object ID + scale/offset/decimals of the `CNumberVariable` (calibrated value)
- **ID_WRITE** (`WSTRING`): Local re-publish address (`REAL`, `ACTION=PUBLISH`) for further local consumers on this station

Keys C_MIN/C_MID/C_MAX:

- **u16ObjId_C_MIN**, **u16ObjId_C_MID**, **u16ObjId_C_MAX** (`UINT`, default `ID_NULL`): Object IDs of the keys “C_MIN”, “C_MID”, “C_MAX”, physically here on the VT
- **ID_MIN_CALL**, **ID_MID_TRIGGER_CALL**, **ID_MAX_CALL** (`WSTRING`): Remote method addresses (`ACTION=CALL_METHOD`); call `ID_MIN_METHOD`, `ID_MID_TRIGGER_METHOD` and `ID_MAX_METHOD` respectively directly on the sensor station

Raw value displays (pure diagnostics):

- **ID_RAW_M2M_READ** (`WSTRING`): Remote subscribe address of the uncalibrated raw value (`DWORD` 0-4095); counterpart of `ID_RAW_WRITE` on the sensor station
- **stObjRaw** (`NumericObjectPool_S`, `u8Decimals := 0`): Raw value display field
- **ID_RAW_WRITE** (`WSTRING`): Local re-publish address (`DWORD`, `ACTION=PUBLISH`)
- **ID_MINRAW_M2M_READ** (`WSTRING`): Remote subscribe address of the raw value at the MIN calibration point; counterpart of `ID_MIN_RAW_WRITE` on the sensor station
- **stObjMinRaw** (`NumericObjectPool_S`, `u8Decimals := 0`): Display field for the raw value at the MIN calibration point
- **ID_MINRAW_WRITE** (`WSTRING`): Local re-publish address (`DWORD`, `ACTION=PUBLISH`)
- **ID_MIDRAW_M2M_READ** (`WSTRING`): Remote subscribe address of the raw value at the MID calibration point; counterpart of `ID_MID_RAW_WRITE` on the sensor station
- **stObjMidRaw** (`NumericObjectPool_S`, `u8Decimals := 0`): Display field for the raw value at the MID calibration point
- **ID_MIDRAW_WRITE** (`WSTRING`): Local re-publish address (`DWORD`, `ACTION=PUBLISH`)
- **ID_MAXRAW_M2M_READ** (`WSTRING`): Remote subscribe address of the raw value at the MAX calibration point; counterpart of `ID_MAX_RAW_WRITE` on the sensor station
- **stObjMaxRaw** (`NumericObjectPool_S`, `u8Decimals := 0`): Display field for the raw value at the MAX calibration point
- **ID_MAXRAW_WRITE** (`WSTRING`): Local re-publish address (`DWORD`, `ACTION=PUBLISH`)

Data Outputs

- **QO** (BOOL): Quality Output - TRUE if the service executed successfully (AND of the QO of ValueDisplay, TriggerMIN, TriggerMID, TriggerMAX, RawDisplay, MinRawDisplay, MidRawDisplay and MaxRawDisplay)

Adapters

- **CAL_OUT** (plug, adapter::types::unidirectional::AR): Read-only mirror of the calibrated value (ValueDisplay.VALUE_OUT) for further local consumers on this station (e.g. Fahrwerk_Mittelpunkt_Anzeige for bar graph/status centre), instead of its own OPC-UA self-subscribe

Function Blocks (FBs) Used

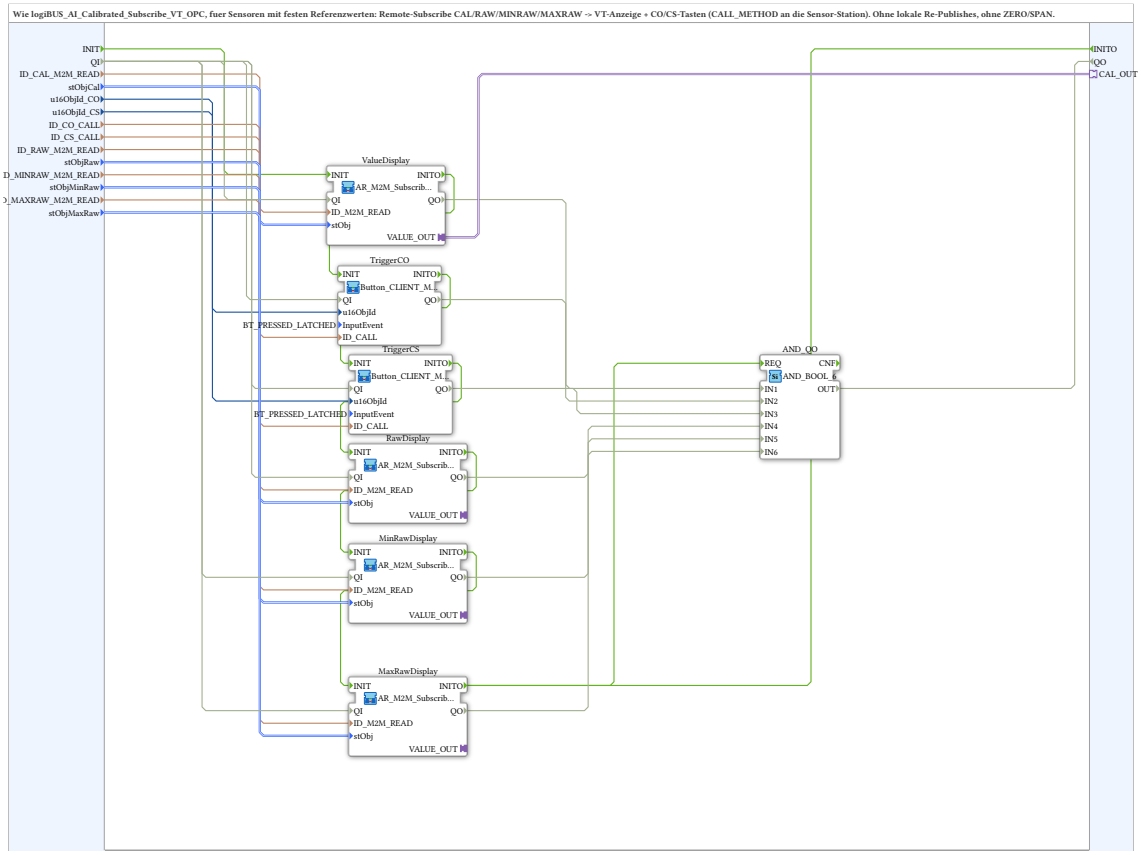
- **ValueDisplay**: SubApp MyLib::sys::AR_M2M_Subscribe_TO_Q_Publish_OPC - calibrated value
- **RawDisplay**, **MinRawDisplay**, **MidRawDisplay**, **MaxRawDisplay**: the same SubApp for the raw value and the raw values of the three calibration points
- **TriggerMIN**, **TriggerMID**, **TriggerMAX**: SubApp MyLib::sys::Button_CLIENT_Method_IE (InputEvent=BT_PRESSED_LATCHED) - key ⟶ remote method call (ID_CALL)
- **AND_QO**: iec61131::booleanOperators::AND_BOOL_8 - ANDs the QO outputs of the eight inner SubApps into the block output QO
- **Imports**: ID_NULL, BT_PRESSED_LATCHED, NumericObjectPool_S

Program Flow and Connections

- ID_CAL_M2M_READ, stObjCal, ID_WRITE ⟶ ValueDisplay (ID_M2M_READ, stObj, ID_WRITE); ValueDisplay.VALUE_OUT ⟶ CAL_OUT
- u16ObjId_C_MIN/ID_MIN_CALL ⟶ TriggerMIN (u16ObjId/ID_CALL); likewise C_MID ⟶ TriggerMID, C_MAX ⟶ TriggerMAX
- ID_RAW_M2M_READ, stObjRaw, ID_RAW_WRITE ⟶ RawDisplay
- ID_MINRAW_M2M_READ, stObjMinRaw, ID_MINRAW_WRITE ⟶ MinRawDisplay
- ID_MIDRAW_M2M_READ, stObjMidRaw, ID_MIDRAW_WRITE ⟶ MidRawDisplay
- ID_MAXRAW_M2M_READ, stObjMaxRaw, ID_MAXRAW_WRITE ⟶ MaxRawDisplay
- Initialization chain: INIT ⟶ ValueDisplay.INIT, ValueDisplay.INITO ⟶ TriggerMIN.INIT, TriggerMIN.INITO ⟶ TriggerMID.INIT, TriggerMID.INITO ⟶ TriggerMAX.INIT, TriggerMAX.INITO ⟶ RawDisplay.INIT, RawDisplay.INITO ⟶ MinRawDisplay.INIT, MinRawDisplay.INITO ⟶ MidRawDisplay.INIT, MidRawDisplay.INITO ⟶ MaxRawDisplay.INIT, MaxRawDisplay.INITO ⟶ INITO and ⟶ AND_QO.REQ
- QI ⟶ QI of all eight inner SubApps
- ValueDisplay.QO, TriggerMIN.QO, TriggerMID.QO, TriggerMAX.QO, RawDisplay.QO, MinRawDisplay.QO, MidRawDisplay.QO, MaxRawDisplay.QO ⟶ AND_QO.IN1..IN8; AND_QO.OUT ⟶ QO

Technical Details

- The calibration itself runs on the sensor station; this block contains no calibration logic
- Version 1.1 (2026-09-26): plug CAL_OUT added - mirrors the already remotely subscribed value for further consumers on STG1, no additional self-subscribe needed
- Version 1.0 (2026-09-26): 3-point counterpart of logiBUS_AI_Calibrated_Subscribe_VT_OPC v1.8, for slope compensation angle B14 (calibration moves from STG1 to STG3)

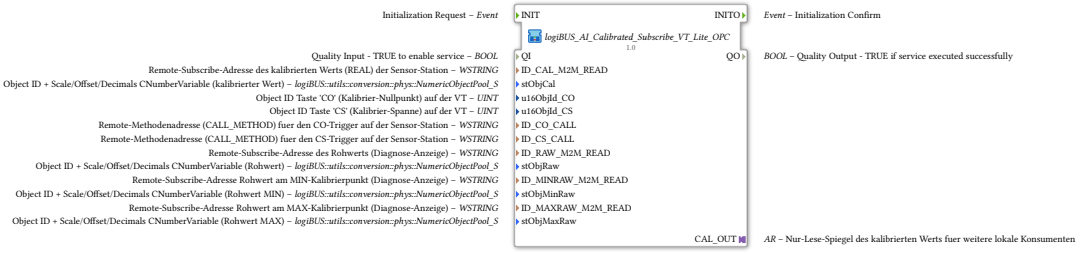


Application Scenarios

- VT station that displays the calibrated tilt angle (B14) of another station and triggers the 3-point calibration (MIN/MID/MAX) via keys

Summary

logiBUS_AI_Calibrated_Subscribe_VT_3P_OPC shows remotely calibrated values and raw values of the calibration points on the VT and forwards the keys C_MIN/C_MID/C_MAX to the sensor station via OPC-UA method calls.



logiBUS_AI_Calibrated_Subscribe_VT_Lite_OPC

• — ○ • — ○ • — ○ •

Introduction

`logiBUS_AI_Calibrated_Subscribe_VT_Lite_OPC` is the lean variant of `logiBUS_AI_Calibrated_Subscribe_VT_OPC` for sensors with fixed reference values. The calibrated value, the raw value and the raw values at the MIN and MAX calibration points are subscribed remotely from the sensor station and shown on the VT; the keys **CO**/**CS** call the calibration methods on the sensor station via `CALL_METHOD`. Compared with the original there are no local re-publishes (no `ID_*_WRITE` mirrors) and no `ZERO`/`SPAN` reference value input fields (`ZeroRef`/`SpanRef` are omitted, the reference values are fixed on the sensor station). Instead of `AR_M2M_Subscribe_TO_Q_Publish_OPC`, `AR_M2M_Subscribe_TO_Q_OPC` is used four times.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; starts the chain `ValueDisplay` ⟶ `TriggerCO` ⟶ `TriggerCS` ⟶ `RawDisplay` ⟶ `MinRawDisplay` ⟶ `MaxRawDisplay`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `MaxRawDisplay.INITO`

Data Inputs

Variable	Type	Default	Comment
QI	BOOL	TRUE	Quality input: enables the service; passed on to all six instances.
ID_CAL_M2M_READ	WSTRING		Remote subscribe address of the calibrated value (REAL) of the sensor station.
stObjIdCal	utils::conversion::phys::NumericObjectID	iQI := TRUE, bID_NULL := FALSE, r32Scale := 1.0, i32Offset := 0, u8Decimals := 1	Object ID plus scale/offset/decimals of the CNumberVariable (calibrated value).
u16ObjId_CO	UINT	ID_NULL	Object ID of the key “CO” (calibration zero point) on the VT.
u16ObjId_CS	UINT	ID_NULL	Object ID of the key “CS” (calibration span) on the VT.
ID_CO_CALL	WSTRING		Remote method address (CALL_METHOD) for the CO trigger on the sensor station.
ID_CS_CALL	WSTRING		Remote method address (CALL_METHOD) for the CS trigger on the sensor station.
ID_RAW_M2M_READ	WSTRING		Remote subscribe address of the raw value (diagnostic display).
stObjIdRaw	utils::conversion::phys::NumericObjectID	iQI := TRUE, bID_NULL := FALSE, r32Scale := 1.0, i32Offset := 0, u8Decimals := 0	Object ID plus scale/offset/decimals of the CNumberVariable (raw value).
ID_MINRAW_M2M_READ	WSTRING		Remote subscribe address of the raw value at the MIN calibration point (diagnostic display).
stObjIdMinRaw	utils::conversion::phys::NumericObjectID	iQI := TRUE, bID_NULL := FALSE, r32Scale := 1.0, i32Offset := 0, u8Decimals := 0	Object ID plus scale/offset/decimals of the CNumberVariable (raw value MIN).
ID_MAXRAW_M2M_READ	WSTRING		Remote subscribe address of the raw value at the MAX calibration point (diagnostic display).
stObjIdMaxRaw	utils::conversion::phys::NumericObjectID	iQI := TRUE, bID_NULL := FALSE, r32Scale :=	Object ID plus scale/offset/decimals of the

		`1.0, i32Offset := 0, u8Decimals := 0)`	`CNumberVariable` (raw value MAX).

Data Outputs

Variable	Type	Default	Comment
`QO`	BOOL		Quality output: `AND` of the `QO` outputs of all six instances (via `AND_QO`, `AND_BOOL_6`).

Adapters

Adapter	Type	Direction	Comment
`CAL_OUT`	`adapter::types::unidirectional::AR`	Plug	Read-only mirror of the calibrated value (`ValueDisplay.VALUE_OUT`) for further local consumers.

Function Blocks (FBs) Used

- **ValueDisplay** (SubApp `MyLib::sys::AR_M2M_Subscribe_TO_Q_OPC`): calibrated value
- **TriggerCO**, **TriggerCS** (SubApp `MyLib::sys::Button_CLIENT_Method_IE`, `InputEvent = BT_PRESSED_LATCHED`): keys CO and CS with method call
- **RawDisplay**, **MinRawDisplay**, **MaxRawDisplay** (SubApp `MyLib::sys::AR_M2M_Subscribe_TO_Q_OPC`): raw value and raw values of the MIN and MAX calibration points
- **AND_QO** (`iec61131::booleanOperators::AND_BOOL_6`): combines the six `QO` outputs

Program Flow and Connections

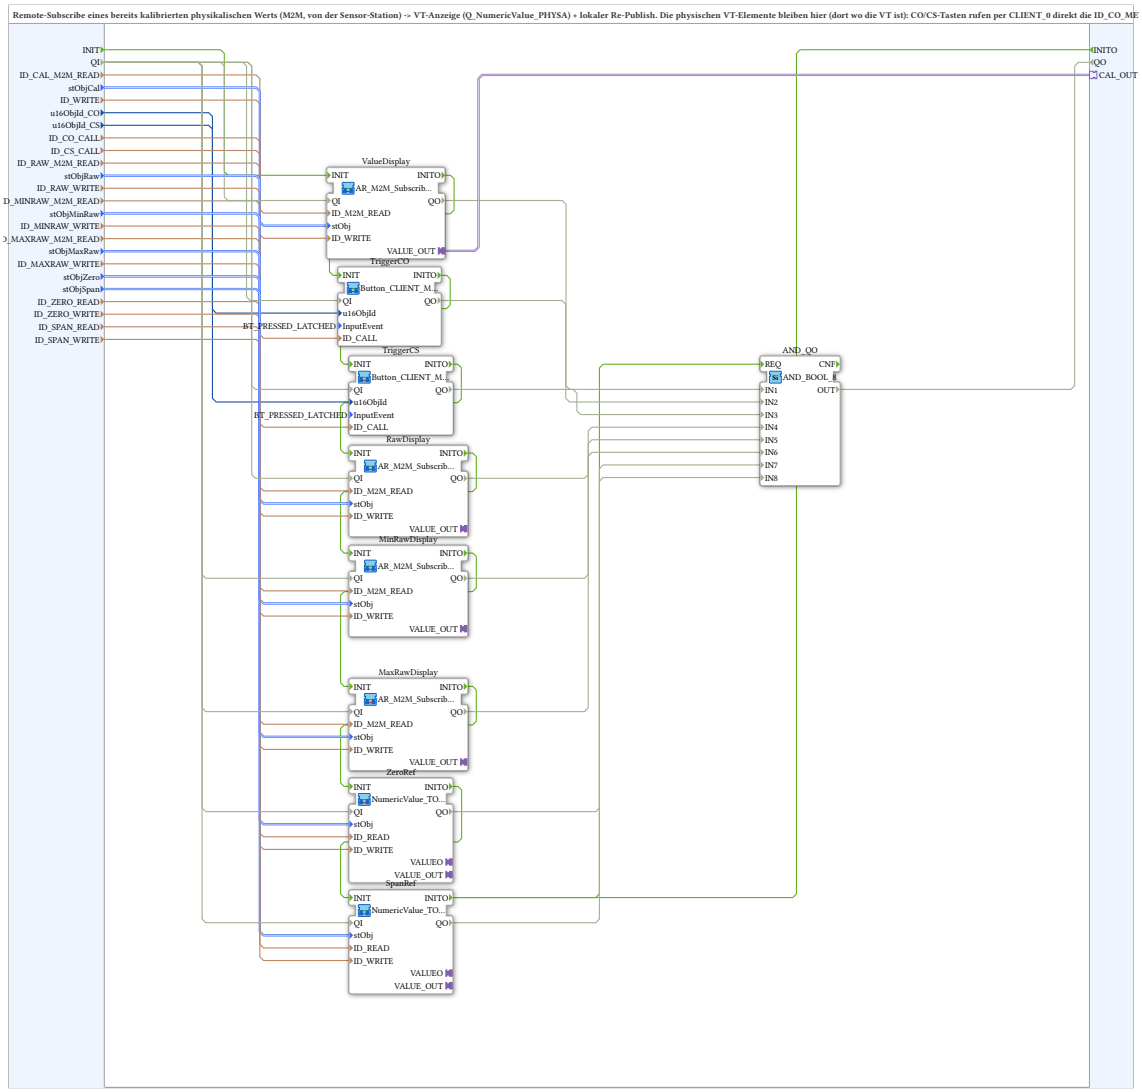
1. Value: `ID_CAL_M2M_READ -> ValueDisplay.ID_M2M_READ`; `stObjCal -> ValueDisplay.stObj`; `ValueDisplay.VALUE_OUT -> CAL_OUT`.
2. Keys: `u16ObjId_CO -> TriggerCO.u16ObjId`; `ID_CO_CALL -> TriggerCO.ID_CALL`; `u16ObjId_CS -> TriggerCS.u16ObjId`; `ID_CS_CALL -> TriggerCS.ID_CALL`.
3. Raw value: `ID_RAW_M2M_READ -> RawDisplay.ID_M2M_READ`; `stObjRaw -> RawDisplay.stObj`.
4. MIN raw value: `ID_MINRAW_M2M_READ -> MinRawDisplay.ID_M2M_READ`; `stObjMinRaw -> MinRawDisplay.stObj`.
5. MAX raw value: `ID_MAXRAW_M2M_READ -> MaxRawDisplay.ID_M2M_READ`; `stObjMaxRaw -> MaxRawDisplay.stObj`.
6. Initialization: `INIT -> ValueDisplay.INIT -> TriggerCO.INIT -> TriggerCS.INIT -> RawDisplay.INIT -> MinRawDisplay.INIT -> MaxRawDisplay.INIT` (each via `INITO`); `MaxRawDisplay.INITO -> INITO` and `-> AND_QO.REQ`.
7. Qualifier: `QI -> .QI` of the six instances.
8. Quality: `ValueDisplay.QO -> AND_QO.IN1`; `TriggerCO.QO -> IN2`; `TriggerCS.QO -> IN3`; `RawDisplay.QO -> IN4`; `MinRawDisplay.QO -> IN5`; `MaxRawDisplay.QO -> IN6`; `AND_QO.OUT -> QO`.

Technical Features

- Without local re-publishes: there are no `ID_*_WRITE` inputs.
- Without `ZERO`/`SPAN`: the reference values are fixed on the sensor station (e.g. filling belt angle).
- The calibration itself runs on the sensor station; this block contains no calibration logic.

Application Scenarios

- VT station that shows calibrated sensor values of another station and triggers their calibration by key, when the sensor has fixed reference values (e.g. filling belt angle) and no local re-publishes are needed.



Summary

`logiBUS_AI_Calibrated_Subscribe_VT_Lite_OPC` shows remotely calibrated values and raw values on the VT and forwards the calibration keys to the sensor station via method call - without local re-publishes and without `ZERO`/`SPAN`.

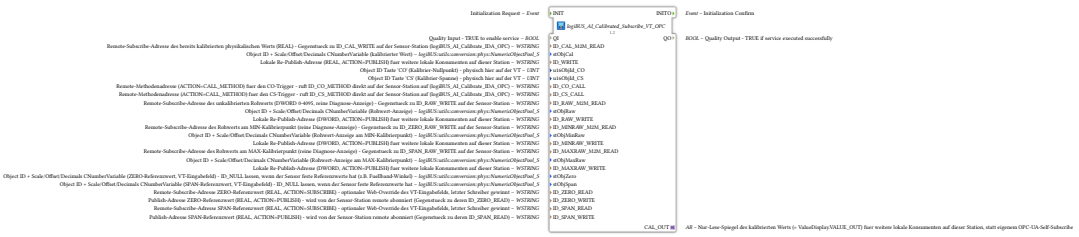
logiBUS_AI_Calibrated_Subscribe_VT_OPC



• — ○ • — ○ • — ○ •

Introduction

`logiBUS_AI_Calibrated_Subscribe_VT_OPC` subscribes via remote subscribe (M2M, from the sensor station) to an **already calibrated physical value** and shows it on the VT (`Q_NumericValue_PHYSA`) with a local re-publish. The physical VT elements stay where the VT is: the keys **CO**/**CS** call the methods `ID_CO_METHOD`/`ID_CS_METHOD` directly on the sensor station (`logiBUS_AI_Calibrate_IDA_OPC`) via `CLIENT_0` - a genuine event-to-event method call, no toggle/publish/subscribe detour (see `OPC_UA_VERNETZUNG.md`, item 14).

The block replaces `logiBUS_AI_Calibrate_Remote_IDA_OPC`: the calibration itself now runs on the sensor station, only the display and the forwarding of the VT controls remain here. The `ZERO`/`SPAN` reference value input fields (`stObjZero`/`stObjSpan`) are optional: leave `ID_NULL` if the sensor has fixed reference values (filling belt angle: 0/100 as a literal on the sensor station), pass real values through if the operator enters them (pressure: 0/250 bar, no calibrator always at hand).

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; starts the chain `ValueDisplay` ⟶ `TriggerCO` ⟶ `TriggerCS` ⟶ `RawDisplay` ⟶ `MinRawDisplay` ⟶ `MaxRawDisplay` ⟶ `ZeroRef` ⟶ `SpanRef`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `SpanRef.INITO`

Data Inputs

Enable:

- **QI** (`BOOL`, default `TRUE`): quality input, service enable; passed on to all eight instances (`ValueDisplay`, `TriggerCO`, `TriggerCS`, `RawDisplay`, `MinRawDisplay`, `MaxRawDisplay`, `ZeroRef`, `SpanRef`)

Calibrated value:

- **ID_CAL_M2M_READ** (`WSTRING`): Remote subscribe address of the already calibrated physical value (`REAL`); counterpart of `ID_CAL_WRITE` on the sensor station
- **stObjCal** (`NumericObjectPool_S`): Object ID + scale/offset/decimals of the `CNumberVariable` (calibrated value)
- **ID_WRITE** (`WSTRING`): Local re-publish address (`REAL`, `ACTION=PUBLISH`) for further local consumers

Keys CO/CS:

- **u16ObjId_CO** (`UINT`, default `ID_NULL`): Object ID of the key “CO” (calibration zero point), physically here on the VT
- **u16ObjId_CS** (`UINT`, default `ID_NULL`): Object ID of the key “CS” (calibration span), physically here on the VT
- **ID_CO_CALL**, **ID_CS_CALL** (`WSTRING`): Remote method addresses (`ACTION=CALL_METHOD`); call `ID_CO_METHOD`/`ID_CS_METHOD` directly on the sensor station

Raw value displays (pure diagnostics):

- **ID_RAW_M2M_READ** (`WSTRING`): Remote subscribe address of the uncalibrated raw value (`DWORD` 0-4095); counterpart of `ID_RAW_WRITE` on the sensor station
- **stObjRaw** (`NumericObjectPool_S`, `u8Decimals := 0`): Display field raw value
- **ID_RAW_WRITE** (`WSTRING`): Local re-publish address (`DWORD`, `ACTION=PUBLISH`)
- **ID_MINRAW_M2M_READ** (`WSTRING`): Remote subscribe address of the raw value at the MIN calibration point; counterpart of `ID_ZERO_RAW_WRITE` on the sensor station
- **stObjMinRaw** (`NumericObjectPool_S`, `u8Decimals := 0`): Display field raw value at the MIN calibration point
- **ID_MINRAW_WRITE** (`WSTRING`): Local re-publish address (`DWORD`, `ACTION=PUBLISH`)
- **ID_MAXRAW_M2M_READ** (`WSTRING`): Remote subscribe address of the raw value at the MAX calibration point; counterpart of `ID_SPAN_RAW_WRITE` on the sensor station
- **stObjMaxRaw** (`NumericObjectPool_S`, `u8Decimals := 0`): Display field raw value at the MAX calibration point
- **ID_MAXRAW_WRITE** (`WSTRING`): Local re-publish address (`DWORD`, `ACTION=PUBLISH`)

Reference values (optional):

- **stObjZero**, **stObjSpan** (`NumericObjectPool_S`): VT input fields for the ZERO/SPAN reference value; leave `ID_NULL` if the sensor has fixed reference values
- **ID_ZERO_READ**, **ID_SPAN_READ** (`WSTRING`): Remote subscribe addresses (`REAL`, `ACTION=SUBSCRIBE`) - optional web override of the VT input field, last writer wins

- **ID_ZERO_WRITE**, **ID_SPAN_WRITE** (WSTRING): Publish addresses (REAL, ACTION=PUBLISH), subscribed remotely by the sensor station (counterpart of its ID_ZERO_READ/ID_SPAN_READ)

Data Outputs

- **QO** (BOOL): quality output, AND of the QO outputs of all eight instances (via AND_QO, AND_BOOL_8)

Adapters

- **CAL_OUT** (plug, adapter::types::unidirectional::AR): Read-only mirror of the calibrated value (ValueDisplay.VALUE_OUT) for further local consumers on this station, instead of its own OPC-UA self-subscribe

Function Blocks (FBs) Used

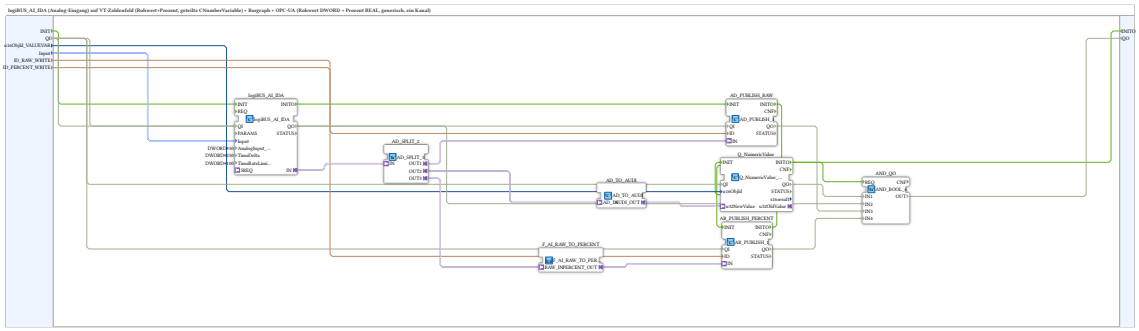
- **ValueDisplay**: SubApp MyLib::sys::AR_M2M_Subscribe_TO_Q_Publish_OPC - calibrated value
- **RawDisplay**, **MinRawDisplay**, **MaxRawDisplay**: same SubApp for the raw value and the raw values of the calibration points
- **TriggerCO**, **TriggerCS**: SubApp MyLib::sys::Button_CLIENT_Method_IE (InputEvent=BT_PRESSED_LATCHED)
- **ZeroRef**, **SpanRef**: SubApp MyLib::sys::NumericValue_TO_AR2_OPC - reference value input fields
- **AND_QO**: iec61131::booleanOperators::AND_BOOL_8 - combines the eight QO outputs into the SubApp output QO

Program Flow and Connections

- ID_CAL_M2M_READ, stObjCal, ID_WRITE → ValueDisplay; ValueDisplay.VALUE_OUT → CAL_OUT
- u16ObjId_CO/ID_CO_CALL → TriggerCO; u16ObjId_CS/ID_CS_CALL → TriggerCS
- ID_RAW_M2M_READ, stObjRaw, ID_RAW_WRITE → RawDisplay
- ID_MINRAW_M2M_READ, stObjMinRaw, ID_MINRAW_WRITE → MinRawDisplay
- ID_MAXRAW_M2M_READ, stObjMaxRaw, ID_MAXRAW_WRITE → MaxRawDisplay
- stObjZero, ID_ZERO_READ, ID_ZERO_WRITE → ZeroRef
- stObjSpan, ID_SPAN_READ, ID_SPAN_WRITE → SpanRef
- Initialization: INIT → ValueDisplay.INIT → TriggerCO.INIT → TriggerCS.INIT → RawDisplay.INIT → MinRawDisplay.INIT → MaxRawDisplay.INIT → ZeroRef.INIT → SpanRef.INIT (each via INITO); SpanRef.INITO → INITO and → AND_QO.REQ
- Quality: QI → .QI of the eight instances; ValueDisplay.QO → AND_QO.IN1, TriggerCO.QO → IN2, TriggerCS.QO → IN3, RawDisplay.QO → IN4, MinRawDisplay.QO → IN5, MaxRawDisplay.QO → IN6, ZeroRef.QO → IN7, SpanRef.QO → IN8; AND_QO.OUT → QO

Technical Details

- The button + CLIENT_0 call formerly occurred twice identically here (CO and CS) and was factored out into Button_CLIENT_Method_IE.
- The calibration itself runs on the sensor station; this block contains no calibration logic.

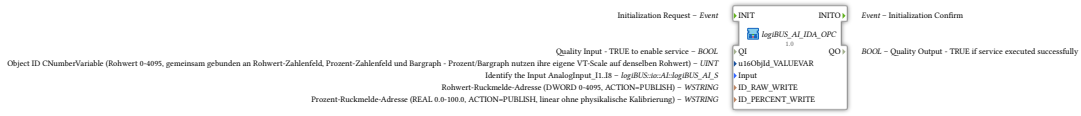


Application Scenarios

- VT station that displays calibrated sensor values of another station and triggers its calibration via key (e.g. filling belt angle, pressure)

Summary

logiBUS_AI_Calibrated_Subscribe_VT_OPC shows remotely calibrated values and raw values on the VT and forwards the calibration keys to the sensor station via OPC-UA method call.



logiBUS_AI_IDA_OPC

• – ○ • – ○ • – ○ •

Introduction

`logiBUS_AI_IDA_OPC` connects a physical analog input (`logiBUS_AI_IDA`, raw value 0-4095, see logiBUS_AI hardware documentation) simultaneously to a VT numeric field (raw value), a second VT numeric field/bargraph (percent), and OPC-UA: the raw value (DWORD) and a linearly converted percent value (REAL) are both published separately via OPC-UA. The percent conversion is done via `F_AI_RAW_TO_PERCENT_AD`.

Function Blocks Used

Sub-blocks: logiBUS_AI_IDA_OPC

- **Type**: SubAppType
- **Internal FBs used**:
  - **logiBUS_AI_IDA**: `logiBUS::io::AI::logiBUS_AI_IDA` — physical analog input, raw value 0-4095 (12-bit), `AnalogInput_hysteresis=DWORD#0`, `TimeDelta=DWORD#250`, `TimeRateLimit=DWORD#100`, `QI` comes from the input `QI`.
  - **AD_SPLIT_2** (type `AD_SPLIT_3`): `adapter::events::unidirectional::AD_SPLIT_3` — splits the DWORD adapter value into three independent outputs (`OUT1..OUT3`).
  - **AD_PUBLISH_RAW** (type `AD_PUBLISH_1`): `adapter::net::AD_PUBLISH_1` — publishes the raw value (DWORD) via OPC-UA, target address `ID_RAW_WRITE`, `QI` comes from the input `QI`.
  - **Q_NumericValue** (type `Q_NumericValue_AUDI`): `isobus::UT::Q::Q_NumericValue_AUDI` — writes the raw value into the VT numeric field `u16ObjId_VALUEVAR`.
  - **F_AI_RAW_TO_PERCENT** (SubApp, type `F_AI_RAW_TO_PERCENT_AD`): `MyLib::sys::F_AI_RAW_TO_PERCENT_AD` — linearly converts the raw value to percent (see F_AI_RAW_TO_PERCENT / F_AI_RAW_TO_PERCENT_AD).
  - **AR_PUBLISH_PERCENT** (type `AR_PUBLISH_1`): `adapter::net::AR_PUBLISH_1` — publishes the percent value (REAL) via OPC-UA, target address `ID_PERCENT_WRITE`, `QI` comes from the input `QI`.
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_4` — combines the `QO` outputs of `Q_NumericValue`, `logiBUS_AI_IDA`, `AD_PUBLISH_RAW` and `AR_PUBLISH_PERCENT` into the output `QO`.
  - **AD_TO_AUDI**: `adapter::conversion::unidirectional::AD_TO_AUDI` — converts the DWORD raw value to UDINT for the VT numeric field.
- **Operation**: The raw value is split three ways via `AD_SPLIT_2`: one branch goes directly to the raw-value OPC-UA publication, a second via `AD_TO_AUDI` to the VT raw-value numeric field, and a third via `F_AI_RAW_TO_PERCENT_AD` for percent conversion followed by OPC-UA publication.

Program Flow and Connections

1. `Input` ⟶ `logiBUS_AI_IDA.Input`; `u16ObjId_VALUEVAR` ⟶ `Q_NumericValue.u16ObjId`; `ID_RAW_WRITE` ⟶ `AD_PUBLISH_RAW.ID`; `ID_PERCENT_WRITE` ⟶ `AR_PUBLISH_PERCENT.ID`.
2. `logiBUS_AI_IDA.IN` (adapter) ⟶ `AD_SPLIT_2.IN` (adapter).
3. `AD_SPLIT_2.OUT1` ⟶ `AD_PUBLISH_RAW.IN` (raw-value OPC-UA branch).

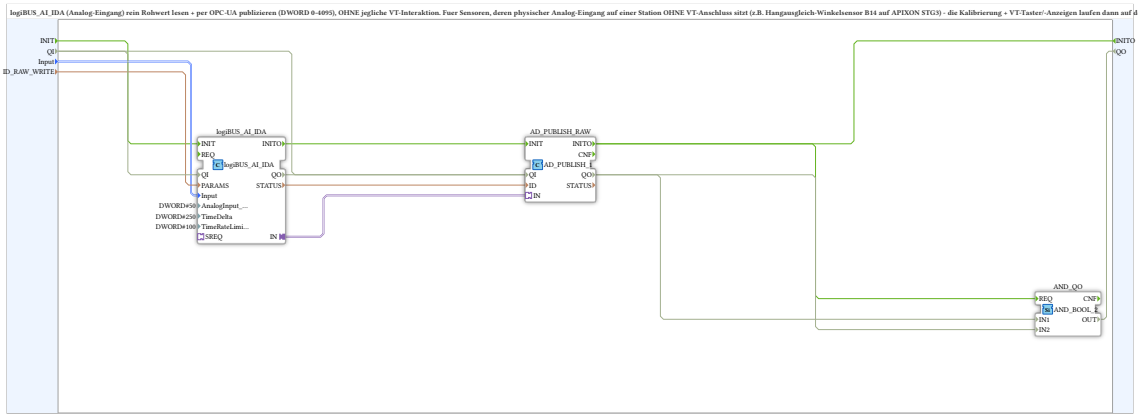
4. `AD_SPLIT_2.OUT2` ⟶ `AD_TO_AUDI.AD_IN`; `AD_TO_AUDI.AUDI_OUT` ⟶ `Q_NumericValue.u32NewValue` (VT raw-value branch).
5. `AD_SPLIT_2.OUT3` ⟶ `F_AI_RAW_TO_PERCENT.RAW_IN`; `F_AI_RAW_TO_PERCENT.PERCENT_OUT` ⟶ `AR_PUBLISH_PERCENT.IN` (percent OPC-UA branch).
6. `QI` (`BOOL`, default `TRUE`) ⟶ `Q_NumericValue.QI`, `logiBUS_AI_IDA.QI`, `AD_PUBLISH_RAW.QI` and `AR_PUBLISH_PERCENT.QI`; their `QO` outputs ⟶ `AND_QO.IN1` (`Q_NumericValue`), `IN2` (`logiBUS_AI_IDA`), `IN3` (`AD_PUBLISH_RAW`), `IN4` (`AR_PUBLISH_PERCENT`); `AND_QO.OUT` ⟶ `QO` (`BOOL`, Quality Output - `TRUE` if all four services succeeded).
7. Initialization chain (event input `INIT` / event output `INITO`, both `EInit`): `INIT` ⟶ `logiBUS_AI_IDA.INIT` ⟶ `AD_PUBLISH_RAW.INIT` ⟶ `AR_PUBLISH_PERCENT.INIT` ⟶ `Q_NumericValue.INIT` (each `INITO` ⟶ next `INIT`); `Q_NumericValue.INITO` ⟶ `INITO` and `AND_QO.REQ`.

Technical Details

- Raw value range 0-4095 (12-bit) — see the verified AI hardware documentation for details.
- The percent conversion is purely linear and uncalibrated (no physical scaling), as explicitly noted in the SubApp definition's comment.
- Three independent consumers (two VT displays + two OPC-UA publications) run in parallel from the same `AD_SPLIT_3` branch, so all values reflect the same acquisition cycle synchronously.

Application Scenarios

- An analog process value (e.g. level, pressure) that should be shown locally on the VT (raw and percent) and also read by an upstream SCADA system via OPC-UA in both representations (raw and percent).



Summary

Full VT and OPC-UA integration of a physical analog input with parallel raw-value and percent representations, built from standard adapter blocks and the reusable percent conversion.

logiBUS_AI_Raw_Publish_OPC

• – ○ • – ○ • – ○ •

Introduction

`logiBUS_AI_Raw_Publish_OPC` reads an analog input (`logiBUS_AI_IDA`) as a raw value (DWORD, 0-4095) and publishes it via OPC-UA, **without any VT interaction**. It is intended for sensors whose physical analog input sits on a station without a VT connection (e.g. slope compensation angle sensor B14 on APIXON STG3). Calibration as well as VT buttons and displays then run on the station with a VT connection and are fed by remote subscribe of this raw value (see `logiBUS_AI_Calibrate_3P_Remote_IDA_OPC`).

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; goes to `logiBUS_AI_IDA.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirm; comes from `AD_PUBLISH_RAW.INITO`

Data Inputs

- **QI** (BOOL): quality input - TRUE enables the service (default `TRUE`); goes to `logiBUS_AI_IDA.QI` and `AD_PUBLISH_RAW.QI`
- **Input** (`logiBUS::io::AI::logiBUS_AI_S`): selection of the analog input `AnalogInput_I1..I8` (default `logiBUS_AI::Invalid`)
- **ID_RAW_WRITE** (WSTRING): publish address of the raw value (DWORD 0-4095, `ACTION=PUBLISH`), local on this station

Data Outputs

- **QO** (BOOL): quality output - TRUE if the service was executed successfully (AND of `logiBUS_AI_IDA.QO` and `AD_PUBLISH_RAW.QO`)

Adapters

No adapters are used.

Functionality

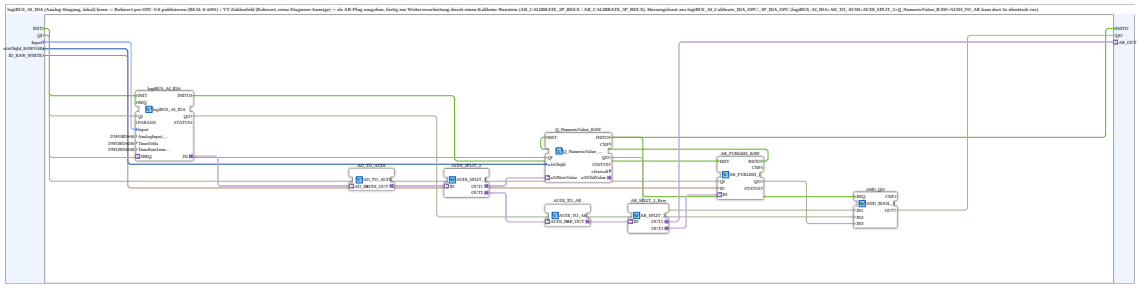
The network consists of three blocks (two function blocks plus the combination `AND_QO`):

- `logiBUS_AI_IDA` (`logiBUS::io::AI::logiBUS_AI_IDA`, `QI` from outside): reads the selected analog input (`Input` ⟶ `logiBUS_AI_IDA.Input`). Parameterised are `AnalogInput_hysteresis = DWORD#50`, `TimeDelta = DWORD#250` and `TimeRateLimit = DWORD#100`.
- `AD_PUBLISH_RAW` (`adapter::net::AD_PUBLISH_1`, `QI` from outside): `logiBUS_AI_IDA.IN` ⟶ `AD_PUBLISH_RAW.IN`; publishes the raw value to the address `ID_RAW_WRITE` (`ID_RAW_WRITE` ⟶ `AD_PUBLISH_RAW.ID`).
- `AND_QO` (`iec61131::booleanOperators::AND_BOOL_2`): combines `logiBUS_AI_IDA.QO` (`IN1`) and `AD_PUBLISH_RAW.QO` (`IN2`) into the output `QO`; `REQ` comes from `AD_PUBLISH_RAW.INITO`.

Initialization: `INIT` ⟶ `logiBUS_AI_IDA.INIT`, `logiBUS_AI_IDA.INITO` ⟶ `AD_PUBLISH_RAW.INIT`, `AD_PUBLISH_RAW.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`).

Technical Details

- Raw value half of `logiBUS_AI_Calibrate_3P_IDA_OPC`: calibration does not take place here but on the station with a VT connection
- No further ports apart from `INIT`/`INITO`, `QI`/`QO` and the two input variables `Input` and `ID_RAW_WRITE`; no adapters
- The behaviour of the raw value input (hysteresis, `TimeDelta`, `TimeRateLimit`) is set through the parameters of `logiBUS_AI_IDA`

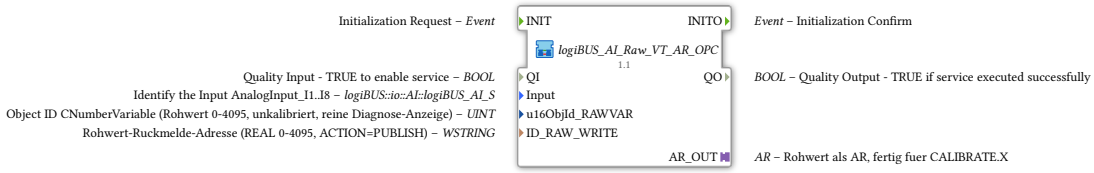


Application Scenarios

- Sensors on stations without a VT connection whose calibration and display run on another station

Conclusion

`logiBUS_AI_Raw_Publish_OPC` provides the raw value of an analog input via OPC-UA and is thus the sensor side of a cross-station calibration.



logiBUS_AI_Raw_VT_AR_OPC

• – ○ • – ○ • – ○ •

Introduction

`logiBUS_AI_Raw_VT_AR_OPC` reads a local logiBUS analog input (`logiBUS_AI_IDA`), publishes the raw value via OPC-UA (`REAL`, 0..4095) and shows it in a VT number field (raw value, pure diagnostic display). In addition it is output as an `AR` plug, ready for further processing by a calibration block (`AR_CALIBRATE_2P_REF.X` or `AR_CALIBRATE_3P_REF.X`). The block was extracted from `logiBUS_AI_Calibrate_IDA_OPC` and `logiBUS_AI_Calibrate_3P_IDA_OPC`, where the combination `logiBUS_AI_IDA + AD_TO_AUDI + AUDI_SPLIT_2 + Q_NumericValue_RAW + AUDI_TO_AR` occurred twice identically. Related: `logiBUS_AI_Raw_Publish_OPC`.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirmation (from `Q_NumericValue_RAW.INITO`)

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - `TRUE` enables the services (⟶ `Q_NumericValue_RAW.QI`, `logiBUS_AI_IDA.QI` and `AR_PUBLISH_RAW.QI`)
- **Input** (`logiBUS::io::AI::logiBUS_AI_S`): selection of the input `AnalogInput_I1..I8` (default `logiBUS_AI::Invalid`)
- **u16ObjId_RAWVAR** (`UINT`): object ID of the `CNumberVariable` (raw value 0..4095, uncalibrated, pure diagnostic display)
- **ID_RAW_WRITE** (`WSTRING`): raw value feedback address (`REAL` 0..4095, `ACTION=PUBLISH`)

Data Outputs

- **QO** (`BOOL`): Quality Output - `TRUE` if all services succeeded (AND of `Q_NumericValue_RAW.QO`, `logiBUS_AI_IDA.QO` and `AR_PUBLISH_RAW.QO`)

Adapters

- **AR_OUT** (plug, `adapter::types::unidirectional::AR`): raw value as `AR`, ready for `CALIBRATE.X`

Function Blocks (FBs) Used

- **`logiBUS_AI_IDA`** (`logiBUS::io::AI::logiBUS_AI_IDA`): parameters `AnalogInput_hysteresis = DWORD#50`, `TimeDelta = DWORD#250`, `TimeRateLimit = DWORD#100`
- **`AD_TO_AUDI`** (`adapter::conversion::unidirectional::AD_TO_AUDI`)
- **`AUDI_SPLIT_2`** (`adapter::events::unidirectional::AUDI_SPLIT_2`)
- **`Q_NumericValue_RAW`** (`isobus::UT::Q::Q_NumericValue_AUDI`): VT raw value display
- **`AUDI_TO_AR`** (`adapter::conversion::unidirectional::AUDI_TO_AR`)

- **AR_SPLIT_2_Raw** (adapter::events::unidirectional::AR_SPLIT_2)
- **AR_PUBLISH_RAW** (adapter::net::AR_PUBLISH_1): OPC-UA publish
- **AND_QO** (iec61131::booleanOperators::AND_BOOL_3): combines the QO outputs of Q_NumericValue_RAW, logiBUS_AI_IDA and AR_PUBLISH_RAW

Functionality

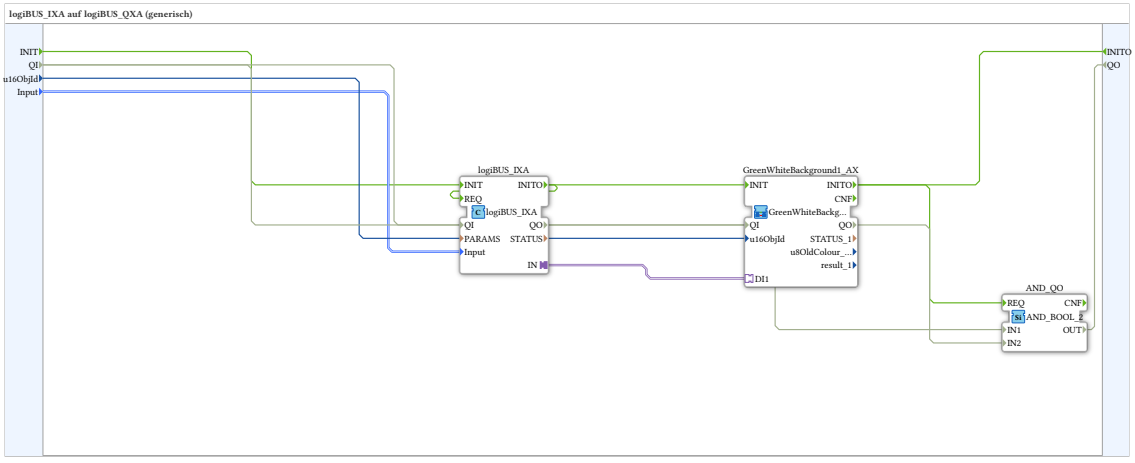
- Input ⟶ logiBUS_AI_IDA.Input
- logiBUS_AI_IDA.IN ⟶ AD_TO_AUDI.AD_IN ⟶ AUDI_SPLIT_2.IN
- AUDI_SPLIT_2.OUT1 ⟶ Q_NumericValue_RAW.u32NewValue (VT display); u16ObjId_RAWVAR ⟶ Q_NumericValue_RAW.u16ObjId
- INIT ⟶ logiBUS_AI_IDA.INIT; logiBUS_AI_IDA.INITO ⟶ AR_PUBLISH_RAW.INIT; AR_PUBLISH_RAW.INITO ⟶ Q_NumericValue_RAW.INIT; Q_NumericValue_RAW.INITO ⟶ INITO (and ⟶ AND_QO.REQ)
- QI ⟶ Q_NumericValue_RAW.QI, logiBUS_AI_IDA.QI and AR_PUBLISH_RAW.QI
- Q_NumericValue_RAW.QO ⟶ AND_QO.IN1; logiBUS_AI_IDA.QO ⟶ AND_QO.IN2; AR_PUBLISH_RAW.QO ⟶ AND_QO.IN3; AND_QO.OUT ⟶ QO
- AUDI_SPLIT_2.OUT2 ⟶ AUDI_TO_AR.AUDI_IN ⟶ AR_SPLIT_2_Raw.IN
- AR_SPLIT_2_Raw.OUT1 ⟶ AR_OUT
- AR_SPLIT_2_Raw.OUT2 ⟶ AR_PUBLISH_RAW.IN; ID_RAW_WRITE ⟶ AR_PUBLISH_RAW.ID

Technical Details

- The raw value is uncalibrated (0..4095); calibration takes place in the downstream block
- Two splitters (AUDI_SPLIT_2, AR_SPLIT_2_Raw), since an adapter must not branch to several targets
- Input parameters of logiBUS_AI_IDA: hysteresis 50, TimeDelta 250, TimeRateLimit 100

Application Scenarios

- Showing the raw value of an analog input, publishing it via OPC-UA and feeding it to a calibration block



Summary

logiBUS_AI_Raw_VT_AR_OPC delivers the analog raw value simultaneously to the VT, OPC-UA and an AR output.

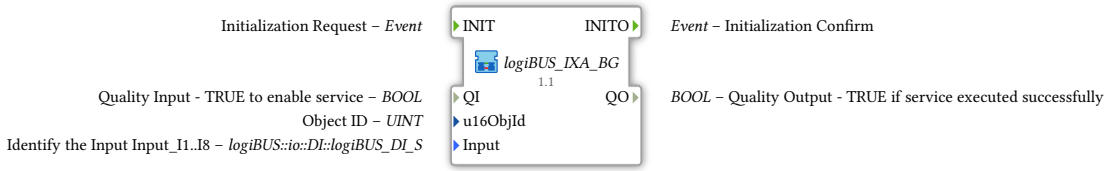
logiBUS_IXA_BG



• – ○ • – ○ • – ○ •

Introduction

logiBUS_IXA_BG connects a physical digital input (logiBUS_IXA) to a VT status indication via the background-color family GreenWhiteBackground1_AX (see Background Color Blocks (shared pattern)) –

the current state of the input is made visible on the VT as a green/white background, with no OPC-UA connection. For the variant with additional OPC-UA feedback, see `logiBUS_IXA_BG_OPC`.

Function Blocks Used

Sub-blocks: logiBUS_IXA_BG

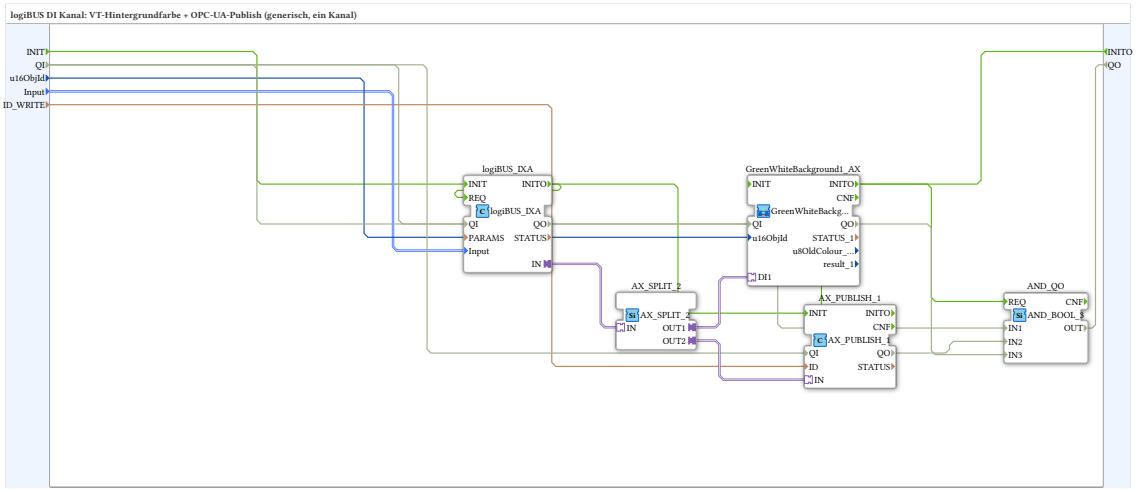
- **Type**: SubAppType
- **Interface (additional)**: event input `INIT`, event output `INITO` (each `EInit`), data input `QI` (`BOOL`, default `TRUE`), data output `QO` (`BOOL`).
- **Internal FBs used**:
  - **logiBUS_IXA**: `logiBUS::io::DI::logiBUS_IXA` — physical digital input, adapter output `IN`; `QI` comes from the subapp input `QI`.
  - **GreenWhiteBackground1_AX** (SubApp): `MyLib::sys::GreenWhiteBackground1_AX` — single-object background-color block from the Background Color family, drives the VT object background color from `DI1`.
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` — combines the `QO` outputs of `logiBUS_IXA` and `GreenWhiteBackground1_AX` into `QO`.
- **Operation**: The physical input's adapter output is wired directly to the `DI1` adapter input of the background-color block, which handles the color switch of a VT object.

Program Flow and Connections

1. `Input` ⟶ `logiBUS_IXA.Input`; `u16ObjId` ⟶ `GreenWhiteBackground1_AX.u16ObjId`.
2. `logiBUS_IXA.IN` (adapter) ⟶ `GreenWhiteBackground1_AX.DI1` (adapter).
3. Initialization: `INIT` ⟶ `logiBUS_IXA.INIT`; `logiBUS_IXA.INITO` ⟶ `GreenWhiteBackground1_AX.INIT`; `GreenWhiteBackground1_AX.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`.
4. Quality: `QI` ⟶ `logiBUS_IXA.QI` and `GreenWhiteBackground1_AX.QI`; `logiBUS_IXA.QO` ⟶ `AND_QO.IN1`, `GreenWhiteBackground1_AX.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.

Application Scenarios

- Purely visual status indication of a physical digital input on the VT (e.g. limit switch state), where the value does not need to be reported externally via OPC-UA.

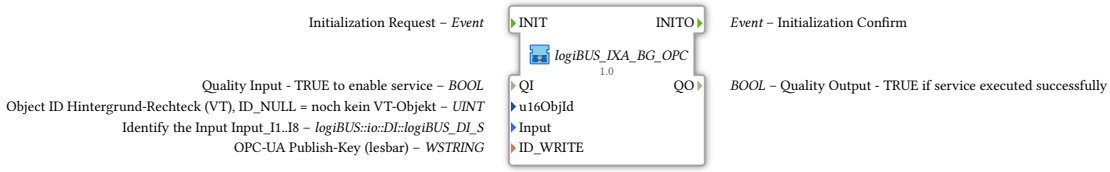


Summary

Combines a physical digital input with the standard background-color family into a simple VT status indication.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



logiBUS_IXA_BG_OPC

• – ○ • – ○ • – ○ •

Introduction

`logiBUS_IXA_BG_OPC` is the reusable block for **a single digital input** with VT status display (background color) and OPC-UA publish. It is instantiated 8 times with different parameters in `InputOutputTesterButton_DIDO_OPC_UA` and is reused unchanged for the 8 inputs in the PWM example `InputOutputTesterButton_PWM_OPC_UA`.

Interface

- **Event input**: `INIT` (`EInit`, Initialization Request)
- **Event output**: `INITO` (`EInit`, Initialization Confirm)
- **Data inputs**: `QI` (`BOOL`, default `TRUE`, Quality Input), `u16ObjId`, `Input`, `ID_WRITE`
- **Data output**: `QO` (`BOOL`, Quality Output)

Function Blocks (FBs) Used

Sub-blocks: logiBUS_IXA_BG_OPC

- **Type**: SubAppType
- **Internal FBs used**:
  - **logiBUS_IXA**: `logiBUS::io::DI::logiBUS_IXA` — adapter-based digital input; `QI` from the block input, `Input` identifies `Input_I1..I8`.
  - **AX_SPLIT_2**: `adapter::events::unidirectional::AX_SPLIT_2` — splits the single adapter signal from `logiBUS_IXA.IN` into two independent destinations.
  - **GreenWhiteBackground1_AX** (SubApp, `MyLib::sys`): sets the VT background color (green/white) to match the input state.
  - **AX_PUBLISH_1**: `adapter::net::AX_PUBLISH_1` — OPC-UA publish adapter, `QI` from the block input.
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_3` — ANDs the `QO` outputs of `logiBUS_IXA`, `AX_PUBLISH_1` and `GreenWhiteBackground1_AX` into the block output `QO`.
- **Functionality**: Purely one-way data flow from the physical input to two display/reporting paths — no write-back possible, since a digital input cannot be set externally.

Program Flow and Connections

1. `Input` (parameter, identifies `Input_I1..I8`) ⟶ `logiBUS_IXA.Input` (data connection, hidden).
2. `u16ObjId` (VT object ID of the status display) ⟶ `GreenWhiteBackground1_AX.u16ObjId`.

3. `ID_WRITE` (OPC-UA address) ⟶ `AX_PUBLISH_1.ID`.
4. **Adapter chain**: `logiBUS_IXA.IN` ⟶ `AX_SPLIT_2.IN` ⟶ `AX_SPLIT_2.OUT1` ⟶ `GreenWhiteBackground1_AX.DI1` (VT display) and `AX_SPLIT_2.OUT2` ⟶ `AX_PUBLISH_1.IN` (OPC-UA publish).
5. **Initialization chain**: `INIT` ⟶ `logiBUS_IXA.INIT`, `logiBUS_IXA.INITO` ⟶ `AX_PUBLISH_1.INIT`, `AX_PUBLISH_1.INITO` ⟶ `GreenWhiteBackground1_AX.INIT`, `GreenWhiteBackground1_AX.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`.
6. `QI` ⟶ `logiBUS_IXA.QI`, `AX_PUBLISH_1.QI` and `GreenWhiteBackground1_AX.QI`.
7. `logiBUS_IXA.QO` ⟶ `AND_QO.IN1`, `AX_PUBLISH_1.QO` ⟶ `AND_QO.IN2`, `GreenWhiteBackground1_AX.QO` ⟶ `AND_QO.IN3`; `AND_QO.OUT` ⟶ `QO`.

Technical Details

- **AX_SPLIT_2 instead of two data connections**: since an adapter output can only be connected directly to one place, `AX_SPLIT_2` splits the signal for the VT display and the OPC-UA publish.
- **Unidirectional**: unlike its output counterpart `Button_IXA_TO_logiBUS_QXA_BG_OPC`, there is no `AX_SUBSCRIBE_1` here — an input is never written from the web.

Application Scenarios

- Any exercise with digital inputs that should be visible both on the VT (status color) and via OPC-UA (web client).

Summary

`logiBUS_IXA_BG_OPC` encapsulates the standard combination “digital input + VT status color + OPC-UA publish” in a single, repeatedly reusable block.

logiBUS_IXA_BG_OPC_AX

• – ○ • – ○ • – ○ •

Introduction

`logiBUS_IXA_BG_OPC_AX` is a generic block for **one logiBUS DI channel** with VT background colour and OPC-UA publish. Compared with `logiBUS_IXA_BG_OPC`, it additionally passes the input state on as the `AX` plug `OUT`, so that other blocks can use the level.

Function Blocks (FBs) Used

Sub-blocks: logiBUS_IXA_BG_OPC_AX

- **Type**: SubAppType
- **Internal blocks used**:
  - **logiBUS_IXA**: `logiBUS::io::DI::logiBUS_IXA` - digital input; `Input` identifies `Input_I1..I8`
  - **AX_SPLIT_2_UNGATED**: `adapter::events::unidirectional::AX_SPLIT_2_UNGATED` - branches the input state into the plug `OUT` and into the second branch
  - **AX_SPLIT_2**: `adapter::events::unidirectional::AX_SPLIT_2` - branches the second branch into VT display and publish
  - **GreenWhiteBackground1_AX**: SubApp `MyLib::sys::GreenWhiteBackground1_AX` - sets the background colour (green/white)
  - **AX_PUBLISH_1**: `adapter::net::AX_PUBLISH_1` - OPC-UA publish
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_3` - combines the `QO` outputs of `logiBUS_IXA`, `AX_PUBLISH_1` and `GreenWhiteBackground1_AX` into the SubApp output `QO`
- **Imports**: `ID_NULL`, `logiBUS_DI`, `logiBUS_DI_S`

Interface Structure

Event Inputs / Event Outputs

- **INIT** (`EInit`, input): initialization request; passed on to `logiBUS_IXA.INIT`
- **INITO** (`EInit`, output): initialization confirmation; comes from `GreenWhiteBackground1_AX.INITO`

The runtime events still travel via the adapter.

Data Inputs

- **QI** (`BOOL`, default `TRUE`): quality input, service enable; passed on to `logiBUS_IXA`, `AX_PUBLISH_1` and `GreenWhiteBackground1_AX`
- **u16ObjId** (`UINT`, default `ID_NULL`): Object ID of the background rectangle (VT); `ID_NULL` = no VT object yet
- **Input** (`logiBUS::io::DI::logiBUS_DI_S`, default `logiBUS_DI::Invalid`): Identifies the input `Input_I1..I8`
- **ID_WRITE** (`WSTRING`): OPC-UA publish key (readable)

Data Outputs

- **QO** (`BOOL`): quality output, `AND` of the `QO` outputs of `logiBUS_IXA`, `AX_PUBLISH_1` and `GreenWhiteBackground1_AX` (via `AND_QO`)

Adapters

- **OUT** (plug): `adapter::types::unidirectional::AX` - input state as a level

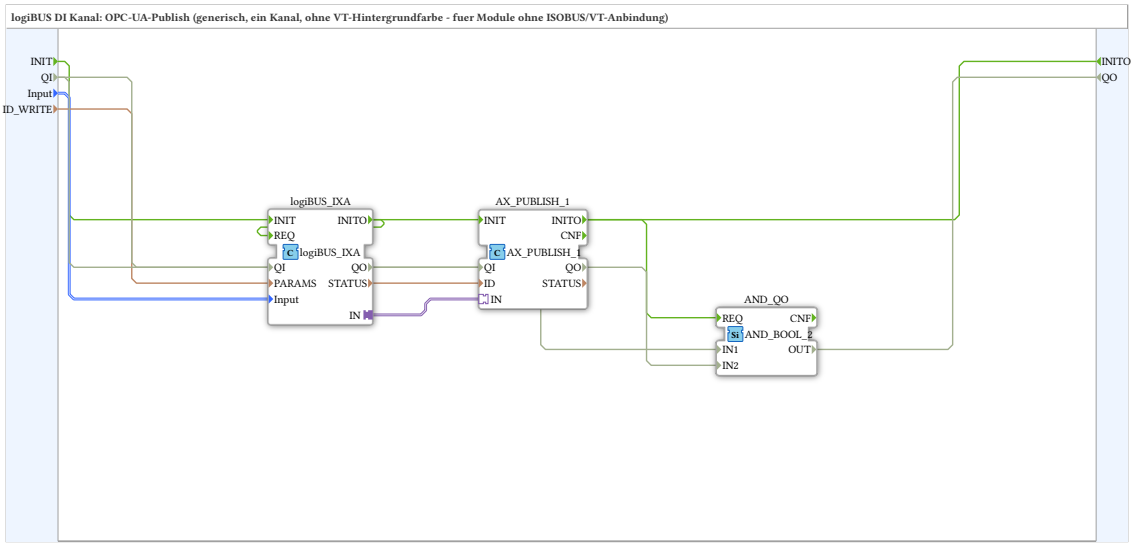
Program Flow and Connections

- `Input` ⟶ `logiBUS_IXA.Input`; `logiBUS_IXA.INITO` ⟶ `logiBUS_IXA.REQ` (first read after initialisation)
- `logiBUS_IXA.IN` ⟶ `AX_SPLIT_2_UNGATED.IN`
- `AX_SPLIT_2_UNGATED.OUT1` ⟶ `OUT`
- `AX_SPLIT_2_UNGATED.OUT2` ⟶ `AX_SPLIT_2.IN`
- `AX_SPLIT_2.OUT1` ⟶ `GreenWhiteBackground1_AX.DI1`; `u16ObjId` ⟶ `GreenWhiteBackground1_AX.u16ObjId`
- `AX_SPLIT_2.OUT2` ⟶ `AX_PUBLISH_1.IN`; `ID_WRITE` ⟶ `AX_PUBLISH_1.ID`
- Initialization: `INIT` ⟶ `logiBUS_IXA.INIT`; `logiBUS_IXA.INITO` ⟶ `AX_PUBLISH_1.INIT` (in addition to `logiBUS_IXA.INITO` ⟶ `logiBUS_IXA.REQ`); `AX_PUBLISH_1.INITO` ⟶ `GreenWhiteBackground1_AX.INIT`; `GreenWhiteBackground1_AX.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`

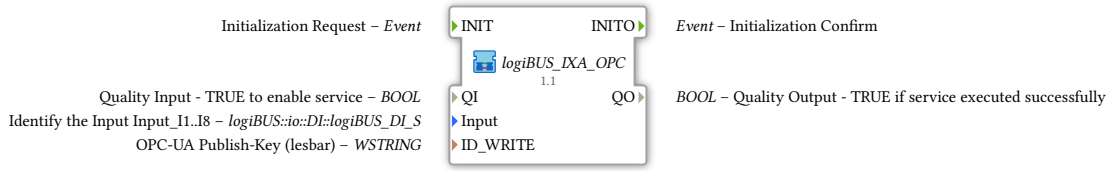
- Quality: `QI` ⟶ `logiBUS_IXA.QI`, `AX_PUBLISH_1.QI` and `GreenWhiteBackground1_AX.QI`; their `QO` outputs ⟶ `AND_QO.IN1` (`logiBUS_IXA`), `IN2` (`AX_PUBLISH_1`), `IN3` (`GreenWhiteBackground1_AX`); `AND_QO.OUT` ⟶ `QO`

Technical Details

- Two splitters in series, because an adapter plug can be connected to only one destination and three destinations (`OUT`, VT display, publish) are served here
- One-way data flow: a digital input is not written from outside
- Version 1.0 (2023-10-23)



Application Scenarios



- Digital input with VT status colour and OPC-UA publish whose state should additionally be used by other blocks

Summary

`logiBUS_IXA_BG_OPC_AX` extends `logiBUS_IXA_BG_OPC` with a passed-through `AX` output `OUT` for the input state.

logiBUS_IXA_OPC

• – ○ • – ○ • – ○ •

Introduction

The logiBUS_IXA_OPC subapplication provides a generic single-channel logiBUS digital input (DI) monitoring solution with built-in OPC-UA publish capability. It is designed for modules that do not require ISOBUS/VT integration, as it omits VT background color handling. The subapp combines the logiBUS_IXA function block for digital input processing with the AX_PUBLISH_1 adapter for publishing input states to an OPC-UA server.

Interface Structure

The subapplication exposes the events `INIT`/`INITO`, the data `QI`/`QO` and two further data inputs. All data processing and publishing logic is encapsulated internally within the subapp network.

Event Inputs

- **INIT** (`EInit`): initialization request; starts the init chain at `logiBUS_IXA.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `AX_PUBLISH_1.INITO`, the end of the init chain

Data Inputs

Name	Type	Initial Value	Comment
QI	BOOL	TRUE	Quality input; passed on to `logiBUS_IXA.QI` and `AX_PUBLISH_1.QI`
Input	logiBUS::io::DI::logiBUS_DI_S	logiBUS_DI::Invalid	Identifies the logiBUS digital input channel (Input_I1..I8)
ID_WRITE	WSTRING	—	OPC-UA publish key (readable)

Data Outputs

- **QO** (BOOL): quality output, AND combination (`AND_QO`, `AND_BOOL_2`) of `logiBUS_IXA.QO` and `AX_PUBLISH_1.QO`.

The digital input state itself is published externally via the OPC-UA mechanism rather than through output variables.

Adapters

No adapters are exposed on the subapplication interface. Internally, the adapter connection between logiBUS_IXA.IN and AX_PUBLISH_1.IN transfers the processed digital input data to the publisher adapter.

Functionality

The subapplication accepts a selected logiBUS digital input channel (specified via the Input variable of type logiBUS_DI_S, allowing selection from Input_I1 through Input_I8) and routes it to the internal logiBUS_IXA function block. This block processes the raw digital input data. The processed result is then passed via an internal adapter connection to the AX_PUBLISH_1 adapter, which publishes the data to an OPC-UA server. The ID_WRITE parameter supplies a readable publish key used by the OPC-UA publisher to identify the published data item.

Initialization and quality: `INIT` ⟶ `logiBUS_IXA.INIT`, `logiBUS_IXA.INITO` ⟶ `AX_PUBLISH_1.INIT`, `AX_PUBLISH_1.INITO` ⟶ `INITO` and `AND_QO.REQ`. `QI` is passed on to `logiBUS_IXA.QI` and `AX_PUBLISH_1.QI`; `logiBUS_IXA.QO` ⟶ `AND_QO.IN1`, `AX_PUBLISH_1.QO` ⟶ `AND_QO.IN2` (`iec61131::booleanOperators::AND_BOOL_2`), `AND_QO.OUT` ⟶ `QO`.

Technical Features

- Single-channel logiBUS digital input handling with support for Input_I1 to Input_I8.
- OPC-UA publish functionality through the internal AX_PUBLISH_1 adapter.
- Generic design for modules without ISOBUS/VT connectivity (no VT background color handling).
- Configurable OPC-UA publish key via the WSTRING ID_WRITE parameter.
- Initial input state set to logiBUS_DI::Invalid, ensuring undefined states are explicitly handled.
- The internal enable signals (QI) of the logiBUS_IXA and AX_PUBLISH_1 blocks come from the block input `QI` (initial value TRUE).

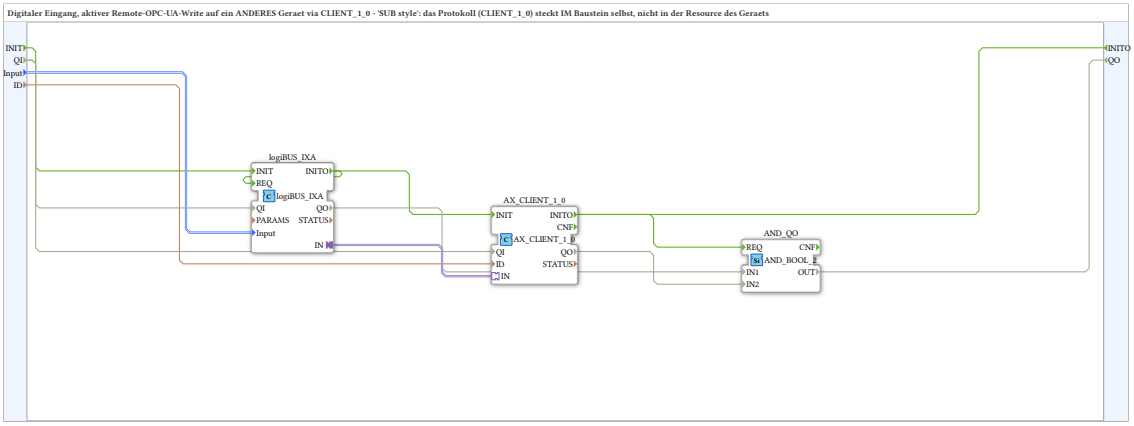
State Overview

The subapplication does not define explicit state machines of its own. Its behavior is determined by the internal logiBUS_IXA function block, which manages the digital input processing states. The initial state of the Input variable is logiBUS_DI::Invalid, representing an undefined or unselected input channel until a valid channel is configured.

Application Scenarios

- Industrial automation environments where logiBUS digital input states need to be monitored and forwarded to OPC-UA-based SCADA or MES systems.
- Modular systems that lack ISOBUS/VT connectivity but require OPC-UA data publishing for remote supervision.

- Generic single-channel DI monitoring applications where a readable OPC-UA key is needed for data identification.
- Retrofit or extension scenarios where existing logiBUS DI inputs are integrated into OPC-UA-based supervisory layers.

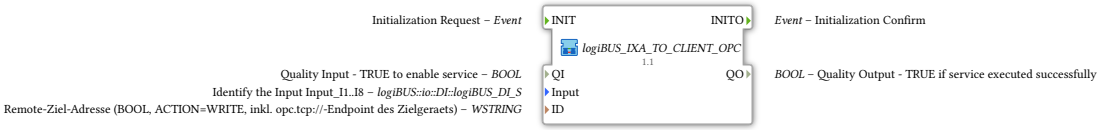


Comparison with Similar Blocks

Compared to other logiBUS DI subapplications, this block distinguishes itself through its OPC-UA publishing focus. While blocks like logiBUS_DI or logiBUS_DI_S provide raw digital input handling, logiBUS_IXA_OPC adds the AX_PUBLISH_1 adapter for direct OPC-UA publication. Unlike subapplications that include ISOBUS/VT integration, this block deliberately omits VT background color handling, making it lighter and more suitable for non-VT modules. It also differs from multi-channel variants by supporting a single channel, simplifying configuration for one-input scenarios.

Conclusion

The logiBUS_IXA_OPC subapplication offers a compact, generic solution for publishing a single logiBUS digital input channel to an OPC-UA server. By combining the logiBUS_IXA processing block with the AX_PUBLISH_1 publisher adapter, it delivers a complete publish path in a single subapp. Its lack of ISOBUS/VT dependencies and its configurable publish key make it well suited for straightforward automation scenarios where OPC-UA connectivity of DI states is required.



logiBUS_IXA_TO_CLIENT_OPC

• – ○ • – ○ • – ○ •

Introduction

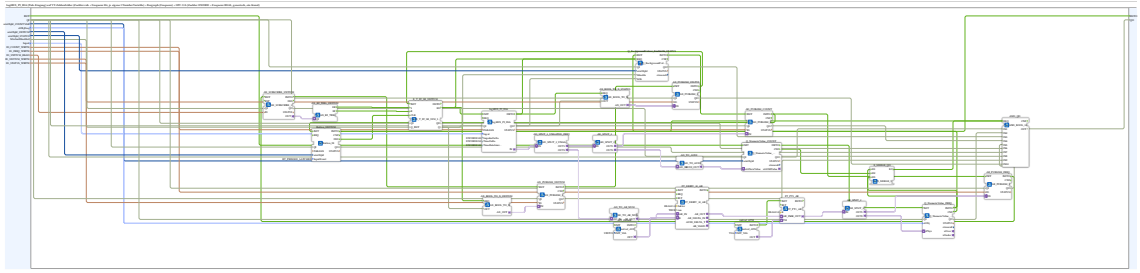
`logiBUS_IXA_TO_CLIENT_OPC` reads a digital input (`logiBUS_IXA`) and actively writes the value to ANOTHER device via OPC-UA using `AX_CLIENT_1_0` - "Krauternter style" (per the source comment): the protocol (`AX_CLIENT_1_0`) lives INSIDE the block itself, not in the device's resource, unlike the "SUB style" of the PC_A/PC_B blocks, where trigger/server instances are wired separately in the composite.

Function blocks used

- **logiBUS_IXA** (`logiBUS::io::DI::logiBUS_IXA`): physical digital input, identified via `Input_I1..I8`.
- **AX_CLIENT_1_0** (`adapter::net::AX_CLIENT_1_0`): actively writes the adapter value to the remote target address `ID` (including the target device's `opc.tcp://` endpoint).

Initialization and quality

The block has the event input `INIT`, the event output `INITO` (both `EInit`), the data input `QI` (`BOOL`, default `TRUE`) and the data output `QO` (`BOOL`). `INIT` ⟶ `logiBUS_IXA.INIT`, `logiBUS_IXA.INITO` ⟶ `AX_CLIENT_1_0.INIT` (and ⟶ `logiBUS_IXA.REQ`), `AX_CLIENT_1_0.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`. `QI` is passed to `logiBUS_IXA` and `AX_CLIENT_1_0`. `QO` is the output of the instance `AND_QO` (`iec61131::booleanOperators::AND_BOOL_2`), which combines `logiBUS_IXA.QO` and `AX_CLIENT_1_0.QO`.



Summary

Single-block bridge from a physical digital input to an active remote write on another device - counterpart to `logiBUS_QXA_FROM_SUBSCRIBE_OPC` on the receiving side.

logiBUS_PI_IDA_OPC

• – ○ • – ○ • – ○ •

Introduction

`logiBUS_PI_IDA_OPC` connects a physical pulse/counter input (`logiBUS_PI_IDA`, one channel) to two independent VT number fields (raw counter value and the frequency in Hz derived from it) and to OPC-UA: the raw counter value (DWORD) is published directly, the frequency is computed by time derivative (`FT_DERIV_10_AR`) from the counter value, smoothed with a PT1 element (`FT_PT1_AR`) and published separately (REAL, physically scaled via `NumericObjectPool_S`). In addition, the channel can be switched on and off (enable) via a VT key or an OPC-UA switch; a status display (background colour) and an OPC-UA status report disabled/active/fault.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirmation (from `Button_SWITCH.INITO`)

Data Inputs

- **QI** (`BOOL`, default `TRUE`): Quality Input - TRUE enables the services
- **u16ObjId_COUNTVAR** (`UINT`, default `ID_NULL`): object ID of the `CNumberVariable` for the raw counter value (ever-increasing, scale=1 in the VT pool)
- **stObjFreq** (`NumericObjectPool_S`): object ID + scale/offset/decimals of the `CNumberVariable` for the frequency in Hz (own, independent variable, no rescaling of the counter)
- **u16ObjId_SWITCH** (`UINT`, default `ID_NULL`): object ID of the channel on/off key on the VT (a key press toggles the enable, via `Button_IE`)
- **u16ObjId_STATUS** (`UINT`, default `ID_NULL`): object ID of the status display (background colour white = channel disabled, green = active and `logiBUS_PI_IDA.QO` TRUE, red = active and `QO` FALSE, fault)
- **bDefaultEnabled** (`BOOL`): channel state at start (TRUE = active, e.g. channels 1-4; FALSE = inactive, e.g. channels 5-8, since only 4 channels are available at the same time)
- **Input** (`logiBUS::io::PI::logiBUS_PI_S`): selection of the input `PulseInput_I1..I8` (default `logiBUS_PI::Invalid`)
- **ID_COUNT_WRITE** (`WSTRING`): counter feedback address (DWORD, raw, `ACTION=PUBLISH`)

- **ID_FREQ_WRITE** (WSTRING): frequency feedback address (REAL Hz, ACTION=PUBLISH)
- **ID_SWITCH_READ** (WSTRING): remote switch address (BOOL, ACTION=SUBSCRIBE, toggles the channel enable like a key press)
- **ID_SWITCH_WRITE** (WSTRING): echo feedback address (BOOL, ACTION=PUBLISH, current channel enable state)
- **ID_STATUS_WRITE** (WSTRING): status feedback address (BOOL, ACTION=PUBLISH, read-only, logiBUS_PI_IDA.QO)

Data Outputs

- **QO** (BOOL): Quality Output - TRUE if the services were executed successfully (AND_QO, AND_BOOL_10: AND of Q_NumericValue_COUNT.QO, Q_NumericValue_FREQ.QO, Q_BackgroundColour_EnableOk_STATUS.QO, AD_PUBLISH_COUNT.QO, AR_PUBLISH_FREQ.QO, E_T_FF_SR_SWITCH.QO, Button_SWITCH.QO, AX_SUBSCRIBE_SWITCH.QO, AX_PUBLISH_SWITCH.QO and AX_PUBLISH_STATUS.QO)

Function Blocks Used

Sub-blocks: logiBUS_PI_IDA_OPC

- **Type**: SubAppType
- **Internal FBs used**:
  - **logiBUS_PI_IDA**: logiBUS::io::PI::logiBUS_PI_IDA — physical pulse input, ImpulseDelta=DWORD#100, TimeDelta=DWORD#250, TimeRateLimit=DWORD#100; its QI comes from the channel enable (E_T_FF_SR_SWITCH.Q).
  - **AD_SPLIT_2_UNGATED_FREQ**: adapter::events::unidirectional::AD_SPLIT_2_UNGATED — branches the DWORD counter value into the counter branch and the frequency branch.
  - **AD_SPLIT_2**: adapter::events::unidirectional::AD_SPLIT_2 — branches the counter value to the OPC-UA publish and the VT display.
  - **AD_PUBLISH_COUNT**: adapter::net::AD_PUBLISH_1 — publishes the raw counter value via OPC-UA, target address ID_COUNT_WRITE.
  - **AD_TO_AUDI**: adapter::conversion::unidirectional::AD_TO_AUDI — bit reinterpretation DWORD→UDINT for the VT counter field.
  - **Q_NumericValue_COUNT**: isobus::UT::Q::Q_NumericValue_AUDI — writes the raw counter value to u16ObjId_COUNTVAR.
  - **AD_TO_AR_NUM**: adapter::conversion::unidirectional::AD_TO_AR_NUM — numerically correct conversion DWORD counter value → REAL for the derivative.
  - **FT_DERIV_10_AR**: OSCAT_adapter::Control::FT_DERIV_10_AR (Faktor=1.0, run=TRUE) — time derivative, delivers the rate of change of the counter value = frequency in Hz; the parameter K is an AUI adapter socket fed by LIT_DerivK (adapter::types::unidirectional::AUI::initval::initval_AUI, INIT_VAL=9).
  - **FT_PT1_AR**: OSCAT_adapter::Control::FT_PT1_AR (K=1.0) — PT1 smoothing of the frequency; the time constant TM comes from initval_ATM (adapter::types::unidirectional::ATM::initval::initval_ATM, INIT_VAL=T#2s).
  - **AR_SPLIT_2**: adapter::events::unidirectional::AR_SPLIT_2 — branches the smoothed frequency value to two outputs.
  - **AR_PUBLISH_FREQ**: adapter::net::AR_PUBLISH_1 — publishes the frequency via OPC-UA, target address ID_FREQ_WRITE.
  - **Q_NumericValue_FREQ**: isobus::UT::Q::Q_NumericValue_PHYSA — writes the frequency, physically scaled (stObjFreq: r32Scale, i32Offset, u8Decimals), into the VT number field/bargraph.
  - **Button_SWITCH**: isobus::UT::io::Button::Button_IE (InputEvent=BT_PRESSED_LATCHED) — reads the channel on/off key (u16ObjId_SWITCH).
  - **AX_SUBSCRIBE_SWITCH** / **AX_RF_TRIG_SWITCH**: adapter::net::AX_SUBSCRIBE_1 and adapter::events::unidirectional::AX_RF_TRIG — remote switch (ID_SWITCH_READ) with edge detection (ER → set, EF → reset of the enable flip-flop).
  - **E_T_FF_SR_SWITCH**: iec61499::events::E_T_FF_SR_SYM_INIT — enable flip-flop (Q_INIT = bDefaultEnabled); Button_SWITCH.IND clocks CLK.
  - **AX_BOOL_TO_X_SWITCH** / **AX_PUBLISH_SWITCH**: adapter::conversion::unidirectional::AX_BOOL_TO_X and adapter::net::AX_PUBLISH_1 — publish the enable state (ID_SWITCH_WRITE).

  - **Q_BackgroundColour_EnableOk_STATUS**: SubApp `MyLib::sys::Q_BackgroundColour_EnableOk_A` — status background colour (`u16ObjId_STATUS`, `bEnable` = enable, `bOk` = `logiBUS_PI_IDA.QO`).
  - **AX_BOOL_TO_X_STATUS** / **AX_PUBLISH_STATUS**: `adapter::conversion::unidirectional::AX_BOOL_TO_X` and `adapter::net::AX_PUBLISH_1` — publish `logiBUS_PI_IDA.QO` (`ID_STATUS_WRITE`).
  - **E_MERGE_QO**: `iec61499::events::E_MERGE_3` — merges `Q_NumericValue_FREQ.INITO`, `Q_NumericValue_COUNT.CNF` and `Q_NumericValue_FREQ.CNF`; its output `EO` triggers `AND_QO.REQ`, so `QO` is re-evaluated on every new `Q_NumericValue_COUNT`/`Q_NumericValue_FREQ` value (`CNF`) (up to v1.1 `EO` was not connected and `QO` was only computed at start-up).
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_10` — forms `QO` (see Data Outputs).
- **Functionality**: The raw counter value is branched: one branch goes directly to the OPC-UA publication, a second one via `AD_TO_AUDI` to the VT counter field, a third one via `AD_TO_AR_NUM`, `FT_DERIV_10_AR` and `FT_PT1_AR` to the frequency calculation, whose result is duplicated again (OPC-UA publication and VT display). The channel enable (key, remote switch) releases `logiBUS_PI_IDA`.

Program Flow and Connections

1. `Input` ⟶ `logiBUS_PI_IDA.Input`; `u16ObjId_COUNTVAR` ⟶ `Q_NumericValue_COUNT.u16ObjId`; `stObjFreq` ⟶ `Q_NumericValue_FREQ.stObj`; `ID_COUNT_WRITE` ⟶ `AD_PUBLISH_COUNT.ID`; `ID_FREQ_WRITE` ⟶ `AR_PUBLISH_FREQ.ID`.
2. `logiBUS_PI_IDA.IN` (adapter) ⟶ `AD_SPLIT_2_UNGATED_FREQ.IN`; `AD_SPLIT_2_UNGATED_FREQ.OUT1` ⟶ `AD_SPLIT_2.IN`; `AD_SPLIT_2_UNGATED_FREQ.OUT2` ⟶ `AD_TO_AR_NUM.AD_IN`.
3. `AD_SPLIT_2.OUT1` ⟶ `AD_PUBLISH_COUNT.IN` (counter OPC-UA branch).
4. `AD_SPLIT_2.OUT2` ⟶ `AD_TO_AUDI.AD_IN`; `AD_TO_AUDI.AUDI_OUT` ⟶ `Q_NumericValue_COUNT.u32NewValue` (VT counter branch).
5. `AD_TO_AR_NUM.AR_OUT` ⟶ `FT_DERIV_10_AR.AR_IN`; `LIT_DerivK.OUT` ⟶ `FT_DERIV_10_AR.K`; `FT_DERIV_10_AR.AR_OUT` ⟶ `FT_PT1_AR.AR_IN` (with `initval_ATM.OUT` ⟶ `FT_PT1_AR.TM`); `FT_PT1_AR.AR_OUT` ⟶ `AR_SPLIT_2.IN` (frequency calculation branch).
6. `AR_SPLIT_2.OUT1` ⟶ `AR_PUBLISH_FREQ.IN` (frequency OPC-UA branch).
7. `AR_SPLIT_2.OUT2` ⟶ `Q_NumericValue_FREQ.rPhys` (frequency VT branch).
8. **Channel enable**: `Button_SWITCH.IND` ⟶ `E_T_FF_SR_SWITCH.CLK`; `AX_SUBSCRIBE_SWITCH.OUT` ⟶ `AX_RF_TRIG_SWITCH.QI`, `AX_RF_TRIG_SWITCH.ER` ⟶ `E_T_FF_SR_SWITCH.S`, `AX_RF_TRIG_SWITCH.EF` ⟶ `E_T_FF_SR_SWITCH.R`; `bDefaultEnabled` ⟶ `E_T_FF_SR_SWITCH.Q_INIT`; `E_T_FF_SR_SWITCH.Q` ⟶ `logiBUS_PI_IDA.QI`, `Q_BackgroundColour_EnableOk_STATUS.bEnable` and `AX_BOOL_TO_X_SWITCH.OUT` (⟶ `AX_PUBLISH_SWITCH.IN`); `E_T_FF_SR_SWITCH.EO` ⟶ `logiBUS_PI_IDA.INIT`, `Q_BackgroundColour_EnableOk_STATUS.REQ` and `AX_BOOL_TO_X_SWITCH.REQ`.
9. **Status**: `logiBUS_PI_IDA.QO` ⟶ `Q_BackgroundColour_EnableOk_STATUS.bOk` and `AX_BOOL_TO_X_STATUS.OUT` (⟶ `AX_PUBLISH_STATUS.IN`); `logiBUS_PI_IDA.INITO` ⟶ `Q_BackgroundColour_EnableOk_STATUS.REQ` and `AX_BOOL_TO_X_STATUS.REQ`; `u16ObjId_STATUS` ⟶ `Q_BackgroundColour_EnableOk_STATUS.u16ObjId`.
10. **Initialization chain**: `INIT` ⟶ `Q_NumericValue_COUNT.INIT` ⟶ `Q_NumericValue_FREQ.INIT` ⟶ `Q_BackgroundColour_EnableOk_STATUS.INIT` ⟶ `AD_PUBLISH_COUNT.INIT` ⟶ `Button_SWITCH.INIT` ⟶ `INITO` (and ⟶ `AND_QO.REQ`; additionally `E_MERGE_QO.EO` ⟶ `AND_QO.REQ` triggers it). In parallel, from `AD_PUBLISH_COUNT.INITO` the chain `AR_PUBLISH_FREQ` ⟶ `AX_SUBSCRIBE_SWITCH` ⟶ `AX_PUBLISH_SWITCH` ⟶ `AX_PUBLISH_STATUS` ⟶ `E_T_FF_SR_SWITCH` runs (each `INITO` ⟶ next `INIT`); `initval_ATM.INITO` ⟶ `FT_PT1_AR.INIT`.
11. **Quality**: `QI` ⟶ `.QI` of `Q_NumericValue_COUNT`, `Q_NumericValue_FREQ`, `AD_PUBLISH_COUNT`, `AR_PUBLISH_FREQ`, `E_T_FF_SR_SWITCH`, `Button_SWITCH`, `AX_SUBSCRIBE_SWITCH`, `AX_PUBLISH_SWITCH`, `AX_PUBLISH_STATUS` and `Q_BackgroundColour_EnableOk_STATUS`; their `QO` outputs ⟶ `AND_QO.IN1`..`IN10`; `AND_QO.OUT` ⟶ `QO`.

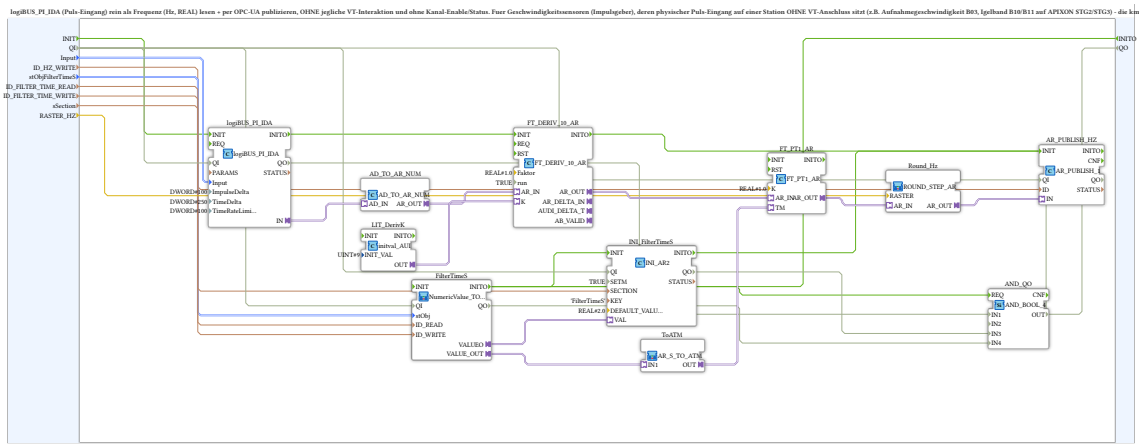
Technical Details

- The frequency is not delivered by the hardware FB itself but computed purely from the time derivative (`FT_DERIV_10_AR`, `Faktor=1.0`, `K=9`) of the raw, monotonically increasing counter value and smoothed with `FT_PT1_AR` (`TM=T#2s`) — the counter itself is never reset.
- `K` of `FT_DERIV_10_AR` is an AUI adapter socket and no longer a parameter (version 1.1); the value 9 comes via `LIT_DerivK`.

- `AD_TO_AR_NUM` is deliberately used instead of `AD_TO_AR` to obtain a numerically correct DWORD→REAL conversion rather than a bit reinterpretation (the same pitfall described for `F_AI_RAW_TO_PERCENT_AD`).
- Counter value and frequency use independent VT numeric fields (`u16ObjId_COUNTVAR` and `stObjFreq`) with different scaling — the frequency display additionally uses `NumericObjectPool_S` for physical scaling/decimals, the counter does not.
- The `QI` inputs of the internal blocks are no longer hard-wired to `TRUE` but are enabled via the `QI` of the SubApp (exception: `logiBUS_PI_IDA.QI` is tied to the channel enable).

Application Scenarios

- A flow meter or speed sensor where both the raw (unbounded, ever-increasing) counter value for diagnostic purposes and a derived, immediately interpretable frequency (e.g. Hz, RPM) should be displayed and transmitted; the channel can be switched on and off via a VT key or OPC-UA.



Summary

Complete VT and OPC-UA connection of a physical pulse input with a parallel raw counter value, a frequency computed from it by time derivative and PT1 smoothing, and a switchable channel enable with status display; `INIT`/`INITO` are chained through the services, `QO` is the AND of the services.

logiBUS_PI_Raw_Publish_OPC

• — ○ • — ○ • — ○ •

Introduction

`logiBUS_PI_Raw_Publish_OPC` reads a logiBUS pulse input (`logiBUS_PI_IDA`) purely as a **frequency (Hz, `REAL`)** and publishes it via OPC-UA - **without any VT interaction** and without channel enable/status. It is intended for speed sensors (pulse generators) whose physical pulse input sits on a station **without a VT connection** (e.g. pickup speed B03, hedgehog belt B10/B11 on APIXON STG2/STG3). The km/h conversion and VT display then run on the station with the VT connection, fed by a remote subscribe of this frequency (analogous to `logiBUS_AI_Raw_Publish_OPC`/`logiBUS_AI_Calibrate_Remote_IDA_OPC`).

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request

Event Outputs

- **INITO** (`EInit`): initialization confirm

Data Inputs

- **QI** (BOOL, default TRUE): quality input, TRUE enables the service
- **Input** (logiBUS::io::PI::logiBUS_PI_S, default logiBUS_PI::Invalid): Identifies the pulse input PulseInput_I1..I9
- **ID_HZ_WRITE** (WSTRING): Frequency publish address (REAL Hz, ACTION=PUBLISH), local on this station
- **stObjFilterTimeS** (NumericObjectPool_S): Object ID + scale/offset/decimals of the CNumberVariable for the PT1 filter time in seconds (VT input field)
- **ID_FILTER_TIME_READ** (WSTRING): Remote subscribe address (REAL seconds, ACTION=SUBSCRIBE) for the web override of the filter time
- **ID_FILTER_TIME_WRITE** (WSTRING): Local echo/re-publish address (REAL seconds, ACTION=PUBLISH) of the current filter time
- **sSection** (STRING): INI section in settings.ini for the persisted filter time (unique per sensor instance)
- **RASTER_HZ** (REAL, default 0.0001): Rounding grid (Hz) before AR_PUBLISH_HZ. The default corresponds to practically no rounding (unchanged for existing callers); set via parameter to the desired resolution (e.g. 0.00208333 = 0.125 rpm at SCALE=60 Hz ⟶ rpm downstream)

Data Outputs

- **QO** (BOOL): quality output, AND combination (AND_QO, AND_BOOL_4) of the QO outputs of logiBUS_PI_IDA, AR_PUBLISH_HZ, INI_FilterTimeS and FilterTimeS

Adapters

This function block has no adapters at its interface; AR/AD adapters are used internally.

Function Blocks (FBs) Used

- **logiBUS_PI_IDA**: logiBUS::io::PI::logiBUS_PI_IDA (ImpulseDelta=100, TimeDelta=250, TimeRateLimit=100) - pulse input as an AD adapter
- **AD_TO_AR_NUM**: adapter::conversion::unidirectional::AD_TO_AR_NUM - converts the count value to REAL
- **FT_DERIV_10_AR**: OSCAT_adapter::Control::FT_DERIV_10_AR (Faktor=1.0, run=TRUE) - derivative (pulses per time = frequency)
- **LIT_DerivK**: initval_AUI (INIT_VAL=9) - constant K of the derivative
- **FT_PT1_AR**: OSCAT_adapter::Control::FT_PT1_AR (K=1.0) - PT1 filter
- **Round_Hz**: OSCAT_adapter::Mathematical::ROUND_STEP_AR - rounds to the grid RASTER_HZ
- **AR_PUBLISH_HZ**: adapter::net::AR_PUBLISH_1 - publishes the frequency
- **FilterTimeS**: SubApp MyLib::sys::NumericValue_TO_AR2_OPC - filter time from VT input field or OPC-UA
- **INI_FilterTimeS**: eclipse4diac::storage::INI_AR2 (SETM=TRUE, KEY='FilterTimeS', default 2.0) - persists the filter time
- **ToATM**: SubApp MyLib::sys::AR_S_TO_ATM - converts seconds into an ATM time value
- **AND_QO**: iec61131::booleanOperators::AND_BOOL_4 - combines the QO outputs of logiBUS_PI_IDA, AR_PUBLISH_HZ, INI_FilterTimeS and FilterTimeS into QO

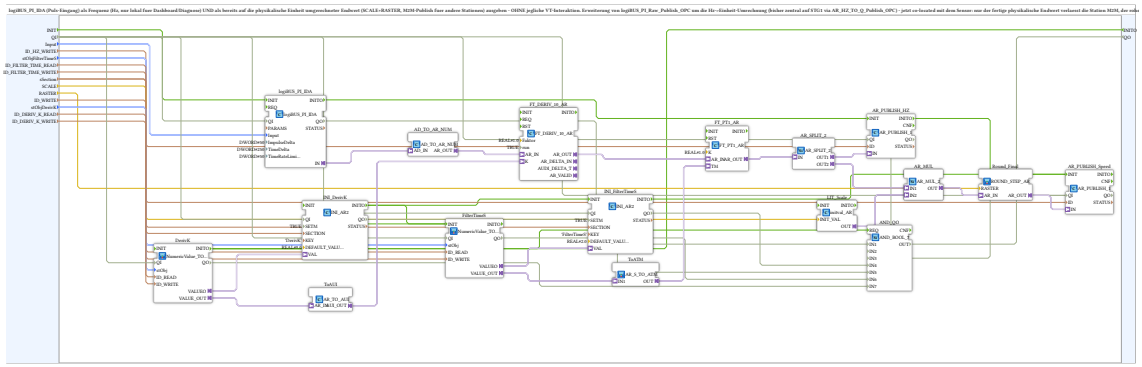
Program Flow and Connections

1. Input ⟶ logiBUS_PI_IDA.Input; logiBUS_PI_IDA.IN ⟶ AD_TO_AR_NUM.AD_IN.
2. AD_TO_AR_NUM.AR_OUT ⟶ FT_DERIV_10_AR.AR_IN; LIT_DerivK.OUT ⟶ FT_DERIV_10_AR.K.
3. FT_DERIV_10_AR.AR_OUT ⟶ FT_PT1_AR.AR_IN.
4. Filter time: FilterTimeS.VALUEO ⟶ INI_FilterTimeS.VAL (persistence); FilterTimeS.VALUE_OUT ⟶ ToATM.IN1; ToATM.OUT ⟶ FT_PT1_AR.TM.
5. FT_PT1_AR.AR_OUT ⟶ Round_Hz.AR_IN (RASTER_HZ ⟶ Round_Hz.RASTER) ⟶ AR_PUBLISH_HZ.IN.
6. ID_HZ_WRITE ⟶ AR_PUBLISH_HZ.ID.
7. Initialization: INIT ⟶ logiBUS_PI_IDA.INIT; logiBUS_PI_IDA.INITO ⟶ AR_PUBLISH_HZ.INIT; AR_PUBLISH_HZ.INITO ⟶ INI_FilterTimeS.INIT; INI_FilterTimeS.INITO ⟶ FilterTimeS.INIT; FilterTimeS.INITO ⟶ INITO and ⟶ AND_QO.REQ.
8. Quality: QI is distributed to logiBUS_PI_IDA, AR_PUBLISH_HZ, INI_FilterTimeS and FilterTimeS (no hard-wired QI parameter any more); their QO ⟶ AND_QO.IN1 to AND_QO.IN4 (in this order); AND_QO.OUT ⟶ QO.

Technical Details

- No VT interaction for the frequency itself, no channel enable and no status.

- The filter time is INI-persisted and can be changed via the VT input field or OPC-UA.
- `RASTER_HZ` can be used to limit the resolution in order to avoid unnecessary publish events.

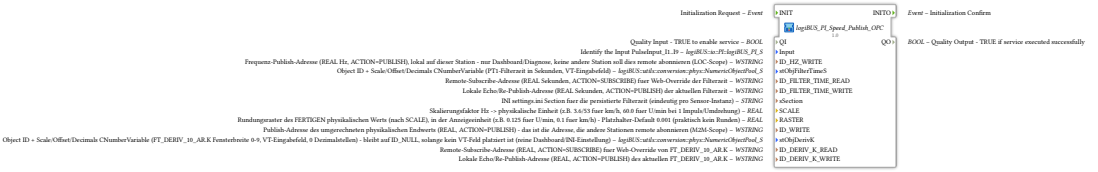


Application Scenarios

- Speed/rotation sensors on stations without a VT, whose frequency is transmitted via OPC-UA to the VT station (e.g. complemented by `AR_HZ_TO_Q_Publish_OPC` on the VT station)

Summary

`logiBUS_PI_Raw_Publish_OPC` produces a filtered, rounded frequency in Hz from a pulse input and publishes it via OPC-UA.



logiBUS_PI_Speed_Publish_OPC

• — ○ • — ○ • — ○ •

Introduction

`logiBUS_PI_Speed_Publish_OPC` outputs a pulse input (`logiBUS_PI_IDA`) in two ways: as a **frequency in Hz** (local only, for dashboard/diagnostics) and as a **final value already converted to the physical unit** (SCALE + RASTER, M2M publish for other stations). There is **no** VT interaction. The block extends `logiBUS_PI_Raw_Publish_OPC` with the Hz-to-unit conversion that used to run centrally on STG1 (`AR_HZ_TO_Q_Publish_OPC`) and now sits at the sensor: only the finished physical final value leaves the station via M2M, the raw Hz value stays local.

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization Request

Event Outputs

- **INITO** (`EInit`): Initialization Confirm

Data Inputs

- **QI** (BOOL, default `TRUE`): Quality Input - TRUE to enable the service
- **Input** (`logiBUS::io::PI::logiBUS_PI_S`): selection of the pulse input `PulseInput_I1..I9` (default `logiBUS_PI::Invalid`)
- **ID_HZ_WRITE** (WSTRING): frequency publish address (REAL Hz, `ACTION=PUBLISH`), local; dashboard/diagnostics only, no other station should subscribe to it remotely (scope LOC)
- **stObjFilterTimeS** (`NumericObjectPool_S`): object ID + scale/offset/decimals of the CNumberVariable for the PT1 filter time in seconds (VT input field); default `u8Decimals := 1`
- **ID_FILTER_TIME_READ** (WSTRING): remote subscribe address (REAL seconds, `ACTION=SUBSCRIBE`) for a web override of the filter time

- **ID_FILTER_TIME_WRITE** (WSTRING): local echo/republish address (REAL seconds, ACTION=PUBLISH) of the current filter time
- **sSection** (STRING): INI section in settings.ini for the persisted values (filter time and DerivK), unique per sensor instance
- **SCALE** (REAL): scaling factor Hz → physical unit (e.g. 3.6/53 for km/h, 60.0 for rpm at 1 pulse/revolution)
- **RASTER** (REAL): rounding grid of the **finished** physical value (after SCALE) in the display unit (e.g. 0.125 for rpm, 0.1 for km/h); placeholder default 0.001 (practically no rounding)
- **ID_WRITE** (WSTRING): publish address of the converted physical final value (REAL, ACTION=PUBLISH); other stations subscribe to this address remotely (scope M2M)
- **stObjDerivK** (NumericObjectPool_S): object ID + scale/offset/decimals of the CNumberVariable for FT_DERIV_10_AR.K (window width 0-9, 0 decimals); stays at ID_NULL as long as no VT field is placed (dashboard/INI setting only)
- **ID_DERIV_K_READ** (WSTRING): remote subscribe address (REAL, ACTION=SUBSCRIBE) for a web override of FT_DERIV_10_AR.K
- **ID_DERIV_K_WRITE** (WSTRING): local echo/republish address (REAL, ACTION=PUBLISH) of the current FT_DERIV_10_AR.K

Data Outputs

- **QO** (BOOL): Quality Output - TRUE if the service executed successfully (AND of the QO of logiBUS_PI_IDA, AR_PUBLISH_HZ, AR_PUBLISH_Speed, INI_FilterTimeS, INI_DerivK, FilterTimeS and DerivK; block AND_QO, type iec61131::booleanOperators::AND_BOOL_7)

Adapters

No adapters are used.

Functionality

Measurement chain (frequency): logiBUS_PI_IDA (logiBUS::io::PI::logiBUS_PI_IDA, QI from the block input, ImpulseDelta = DWORD#50, TimeDelta = DWORD#250, TimeRateLimit = DWORD#50) → AD_TO_AR_NUM → FT_DERIV_10_AR (OSCAT_adapter::Control, Faktor = 1.0, run = TRUE) → FT_PT1_AR (K = 1.0) → AR_SPLIT_2.

Two output paths from AR_SPLIT_2:

- OUT1 → AR_PUBLISH_HZ (AR_PUBLISH_1, QI from the block input): publishes the frequency in Hz to ID_HZ_WRITE (local, unrounded).
- OUT2 → AR_MUL.IN1 (AR_MUL_2), LIT_Scale.OUT → AR_MUL.IN2 (LIT_Scale is an initval_AR with INIT_VAL from SCALE) → Round_Final (OSCAT_adapter::Mathematical::ROUND_STEP_AR, RASTER) → AR_PUBLISH_Speed (AR_PUBLISH_1, QI from the block input): publishes the converted final value, rounded to RASTER, to ID_WRITE.

Adjustable PT1 filter time: FilterTimeS (MyLib::sys::NumericValue_TO_AR2_OPC stObjFilterTimeS, ID_FILTER_TIME_READ, ID_FILTER_TIME_WRITE) supplies the filter time in seconds. FilterTimeS.VALUEO ↔ INI_FilterTimeS.VAL (eclipse4diac::storage::INI_AR2, QI from the block input, SETM = TRUE, KEY = 'FilterTimeS', DEFAULT_VALUE = REAL#2.0, SECTION from sSection) persists it. FilterTimeS.VALUE_OUT → ToATM.IN1 (MyLib::sys::AR_S_TO_ATM), ToATM.OUT → FT_PT1_AR.TM.

Adjustable derivative window width: DerivK (NumericValue_TO_AR2_OPC; stObjDerivK, ID_DERIV_K_READ, ID_DERIV_K_WRITE) supplies K. DerivK.VALUEO ↔ INI_DerivK.VAL (INI_AR2, KEY = 'DerivK', DEFAULT_VALUE = REAL#9.0, SECTION from sSection) persists the value. DerivK.VALUE_OUT → ToAUI.AR_IN (AR_TO_AUI), ToAUI.AUI_OUT → FT_DERIV_10_AR.K.

Initialization and status: The initialization chain is INIT → logiBUS_PI_IDA.INIT, logiBUS_PI_IDA.INITO → AR_PUBLISH_HZ.INIT, AR_PUBLISH_HZ.INITO → AR_PUBLISH_Speed.INIT, AR_PUBLISH_Speed.INITO → INI_FilterTimeS.INIT, INI_FilterTimeS.INITO → INI_DerivK.INIT, INI_DerivK.INITO → FilterTimeS.INIT, FilterTimeS.INITO → DerivK.INIT, DerivK.INITO → INITO and → AND_QO.REQ. QI is forwarded to logiBUS_PI_IDA, AR_PUBLISH_HZ, AR_PUBLISH_Speed, INI_FilterTimeS, INI_DerivK, FilterTimeS and DerivK; their QO outputs → AND_QO.IN1..IN7, AND_QO.OUT → QO.

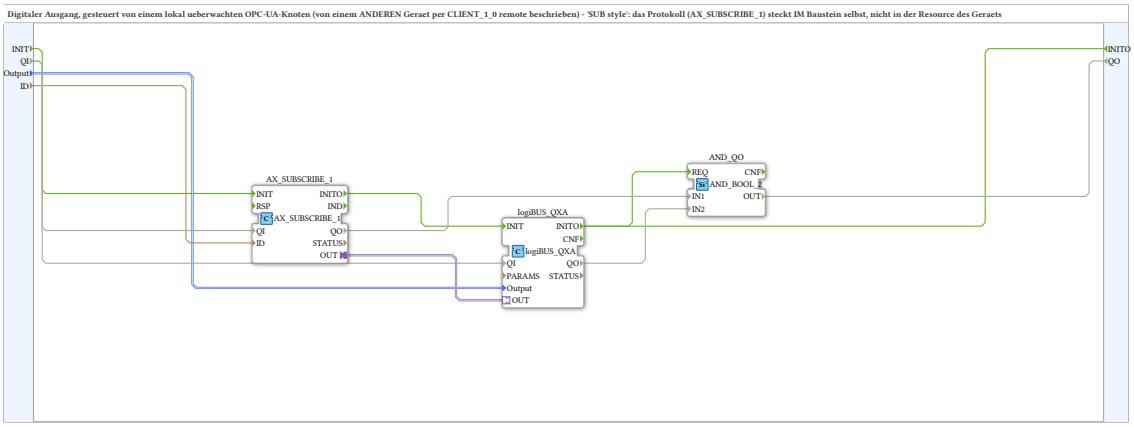
Technical Details

- The Hz value (ID_HZ_WRITE) is deliberately left unrounded and purely local (scope LOC); only ID_WRITE is intended for M2M subscribers

- RASTER rounds the **finished** physical value after the SCALE multiplication (no longer in Hz as RASTER_HZ used to do in logiBUS_PI_Raw_Publish_OPC), so intuitive values arise directly in the display unit
- Filter time (FilterTimeS) and window width (DerivK) are adjustable via VT field, web override and INI persistence; K of FT_DERIV_10_AR is itself an AUI adapter socket, so the earlier unpacking workaround is no longer needed
- The configuration applies automatically to all five pulse sensors that use this common block (pickup B03, hedgehog belt 1/2 B10/B11, PTO B21, saw blade B08)
- Both INI entries share the same sSection but have different KEYs (FilterTimeS, DerivK)

Application Scenarios

- Speed or rotational speed measurement (km/h, rpm) on stations without a VT connection with cross-station provision of the finished value

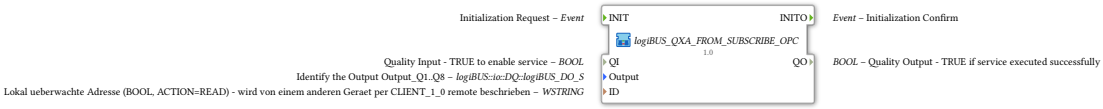


⚖️ Comparison with Similar Blocks

In contrast to logiBUS_PI_Raw_Publish_OPC, this block rounds in the display unit grid and additionally supplies the converted final value. The subscribing counterpart is AR_M2M_Subscribe_TO_Q_Publish_OPC.

Conclusion

logiBUS_PI_Speed_Publish_OPC covers the complete sensor side of a speed/rotational speed measurement: frequency determination with an adjustable filter, conversion and rounding to the display unit as well as local and M2M publication.



logiBUS_QXA_FROM_SUBSCRIBE_OPC

• — ○ • — ○ • — ○ •

Introduction

logiBUS_QXA_FROM_SUBSCRIBE_OPC drives a digital output (logiBUS_QXA) from a locally-subscribed OPC-UA node that is remotely written by ANOTHER device via AX_CLIENT_1_0 - "Krauternter style" (per the source comment): the protocol (AX_SUBSCRIBE_1) lives INSIDE the block itself, not in the device's resource.

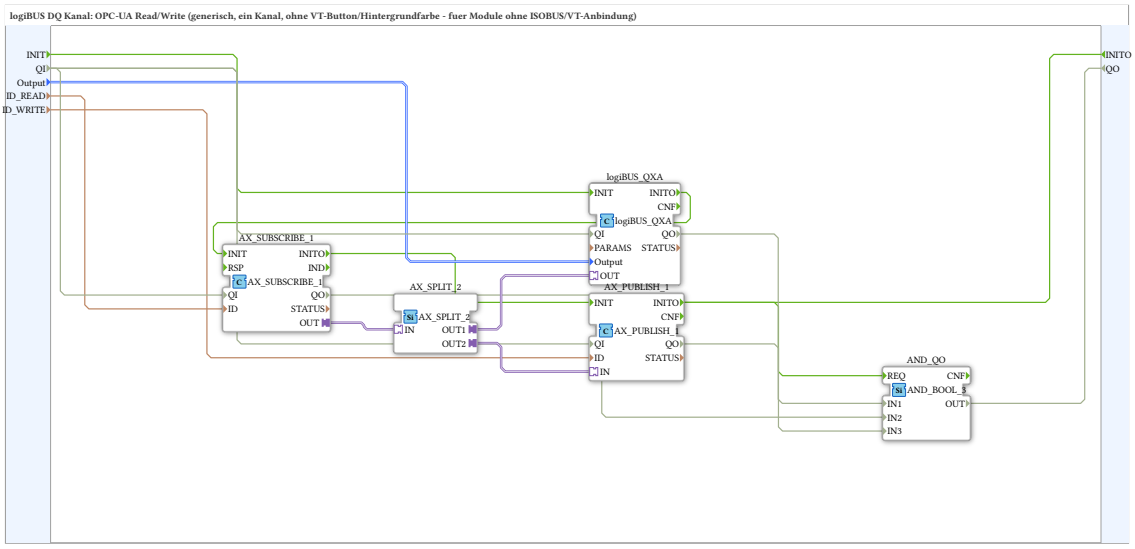
Function blocks used

- **AX_SUBSCRIBE_1** (adapter::net::AX_SUBSCRIBE_1): subscribes to the locally-monitored address ID (BOOL, written remotely).
- **logiBUS_QXA** (logiBUS::io::DQ::logiBUS_QXA): physical digital output, identified via Output_Q1..Q8.
- **AND_QO** (iec61131::booleanOperators::AND_BOOL_2): combines AX_SUBSCRIBE_1.QO and logiBUS_QXA.QO into the SubApp output QO.

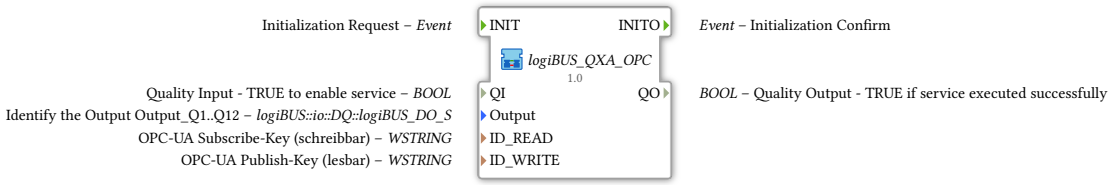
Initialization and quality

- Events: INIT (EInit, input) and INITO (EInit, output, comes from logiBUS_QXA.INITO).

- Data input `QI` (BOOL, default `TRUE`) and data output `QO` (BOOL); `AX_SUBSCRIBE_1` and `logiBUS_QXA` no longer carry a fixed `QI=TRUE`.
- Initialization: `INIT` ⟶ `AX_SUBSCRIBE_1.INIT`, `AX_SUBSCRIBE_1.INITO` ⟶ `logiBUS_QXA.INIT`, `logiBUS_QXA.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`.
- Quality: `QI` ⟶ `AX_SUBSCRIBE_1.QI` and `logiBUS_QXA.QI`; `AX_SUBSCRIBE_1.QO` ⟶ `AND_QO.IN1`, `logiBUS_QXA.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.



Summary



Single-block bridge from a locally-subscribed OPC-UA value to a physical digital output - counterpart to `logiBUS_IXA_TO_CLIENT_OPC` on the sending side.

logiBUS_QXA_OPC

• — ○ • — ○ • — ○ •

Introduction

`logiBUS_QXA_OPC` is a composite subapplication designed to provide a generic single-channel OPC UA read/write access to a logiBUS digital output (DQ) module. It is specifically intended for modules that lack ISOBUS or Virtual Terminal (VT) support, offering a standard OPC UA interface for remote control and monitoring. The subapp internally couples a `logiBUS_QXA` FB with OPC UA subscribe and publish adapters, enabling bidirectional communication over the network.

Interface Structure

The subapp exposes the events `INIT`/`INITO`, the data `QI`/`QO` and three further data input variables. It has no adapter interfaces at its boundary; the actual communication is handled internally.

Event Inputs

- **INIT** (`EInit`): initialization request; starts the init chain at `logiBUS_QXA.INIT`

Event Outputs

- **INITO** (`EInit`): initialization confirmation; comes from `AX_PUBLISH_1.INITO`, the end of the init chain

Data Inputs

Name	Type	Initial Value	Comment
QI	BOOL	TRUE	Quality input, enables the service; passed on to logiBUS_QXA, AX_SUBSCRIBE_1 and AX_PUBLISH_1.
Output	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Identifies the target output channel (e.g., Output_Q1..Q12).
ID_READ	WSTRING	–	OPC UA subscribe key (used to receive commands or status requests).
ID_WRITE	WSTRING	–	OPC UA publish key (used to send data back to the network).

Data Outputs

- **QO** (BOOL): quality output, AND combination (AND_QO, AND_BOOL_3) of the QO outputs of logiBUS_QXA, AX_SUBSCRIBE_1 and AX_PUBLISH_1

Adapters

None at the subapp level. Internally, the following adapter instances are utilised:

- AX_SUBSCRIBE_1 – subscribes to an OPC UA data source.
- AX_PUBLISH_1 – publishes data to an OPC UA target.
- AX_SPLIT_2 – splits the incoming event stream for parallel processing.

Functionality

The subapp acts as a bridge between an OPC UA client and a physical logiBUS digital output. The external inputs configure the behaviour:

- The Output input selects which specific DQ output channel is to be controlled (e.g., Q1…Q12).
- ID_READ defines the OPC UA subscribe key – incoming events on this topic are processed.
- ID_WRITE defines the OPC UA publish key – outgoing events are sent to this topic.

Internally, the OPC UA subscribe adapter receives events. These events are then split into two paths:

1. The first path goes directly to the logiBUS_QXA FB, which interprets the event as a control command and sets the selected output accordingly.
2. The second path is forwarded to the OPC UA publish adapter, allowing the same event to be echoed back or used for acknowledgment/status purposes.

Initialization and quality: INIT → logiBUS_QXA.INIT, logiBUS_QXA.INITO → AX_SUBSCRIBE_1.INIT, AX_SUBSCRIBE_1.INITO → AX_PUBLISH_1.INIT, AX_PUBLISH_1.INITO → INITO and AND_QO.REQ. QI is passed on to logiBUS_QXA.QI, AX_SUBSCRIBE_1.QI and AX_PUBLISH_1.QI; their QO outputs go in this order to AND_QO.IN1 to AND_QO.IN3 (iec61131::booleanOperators::AND_BOOL_3), AND_QO.OUT → QO.

The publish adapter can also transmit status information back to the OPC UA server, enabling read access to the current state of the output. The separation of read and write keys allows for fine-grained access control.

Technical Features

- **Single-channel configuration**: The subapp handles one DQ output at a time, selected via the Output input.
- **OPC UA integration**: Uses standard 4diac adapter types AX_SUBSCRIBE_1 and AX_PUBLISH_1 for seamless OPC UA connectivity.
- **Event splitting**: AX_SPLIT_2 ensures that an incoming event can be both processed locally and forwarded to the publishing side without loss.

- **Flexible addressing**: The keys `ID_READ` and `ID_WRITE` are runtime-writable, allowing dynamic re-binding to different OPC UA nodes.
- **No VT dependency**: Works with modules that do not implement ISOBUS VT, making it suitable for simpler or custom hardware.

State Overview

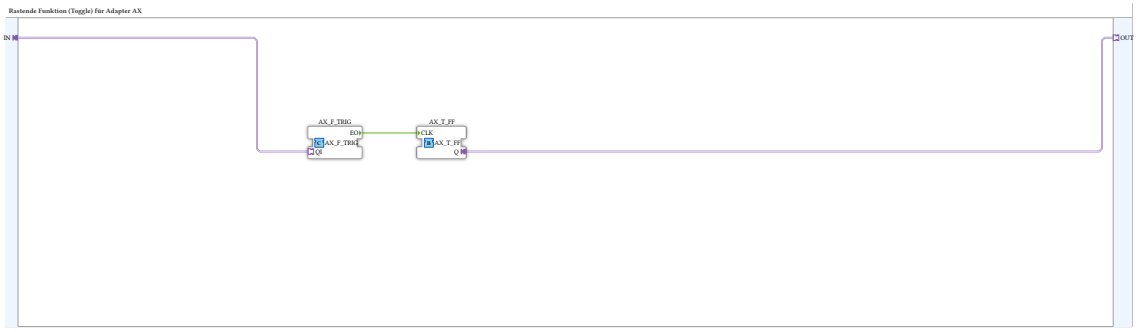
The subapp does not maintain an explicit state machine. The internal FBs (`logiBUS_QXA`, the adapters, and the splitter) operate asynchronously. However, the overall behaviour can be described by the following data flow:

- **Idle**: Waiting for incoming OPC UA events on the subscribe key.
- **Event received**: The subscribe adapter emits an event; the splitter forwards it in parallel to the `logiBUS_QXA` FB (which updates the output) and to the publish adapter (which may send an acknowledgment or status).
- **Publish operation**: The publish adapter sends data on the configured key, which can be used for read-back of the current output state or for broadcasting the received command.

Application Scenarios

- Remote control of logiBUS digital outputs via OPC UA in industrial automation environments.
- Integration of logiBUS modules into OPC UA-based supervisory control and data acquisition (SCADA) systems.
- Use cases where the module has no ISOBUS or VT interface, and a simple OPC UA channel is required.
- Generic deployment across multiple DQ channels by re-configuring the `Output` input per instance.

Comparison with Similar Blocks



- **logiBUS_QXA** (the internal FB): This is the raw DQ control block. `logiBUS_QXA_OPC` extends it with OPC UA connectivity and a fixed single-channel configuration.
- **logiBUS_QXA_VT**: A variant that likely includes VT button and background color support – `logiBUS_QXA_OPC` omits these for modules without VT, reducing complexity.
- **Generic OPC UA I/O blocks**: Many OPC UA adapters exist, but this subapp encapsulates both subscribe and publish directions specifically for logiBUS DQ control, saving integration time.

Conclusion

`logiBUS_QXA_OPC` provides a compact, reusable solution for integrating logiBUS digital outputs with OPC UA. Its generic single-channel design makes it adaptable to various modules, while the separation of read and write keys offers flexible access control. The use of standard 4diac adapters ensures easy integration into existing projects. This subapp is ideal for environments where a lightweight, network-based control path is required.

Rastend

• – ◦ • – ◦ • – ◦ •

Introduction

This exercise implements a latching switching function that is triggered when a signal is released. The sub-application uses adapters for signal processing and event control to achieve reliable latching functionality.

Function Blocks Used (FBs)

Sub-modules: rastend

- **Type**: SubAppType
- **Internal FBs Used**:
  - **E_T_FF**: iec61499::events::E_T_FF
    - Event Input: CLK
    - Event Output: EO
    - Data Output: Q
  - **E_SWITCH**: iec61499::events::E_SWITCH
    - Event Input: EI
    - Event Output: EO0
    - Data Input: G
  - **AX_X_TO_BOOL**: adapter::conversion::unidirectional::AX_X_TO_BOOL
    - Adapter Input: AX_IN
    - Event Output: CNF
    - Data Input: IN
  - **AX_BOOL_TO_X**: adapter::conversion::unidirectional::AX_BOOL_TO_X
    - Event Input: REQ
    - Adapter Output: AX_OUT
    - Data Input: OUT
- **Functionality**: The subapplication converts incoming AX signals into Boolean values, processes them using a toggle flip-flop, and outputs the result back as an AX signal.

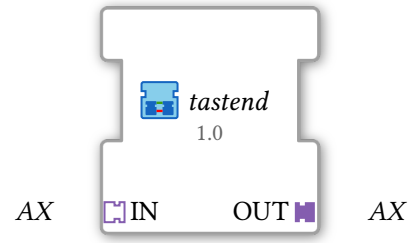
Program Flow and Connections

The program flow follows this signal processing chain:

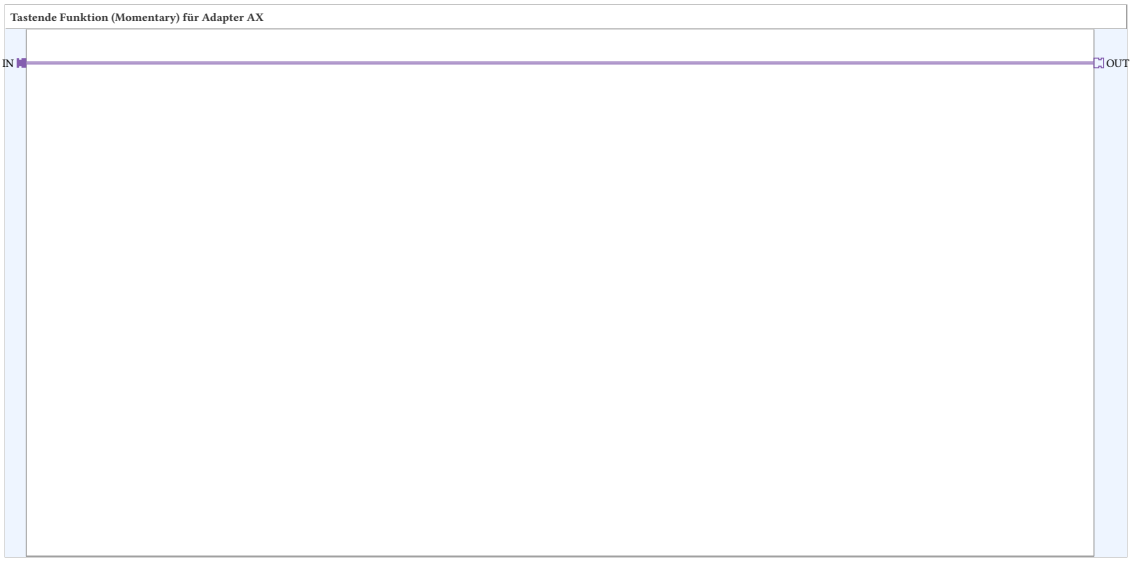
1. **Input Signal Processing**: The incoming AX signal is passed through the IN adapter to AX_X_TO_BOOL.
2. **Signal Conversion**: AX_X_TO_BOOL converts the AX signal into a Boolean value.
3. **Switch Control**: The Boolean value controls E_SWITCH, which forwards events to the toggle flip-flop.
4. **Latching Function**: E_T_FF implements the actual latching function and stores the state.
5. **Output Signal Generation**: AX_BOOL_TO_X converts the Boolean output value back into an AX signal.

Connections in Detail:

- Event Connections: E_SWITCH.EO0 → E_T_FF.CLK, E_T_FF.EO → AX_BOOL_TO_X.REQ, AX_X_TO_BOOL.CNF → E_SWITCH.EI
- Data connections: E_T_FF.Q → AX_BOOL_TO_X.OUT, AX_X_TO_BOOL.IN → E_SWITCH.G
- Adapter connections: IN → AX_X_TO_BOOL.AX_IN, AX_BOOL_TO_X.AX_OUT → OUT



Summary



This exercise demonstrates the implementation of a latching switching function with adapters for signal conversion. It shows the use of toggle flip-flops for state storage and structured signal processing via various function blocks. The solution is particularly suitable for applications where a signal should remain active after being released.

Touch-sensitive

• – ◦ • – ◦ • – ◦ •

Introduction

This exercise deals with creating and using a sub-application type in the 4diac IDE. The “touch-sensitive” function block serves as a sub-application and implements a unidirectional adapter connection between input and output adapters.

Function Blocks (FBs) Used

Sub-block: touch-sensitive

- **Type**: SubAppType
- **Internal FBs Used**: No internal FBs present
- **Functionality**: The “touch-sensitive” sub-block establishes an adapter connection between an input adapter (IN) and an output adapter (OUT). Both adapters use the type “adapter::types::unidirectional::AX” and enable unidirectional data transmission.

Program Flow and Connections

The “tactile” sub-module has the following interfaces:

- **Input Adapter**: IN (Type: adapter::types::unidirectional::AX)
- **Output Adapter**: OUT (Type: adapter::types::unidirectional::AX)

The connection is made directly from the input adapter IN to the output adapter OUT. This configuration allows for easy forwarding of signals or data through the sub-module.

Difficulty Level: Easy

Required Prior Knowledge: Basic knowledge of 4diac-IDE, understanding of adapter connections and sub-applications

Starting the Exercise: The sub-module can be integrated into larger applications and controlled via the defined adapter interfaces.

Summary

The “tactile” exercise demonstrates the creation of a simple sub-application type with adapter connections. It shows the basic structure of sub-modules in 4diac-IDE and their integration into larger control applications using standardized adapter interfaces.

tactile_TON_5s

• – ○ • – ○ • – ○ •

Introduction

This exercise demonstrates the use of a time-delay relay (timer on-delay) with a fixed time setting of 5 seconds. The sub-application serves as a reusable component for time-delayed signal processing.

Function Blocks Used (FBs)

Sub-Blocks: tastend_TON_5s

- **Type**: SubAppType
- **Internal FBs Used**:
- **AX_X_TO_BOOL**: adapter::conversion::unidirectional::AX_X_TO_BOOL
- Parameters: None
- Event Output/Input: CNF (Output), REQ (Input)
- Data Output/Input: IN (Input), OUT (Output)
- **E_TON**: iec61499::events::timers::E_TON
- Parameters: PT = t#5s
- Event Output/Input: CNF (Output), REQ (Input)
- Data Output/Input: IN (Input), Q (Output)
- **AX_BOOL_TO_X**: adapter::conversion::unidirectional::AX_BOOL_TO_X

- Parameters: None
- Event output/input: REQ (input), CNF (output)

Data output/input: OUT (input), AX_OUT (output)
Functionality:
The subapplication converts an incoming adapter signal (IN) into a Boolean value via AX_X_TO_BOOL, which is then passed to the E_TON timer. The timer waits 5 seconds before activating the output signal via Q. This signal is then converted back into an adapter signal (OUT) via AX_BOOL_TO_X.

Program Flow and Connections

Adapter Connections:

- Input: IN ⟶ AX_X_TO_BOOL.AX_IN
- Output: AX_BOOL_TO_X.AX_OUT ⟶ OUT

Event Connections:

- AX_X_TO_BOOL.CNF ⟶ E_TON.REQ
- E_TON.CNF ⟶ AX_BOOL_TO_X.REQ

Data Connections:

- AX_X_TO_BOOL.IN ⟶ E_TON.IN
- E_TON.Q ⟶ AX_BOOL_TO_X.OUT

Learning Objectives:

- Understanding of Timer Function Blocks (E_TON)
- Working with Adapter Conversion Blocks
- Building Reusable Subapplications
- Time-Controlled Signal Processing

Difficulty Level: Beginner
Required Prior Knowledge: Basic knowledge of the 4diac IDE, understanding of function blocks and Adapters
Start of the exercise: The sub-application can be integrated into larger applications where a 5-second delay is required.

Summary

The sub-application tastend_TON_5s provides a compact solution for time-delayed signal processing. Thanks to its fixed 5-second delay and the use of standardized adapter interfaces, it can be easily integrated into various control applications. Its clear structure, including signal conversion, timer functionality, and feedback, makes its operation transparent and comprehensible.

values_50_75_25

• — ○ • — ○ • — ○ •

Introduction

The **values_50_75_25** subapplication provides three constant REAL values (50.0, 75.0, and 25.0) as outputs via unidirectional AR adapters. It is designed to supply fixed setpoints to a downstream selection logic, such as an `AR_AUI_MUX_3` block, where the selection index `K` maps to one of the three constant values. The subapplication encapsulates three independent constant sources, each implemented using an internal `initval_AR` function block.

Interface Structure

The subapplication exposes only adapter outputs; it has no event inputs, event outputs, data inputs, or data outputs.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Adapter Name	Type	Description
OUT_50	unidirectional::AR	Fixed value 50.0
OUT_75	unidirectional::AR	Fixed value 75.0
OUT_25	unidirectional::AR	Fixed value 25.0

All adapters are of type `adapter::types::unidirectional::AR`, representing a unidirectional connection that carries a REAL value.

Functionality

The subapplication internally instantiates three `initval_AR` function blocks, each parameterized with a specific initial value:

- `initval_AR_50` with `INIT_VAL = 50.0`
- `initval_AR_75` with `INIT_VAL = 75.0`
- `initval_AR_25` with `INIT_VAL = 25.0`

Each block writes its constant to its `OUT` adapter, which is directly connected to the corresponding subapplication adapter output. Thus, the subapplication continually provides the three predefined constant values on its outputs.

Technical Features

- **Pure constant output:** No dynamic calculation or external inputs are involved; the values are fixed at design time.
- **Unidirectional adapters:** The AR adapter type is specifically designed for continuous value transfer from producer to consumer without handshaking.
- **Parameterization:** The internal `initval_AR` blocks are simple and robust, ensuring immediate availability of the output values.
- **Separation of concerns:** The subapplication isolates constant generation, making the source of different setpoints explicit and exchangeable.

State Overview

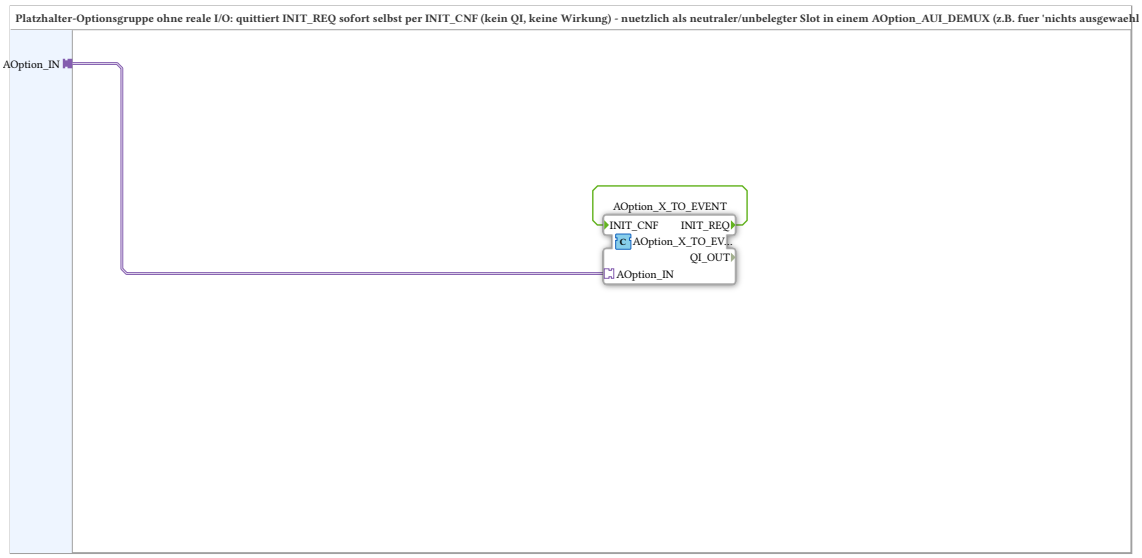
This subapplication is stateless. The internal function blocks are combinatorial in nature (or initial value based) and do not maintain any runtime state. Outputs are available as soon as the subapplication is activated.

Application Scenarios

- **Setpoint selection for automation tasks:** Used in conjunction with a multiplexer (e.g., `AR_AUI_MUX_3`) where different constant outputs (50, 75, 25) are selected via an index.
- **Test and simulation environments:** Provide fixed reference values for validating control algorithms or monitoring logic.
- **Reusable constant library:** The subapplication can be instantiated multiple times in a project to supply identical constant values without duplicating individual function blocks.

Comparison with Similar Blocks

- **vs. simple constant function block:** A single constant block provides only one value; this subapplication encapsulates three related constants with dedicated outputs, improving readability and maintainability.
- **vs. parameterized subapplication:** If the constants were dynamic, a subapplication would require data inputs. Here, because the values are fixed, the adapter-only interface is sufficient and simplifies external wiring.
- **vs. direct use of internal blocks:** By hiding the internal implementation, the subapplication offers a clean interface and makes the intended logic (three distinct setpoints) immediately obvious to other engineers.



Conclusion

The `values_50_75_25` subapplication is a straightforward solution for providing three fixed REAL constants via unidirectional adapters. Its simplicity, clear naming, and encapsulation make it ideal for use in selector or multiplexer scenarios where predefined setpoints are required. With no dynamic parts, it is easy to integrate and guarantees consistent output values across the entire runtime.

2.1.5 MyLib_AX_Option

2.1.5.1 sys

DummyGroup

• – ◦ • – ◦ • – ◦ •

Introduction

`DummyGroup` is a placeholder option group without real I/O. It acknowledges `INIT_REQ` immediately by itself with `INIT_CNF` (no `QI` effect, no action). It serves as a neutral, unassigned slot in an `AOption_AUI_DEMUX`, e.g. for "nothing selected" at `K=1` when real options only start at `K=2`. This avoids an override literal for "which number means off".

Used Function Blocks (FBs)

Sub-blocks: DummyGroup

- **Type**: SubAppType
- **Interface**: socket `AOption_IN` of type `Option::AOption`.
- **Internal FBs used**:
  - **AOption_X_TO_EVENT**: `Option::conversion::AOption_X_TO_EVENT`.

Program Flow and Connections

- `AOption_IN` -> `AOption_X_TO_EVENT.AOption_IN`
- `AOption_X_TO_EVENT.INIT_REQ` -> `AOption_X_TO_EVENT.INIT_CNF` (self-acknowledgement)

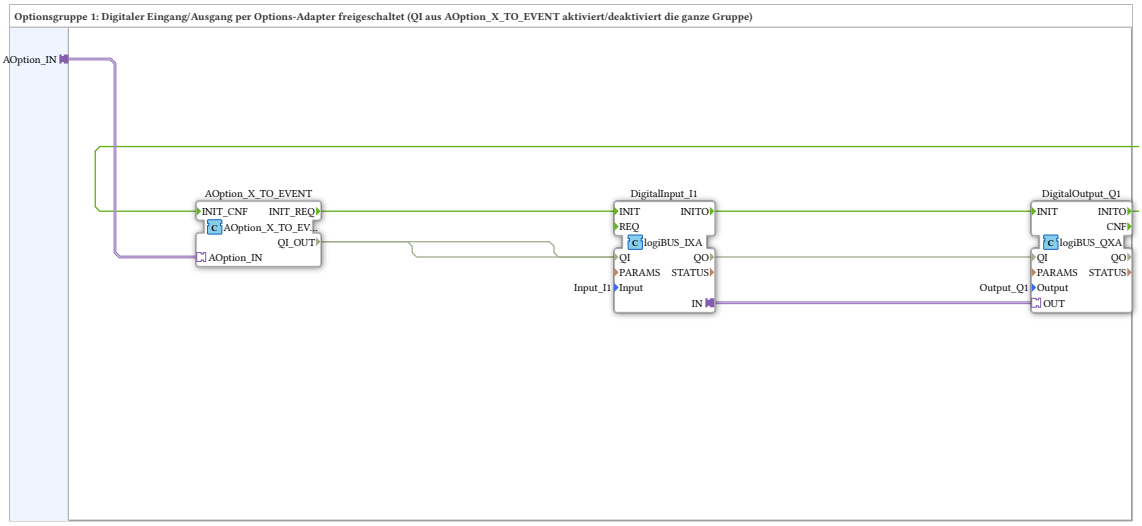
`QI_OUT` remains unused.

Technical Features

- No I/O blocks, no effect on the application.

Application Scenarios

- Neutral slot in an option DEMUX, e.g. `AOption_AUI_DEMUX_n`.



Summary

DummyGroup is an option group without effect that acknowledges requests immediately.

OptionalGroup_001

• – ◦ • – ◦ • – ◦ •

Introduction

OptionalGroup_001 is a SubApp (library MyLib_AX_Option): option group 1, whose digital input Input_I1 and digital output Output_Q1 (logiBUS) are enabled via the option adapter. The QI from AOption_X_TO_EVENT activates or deactivates the whole group.

Used Function Blocks (FBs)

Sub-blocks: OptionalGroup_001

- **Type**: SubAppType
- **Interface**: socket AOption_IN of type Option::AOption.
- **Internal FBs used**:
  - **AOption_X_TO_EVENT**: Option::conversion::AOption_X_TO_EVENT, converts the adapter into INIT_REQ/QI_OUT/INIT_CNF.
  - **DigitalInput_I1**: logiBUS::io::DI::logiBUS_IXA, parameter Input = Input_I1.
  - **DigitalOutput_Q1**: logiBUS::io::DQ::logiBUS_QXA, parameter Output = Output_Q1.

Program Flow and Connections

- AOption_IN -> AOption_X_TO_EVENT.AOption_IN
- Init chain: AOption_X_TO_EVENT.INIT_REQ -> DigitalInput_I1.INIT; DigitalInput_I1.INITO -> DigitalOutput_Q1.INIT; DigitalOutput_Q1.INITO -> AOption_X_TO_EVENT.INIT_CNF
- AOption_X_TO_EVENT.QI_OUT -> DigitalInput_I1.QI and DigitalOutput_Q1.QI

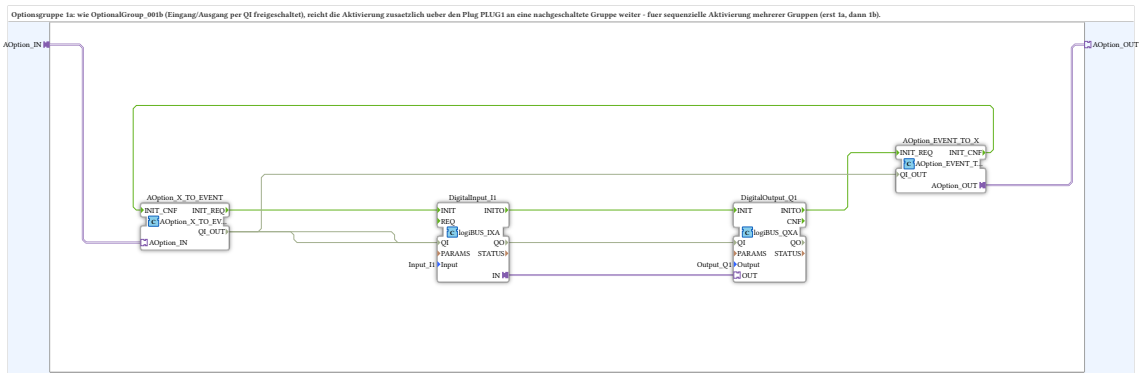
- Adapter connection `DigitalInput_I1.IN` -> `DigitalOutput_Q1.OUT`: the input is routed through to the output.

Technical Features

- The initialization (input, then output) is only acknowledged to the plug once both blocks are done.
- The group's `QI` is passed on to the `QI` of input and output.

Application Scenarios

- Optional digital input/output that is switched on or off by a selection block such as `AOption_AD_DEMUX_2`.



Summary

`OptionalGroup_001` bundles `Input_I1` and `Output_Q1` into an option group that can be switched on and off via `AOption`.

OptionalGroup_001a

• – ○ • – ○ • – ○ •

Introduction

`OptionalGroup_001a` is a SubApp (library `MyLib_AX_Option`): option group 1a. Like `OptionalGroup_001b`, its digital input `Input_I1` and digital output `Output_Q1` (logiBUS) are enabled via the option adapter. In addition, the group passes the activation on through the plug `AOption_OUT` to a downstream group - for sequential activation of several groups (first 1a, then 1b).

Used Function Blocks (FBs)

Sub-blocks: OptionalGroup_001a

- **Type**: SubAppType
- **Interface**: socket `AOption_IN` of type `Option::AOption` (adapter input) and plug `AOption_OUT` of type `Option::AOption` (adapter output).
- **Internal FBs used**:
  - **AOption_X_TO_EVENT**: `Option::conversion::AOption_X_TO_EVENT`, converts the adapter at the socket into `INIT_REQ/QI_OUT/INIT_CNF`.
  - **DigitalInput_I1**: `logiBUS::io::DI::logiBUS_IXA`, parameter `Input = Input_I1`.
  - **DigitalOutput_Q1**: `logiBUS::io::DQ::logiBUS_QXA`, parameter `Output = Output_Q1`.
  - **AOption_EVENT_TO_X**: `Option::conversion::AOption_EVENT_TO_X`, converts `INIT_REQ/QI_OUT` into the adapter at the plug `AOption_OUT` and reports `INIT_CNF` back.

Program Flow and Connections

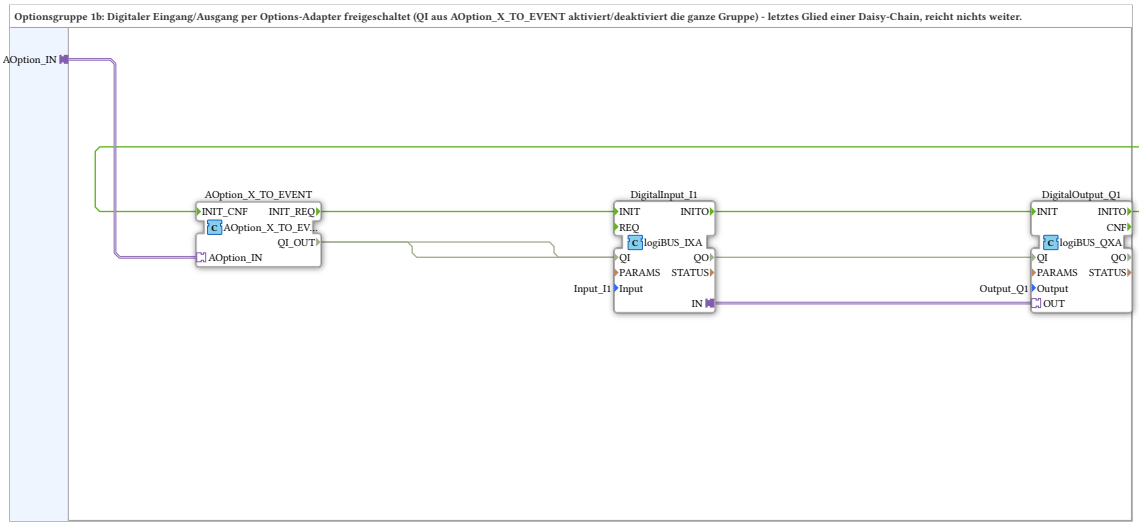
- `AOption_IN` -> `AOption_X_TO_EVENT.AOption_IN`
- Init chain: `AOption_X_TO_EVENT.INIT_REQ -> DigitalInput_I1.INIT; DigitalInput_I1.INITO -> DigitalOutput_Q1.INIT; DigitalOutput_Q1.INITO -> AOption_EVENT_TO_X.INIT_REQ; AOption_EVENT_TO_X.INIT_CNF -> AOption_X_TO_EVENT.INIT_CNF`
- `AOption_X_TO_EVENT.QI_OUT -> DigitalInput_I1.QI, DigitalOutput_Q1.QI` and `AOption_EVENT_TO_X.QI_OUT`
- `AOption_EVENT_TO_X.AOption_OUT` -> `AOption_OUT`
- Adapter connection `DigitalInput_I1.IN` -> `DigitalOutput_Q1.OUT`: the input is routed through to the output.

Technical Features

- `AOption_OUT` is only triggered once `DigitalOutput_Q1` itself is initialized (`DigitalOutput_Q1.INITO -> AOption_EVENT_TO_X.INIT_REQ`).
- Its `INIT_CNF` is reported back to the own socket `AOption_IN` of the group. The calling DEMUX therefore only sees the group as done once the entire chain (including downstream groups at `AOption_OUT`) has acknowledged.
- The `QI` of the group is passed on to input, output and the plug `AOption_OUT`.

Application Scenarios

- First link of a daisy chain: `AOption_OUT` is connected to the socket of a downstream group such as `OptionalGroup_001b`, so both groups are activated one after the other (first a, then b).



Summary

`OptionalGroup_001a` bundles `Input_I1` and `Output_Q1` into an option group switchable via `AOption` and passes the activation on to the next group via `AOption_OUT`.

🛠️ Related Exercises

- Uebung_094b3c_AX

OptionalGroup_001b

• – ○ • – ○ • – ○ •

Introduction

`OptionalGroup_001b` is a SubApp (library `MyLib_AX_Option`): option group 1b, whose digital input `Input_I1` and digital output `Output_Q1` (logiBUS) are enabled via the option adapter. The `QI` from `AOption_X_TO_EVENT` activates or deactivates the whole group. It is the last link of a daisy chain and passes nothing on.

Used Function Blocks (FBs)

Sub-blocks: OptionalGroup_001b

- **Type**: SubAppType
- **Interface**: socket `AOption_IN` of type `Option::AOption`.
- **Internal FBs used**:
  - **AOption_X_TO_EVENT**: `Option::conversion::AOption_X_TO_EVENT`, converts the adapter into `INIT_REQ/QI_OUT/INIT_CNF`.
  - **DigitalInput_I1**: `logiBUS::io::DI::logiBUS_IXA`, parameter `Input = Input_I1`.
  - **DigitalOutput_Q1**: `logiBUS::io::DQ::logiBUS_QXA`, parameter `Output = Output_Q1`.

Program Flow and Connections

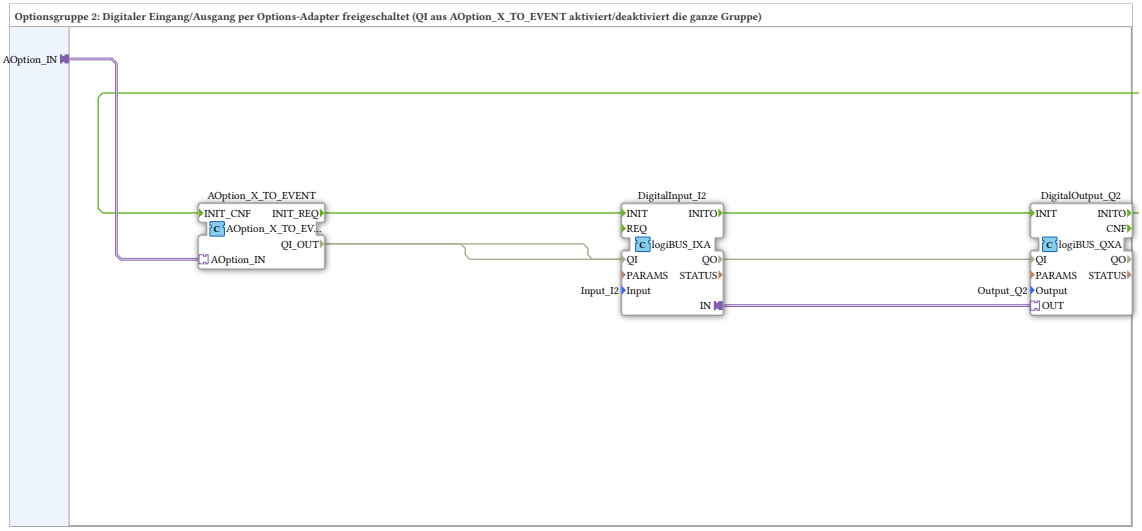
- `AOption_IN` -> `AOption_X_TO_EVENT.AOption_IN`
- Init chain: `AOption_X_TO_EVENT.INIT_REQ` -> `DigitalInput_I1.INIT`; `DigitalInput_I1.INITO` -> `DigitalOutput_Q1.INIT`; `DigitalOutput_Q1.INITO` -> `AOption_X_TO_EVENT.INIT_CNF`
- `AOption_X_TO_EVENT.QI_OUT` -> `DigitalInput_I1.QI` and `DigitalOutput_Q1.QI`
- Adapter connection `DigitalInput_I1.IN` -> `DigitalOutput_Q1.OUT`: the input is routed through to the output.

Technical Features

- Identical in construction to `OptionalGroup_001a`, but without the plug `AOption_OUT`.
- The initialization (input, then output) is only acknowledged to the socket once both blocks are done.

Application Scenarios

- Typically attached to `AOption_OUT` of an upstream `OptionalGroup_001a`, so both groups are activated one after the other (first a, then b) before the original caller receives its acknowledgment.



Summary

`OptionalGroup_001b` bundles `Input_I1` and `Output_Q1` into an option group switchable via `AOption` and forms the end of a daisy chain.

OptionalGroup_002

• – ◦ • – ◦ • – ◦ •

Introduction

`OptionalGroup_002` is a SubApp (library `MyLib_AX_Option`): option group 2, whose digital input `Input_I2` and digital output `Output_Q2` (logiBUS) are enabled via the option adapter. The `QI` from `AOption_X_TO_EVENT` activates or deactivates the whole group.

Used Function Blocks (FBs)

Sub-blocks: OptionalGroup_002

- **Type**: SubAppType
- **Interface**: socket `AOption_IN` of type `Option::AOption`.
- **Internal FBs used**:
  - **AOption_X_TO_EVENT**: `Option::conversion::AOption_X_TO_EVENT`, converts the adapter into `INIT_REQ/QI_OUT/INIT_CNF`.
  - **DigitalInput_I2**: `logiBUS::io::DI::logiBUS_IXA`, parameter `Input = Input_I2`.
  - **DigitalOutput_Q2**: `logiBUS::io::DQ::logiBUS_QXA`, parameter `Output = Output_Q2`.

Program Flow and Connections

- `AOption_IN -> AOption_X_TO_EVENT.AOption_IN`

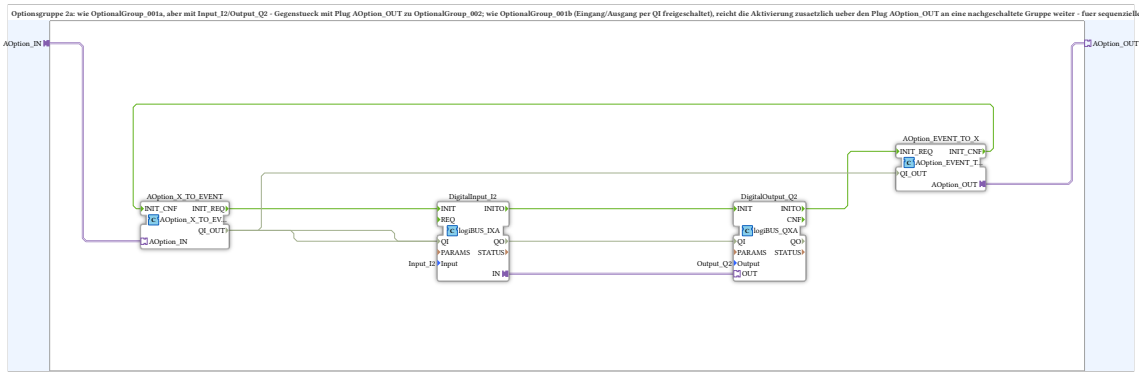
- Init chain: `AOption_X_TO_EVENT.INIT_REQ -> DigitalInput_I2.INIT; DigitalInput_I2.INITO -> DigitalOutput_Q2.INIT; DigitalOutput_Q2.INITO -> AOption_X_TO_EVENT.INIT_CNF`
- `AOption_X_TO_EVENT.QI_OUT -> DigitalInput_I2.QI` and `DigitalOutput_Q2.QI`
- Adapter connection `DigitalInput_I2.IN -> DigitalOutput_Q2.OUT`: the input is routed through to the output.

Technical Features

- The initialization (input, then output) is only acknowledged to the plug once both blocks are done.
- The group's `QI` is passed on to the `QI` of input and output.

Application Scenarios

- Optional digital input/output that is switched on or off by a selection block such as `AOption_AD_DEMUX_2`.



Summary

`OptionalGroup_002` bundles `Input_I2` and `Output_Q2` into an option group that can be switched on and off via `AOption`.

OptionalGroup_002a

• — ○ • — ○ • — ○ •

Introduction

`OptionalGroup_002a` is a SubApp (library `MyLib_AX_Option`): option group 2a. Like `OptionalGroup_001b`, its digital input `Input_I2` and digital output `Output_Q2` (logiBUS) are enabled via the option adapter. In addition, the group passes the activation on through the plug `AOption_OUT` to a downstream group - for sequential activation of several groups (first 2a, then the downstream group).

Used Function Blocks (FBs)

Sub-blocks: OptionalGroup_002a

- **Type**: SubAppType
- **Interface**: socket `AOption_IN` of type `Option::AOption` (adapter input) and plug `AOption_OUT` of type `Option::AOption` (adapter output).
- **Internal FBs used**:
  - **AOption_X_TO_EVENT**: `Option::conversion::AOption_X_TO_EVENT`, converts the adapter at the socket into `INIT_REQ/QI_OUT/INIT_CNF`.
  - **DigitalInput_I2**: `logiBUS::io::DI::logiBUS_IXA`, parameter `Input = Input_I2`.
  - **DigitalOutput_Q2**: `logiBUS::io::DQ::logiBUS_QXA`, parameter `Output = Output_Q2`.
  - **AOption_EVENT_TO_X**: `Option::conversion::AOption_EVENT_TO_X`, converts `INIT_REQ/QI_OUT` into the adapter at the plug `AOption_OUT` and reports `INIT_CNF` back.

Program Flow and Connections

- `AOption_IN` -> `AOption_X_TO_EVENT.AOption_IN`
- Init chain: `AOption_X_TO_EVENT.INIT_REQ -> DigitalInput_I2.INIT; DigitalInput_I2.INITO -> DigitalOutput_Q2.INIT; DigitalOutput_Q2.INITO -> AOption_EVENT_TO_X.INIT_REQ; AOption_EVENT_TO_X.INIT_CNF -> AOption_X_TO_EVENT.INIT_CNF`
- `AOption_X_TO_EVENT.QI_OUT -> DigitalInput_I2.QI, DigitalOutput_Q2.QI` and `AOption_EVENT_TO_X.QI_OUT`
- `AOption_EVENT_TO_X.AOption_OUT` -> `AOption_OUT`
- Adapter connection `DigitalInput_I2.IN` -> `DigitalOutput_Q2.OUT`: the input is routed through to the output.

Technical Features

- `AOption_OUT` is only triggered once `DigitalOutput_Q2` itself is initialized (`DigitalOutput_Q2.INITO -> AOption_EVENT_TO_X.INIT_REQ`).
- Its `INIT_CNF` is reported back to the own socket `AOption_IN` of the group. The calling DEMUX therefore only sees the group as done once the entire chain (including downstream groups at `AOption_OUT`) has acknowledged.
- The `QI` of the group is passed on to input, output and the plug `AOption_OUT`.

Application Scenarios

- First link of a daisy chain: `AOption_OUT` is connected to the socket of a downstream group such as `OptionalGroup_001b`, so both groups are activated one after the other (first a, then b).

Summary

`OptionalGroup_002a` bundles `Input_I2` and `Output_Q2` into an option group switchable via `AOption` and passes the activation on to the next group via `AOption_OUT`.

AE2_ILOCK_T_FF_TO_BOOL_EVENT

• – ○ • – ○ • – ○ •

Introduction

`AE2_ILOCK_T_FF_TO_BOOL_EVENT` is a reusable IEC 61499 subapplication that implements one link of a mutually interlocked toggle flip-flop chain. It uses an AE2 bidirectional adapter interface with a `SOCKET`/`PLUG` chain topology and provides the current state as a Boolean output `Q` together with a confirmation event `EO`.

The block is designed as a chain element: several instances can be connected by linking the `PLUG` of one element to the `SOCKET` of the next element. This makes the interlock logic scalable for an arbitrary number of participants.

• – ○ • – ○ • – ○ •

Interface Structure

The subapplication has one event input, one event output, one Boolean data output, and two bidirectional adapter interfaces.

Event Inputs

Name	Type	Description
IND	Event	Trigger input used to toggle the local flip-flop state.

Event Outputs

Name	Type	Description
EO	Event	Emitted when the local E_SR flip-flop has been updated and Q has changed.

Data Inputs

None.

Data Outputs

Name	Type	Description
Q	BOOL	Current state of the local toggle flip-flop.

Adapters

Name	Type	Description
SOCKET	adapter::types::bidirectional::AE2	Bidirectional adapter connection to the previous element in the chain.
PLUG	adapter::types::bidirectional::AE2	Bidirectional adapter connection to the next element in the chain.

• – ◦ • – ◦ • – ◦ •

Functionality

The subapplication behaves as one interlock-capable toggle flip-flop inside a chain of identical elements.

When an event arrives at IND, the event is routed by the internal E_SWITCH according to the current value of Q:

- If Q = FALSE, the event is routed to the set branch of the internal E_SR. The internal state is set, so Q becomes TRUE.
- If Q = TRUE, the event is routed to the reset branch of the internal E_SR. The internal state is reset, so Q becomes FALSE.

In both cases, the internal E_SR issues its output event, which is propagated to the subapplication output EO.

The AE2 adapter part is responsible for the mutual interlock. The internal conversion FBs AE2_EVENT_TO_E and AE2_E_TO_EVENT exchange interlock events through SOCKET and PLUG. When a participant becomes active, the interlock event is sent into the chain. The event can be forwarded through neighboring elements, preventing conflicting active states in other participants.

The overall result is a decentralized, chainable interlocked toggle flip-flop that can be extended simply by adding more subapplication instances and connecting PLUG to SOCKET.

• – ◦ • – ◦ • – ◦ •

Technical Features

- Standard-compliant IEC 61499 subapplication type.
- Uses standard event FBs E_SR and E_SWITCH for state storage and event routing.
- Bidirectional AE2 adapter interface supports chain-based communication.
- No explicit data inputs are required; the only external data output is the Boolean state Q.
- The application logic is isolated from the adapter protocol by the conversion FBs AE2_EVENT_TO_E and AE2_E_TO_EVENT.

- The SOCKET/PLUG topology allows an arbitrary number of chain participants.
- A sister block AE2_ILOCK_T_FF_TO_AX exists with an AX adapter output instead of BOOL + Event.

• – ◦ • – ◦ • – ◦ •

State Overview

The internal behavior can be described by the two states of the stored flip-flop:

State	Meaning	Behavior on IND
Q = FALSE	Participant is inactive/reset.	The set branch is activated, Q becomes TRUE, and the interlock event is sent through the adapter chain.
Q = TRUE	Participant is active/set.	The reset branch is activated, Q becomes FALSE, and the confirmation event EO is emitted.

Additionally, interlock signals arriving from neighboring chain elements through the adapter interfaces can reset the local flip-flop, implementing the mutual exclusion between participants.

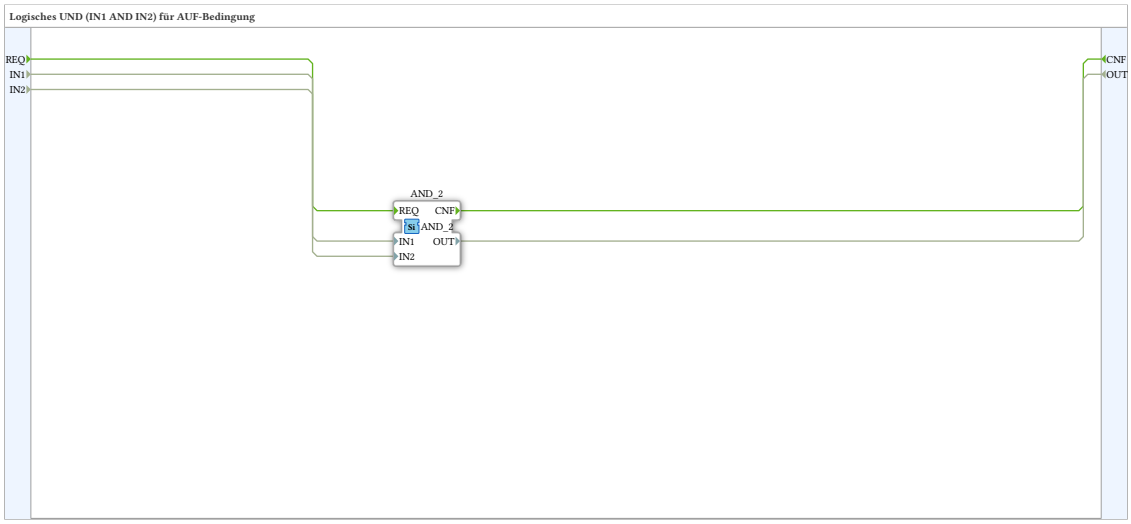
• – ◦ • – ◦ • – ◦ •

Application Scenarios

- Decentralized toggle systems in modular machines where only one station may be active at a time.
- Interlocked control chains built from identical reusable subapplication instances.
- Event-driven applications that need a Boolean state output combined with an event confirmation.
- Educational or experimental IEC 61499 systems demonstrating adapter-based chain communication.
- Architectures where a centralized interlock unit would require too much wiring or configuration.

• – ◦ • – ◦ • – ◦ •

Comparison with Similar Blocks

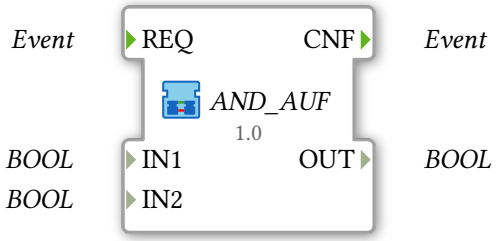


- AE2_ILOCK_T_FF_TO_BOOL_EVENT provides a Boolean output Q and a confirmation event EO, making it convenient for connection to classic IEC 61499 Boolean and event logic.
- The sister block AE2_ILOCK_T_FF_TO_AX provides the same interlocked toggle behavior but outputs an AX adapter instead of a Boolean/event interface. It is intended for systems where the next participant also expects an adapter-based interface.
- Compared with a simple E_SR or toggle flip-flop, this block adds a distributed interlock mechanism through the AE2 adapter chain. A standalone flip-flop cannot coordinate with other participants.
- Compared with a central interlock function block, this subapplication uses a neighbor-to-neighbor chain topology. This reduces central wiring and allows the interlock logic to scale more flexibly.

• – ◦ • – ◦ • – ◦ •

Conclusion

AE2_ILOCK_T_FF_TO_BOOL_EVENT is a compact and reusable IEC 61499 subapplication for building mutually interlocked toggle chains. It combines the simplicity of a Boolean output and event confirmation with the flexibility of a bidirectional AE2 adapter interface. Its SOCKET/PLUG design makes it particularly suitable for decentralized, scalable interlock applications.



AND_AUF

• – ○ • – ○ • – ○ •

Introduction

`AND_AUF` computes the logical `IN1 AND IN2` and provides the enable condition for an "OPEN" movement (e.g. opening a valve/flap): both conditions must be true at the same time. For the complementary "CLOSE" condition, see `AND_ZU`.

Function Blocks Used

Sub-blocks: AND_AUF

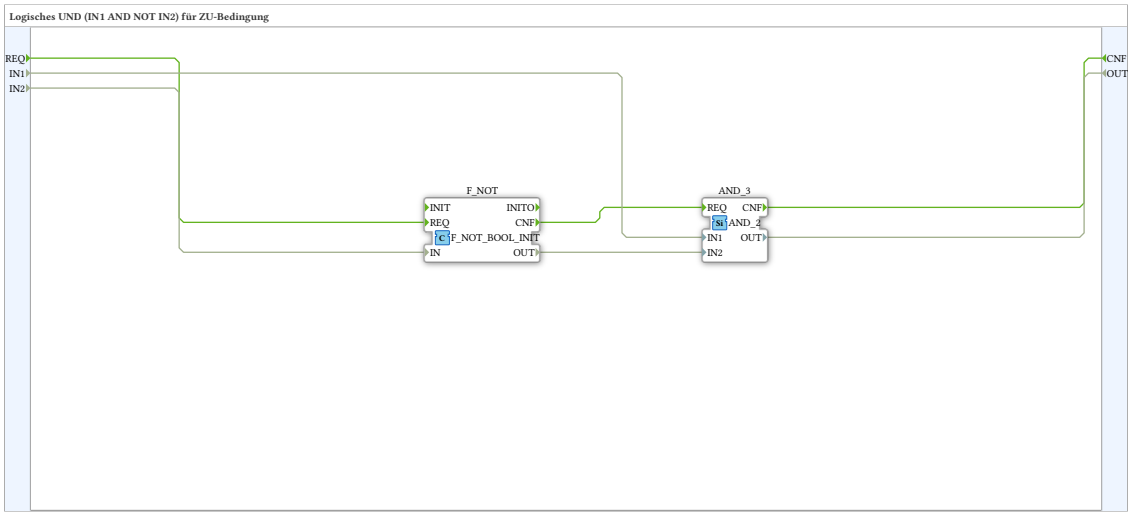
- **Type**: SubAppType
- **Internal FBs used**:
  - **AND_2**: `iec61131::bitwiseOperators::AND_2` — bitwise AND, used here at BOOL level as a logical AND.
- **Operation**: `REQ` triggers `AND_2`; `IN1` and `IN2` are ANDed and returned as `OUT` and `CNF`.

Program Flow and Connections

1. `REQ` ⟶ `AND_2.REQ`.
2. `IN1` ⟶ `AND_2.IN1`; `IN2` ⟶ `AND_2.IN2`.
3. `AND_2.OUT` ⟶ `OUT`; `AND_2.CNF` ⟶ `CNF`.

Application Scenarios

- Enable logic for opening movements where two independent conditions (e.g. CLOSE limit switch not active AND enable button) must be true simultaneously.

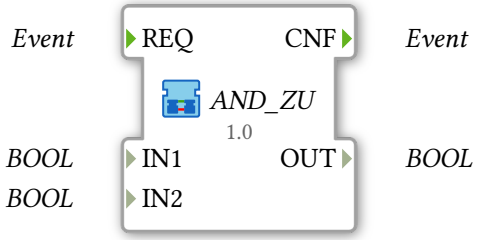


Summary

Simple, reusable AND block, meaningfully named for the OPEN condition of a valve/flap control.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



AND_ZU

• – ◦ • – ◦ • – ◦ •

Introduction

`AND_ZU` computes the logical `IN1 AND NOT IN2` and provides the enable condition for a "CLOSE" movement (e.g. closing a valve/flap): `IN1` must be true and `IN2` must be false. Complementary to `AND_AUF`.

Function Blocks Used

Sub-blocks: AND_ZU

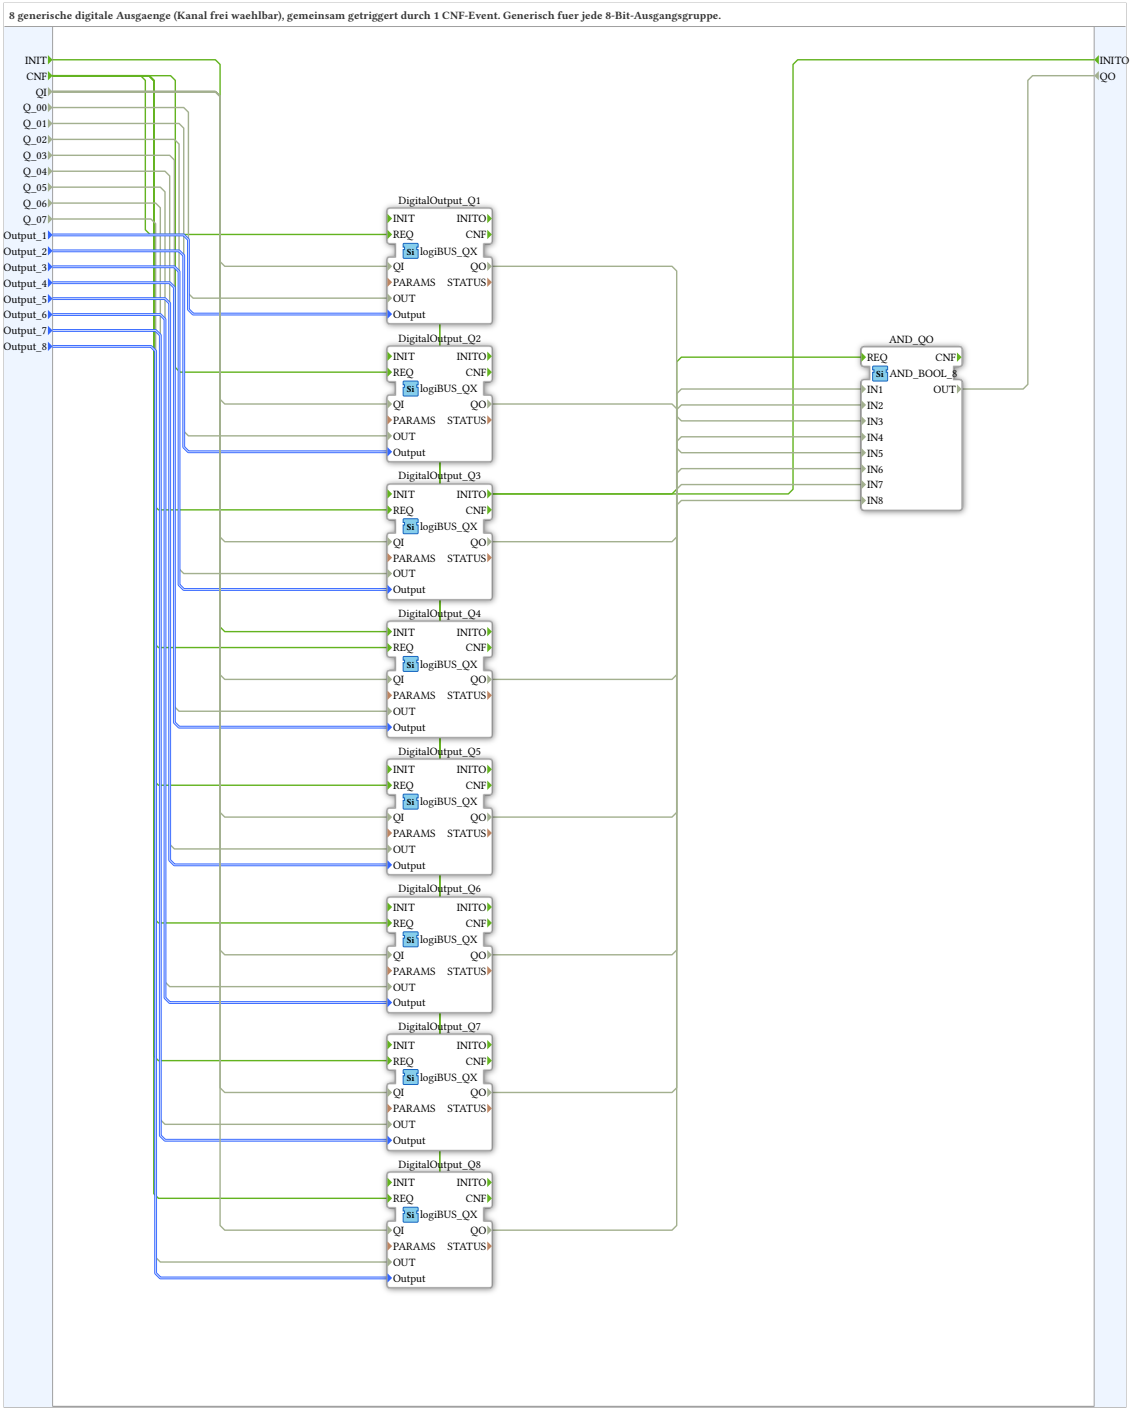
- **Type**: SubAppType
- **Internal FBs used**:
  - **F_NOT** (`F_NOT`): `iec61131::booleanOperators::F_NOT_BOOL_INIT` — negates `IN2` before the AND is computed.
  - **AND_3** (type `AND_2`): `iec61131::bitwiseOperators::AND_2` — ANDs `IN1` with the negated `IN2`.
- **Operation**: `REQ` first triggers `F_NOT`, whose `CNF` in turn triggers `AND_3` — the negation happens before the AND, both in data flow and in event sequencing.

Program Flow and Connections

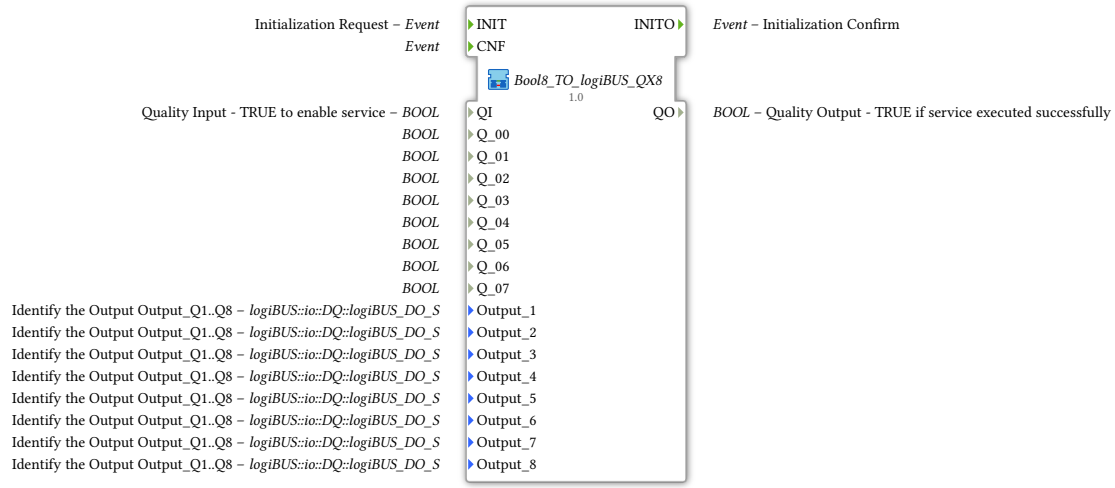
1. `REQ` ⟶ `F_NOT.REQ`; `IN2` ⟶ `F_NOT.IN`.
2. `F_NOT.CNF` ⟶ `AND_3.REQ` (event chain).
3. `IN1` ⟶ `AND_3.IN1`; `F_NOT.OUT` ⟶ `AND_3.IN2`.
4. `AND_3.OUT` ⟶ `OUT`; `AND_3.CNF` ⟶ `CNF`.

Application Scenarios

- Enable logic for closing movements where one condition must be true and a second must explicitly be *false* (e.g. enable button AND OPEN limit switch not active).



Summary



Extends `AND_AUF` with a negation of `IN2` — the matching counterpart logic for the CLOSE condition of a valve/flap control.

Bool8_TO_logiBUS_QX8

• – ○ • – ○ • – ○ •

Introduction

The Bool8_TO_logiBUS_QX8 subapplication provides a generic interface for controlling eight digital output channels on a logiBUS output module. It accepts eight Boolean values (Q_00 to Q_07) and eight channel selector parameters (Output_1 to Output_8), and forwards each Boolean value to its individually selected output channel. All eight channels are triggered simultaneously by a single confirmation (CNF) event, ensuring synchronized updates of the entire 8-bit output group. The subapplication is designed as a reusable building block for any 8-bit output group on logiBUS-based I/O systems.

Interface Structure

The interface consists of one event input, sixteen data inputs, and no event outputs, data outputs, or adapters.

Event Inputs

Event	Description
CNF	Common trigger (confirmation) event. When this event occurs, all eight internal output FBs are requested simultaneously to apply the currently present Q_00..Q_07 values to the configured output channels.
INIT	Initialization request; starts the initialization chain of the eight `logiBUS_QX` instances.

Event Outputs

Event	Description
INITO	Initialization confirm; comes from `DigitalOutput_Q3.INITO`, the end of the chain.

Data Inputs

Data Input	Type	Initial Value	Description
QI	BOOL	TRUE	Quality input - TRUE enables the service; distributed to all eight `logiBUS_QX` instances.
Q_00	BOOL	–	Logic value for channel 1 (bit position 0).
Q_01	BOOL	–	Logic value for channel 2 (bit position 1).

Q_02	BOOL	–	Logic value for channel 3 (bit position 2).
Q_03	BOOL	–	Logic value for channel 4 (bit position 3).
Q_04	BOOL	–	Logic value for channel 5 (bit position 4).
Q_05	BOOL	–	Logic value for channel 6 (bit position 5).
Q_06	BOOL	–	Logic value for channel 7 (bit position 6).
Q_07	BOOL	–	Logic value for channel 8 (bit position 7).
Output_1	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Channel identifier for the first output position.
Output_2	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Channel identifier for the second output position.
Output_3	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Channel identifier for the third output position.
Output_4	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Channel identifier for the fourth output position.
Output_5	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Channel identifier for the fifth output position.
Output_6	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Channel identifier for the sixth output position.
Output_7	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Channel identifier for the seventh output position.
Output_8	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Channel identifier for the eighth output position.

Data Outputs

Data Output	Type	Description
QO	BOOL	Quality output - TRUE if the service was executed successfully (AND of the `QO` of all eight `logiBUS_QX` instances).

Adapters

None.

Functionality

The subapplication encapsulates eight instances of the `logiBUS::io::DQ::logiBUS_QX` function block. Each instance corresponds to one bit position of an 8-bit output group:

- DigitalOutput_Q1 handles Q_00 and is configured by Output_1.
- DigitalOutput_Q2 handles Q_01 and is configured by Output_2.
- DigitalOutput_Q3 handles Q_02 and is configured by Output_3.
- DigitalOutput_Q4 handles Q_03 and is configured by Output_4.
- DigitalOutput_Q5 handles Q_04 and is configured by Output_5.
- DigitalOutput_Q6 handles Q_05 and is configured by Output_6.
- DigitalOutput_Q7 handles Q_06 and is configured by Output_7.
- DigitalOutput_Q8 handles Q_07 and is configured by Output_8.

All internal FBs receive QI from the subapplication's data input QI (default TRUE), so they are active and ready to process requests as long as QI is TRUE.

Initialization and quality: INIT runs as a chain DigitalOutput_Q4 → DigitalOutput_Q7 → DigitalOutput_Q1 → DigitalOutput_Q5 → DigitalOutput_Q2 → DigitalOutput_Q6 → DigitalOutput_Q8 → DigitalOutput_Q3 (each INITO → next INIT); DigitalOutput_Q3.INITO goes to INITO and to AND_QO.REQ. QO is the output of the instance AND_QO (iec61131::booleanOperators::AND_BOOL_8), which combines the QO of the eight instances.

When the CNF event is received, it is forwarded to the REQ input of every internal FB instance. Each instance then reads the current value of its associated Q_x input and writes it to the physical logiBUS output channel referenced by its Output_x parameter.

Because the event broadcast happens in parallel, all eight channels are updated at the same time, providing a consistent 8-bit output pattern on the bus.

Technical Features

- **Channel-individual mapping:** Each bit position (Q_00..Q_07) can be routed to any logiBUS digital output channel by configuring the corresponding Output_1..Output_8 parameter. This makes the subapplication independent of fixed hardware wiring.
- **Synchronized triggering:** A single distributed event (CNF) simultaneously activates all eight internal output blocks, guaranteeing that the complete output word is applied in one cycle.
- **Configurable channel identifiers:** The Output_x inputs are of type logiBUS_DO_S and default to logiBUS_DO::Invalid, forcing the user to explicitly select the desired output channels before operation.
- **Self-contained 8-bit group:** The subapplication encapsulates all control logic, simplifying the reuse of an 8-channel output group in different projects or contexts.
- **Minimal output interface:** Since the result is written directly to the logiBUS hardware, the only outputs are the quality output QO and the event INITO.

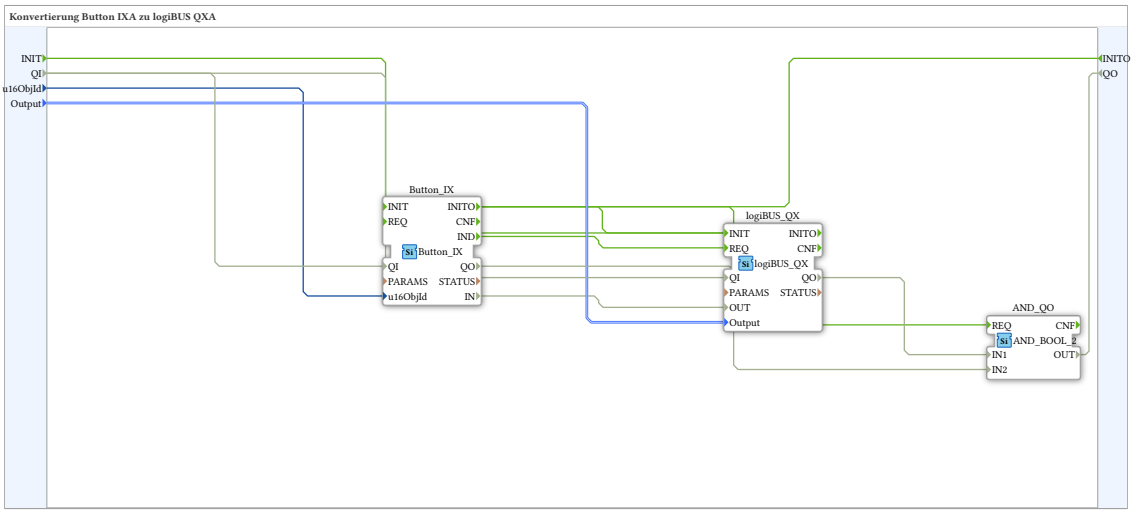
State Overview

The subapplication itself does not contain an execution control chart (ECC) and therefore has no internal state machine. Its behavior is strictly event-driven: the CNF event triggers the internal logiBUS_QX FBs, which may themselves implement their own internal states for handshaking with the logiBUS hardware. From the perspective of the surrounding application, the subapplication behaves deterministically: each CNF event causes a single write operation to the eight configured output channels.

Application Scenarios

- **Distributed output control:** Use the subapplication in a control system that needs to drive eight independent digital actuators (e.g., relays, valves, signal lamps) over a logiBUS fieldbus segment.
- **Standardized output modules:** When a machine or plant contains several identical 8-bit output groups, the same subapplication can be instantiated multiple times with different channel parameters, reducing engineering effort.
- **Flexible hardware mapping:** In commissioning or reconfiguration situations, the physical output channels can be reassigned by simply changing the Output_x parameters without modifying the logic structure.
- **Combined binary word output:** Use the Q_00..Q_07 inputs to transfer an 8-bit binary word (e.g., a value from a step sequencer or pattern generator) and write it to the bus in one atomic action.

Comparison with Similar Blocks

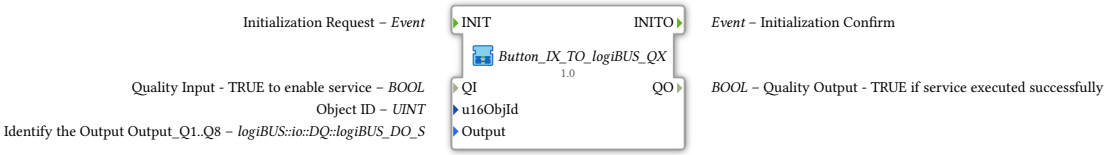


Feature	Bool8_TO_logiBUS_QX8	Individual logiBUS_QX FBs
Number of channels	8 (fixed group)	1 per FB
Channel selection	Parameterized per position (Output_1..Output_8)	Single Output parameter per FB
Synchronization	All 8 channels triggered by one CNF event	Requires individual REQ events per FB
Reusability	Encapsulated, ready-to-use 8-bit group	Requires wiring management by the user
Interface complexity	Reduced (only 9 inputs)	Higher when used in groups

The subapplication adds no functionality beyond the underlying FBs, but it significantly improves the usability, readability, and maintainability of 8-bit output groups.

Conclusion

Bool8_TO_logiBUS_QX8 is a practical, generic subapplication for controlling an 8-bit digital output group on a logiBUS system. By combining eight individually configurable output channels with a common trigger event, it offers synchronized, hardware-independent output control. Its parameterizable channel mapping and pre-integrated structure reduce engineering overhead and make it a valuable building block for modular automation projects.



Button_IX_TO_logiBUS_QX

• — ○ • — ○ • — ○ •

Introduction

`Button_IX_TO_logiBUS_QX` is the test_B counterpart to `Button_IXA_TO_logiBUS_QXA`: a VT button (`Button_IX`) directly switches a physical digital output (`logiBUS_QX`) — here without adapters, using classic event/data connections.

Function Blocks (FBs) Used

Sub-blocks: Button_IX_TO_logiBUS_QX

- **Type**: SubAppType
- **Internal FBs used**:
  - **Button_IX**: `isobus::UT::io::Button::Button_IX` — VT button (non-adapter variant).
  - **logiBUS_QX**: `logiBUS::io::DQ::logiBUS_QX` — physical digital output (non-adapter variant).
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` — combines `logiBUS_QX.QO` and `Button_IX.QO` into the `QO` of the SubApp.
- **Functionality**: `Button_IX.IND` triggers `logiBUS_QX.REQ`; the data value `Button_IX.IN` is wired directly to `logiBUS_QX.OUT`.

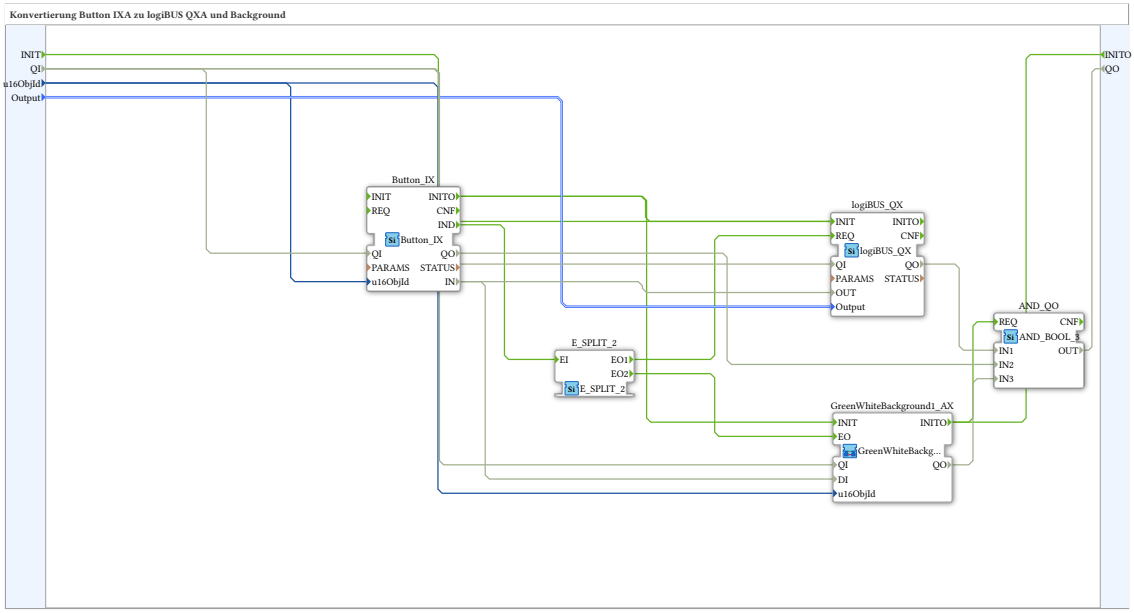
Program Flow and Connections

1. `u16ObjId` ⟶ `Button_IX.u16ObjId`; `Output` ⟶ `logiBUS_QX.Output`.
2. `Button_IX.IND` ⟶ `logiBUS_QX.REQ`; `Button_IX.IN` ⟶ `logiBUS_QX.OUT`.
3. **Initialization**: event input `INIT` (`EInit`) ⟶ `logiBUS_QX.INIT`; `logiBUS_QX.INITO` ⟶ `Button_IX.INIT`; `Button_IX.INITO` ⟶ event output `INITO` (`EInit`) and ⟶ `AND_QO.REQ`.

4. **Quality**: data input `QI` (`BOOL`, default `TRUE`) ⟶ `logiBUS_QX.QI` and `Button_IX.QI`; `logiBUS_QX.QO` ⟶ `AND_QO.IN1`; `Button_IX.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ data output `QO` (`BOOL`).

Application Scenarios

- Minimal VT-button-to-output block for test_B, with no status display.



Summary

test_B counterpart to `Button_IXA_TO_logiBUS_QXA`: same function, classic event/data connections instead of adapters.

Button_IX_TO_logiBUS_QX_BG

• – ○ • – ○ • – ○ •

Introduction

`Button_IX_TO_logiBUS_QX_BG` extends `Button_IX_TO_logiBUS_QX` with a VT status color — the test_B counterpart to `Button_IXA_TO_logiBUS_QXA_BG`.

Function Blocks (FBs) Used

Sub-blocks: Button_IX_TO_logiBUS_QX_BG

- **Type**: SubAppType
- **Interface (additional)**: event input `INIT`, event output `INITO` (each `EInit`), data input `QI` (`BOOL`, default `TRUE`), data output `QO` (`BOOL`).
- **Internal FBs used**:
  - **Button_IX**: `isobus::UT::io::Button::Button_IX` — VT button.
  - **logiBUS_QX**: `logiBUS::io::DQ::logiBUS_QX` — physical digital output.
  - **E_SPLIT_2**: `iec61499::events::E_SPLIT_2` — splits the button event.

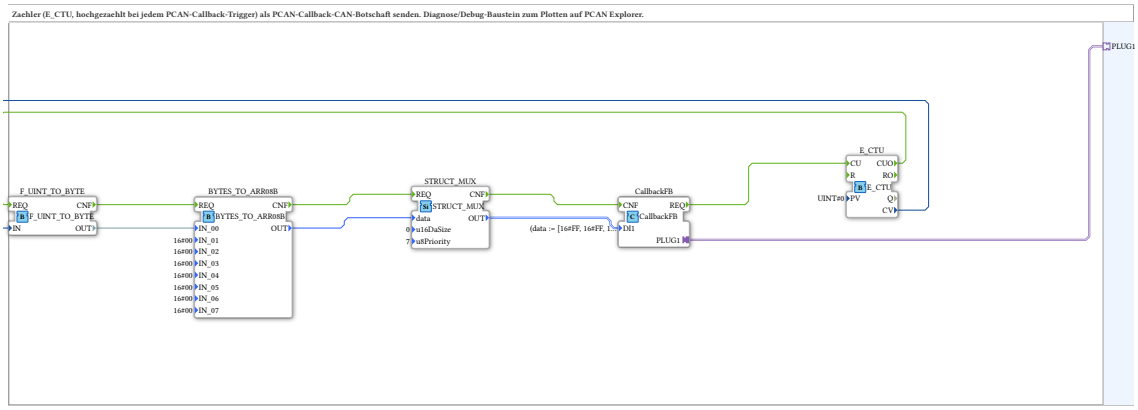
  - **GreenWhiteBackground1_AX** (SubApp, actually of type `MyLib::sys::GreenWhiteBackground1C` — a compact wrapper around the test_B base variant, see Background Color Blocks): sets the status color.
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_3` — combines the `QO` outputs of `logiBUS_QX`, `Button_IX` and `GreenWhiteBackground1_AX` into `QO`.
- **Functionality**: `Button_IX.IND` is distributed via `E_SPLIT_2` to `logiBUS_QX.REQ` and to the color block; the data value `Button_IX.IN` feeds both `logiBUS_QX.OUT` and `GreenWhiteBackground1_AX.DI`.

Program Flow and Connections

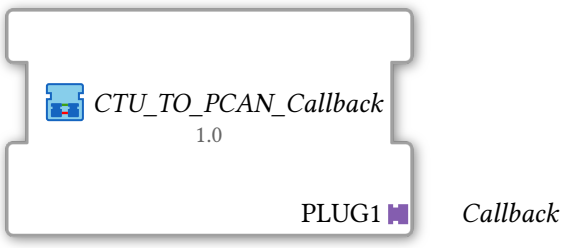
1. `u16ObjId` ⟶ `Button_IX.u16ObjId` and the color block instance's `.u16ObjId`; `Output` ⟶ `logiBUS_QX.Output`.
2. `Button_IX.IND` ⟶ `E_SPLIT_2.EI` ⟶ `E_SPLIT_2.EO1` ⟶ `logiBUS_QX.REQ`, `E_SPLIT_2.EO2` ⟶ color block `.EO`.
3. `Button_IX.IN` ⟶ `logiBUS_QX.OUT` and ⟶ color block `.DI`.
4. Initialization: `INIT` ⟶ `logiBUS_QX.INIT`; `logiBUS_QX.INITO` ⟶ `Button_IX.INIT`; `Button_IX.INITO` ⟶ `GreenWhiteBackground1_AX.INIT`; `GreenWhiteBackground1_AX.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`.
5. Quality: `QI` ⟶ `.QI` of `logiBUS_QX`, `Button_IX` and `GreenWhiteBackground1_AX`; their `QO` ⟶ `AND_QO.IN1` to `AND_QO.IN3` (in this order); `AND_QO.OUT` ⟶ `QO`.

Application Scenarios

- VT button with visual status feedback for test_B, without OPC-UA.



Summary



test_B counterpart to `Button_IXA_TO_logiBUS_QXA_BG`, using `E_SPLIT_2` instead of `AX_SPLIT_2` and the compact-wrapper variant of the background block.

CTU_TO_PCAN_Callback

• – ○ • – ○ • – ○ •

Introduction

CTU_TO_PCAN_Callback is a diagnostic/debug subapplication designed to monitor PCAN callback triggers by incrementing a counter and transmitting the current counter value as a CAN message over the PCAN bus. Each time the connected callback adapter fires, the internal counter is incremented, its value is converted and packed into a CAN message structure, and the message is sent back through the callback interface. This block is intended for visualization and debugging purposes on tools like the PCAN Explorer.

Interface Structure

The subapplication exposes a single adapter plug as its primary interface. All data and event processing happen internally, triggered by the adapter's callback request.

Adapters

Adapter	Type	Description
PLUG1	`isobus::pgn::tx::Callback`	ISOBUS PGN transmission callback. Fires on incoming CAN callback requests and receives the generated CAN message for transmission.

Functionality

The subapplication implements an event-counting and CAN message generation pipeline. It operates entirely on event-driven logic triggered by the callback adapter.

Event & Data Flow

1. **Trigger**: The external callback adapter (connected to `PLUG1`) issues a request event via `CallbackFB.REQ`.
2. **Count**: The `E_CTU` event counter (with initial value 0) increments on the rising edge of the request and outputs the updated count value (`CV`).
3. **Convert**: The counter value is converted from `UINT` to a single `BYTE` by `F_UINT_TO_BYTE`.
4. **Assemble**: `BYTES_TO_ARR08B` places the converted byte into the first position (`IN_00`) of an 8-byte array. The remaining bytes (`IN_01` … `IN_07`) are initialized to `16#00`.
5. **Mux**: `STRUCT_MUX` packs the byte array into a structured `CAN_MSG` (data field, priority = 7, data size = 0) for ISOBUS framing.
6. **Transmit**: `CallbackFB` receives the structured message via its `DI1` input and forwards it as a PCAN message through the adapter (`PLUG1`).

Internal Block Diagram

```
CallbackFB.REQ → E_CTU.CU → E_CTU.CV → F_UINT_TO_BYTE.IN → BYTES_TO_ARR08B.IN_00
                                                                    |
                     STRUCT_MUX.OUT ← STRUCT_MUX.data ← BYTES_TO_ARR08B.OUT
                          |
                     CallbackFB.DI1 → transmitted via PLUG1
```

The event chain is: `CallbackFB.REQ` ⟶ `E_CTU.CU` ⟶ `E_CTU.CUO` ⟶ `F_UINT_TO_BYTE.REQ` ⟶ `F_UINT_TO_BYTE.CNF` ⟶ `BYTES_TO_ARR08B.REQ` ⟶ `BYTES_TO_ARR08B.CNF` ⟶ `STRUCT_MUX.REQ` ⟶ `STRUCT_MUX.CNF` ⟶ `CallbackFB.CNF`, providing a fully synchronous handshake from trigger to acknowledgement.

Technical Features

Feature	Details
Event Counter	`E_CTU` with preset value `0` (`PV = UINT#0`), counts rising edges of the callback request.
Data Conversion	`iec61131::conversion::F_UINT_TO_BYTE` – maps the 16-bit counter value to an 8-bit byte value.
Byte Array Assembly	`logiBUS::utils::conversion::arr::reversing::BYTES_TO_ARR08B` – constructs an 8-byte array; the counter byte occupies `IN_00`, remaining bytes are `0x00`.

CAN Message Packing	`eclipse4diac::convert::STRUCT_MUX` with structured type `isobus::pgn::CAN_MSG`; sets `u8Priority = 7` and `u16DaSize = 0`.
Callback Interface	`isobus::pgn::tx::Callback` – enables sending the generated CAN frame back to the ISOBUS transmission layer.
Flow Control	Full event chain with `REQ`/`CNF` handshakes ensures deterministic processing without race conditions.

State Overview

This subapplication does not define an explicit state machine. Instead, it relies on the built-in event flow of the participating function blocks:

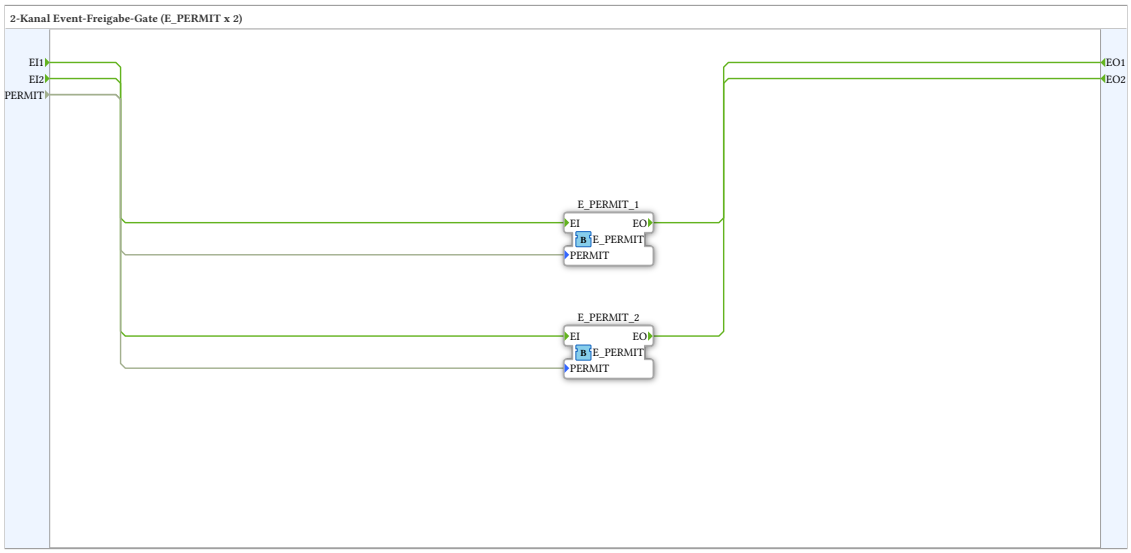
- **Idle State**: No callback request pending; counter holds its last value.
- **Processing State**: Triggered by `CallbackFB.REQ`, the pipeline executes through the counter, converter, array assembler, and mux in a single synchronous pass.
- **Completion State**: `CallbackFB.CNF` acknowledges the processed trigger, and the counter value has been incremented.

The `E_CTU` block internally maintains the count value as its persistent state across cycles.

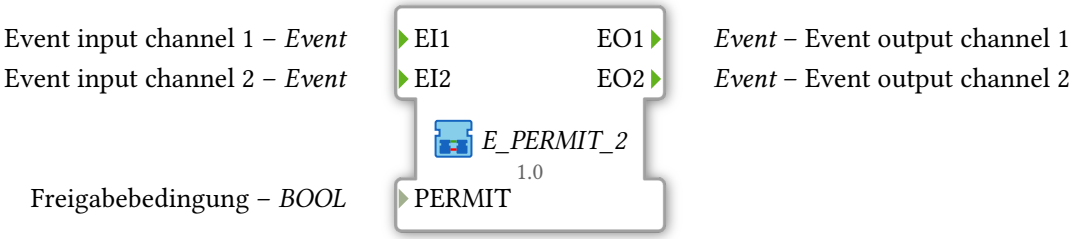
Application Scenarios

- **Debugging / Diagnostics**: Visualizing the number of ISOBUS callback events on the PCAN bus using PCAN Explorer or similar tools.
- **Protocol Monitoring**: Tracking the frequency of incoming PGN transmission callbacks at runtime.
- **System Health Checks**: Verifying that callback paths are active and working by observing monotonically increasing counter values.
- **Signal Generation for Testing**: Producing a repeating CAN frame whose data byte encodes the current trigger count, useful for instrumentation and test benches.

Comparison with Similar Blocks



Block	Data Source	Transmission Type	Use Case
CTU_TO_PCAN_Callback	Internal event counter	ISOBUS PGN callback	Diagnostics of callback frequency on PCAN bus
CTU_TO_PCAN_Send (typical alternative)	External data input	Direct CAN send	Sending arbitrary data upon counter event
E_CTU with IO mapping	Counter output mapped directly to output	No CAN packaging	Simple CPU-local counting, no bus output



Unlike a plain counter or a direct data sender, this subapplication combines counting, byte conversion, CAN message packing, and callback-based transmission in one integrated and reusable unit. Its reverse byte order handling (`reversing::BYTES_TO_ARR08B`) accommodates endianness requirements of the ISOBUS protocol.

Conclusion

CTU_TO_PCAN_Callback is a compact, event-driven diagnostic tool that turns PCAN callback triggers into an easily observable CAN message containing an incrementing counter value. Its well-defined event flow, combined with standard IEC 61499 and ISOBUS building blocks, makes it a reusable and reliable component for debugging and monitoring ISOBUS communication on PCAN hardware. The consistent use of request/confirm handshakes guarantees deterministic behavior and simple integration into larger automation or vehicle electronics applications.

E_PERMIT_2

• – ○ • – ○ • – ○ •

Introduction

The **E_PERMIT_2** is a composite subapplication that provides a two-channel event permission gate. It encapsulates two independent instances of the standard IEC 61499 `E_PERMIT` function block, allowing two separate event streams to be selectively forwarded or blocked using a single common permission signal. This block is particularly useful in safety-oriented or access-controlled automation scenarios where multiple event paths must be gated simultaneously.

Interface Structure

Event Inputs

Name	Type	Description
EI1	Event	Event input channel 1
EI2	Event	Event input channel 2

Event Outputs

Name	Type	Description
EO1	Event	Event output channel 1
EO2	Event	Event output channel 2

Data Inputs

Name	Type	Description
PERMIT	BOOL	Common permission condition for both channels

Data Outputs

None.

Adapters

None.

Functionality

The E_PERMIT_2 subapplication implements two parallel event gate channels. Internally, it instantiates two iec61499::events::E_PERMIT function blocks:

- E_PERMIT_1 connects event input EI1 to event output EO1.
- E_PERMIT_2 connects event input EI2 to event output EO2.

Both internal blocks receive the same boolean PERMIT signal as their gating condition. The behavior of each channel follows the standard E_PERMIT semantics:

- When PERMIT = TRUE, an incoming event at EI1 (or EI2) is immediately forwarded to EO1 (or EO2).
- When PERMIT = FALSE, incoming events are suppressed and not propagated to the outputs.

The two channels operate completely independently in terms of event flow, but share a common permission signal to ensure coordinated gating behavior across both paths.

Technical Features

- **Dual redundant channel structure** – Two identical event gate paths in a single subapplication.
- **Common gating signal** – A single PERMIT data input controls both channels, simplifying external wiring.
- **Event-driven processing** – No cyclic polling; events are processed only when received on the event inputs.
- **Standard IEC 61499 compliance** – Built entirely from standard E_PERMIT function blocks.
- **Zero internal data output** – No data is produced by the subsystem; it purely routes or blocks event flows.

State Overview

Since the internal E_PERMIT blocks are event-triggered and stateless in terms of event propagation, the subapplication does not maintain a persistent internal state machine. The effective state of the gate is solely determined by the value of the PERMIT input:

State	Condition	Behavior
Permitted	PERMIT = TRUE	Events on EI1/EI2 pass to EO1/EO2
Blocked	PERMIT = FALSE	Events on EI1/EI2 are discarded

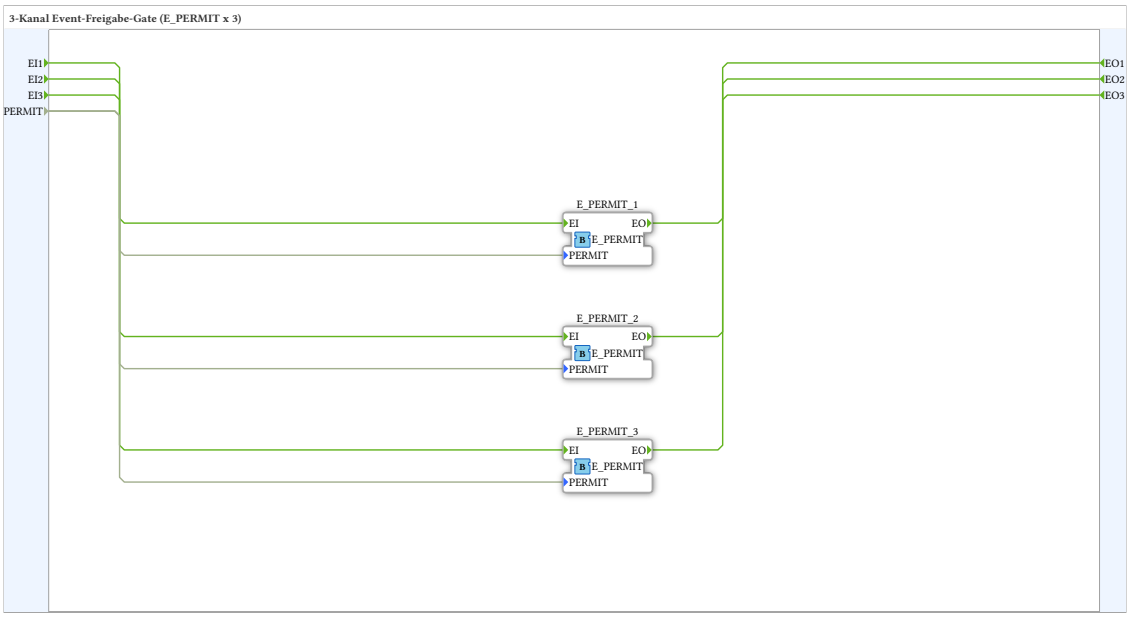
No further internal states or history are retained by the subapplication.

Application Scenarios

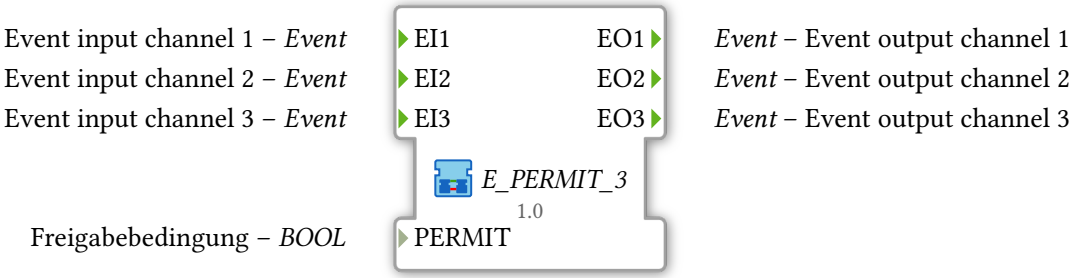
- **Machine safety interlocks** – Block multiple event-driven control commands (e.g., start, stop) when a safety condition is not met.
- **Production line supervision** – Gate two independent processing steps behind a single enable/disable master signal.
- **Conditional data acquisition** – Permit or suppress event notifications from two different sensors or sources based on a common readiness flag.
- **Redundant monitoring paths** – Use both channels to carry safety-relevant events while ensuring that both are disabled together during maintenance.

Comparison with Similar Blocks

Feature	Single E_PERMIT	E_PERMIT_2 (this subapp)
Number of channels	1	2
Gating inputs	1 (own PERMIT)	1 shared PERMIT for both channels
Event inputs	1 (EI)	2 (EI1, EI2)



Event outputs	1 (EO)	2 (EO1, EO2)
Wiring complexity	Requires separate gating per channel	Reduced due to shared permission
Independence	Fully independent if used twice	Channels independent except for gate signal



Compared to simply placing two E_PERMIT blocks manually, the E_PERMIT_2 subapplication offers a cleaner, reusable component with unified control logic, reduced wiring overhead, and a clearer interface for system integrators.

Conclusion

The **E_PERMIT_2** subapplication provides a compact and reusable solution for gating two independent event channels using a single permission input. By reusing the standardized E_PERMIT function block internally, it ensures predictable and IEC 61499-compliant behavior. Its dual-channel design makes it well suited for applications requiring coordinated event blocking across multiple paths, while keeping the external interface minimal and easy to integrate.

E_PERMIT_3

• – ○ • – ○ • – ○ •

Introduction

E_PERMIT_3 is a composite subapplication that implements a three-channel event gating mechanism. It combines three independent instances of the standard IEC 61499 E_PERMIT function block into a single reusable component. Each channel permits or blocks an incoming event stream based on a common Boolean permission signal. This subapp simplifies the design of systems requiring multiple synchronized event gates without duplicating logic.

Interface Structure

Event Inputs

- **EI1**: Event input for channel 1. When triggered, the event is forwarded to output **EO1** if the permission condition is TRUE.
- **EI2**: Event input for channel 2. When triggered, the event is forwarded to output **EO2** if the permission condition is TRUE.
- **EI3**: Event input for channel 3. When triggered, the event is forwarded to output **EO3** if the permission condition is TRUE.

Event Outputs

- **EO1**: Event output for channel 1. Corresponds to the gated event from **EI1**.
- **EO2**: Event output for channel 2. Corresponds to the gated event from **EI2**.
- **EO3**: Event output for channel 3. Corresponds to the gated event from **EI3**.

Data Inputs

- **PERMIT**: Boolean data input (type `BOOL`) that serves as the global gate condition for all three channels. If `PERMIT = TRUE`, incoming events are propagated to the respective outputs; if `FALSE`, events are discarded.

Data Outputs

No data outputs are provided by this subapplication.

Adapters

No adapters are used in this subapplication.

Functionality

The subapplication internally instantiates three identical E_PERMIT function blocks, each wired to one channel. The data input `PERMIT` is broadcast to all three blocks simultaneously. When an event arrives on any of the event inputs (`EI1`, `EI2`, or `EI3`), the corresponding internal E_PERMIT block evaluates the current value of `PERMIT`. If `PERMIT` is `TRUE`, the event is immediately re-emitted on the matching event output; otherwise, the event is suppressed. All three channels operate independently, and the behavior is identical to that of a single E_PERMIT block multiplied by three.

Technical Features

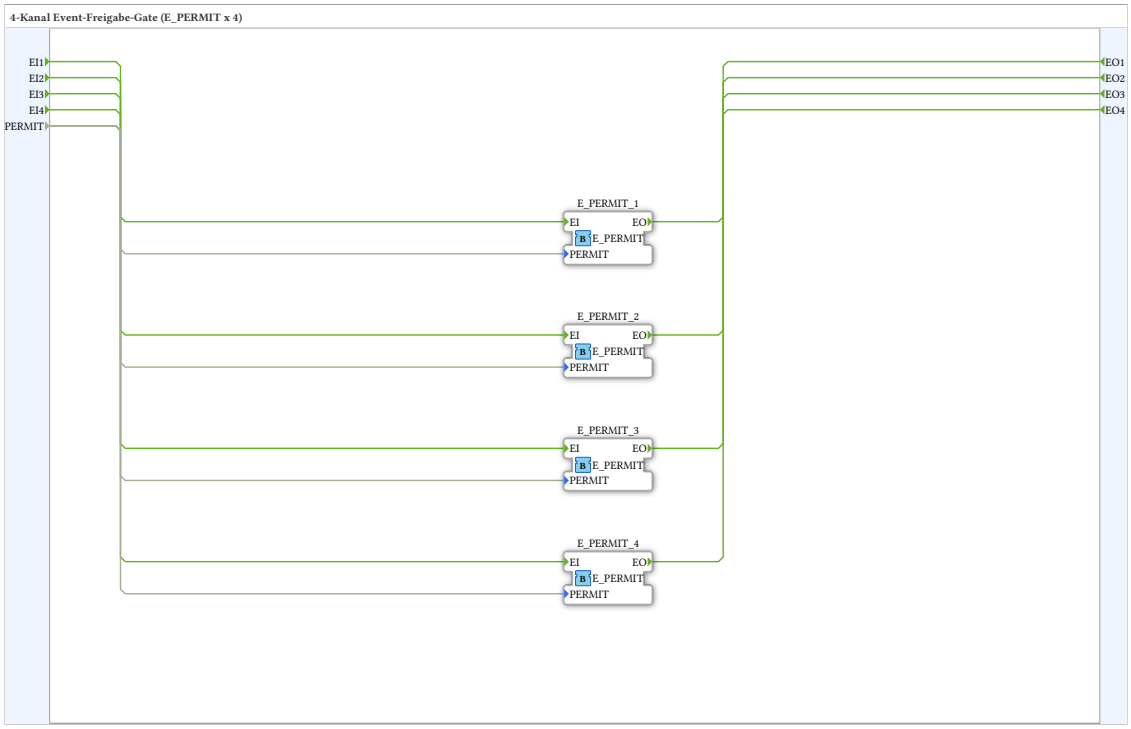
- **Three independent channels**: Each channel has its own event input and output, preventing cross-interference.
- **Shared permission signal**: A single `PERMIT` input controls all channels, simplifying coordination.
- **Standard-based implementation**: The subapplication is composed of standard IEC 61499 E_PERMIT function blocks, ensuring compatibility and predictable behavior.
- **Reusable and compact**: Encapsulates complex wiring into a single, clean interface.
- **No internal state**: The E_PERMIT block is combinational with respect to events; the subapplication does not introduce additional memory.

State Overview

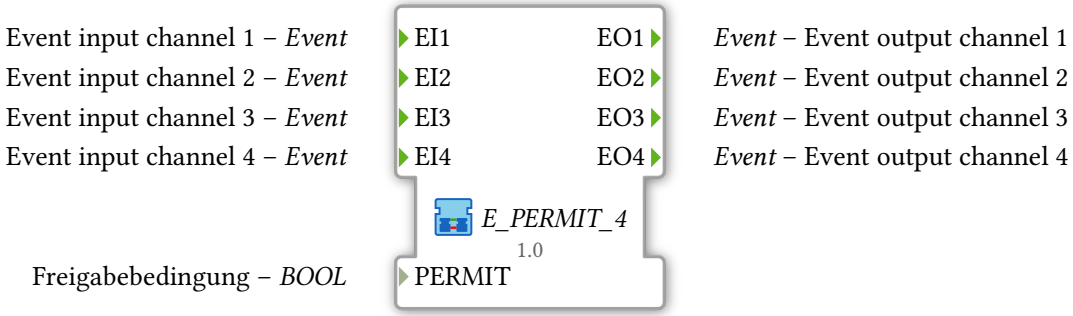
The subapplication does not maintain its own state. Each internal E_PERMIT block is stateless (purely event-driven). The only relevant condition is the value of `PERMIT` at the moment an event is received. No state transitions occur within the subapplication itself.

Application Scenarios

- **Synchronized gating**: When multiple event sources must be enabled or disabled simultaneously, e.g., enabling several production machine signals based on a safety interlock.
- **System mode switching**: A central `PERMIT` can activate or deactivate three different event-driven actions (e.g., data logging, alarm processing, or control outputs) in one go.
- **Multi-channel permission checks**: In distributed control systems, three independent event paths can be selectively allowed based on a common authorization flag.
- **Prototyping and reuse**: The subapplication can be placed in a library and reused across projects where triple-channel event gating is needed.



Comparison with Similar Blocks



- **Single E_PERMIT**: Offers only one channel. E_PERMIT_3 is a direct triplication of the E_PERMIT functionality, providing greater convenience and reducing diagram clutter.
- **Multiple independent E_PERMIT blocks**: While functionally equivalent, wiring three separate blocks manually increases the risk of connection errors and makes the design less maintainable. E_PERMIT_3 centralizes the shared `PERMIT` signal.
- **E_PERMIT with fan-out**: Some designs might use one E_PERMIT and split its output; however, this does not provide per-channel event inputs. E_PERMIT_3 preserves distinct event inputs and outputs for each channel.

Conclusion

E_PERMIT_3 is a straightforward composite subapplication that encapsulates three instances of the standard E_PERMIT function block into a single, reusable unit. It offers a clean, three-channel event gating solution with a shared permission flag, making it ideal for scenarios where multiple event streams must be controlled together. Its simplicity, standard-based construction, and lack of internal state ensure reliable and predictable operation in a variety of automation and control applications.

E_PERMIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The **E_PERMIT_4** is a composite subapplication that bundles four independent event-permission gates (based on the standard IEC 61499 `E_PERMIT` function block) into a single reusable component. It provides

four event channels, each of which can selectively pass or block an incoming event depending on a common Boolean permit condition. This design simplifies the integration of multi-channel event gating logic in distributed control applications.

Interface Structure

Event Inputs

Name	Type	Description
EI1	Event	Event input channel 1
EI2	Event	Event input channel 2
EI3	Event	Event input channel 3
EI4	Event	Event input channel 4

Event Outputs

Name	Type	Description
EO1	Event	Event output channel 1
EO2	Event	Event output channel 2
EO3	Event	Event output channel 3
EO4	Event	Event output channel 4

Data Inputs

Name	Type	Description
PERMIT	BOOL	Permit condition shared by all four channels

Data Outputs

None.

Adapters

None.

Functionality

The subapplication contains four internal instances of the standard `E_PERMIT` function block, connected as follows:

- `EI1` ⟶ `E_PERMIT_1.EI` ⟶ `EO1`
- `EI2` ⟶ `E_PERMIT_2.EI` ⟶ `EO2`
- `EI3` ⟶ `E_PERMIT_3.EI` ⟶ `EO3`
- `EI4` ⟶ `E_PERMIT_4.EI` ⟶ `EO4`

The single Boolean input `PERMIT` is distributed to all four internal blocks.

The operating behavior for each channel is identical:

1. An event arrives at the corresponding event input (e.g., `EI1`).
2. The internal `E_PERMIT` block evaluates the shared `PERMIT` signal.
3. If `PERMIT` is **TRUE**, the event is immediately forwarded to the associated event output (e.g., `EO1`).
4. If `PERMIT` is **FALSE**, the event is discarded and no output event is generated.

The channels are fully independent in terms of event flow, meaning an event on one channel does not influence the others, apart from sharing the same permit value.

Technical Features

- **Four-channel event gating** in a single compact subapplication.

- **One shared permit input** (PERMIT) controlling all channels simultaneously, reducing wiring complexity in higher-level applications.
- **Based on standard IEC 61499** E_PERMIT blocks, ensuring predictable, platform-independent behavior.
- **No internal state retention** – the gate is purely event-driven; each event is processed on arrival.
- **Scalable concept** – the pattern can be extended to more channels if required.
- **Event propagation delay** is minimal, as each channel is a direct pass-through path when permitted.

State Overview

The E_PERMIT_4 subapplication does not maintain any persistent internal state. As it is composed of E_PERMIT blocks, each individual gate behaves in a stateless combinational manner with respect to events:

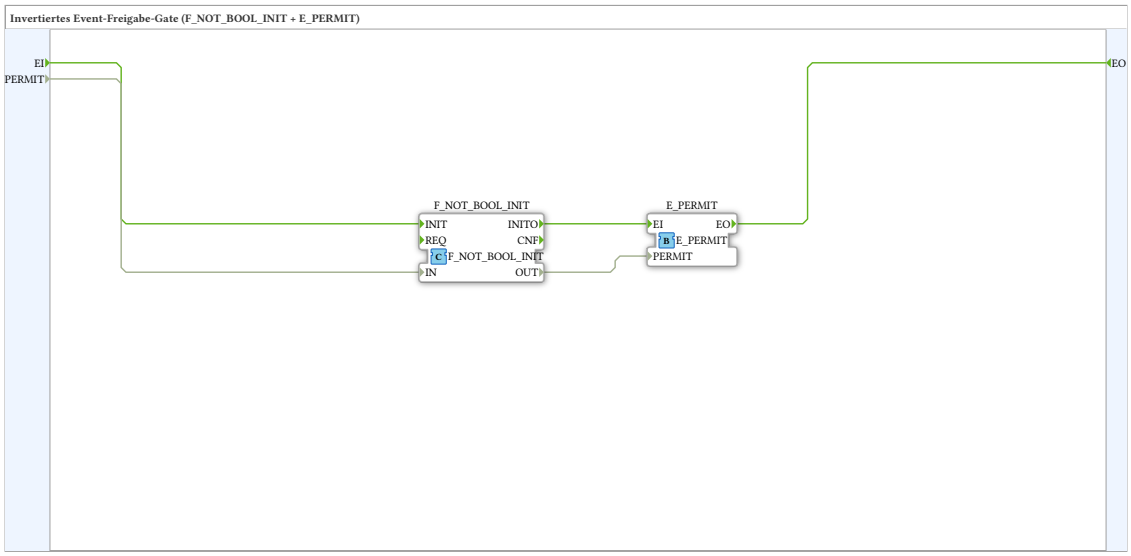
- When no event is present, the subapplication is idle.
- Upon an event input, the gate either forwards (permit = TRUE) or drops (permit = FALSE) the event.
- Changes to PERMIT take effect immediately for subsequent events.

There are no hidden latches, timers, or counters inside the component.

Application Scenarios

- **Multi-channel access control**: Enable or disable several independent event streams (e.g., sensor triggers) based on a single enabling condition.
- **Safe stop / emergency gating**: If a safety signal (PERMIT) becomes FALSE, all outgoing event triggers are suppressed.
- **Sequencing gates**: Conditionally forward start or stop commands to multiple machine axes simultaneously.
- **Test & simulation**: Provide a global switch to block all event-driven communication while simulating or debugging.
- **Batch processing**: Allow a set of parallel process steps only when a common prerequisite is fulfilled.

Comparison with Similar Blocks



Feature	E_PERMIT_4	Single E_PERMIT	E_SWITCH (per MB)
Number of channels	4	1	1 (with 2 outputs)
Permit input	Single shared PERMIT	Dedicated PERMIT per instance	Not applicable
Event routing	Pass or block	Pass or block	Route to one of two outputs
Use case	Multi-channel gating	Single-channel gating	Branching / multiplexing events
Integration effort	Low (one component)	High for many channels	Medium for branching logic

Compared to placing four separate E_PERMIT blocks manually, E_PERMIT_4 offers a cleaner interface, consistent wiring, and a single control point for the permit condition. It does not provide the branching capability of an E_SWITCH, but it is purpose-built for independent channel blocking.

Conclusion

The E_PERMIT_4 subapplication is a practical and reusable building block for applications that require simultaneous enable/disable control over multiple event streams. By wrapping four standard E_PERMIT blocks behind a unified interface, it reduces engineering effort, improves readability of the application logic, and ensures consistent behavior across all channels. It is particularly well suited for access control, safety gating, and multi-axis coordination tasks within IEC 61499-based systems.

E_PERMIT_INVERT

• – ○ • – ○ • – ○ •

Introduction

E_PERMIT_INVERT is an event-gating subapplication that implements an inverted event permission gate. It combines an inversion function and an event-permit block so that an incoming event is only forwarded when the Boolean input `PERMIT` is `FALSE`. This is useful in control logic where a `TRUE` signal should suppress or inhibit an event, rather than enable it.

Interface Structure

Event Inputs

Name	Type	Description
`EI`	Event	Event input. An event arriving here is forwarded to `EO` when `PERMIT` is `FALSE`.

Event Outputs

Name	Type	Description
`EO`	Event	Event output. Fires when `EI` occurs and `PERMIT` is `FALSE`.

Data Inputs

Name	Type	Description
`PERMIT`	BOOL	Inverted enable condition. If `TRUE`, the event is blocked. If `FALSE`, the event is allowed to pass.

Data Outputs

None.

Adapters

None.

Functionality

The internal structure of E_PERMIT_INVERT consists of two standard blocks:

- F_NOT_BOOL_INIT
- E_PERMIT

The PERMIT input is connected to F_NOT_BOOL_INIT.IN. The inverted result is then connected to E_PERMIT.PERMIT. The incoming event EI is connected directly to E_PERMIT.EI, and the output event E_PERMIT.EO is forwarded as EO.

This means:

1. EI triggers the event path.
2. F_NOT_BOOL_INIT inverts the current value of PERMIT.
3. E_PERMIT receives the inverted permission value.
4. If the original PERMIT is FALSE, the inverted value is TRUE, so the event is forwarded to EO.
5. If the original PERMIT is TRUE, the inverted value is FALSE, so the event is blocked.

Technical Features

- Implements an inverted event permission gate.
- Reuses standard IEC 61499 event and IEC 61131 logic blocks.
- Encapsulates the wiring of an inverter and an event gate in one reusable subapplication.
- Provides a single Boolean control input and a single event input/output pair.
- Does not expose any data outputs.
- Behaves as a pure event gate: no output event is generated without an input event.
- Suitable for event-driven control applications.

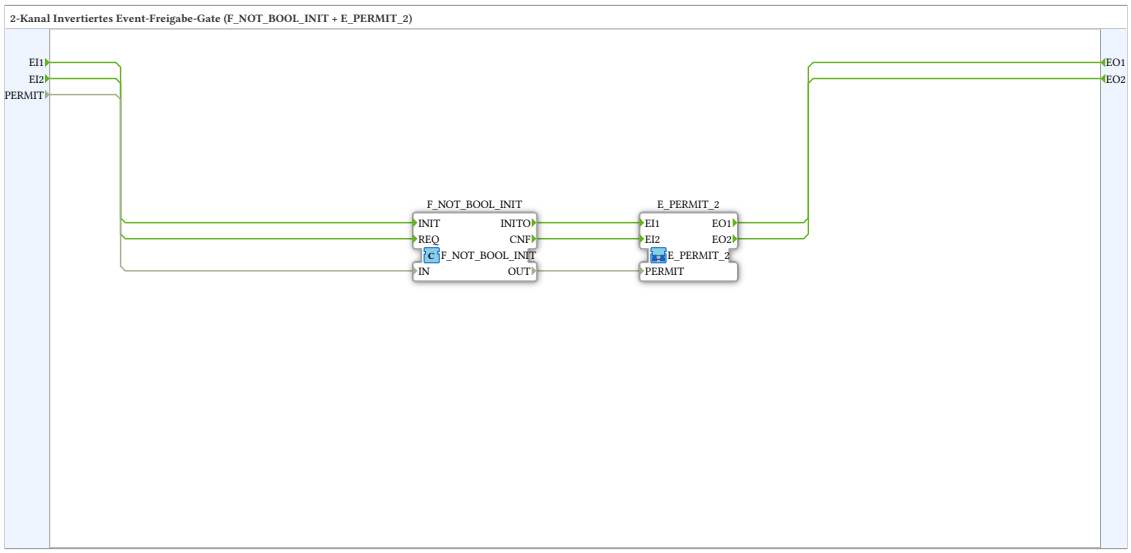
State Overview

E_PERMIT_INVERT has no internal state machine and no persistent state variables. The output behavior depends only on the current value of PERMIT and the occurrence of an event at EI. The gate is combinational with respect to the Boolean condition: a change of PERMIT alone does not generate an output event, but it affects whether the next EI event is passed through.

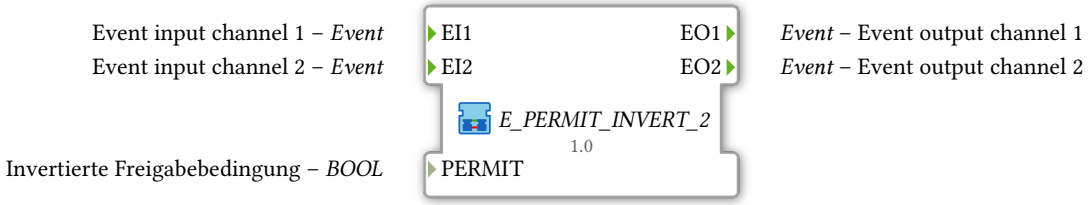
Application Scenarios

- Active-low enable signals: an event is allowed when the enable signal is FALSE.
- Inhibit logic: a TRUE inhibit signal suppresses event-driven actions.
- Interlocking: events are blocked while a safety condition is active.
- Replacing a manual inverter followed by an E_PERMIT with a single reusable component.
- Cleaner design in event-based control systems where inverted permission semantics are required.

Comparison with Similar Blocks



Block / Approach	Behavior
E_PERMIT	Passes an event when the permit input is TRUE.
E_PERMIT_INVERT	Passes an event when the permit input is FALSE.
Manual inverter + E_PERMIT	Equivalent logic, but requires additional wiring and is less reusable.
E_SWITCH	Routes events to different output paths, rather than simply suppressing or passing one event.



E_PERMIT_INVERT is therefore best understood as an “event gate with inverted permission logic”.

Conclusion

E_PERMIT_INVERT is a compact and reusable subapplication that provides inverted event gating logic. By internally combining F_NOT_BOOL_INIT and E_PERMIT, it gives designers a clear, maintainable way to permit event flow when a Boolean condition is FALSE. It is especially useful in event-driven control applications where inhibit or active-low enable signals are required.

E_PERMIT_INVERT_2

• – ○ • – ○ • – ○ •

Introduction

E_PERMIT_INVERT_2 is a two-channel inverted event permit gate. It is implemented as a subapplication that combines an IEC 61131 boolean inverter with a standard IEC 61499 E_PERMIT_2 event gate.

The subapplication accepts two independent event input channels and forwards them to two output channels only when an external BOOL permission signal is FALSE. This makes the block suitable for applications where an active-low permission or release signal must control event forwarding.

Interface Structure

Event Inputs

Name	Type	Description
EI1	Event	Event input channel 1. Forwarded to EO1 when the gate is open.
EI2	Event	Event input channel 2. Forwarded to EO2 when the gate is open.

Event Outputs

Name	Type	Description
EO1	Event	Event output channel 1. Emitted when EI1 is received and the gate is open.
EO2	Event	Event output channel 2. Emitted when EI2 is received and the gate is open.

Data Inputs

Name	Type	Description
PERMIT	BOOL	Inverted permission condition. FALSE enables event forwarding; TRUE blocks event forwarding.

Data Outputs

None.

Adapters

None.

Functionality

The subapplication uses an internal F_NOT_BOOL_INIT block to invert the external PERMIT signal. The resulting value is connected to the PERMIT input of an internal E_PERMIT_2 block.

The behavior is as follows:

- When the external PERMIT input is FALSE, the internal E_PERMIT_2 receives a TRUE permit signal. An event on EI1 is forwarded to EO1, and an event on EI2 is forwarded to EO2.
- When the external PERMIT input is TRUE, the internal E_PERMIT_2 receives a FALSE permit signal. Incoming events on EI1 and EI2 are blocked and no output events are generated.

Each event channel is independent. EI1 only controls EO1, and EI2 only controls EO2. Both channels share the same inverted permission condition.

Technical Features

- Reusable subapplication defined as an IEC 61499 SubAppType.
- Two event input channels and two event output channels.
- One common BOOL permission input.
- No data outputs and no adapters.
- Internally uses the standard function blocks F_NOT_BOOL_INIT and E_PERMIT_2.
- Provides active-low event gating behavior.
- Encapsulates the inverter plus event gate logic into a single application component.
- The gate does not queue or store events. Events arriving while the gate is closed are discarded.

State Overview

The subapplication does not define an internal state machine or sequential function chart. Its behavior is determined by the current value of the external PERMIT input.

External PERMIT	Internal E_PERMIT_2 Input	Result
FALSE	TRUE	Gate is open. EI1 triggers EO1, EI2 triggers EO2.
TRUE	FALSE	Gate is closed. EI1 and EI2 are blocked.

The behavior is combinational with respect to the permission signal. Changing PERMIT immediately changes whether new events are allowed through. No internal state is retained.

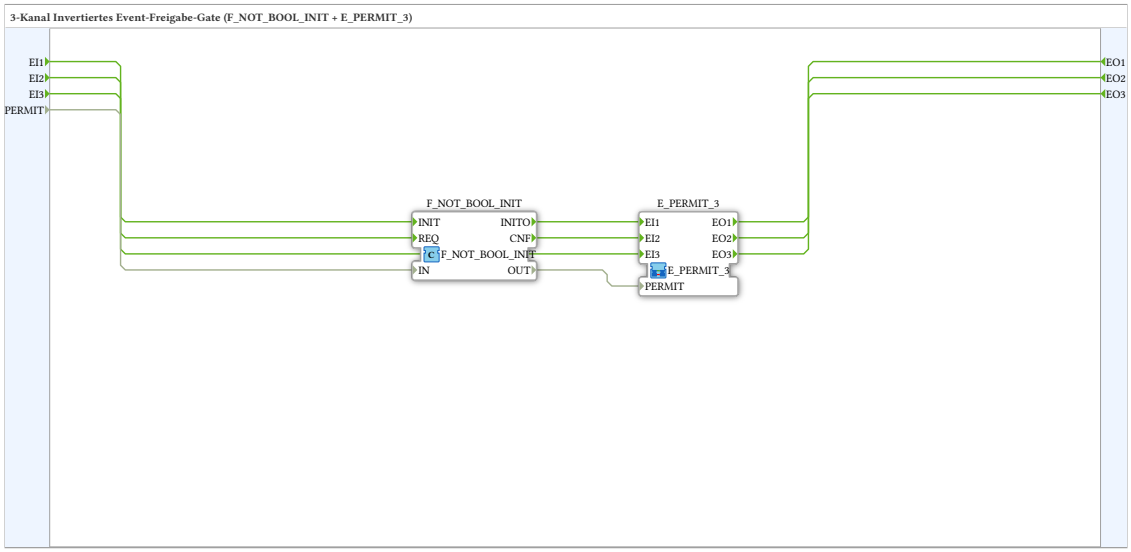
Application Scenarios

E_PERMIT_INVERT_2 is useful in control applications where the available permission signal has inverted logic. Typical scenarios include:

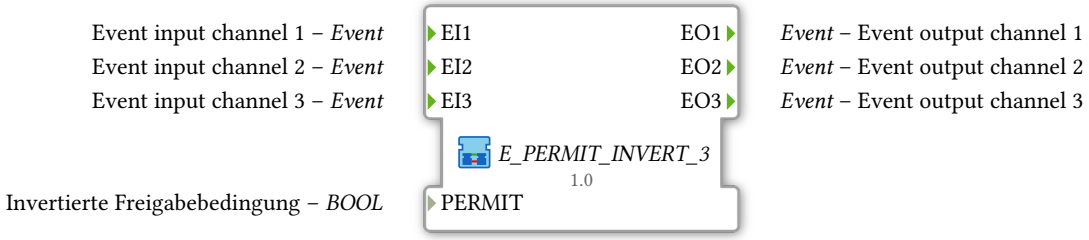
- Using a “fault active” or “blocked” signal as the event gate. Events are only passed when the fault signal is FALSE.
- Gating two independent event streams with a single active-low release condition.
- Integrating inverted enable logic into a reusable subapplication to avoid adding a separate inverter block in the calling application.
- Implementing safety-oriented event suppression where a TRUE signal must prevent event propagation.

Comparison with Similar Blocks

Block / Pattern	Behavior
E_PERMIT_2	Passes events when the PERMIT input is TRUE. Requires an external inverter for active-low permission signals.
E_PERMIT_INVERT_2	Passes events when the external PERMIT input is FALSE. The inversion is integrated internally.



F_NOT_BOOL_INIT	Inverts a BOOL data signal only. It does not gate events.
E_PERMIT	A single-channel permit gate with similar high-active semantics.



E_PERMIT_INVERT_2 is therefore a convenient alternative to manually wiring an inverter in front of an E_PERMIT_2 block.

Conclusion

E_PERMIT_INVERT_2 is a compact and reusable two-channel event gate for inverted permission logic. By combining a boolean inverter with an E_PERMIT_2 event gate, it provides clear active-low event forwarding behavior. It is especially useful when an application uses inhibit or fault signals to control whether events may pass. The subapplication reduces wiring complexity and improves readability in larger IEC 61499 systems.

E_PERMIT_INVERT_3

• – ○ • – ○ • – ○ •

Introduction

E_PERMIT_INVERT_3 is a composite subapplication that combines the IEC 61131 boolean inverter F_NOT_BOOL_INIT with the IEC 61499 event gate E_PERMIT_3. It provides three independent event channels that are only enabled when the external PERMIT signal is FALSE. The subapp therefore behaves as a 3-channel inverted event-enable gate: incoming events are forwarded to the outputs as long as the enable condition is de-asserted.

Interface Structure

Event Inputs

Name	Type	Comment
EI1	Event	Event input channel 1
EI2	Event	Event input channel 2

EI3	Event	Event input channel 3

Event Outputs

Name	Type	Comment
EO1	Event	Event output channel 1
EO2	Event	Event output channel 2
EO3	Event	Event output channel 3

Data Inputs

Name	Type	Comment
PERMIT	BOOL	Inverted enable condition (Freigabebedingung)

Data Outputs

None.

Adapters

None.

Functionality

The subapp implements a three-channel event gate with an inverted enable signal. The external PERMIT input is connected to the IN input of F_NOT_BOOL_INIT, whose output is the logical negation of PERMIT. This negated value is then fed to the PERMIT input of E_PERMIT_3.

Inside E_PERMIT_3, an event arriving on EI1, EI2, or EI3 is forwarded to the corresponding output EO1, EO2, or EO3 only while the PERMIT input of the gate is TRUE. Because the subapp inverts the external PERMIT signal before passing it to the gate, the effective forwarding condition for the external user is:

- PERMIT = FALSE ⟶ internal permit = TRUE ⟶ events are forwarded.
- PERMIT = TRUE ⟶ internal permit = FALSE ⟶ events are blocked.

No data values are consumed or produced by the subapp; it purely controls event propagation.

Technical Features

- Reusable composite design built from standard IEC 61131 and IEC 61499 function blocks.
- Three independent event channels controlled by a single shared enable signal.
- Complementary behavior compared to the plain E_PERMIT_3 block.
- F_NOT_BOOL_INIT provides a deterministic boolean negation with a defined initial output state, which avoids undefined behavior during cold start.
- Easy to integrate into larger 4diac-ide applications due to its simple interface.
- No data outputs or adapters reduce wiring complexity.

State Overview

E_PERMIT_INVERT_3 contains no explicit state machine. Its runtime behavior can be described in terms of the combined states of the internal blocks:

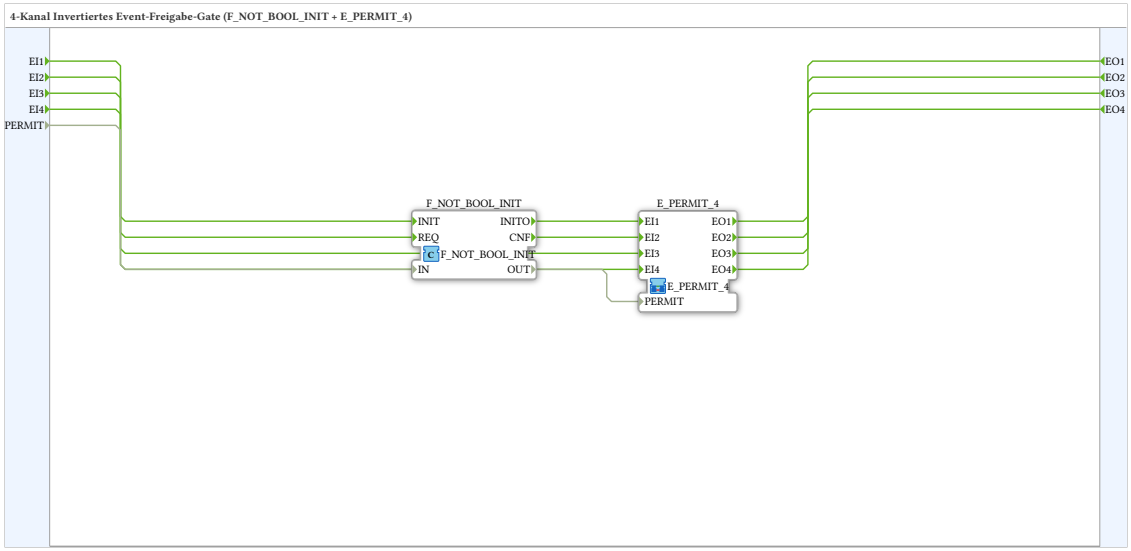
External PERMIT	F_NOT_BOOL_INIT.OUT	E_PERMIT_3 internal permit	Result
FALSE	TRUE	TRUE	Events pass through
TRUE	FALSE	FALSE	Events blocked

There is no event-driven state retention; each incoming event is either forwarded or discarded depending solely on the current value of PERMIT.

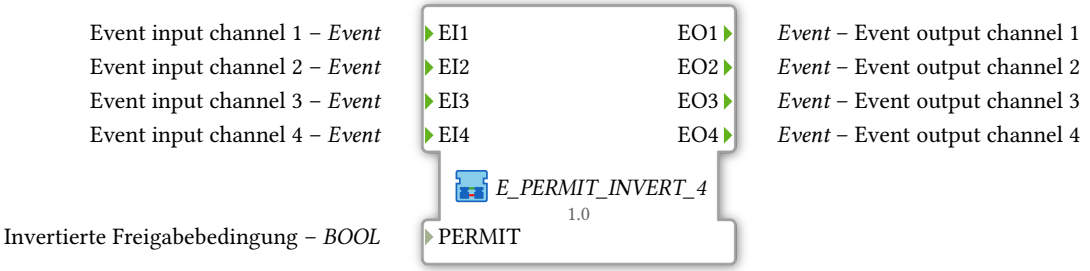
Application Scenarios

- **Safety and emergency-stop logic:** Event processing is permitted only while a safety signal is inactive, e.g. when a stop button is not pressed.

- **Interlock circuits:** Machine event handling is disabled while a guard door is open or a warning condition is active.
- **Supervisory enable/disable:** A central control signal blocks or releases event-driven activities for three parallel subsystems at once.
- **Fail-safe event gating:** In designs where events must be suppressed whenever an alarm flag is set, the inverted permit semantics fit naturally.



Comparison with Similar Blocks



- **E_PERMIT_3:** The standard E_PERMIT_3 forwards events when its PERMIT input is TRUE. E_PERMIT_INVERT_3 behaves exactly opposite from the perspective of the external signal, making it suitable for active-low enable logic.
- **E_SWITCH / E_DEMUX:** These blocks route events to selected outputs based on a control input, whereas E_PERMIT_INVERT_3 only blocks or forwards events on the same channel.
- **F_NOT_BOOL_INIT:** A pure logic element without event gating semantics. E_PERMIT_INVERT_3 adds the event-gate behavior around it.

Conclusion

E_PERMIT_INVERT_3 is a compact and practical subapplication for inverted event gating. By internally combining a boolean inverter with a three-channel event permit gate, it offers a clearly named and reusable component for applications that require event flow to be enabled by an active-low signal. Its simple interface, deterministic initialization, and complementary behavior to E_PERMIT_3 make it a valuable building block in IEC 61499-based control systems.

E_PERMIT_INVERT_4

• – ○ • – ○ • – ○ •

Introduction

`E_PERMIT_INVERT_4` is a typed subapplication that implements a four-channel inverted event-permission gate. It combines an `F_NOT_BOOL_INIT` block with an `E_PERMIT_4` block. The external `PERMIT` input is

logically inverted before it is applied to the internal event gate. Therefore, an event is forwarded only when PERMIT is FALSE. When PERMIT is TRUE, arriving events are suppressed.

The four event channels operate independently from each other, but they all share the same permission condition.

Interface Structure

The subapplication has four event inputs, four event outputs, and one Boolean data input. There are no data outputs and no adapters.

Event Inputs

Name	Type	Description
EI1	Event	Event input channel 1.
EI2	Event	Event input channel 2.
EI3	Event	Event input channel 3.
EI4	Event	Event input channel 4.

Event Outputs

Name	Type	Description
EO1	Event	Event output channel 1.
EO2	Event	Event output channel 2.
EO3	Event	Event output channel 3.
EO4	Event	Event output channel 4.

Data Inputs

Name	Type	Description
PERMIT	BOOL	Inverted enable condition. FALSE opens the event gate; TRUE closes it.

Data Outputs

None.

Adapters

None.

Functionality

E_PERMIT_INVERT_4 performs the following internal operations:

1. The Boolean input PERMIT is negated by F_NOT_BOOL_INIT.
2. The negated value is connected to the PERMIT input of E_PERMIT_4.
3. Each event input EIx is connected to the corresponding event input of E_PERMIT_4.
4. The corresponding event output EOx is emitted only when the internal E_PERMIT_4.PERMIT value is TRUE.

The effective enable condition is:

enable = **NOT PERMIT**

For each channel x:

- When PERMIT = FALSE, enable = TRUE, and an event on EIx produces an event on EOx.
- When PERMIT = TRUE, enable = FALSE, and an event on EIx is suppressed.

The gate does not buffer events. If the gate is closed, the incoming event is discarded.

Technical Features

- Four-channel event gating in a single reusable subapplication.

- Active-low permission behavior due to the inverted PERMIT input.
- Shared gate condition for all four channels.
- Direct one-to-one event routing from each EIx to the corresponding EOx.
- No data outputs or additional data transformation.
- Built from standard blocks: E_PERMIT_4 and F_NOT_BOOL_INIT.
- No adapters required for integration.

State Overview

E_PERMIT_INVERT_4 has no complex internal state machine. The relevant state is determined by the value of PERMIT:

State	PERMIT	Internal E_PERMIT_4.PERMIT	Event behavior
Gate open	FALSE	TRUE	EIx ⟶ EOx
Gate closed	TRUE	FALSE	EIx is suppressed

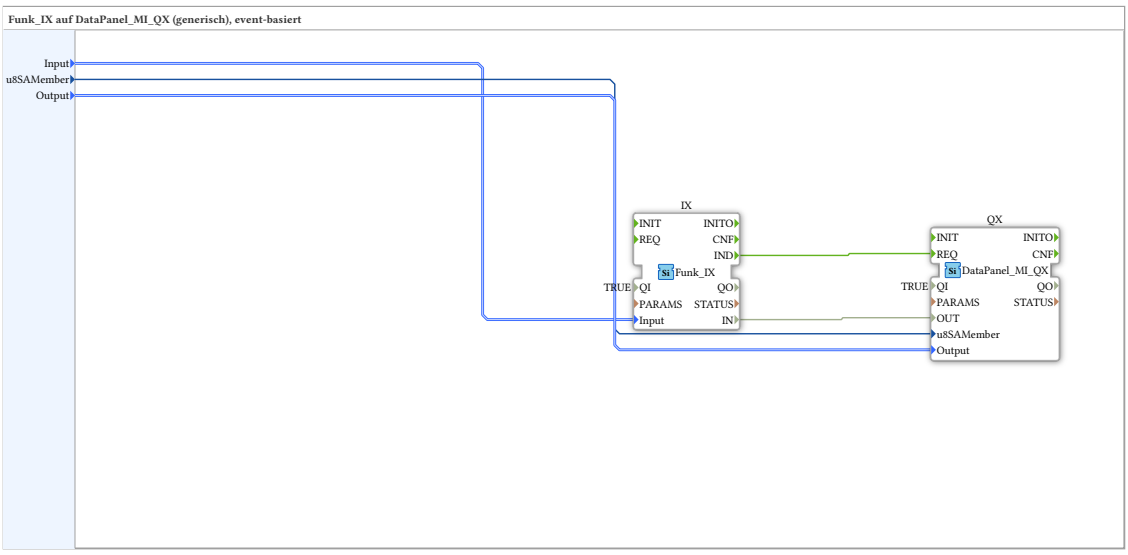
A change of PERMIT takes effect for the next arriving event. The four event channels remain independent and do not synchronize with one another.

Application Scenarios

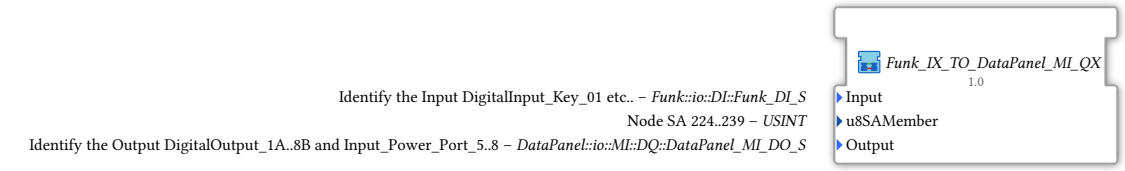
This subapplication is suitable whenever an event stream should be allowed while a signal is inactive. Typical examples include:

- Passing alarm or notification events only when the process is not in an error state.
- Blocking event outputs during maintenance or startup phases, where the control signal is TRUE.
- Implementing fail-safe enable logic in which FALSE means “normal operation” and TRUE means “inhibit”.
- Combining multiple permission-dependent event channels into one compact component.

Comparison with Similar Blocks



E_PERMIT_4 is a non-inverted event gate: events are forwarded when its PERMIT input is TRUE. E_PERMIT_INVERT_4 reverses this behavior, so events are forwarded when the external PERMIT is FALSE.



Compared to manually wiring an F_NOT_BOOL_INIT in front of an E_PERMIT_4, this subapplication reduces connection effort and avoids wiring mistakes. It is not a routing switch like E_SWITCH or E_SELECT; it simply forwards or suppresses an event on the same channel.

Conclusion

E_PERMIT_INVERT_4 is a compact and clear solution for four-channel event gating with an active-low enable condition. By combining a Boolean inverter with the standard E_PERMIT_4 block, it provides predictable event suppression and easy integration into IEC 61499 applications.

Funk_IX_TO_DataPanel_MI_QX

• – ◦ • – ◦ • – ◦ •

Introduction

The `Funk_IX_TO_DataPanel_MI_QX` is a generic, event-based subapplication that bridges a wireless input module (Funk IX) to a DataPanel output module (MI QX). It is designed to be reused in various contexts where a single digital input event (e.g., a key press) must be forwarded to a corresponding digital output on a DataPanel. The subapp encapsulates the wiring and synchronisation between these two function blocks, providing a clean and configurable interface.

Interface Structure

The subapplication exposes three data inputs, no event inputs or outputs, and no adapters. All communication with the outside world is performed via these data ports.

Event Inputs

None.

Event Outputs

None.

Data Inputs

Name	Type	Initial Value	Description
`Input`	`Funk::io::DI::Funk_DI_S`	`Funk_DI::Invalid`	Identifies the incoming digital input (e.g., `DigitalInput_Key_01`).
`u8SAMember`	`USINT`	`MI::MI_00`	Node SA address (range 224..239) used for the output module.
`Output`	`DataPanel::io::MI::DQ::DataPanel_MI_DO_S`	`Invalid`	Identifies the output channel on the DataPanel (e.g., `DigitalOutput_1A..8B` or `Input_Power_Port_5..8`).

Data Outputs

None.

Adapters

None.

Functionality

The subapplication connects an instance of the function block `Funk::io::DI::Funk_IX` to an instance of `DataPanel::io::MI::DQ::DataPanel_MI_QX`. The internal wiring is as follows:

- **Event connection**: The event output `IND` of the Funk block (IX) is connected to the event input `REQ` of the DataPanel block (QX). This ensures that every time a new value is received by the Funk input, the DataPanel output is triggered.
- **Data connection**: The data output `IN` of the Funk block is connected to the data input `OUT` of the DataPanel block. This transfers the actual value (e.g., a button state) from the wireless module to the output stage.

The three external data inputs of the subapplication are passed directly to the corresponding parameters of the internal blocks:

- `Input` is forwarded to `IX.Input`
- `u8SAMember` is forwarded to `QX.u8SAMember`
- `Output` is forwarded to `QX.Output`

Both internal blocks have their `QI` parameter set to `TRUE`, so they are permanently enabled. The `PARAMS` parameter of the Funk block is set to an empty string and is hidden in the configuration.

Technical Features

- **Generic configuration**: The subapplication can be reused for any combination of Funk digital input and DataPanel output by simply setting the three data inputs.
- **Event-driven operation**: The forwarding of an input event to the output is synchronous and triggered by the Funk block's `IND` event.
- **No internal state**: The subapplication itself does not contain any state variables; it only establishes the data and event flow between the two function blocks.
- **Compile-time optimised**: All connections are defined in the subapplication network, allowing the compiler to inline or optimise the data paths.

State Overview

The subapplication does not maintain any state of its own. The behaviour is fully determined by the states of the two internal function blocks:

- **Funk IX**: Waits for a new input event. On arrival, it updates its `IN` output and issues an `IND` event.
- **DataPanel QX**: Upon receiving the `REQ` event, it reads the `OUT` data input and applies the value to the configured output channel.

There is no explicit state machine in the subapplication; the overall system state is the combination of the states of the internal blocks.

Application Scenarios

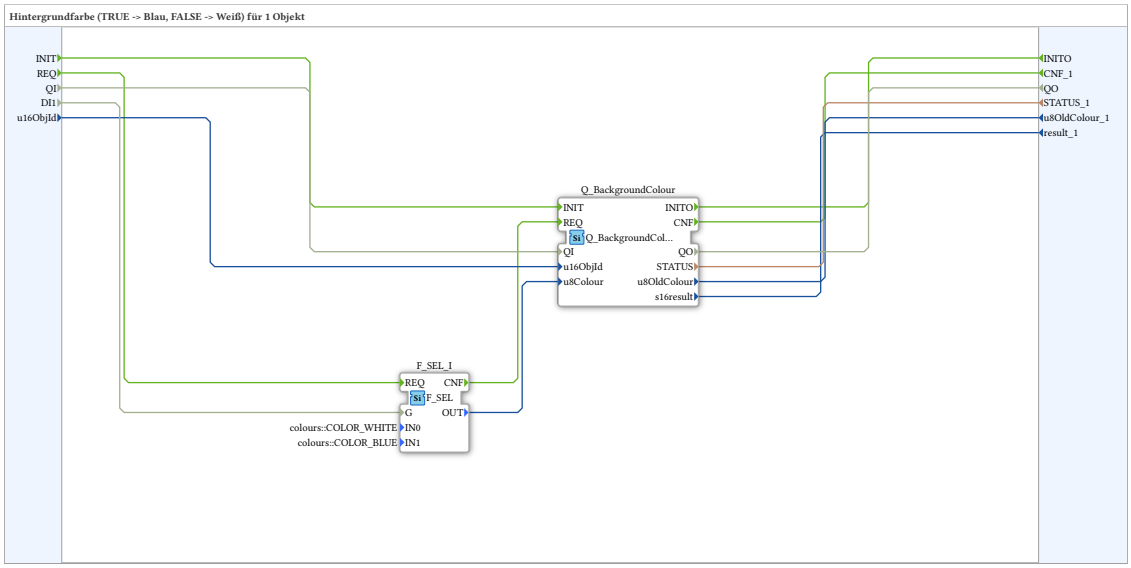
This subapplication is particularly useful in scenarios where a wireless remote control or sensor needs to control a physical output on a DataPanel. Typical use cases include:

- Wireless keypad to activate a light or motor output.
- Remote button to trigger a digital output on a DataPanel in an industrial or building automation environment.
- Generic bridging of any `Funk_DI` input to a `DataPanel_MI_DO` output, with the flexibility to choose the exact input and output channel at runtime.

Because the configuration is done via data inputs, the same subapplication instance can be re-parameterised without changing the internal structure, making it ideal for reusable library components.

Comparison with Similar Blocks

The subapplication is tailored to the specific combination of Funk input and DataPanel output. Similar blocks might include:



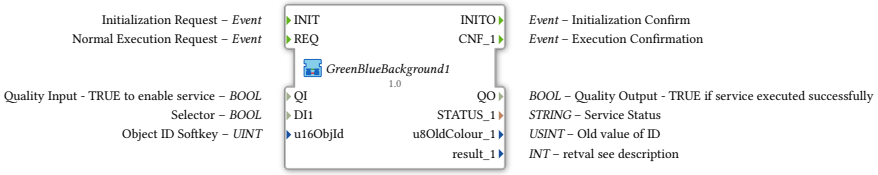
- **Direct Function Block Connection**: Instead of a wrapper subapplication, a designer could directly connect a `Funk_IX` to a `DataPanel_MI_QX` in the parent application. This would be more flexible but would expose internal details and require manual wiring for every new instance.
- **Other bridge blocks**: Other subapplications may exist that combine different input and output types (e.g., Modbus to DataPanel). However, this subapplication is specialised for the Funk wireless input family.

Compared to a direct connection, the subapplication offers the advantages of encapsulation, reusability, and a simplified interface. It also ensures that the correct event and data paths are always used, reducing the chance of wiring errors.

Conclusion

`Funk_IX_TO_DataPanel_MI_QX` is a compact and reusable subapplication that provides a clean bridge between a Funk digital input and a DataPanel digital output. Its event-based nature and configurable parameters make it a practical building block for automation projects that require wireless-to-output connectivity. The subapplication hides the complexity of the internal wiring and can be easily integrated into larger systems, promoting maintainability and consistency.

GreenBlueBackground1



• — ○ • — ○ • — ○ •

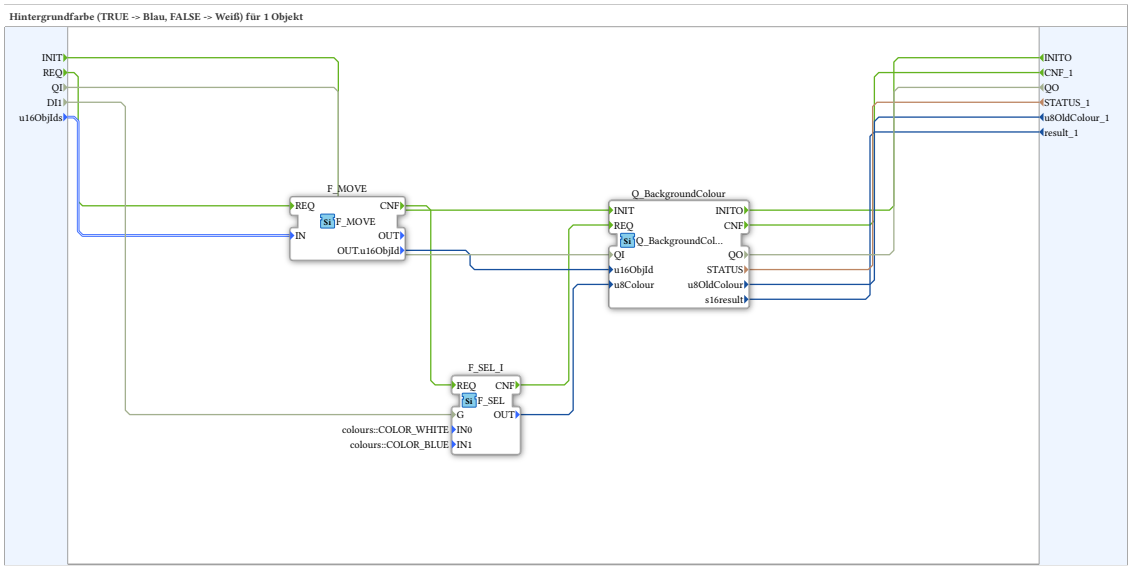
Introduction

`GreenBlueBackground1` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Blau**, `FALSE` ⟶ **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via input `u16ObjId`.

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Interface: Initialization and Quality

- **INIT** (event input, `EInit`) ⟶ `Q_BackgroundColour.INIT`; `Q_BackgroundColour.INITO` ⟶ **INITO** (event output, `EInit`).
- **QI** (data input, `BOOL`, default `TRUE`): Quality Input - `TRUE` enables the service; passed through to `Q_BackgroundColour.QI`.
- **QO** (data output, `BOOL`): Quality Output - `TRUE` if the service executed successfully; comes from `Q_BackgroundColour.QO`.



Summary

One of many variants in the background color block family: color pair Blau/Weiß, 1 object, BOOL selector.

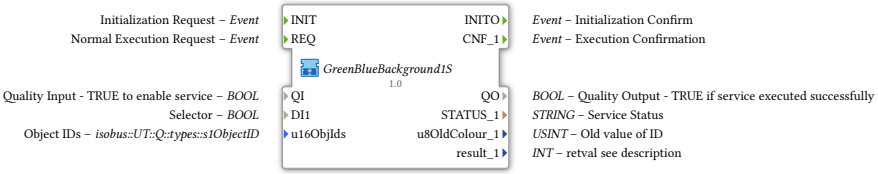
GreenBlueBackground1S



• — ○ • — ○ • — ○ •

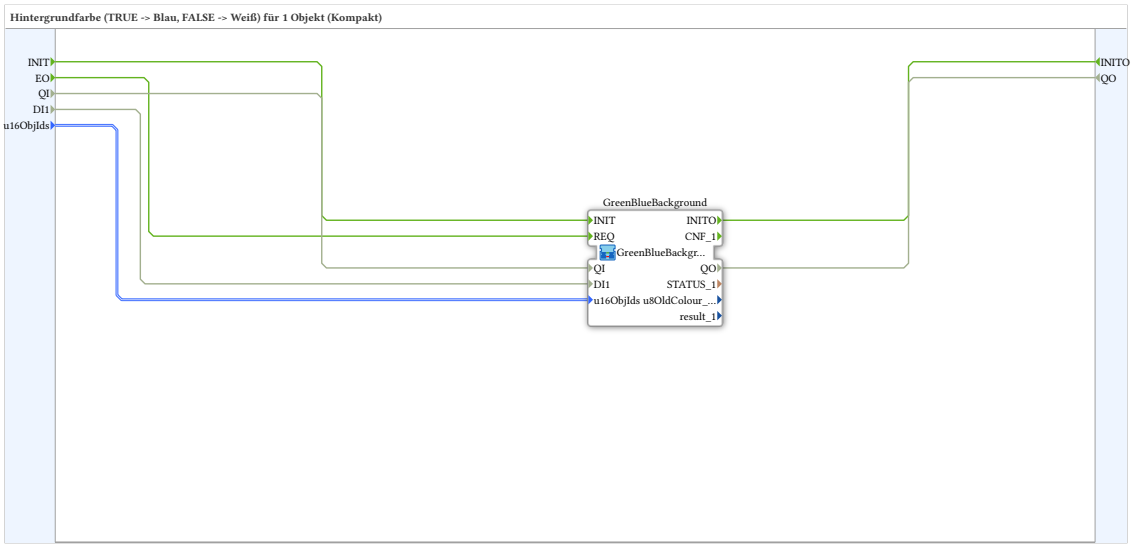
Introduction

`GreenBlueBackground1S` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Blau**, `FALSE` ⟶ **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

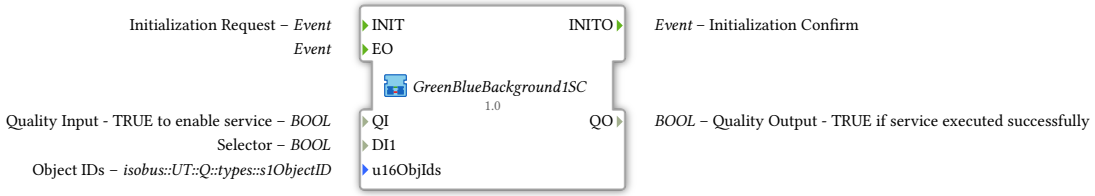
For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Interface: Initialization and Quality

- **INIT** (event input, `EInit`) ⟶ `Q_BackgroundColour.INIT`; `Q_BackgroundColour.INITO` ⟶ **INITO** (event output, `EInit`).
- **QI** (data input, `BOOL`, default `TRUE`): Quality Input - `TRUE` enables the service; passed through to `Q_BackgroundColour.QI`.
- **QO** (data output, `BOOL`): Quality Output - `TRUE` if the service executed successfully; comes from `Q_BackgroundColour.QO`.



Summary



One of many variants in the background color block family: color pair Blau/Weiß, 1 object, BOOL selector, struct. object ID.

GreenBlueBackground1SC

• – ○ • – ○ • – ○ •

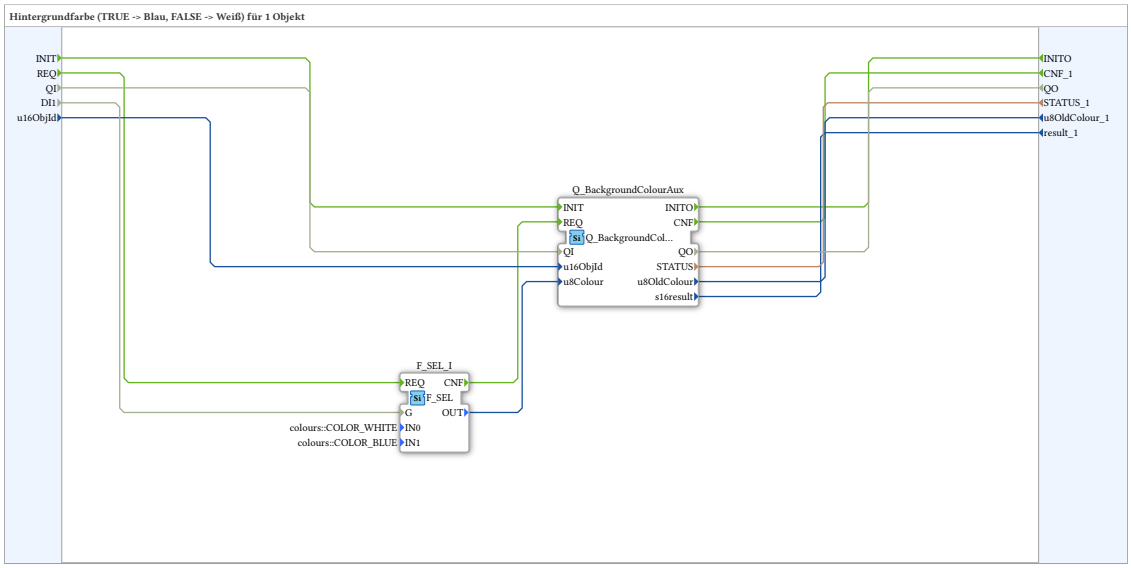
Introduction

`GreenBlueBackground1SC` is a **compact wrapper** around `GreenBlueBackground1S` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

For the shared pattern, see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `GreenBlueBackground.QI`
- **Data output** `QO` (`BOOL`, Quality Output): passed through from `GreenBlueBackground.QO`
- **Initialization chain**: `INIT` ⟶ `GreenBlueBackground.INIT`, `GreenBlueBackground.INITO` ⟶ `INITO`



Summary

A pure pass-through to `GreenBlueBackground1S` for the common case where the diagnostic values aren't needed.

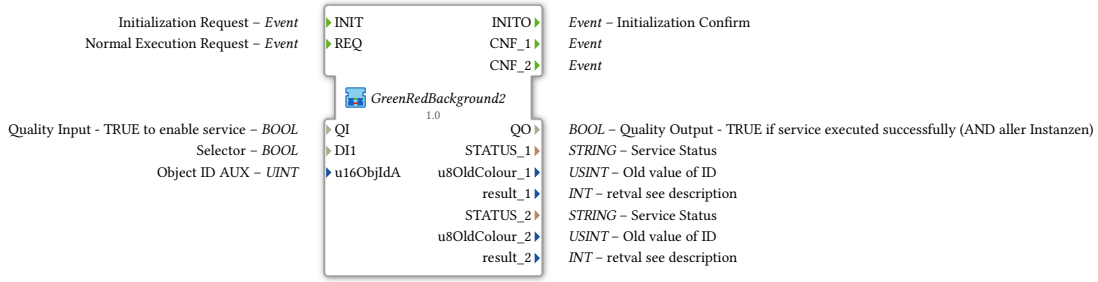
GreenRedBackground2



• – ○ • – ○ • – ○ •

Introduction

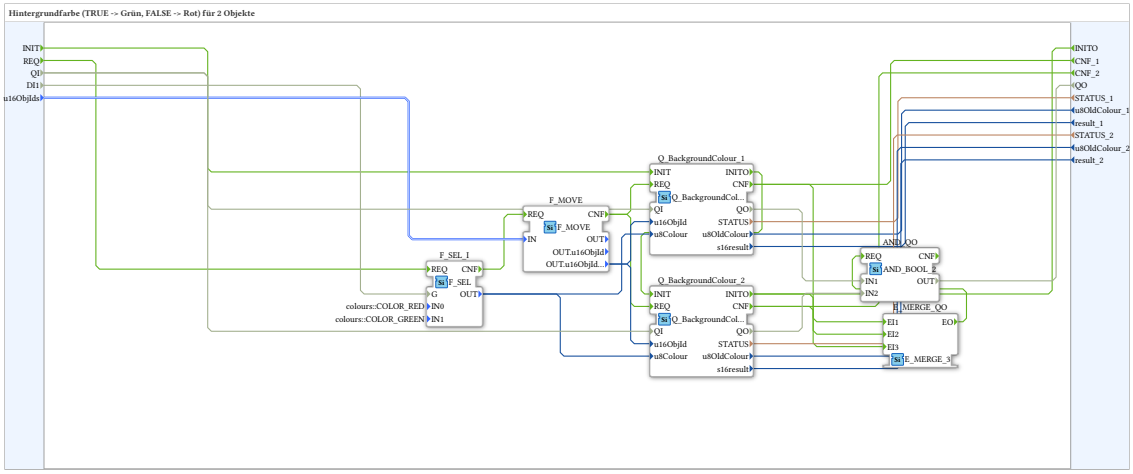
`GreenRedBackground2` switches the VT background color of 2 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Rot**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via inputs `u16ObjIdA`.

Position	Object ID source	Block
1	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`): initialization is chained through the `Q_BackgroundColour` instances: `INIT` ⟶ `Q_BackgroundColour_1.INIT`; `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` ⟶ `INITO`.
- **Data input `QI`** (`BOOL`, default `TRUE`) is distributed to `.QI` of all instances (`Q_BackgroundColour_1`, `Q_BackgroundColour_2`).
- **Data output `QO`** (`BOOL`): AND of all instances via `AND_QO` (`iec61131::booleanOperators::AND_BOOL_2`): `Q_BackgroundColour_1.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.
- `E_MERGE_QO` (`iec61499::events::E_MERGE_3`) merges `Q_BackgroundColour_2.INITO` and the `CNF` events of both instances (`Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF`) and thereby triggers `AND_QO.REQ`.



Summary

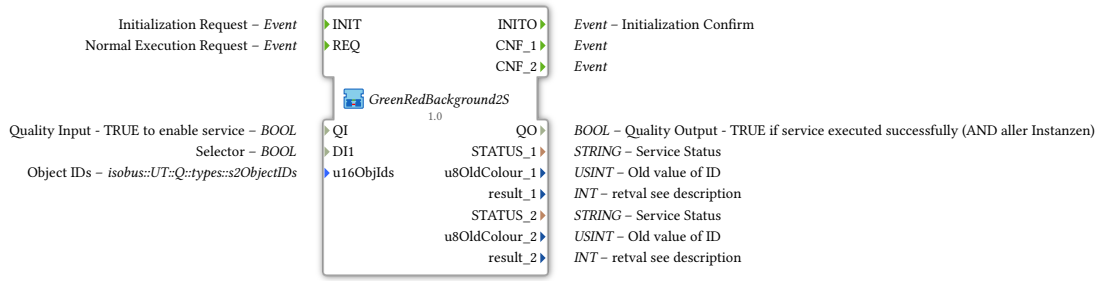
One of many variants in the background color block family: color pair Grün/Rot, 2 objects, BOOL selector.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

GreenRedBackground2S

• – ○ • – ○ • – ○ •



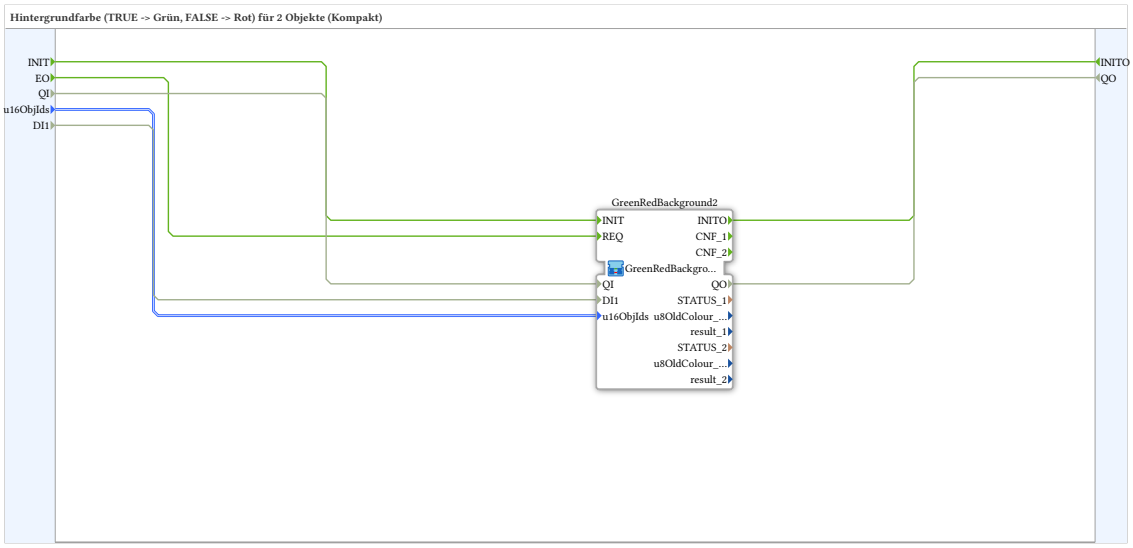
Introduction

`GreenRedBackground2S` switches the VT background color of 2 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Rot**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

Interface (quality pattern): event input `INIT` and event output `INITO` (each `EInit`), data input `QI` (`BOOL`, default `TRUE`) and data output `QO` (`BOOL`, AND of all instances). Initialization: `INIT` ⟶ `Q_BackgroundColour_1.INIT`; `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` ⟶ `INITO`. Quality: `QI` ⟶ `Q_BackgroundColour_1.QI`, `Q_BackgroundColour_2.QI`; `Q_BackgroundColour_1.QO`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN1` to `AND_QO.IN2` (`AND_QO`: `iec61131::booleanOperators::AND_BOOL_2`); `AND_QO.OUT` ⟶ `QO`. The trigger `AND_QO.REQ` comes via `E_MERGE_QO` (`E_MERGE_3`), which merges `Q_BackgroundColour_2.INITO` and the `CNF` of `Q_BackgroundColour_1` and `_2`; `E_MERGE_QO.EO` ⟶ `AND_QO.REQ`.

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).



Summary

One of many variants in the background color block family: color pair Grün/Rot, 2 objects, BOOL selector, struct. object ID.

GreenRedBackground2SC

• – ○ • – ○ • – ○ •

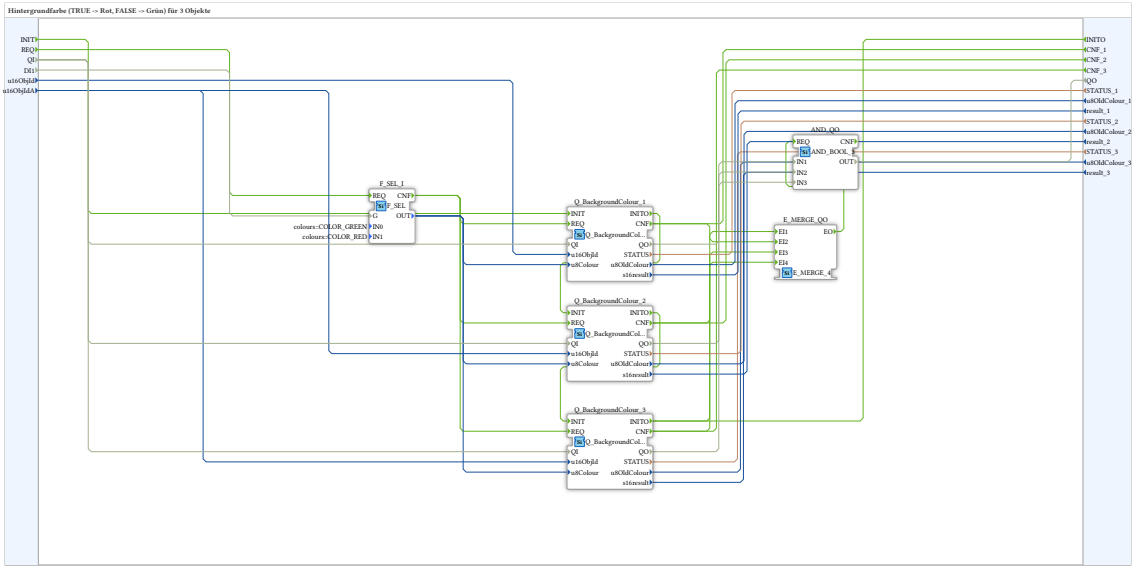
Introduction

`GreenRedBackground2SC` is a **compact wrapper** around `GreenRedBackground2S` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

For the shared pattern, see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `GreenRedBackground2.QI`
- **Data output** `QO` (`BOOL`, Quality Output): passed through from `GreenRedBackground2.QO`
- **Initialization chain**: `INIT` ⟶ `GreenRedBackground2.INIT`, `GreenRedBackground2.INITO` ⟶ `INITO`



Summary

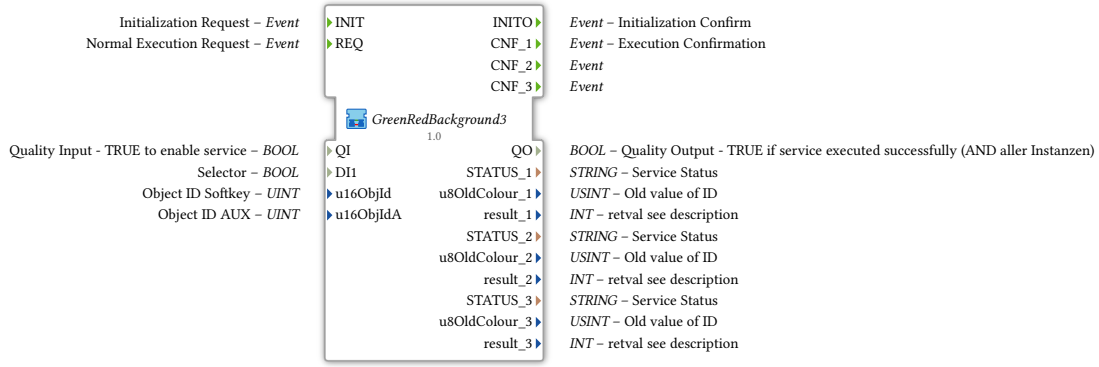
A pure pass-through to `GreenRedBackground2S` for the common case where the diagnostic values aren't needed.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

GreenRedBackground3

• — ○ • — ○ • — ○ •



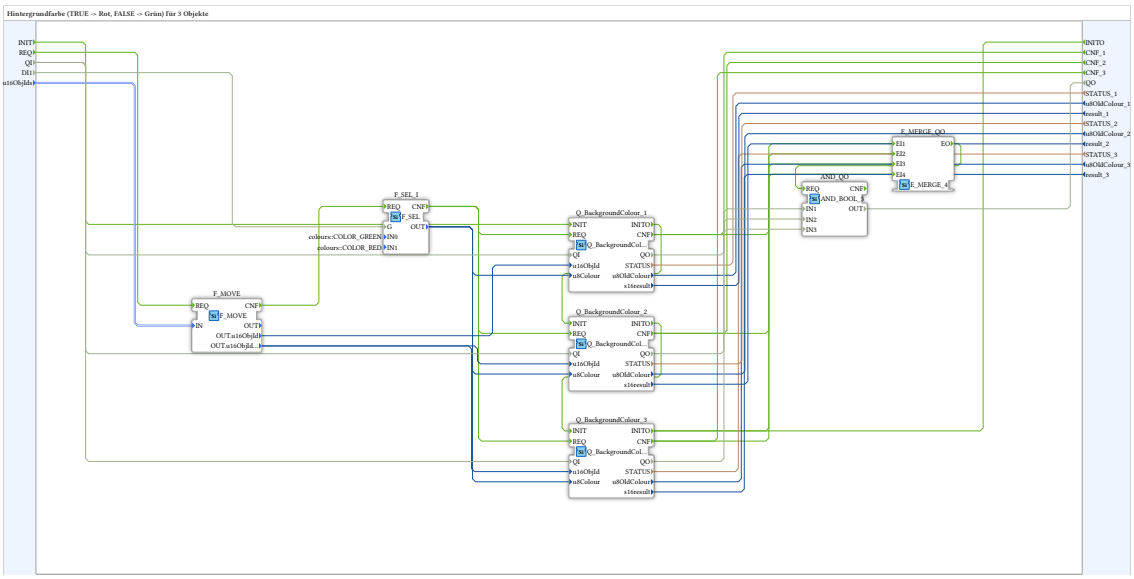
Introduction

`GreenRedBackground3` switches the VT background color of 3 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Grün**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA`.

Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and quality: The SubApp has `INIT`/`INITO` and `QI`/`QO`. `INIT` ⟶ `Q_BackgroundColour_1.INIT` ⟶ `Q_BackgroundColour_2.INIT` ⟶ `Q_BackgroundColour_3.INIT` (each via `INITO`), `Q_BackgroundColour_3.INITO` ⟶ `INITO`. `QI` goes to all three instances. `QO` is the `AND` (`AND_QO`, `AND_BOOL_3`) of the three `QO` outputs; `AND_QO.REQ` is triggered via `E_MERGE_QO` (`E_MERGE_4`: `Q_BackgroundColour_3.INITO`, `Q_BackgroundColour_1.CNF`, `_2.CNF`, `_3.CNF`).



Summary

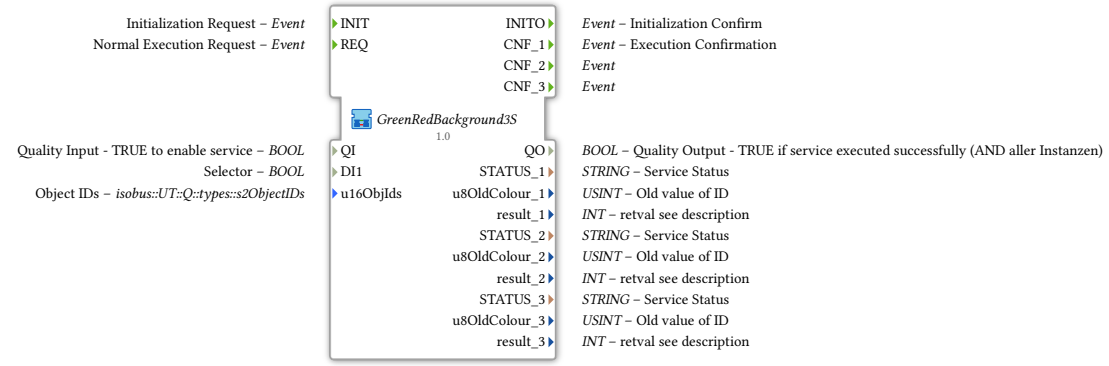
One of many variants in the background color block family: color pair Rot/Grün, 3 objects, BOOL selector.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

GreenRedBackground3S

• – ○ • – ○ • – ○ •



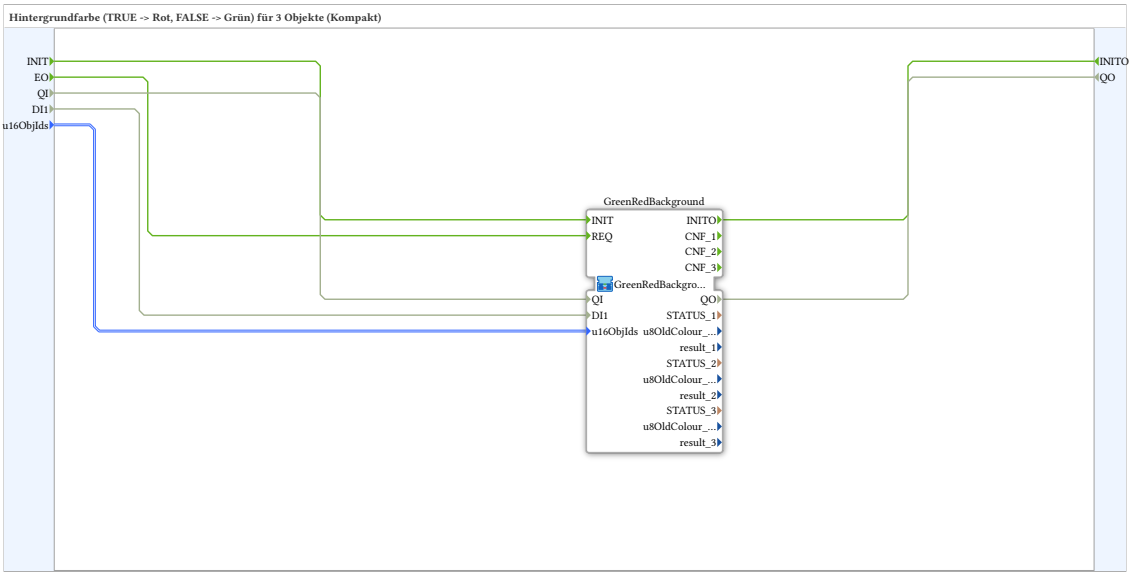
Introduction

`GreenRedBackground3S` switches the VT background color of 3 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Grün**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

Initialization and quality: In addition to the previous events, the block has the event input `INIT`, the event output `INITO`, as well as `QI` (BOOL, input, initial value `TRUE`) and `QO` (BOOL, output, AND of all instances). Init chain: `INIT` ⟶ `Q_BackgroundColour_1` ⟶ `Q_BackgroundColour_2` ⟶ `Q_BackgroundColour_3` ⟶ `INITO` (each `INITO` ⟶ next `INIT`). `QI` is passed on to all `Q_BackgroundColour_n.QI`. `QO` is formed by `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`): `Q_BackgroundColour_1.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN2`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN3`, `AND_QO.OUT` ⟶ `QO`. `E_MERGE_QO` (`E_MERGE_4`) merges `Q_BackgroundColour_3.INITO` and the `CNF` outputs `Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF`, `Q_BackgroundColour_3.CNF`; `E_MERGE_QO.EO` triggers `AND_QO.REQ`.

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).



Summary

One of many variants in the background color block family: color pair Rot/Grün, 3 objects, BOOL selector, struct. object ID.

GreenRedBackground3SC

• — ○ • — ○ • — ○ •

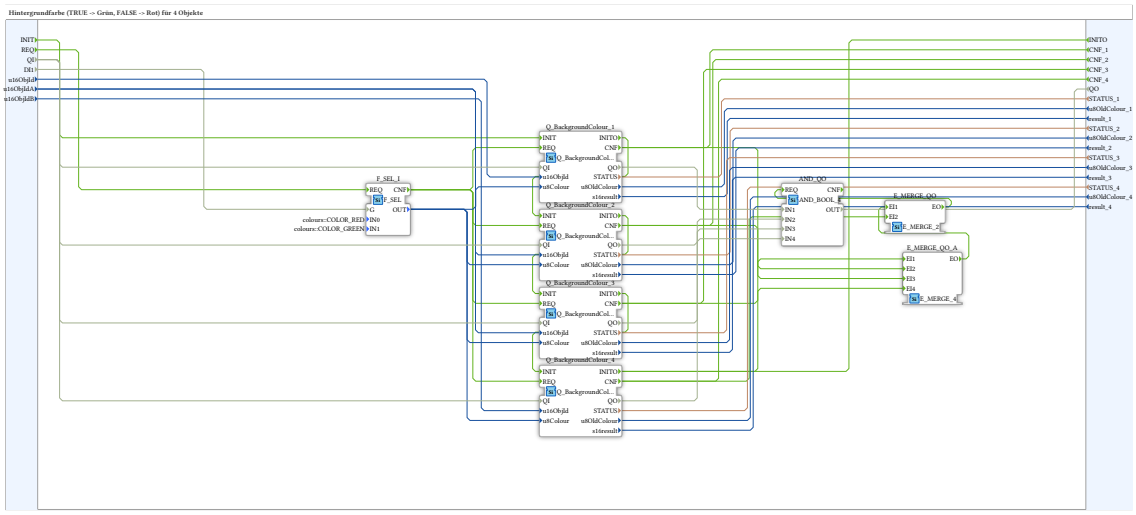
Introduction

`GreenRedBackground3SC` is a **compact wrapper** around `GreenRedBackground3S` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

For the shared pattern, see Background Color Blocks (shared pattern).

In addition, the wrapper exposes the initialization and quality interface: event input `INIT`, event output `INITO`, data input `QI` (`BOOL`, initial value `TRUE`) and data output `QO` (`BOOL`). They are passed 1:1 through to the

inner instance `GreenRedBackground`: `INIT` ⟶ `GreenRedBackground.INIT`, `GreenRedBackground.INITO` ⟶ `INITO`, `QI` ⟶ `GreenRedBackground.QI`, `GreenRedBackground.QO` ⟶ `QO`.



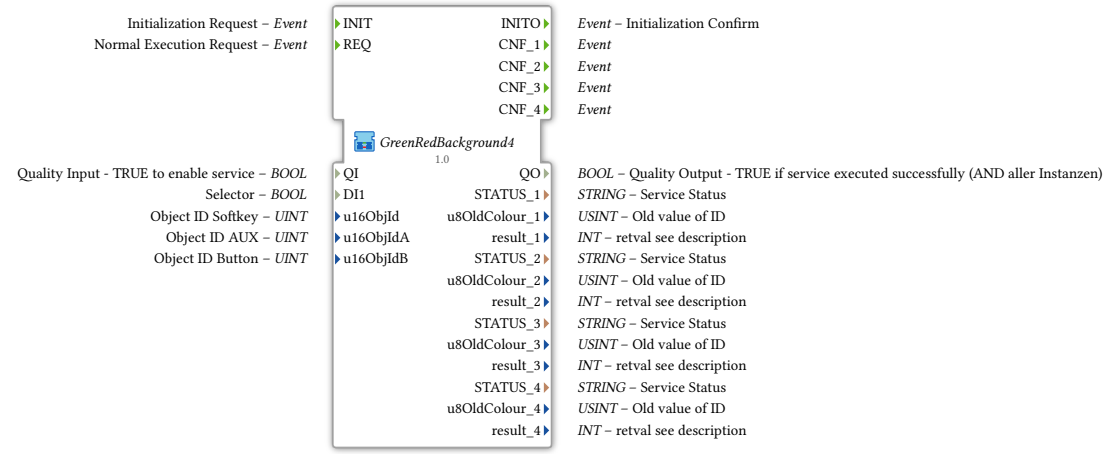
Summary

A pure pass-through to `GreenRedBackground3S` for the common case where the diagnostic values aren't needed.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

GreenRedBackground4



• – ○ • – ○ • – ○ •

Introduction

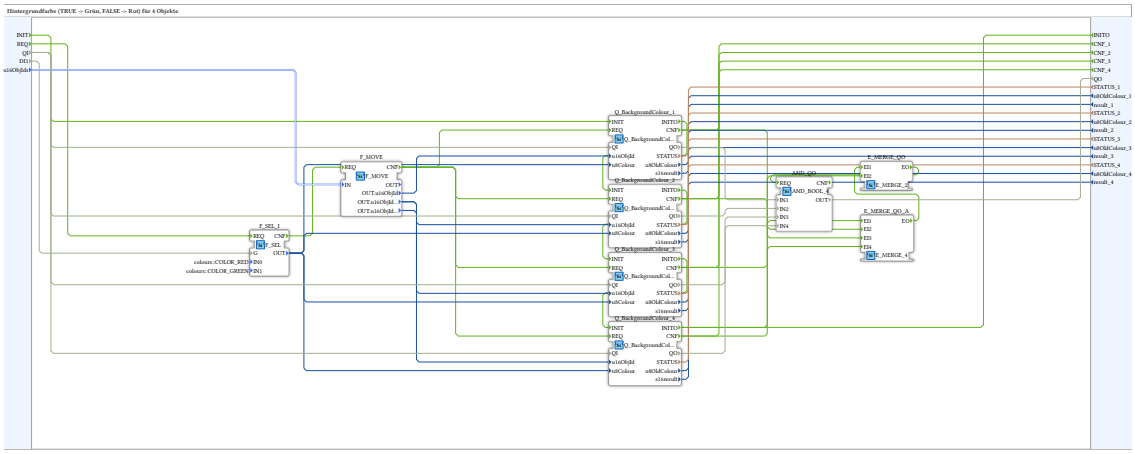
`GreenRedBackground4` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Rot**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA, u16ObjIdB`.

Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`u16ObjIdB`	`Q_BackgroundColour` (regular object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`): initialization is chained through the `Q_BackgroundColour` instances: `INIT` ⟶ `Q_BackgroundColour_1.INIT`; `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`; `Q_BackgroundColour_3.INITO` ⟶ `Q_BackgroundColour_4.INIT`; `Q_BackgroundColour_4.INITO` ⟶ `INITO`.
- **Data input `QI`** (`BOOL`, default `TRUE`) is distributed to `.QI` of all instances (`Q_BackgroundColour_1`, `Q_BackgroundColour_2`, `Q_BackgroundColour_3`, `Q_BackgroundColour_4`).
- **Data output `QO`** (`BOOL`): AND of all instances via `AND_QO` (`iec61131::booleanOperators::AND_BOOL_4`): `Q_BackgroundColour_1.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN2`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN3`, `Q_BackgroundColour_4.QO` ⟶ `AND_QO.IN4`; `AND_QO.OUT` ⟶ `QO`.
- `E_MERGE_QO_A` (`iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_4.INITO` and the `CNF` events of instances 1 to 3; `E_MERGE_QO` (`iec61499::events::E_MERGE_2`) merges its output `E_MERGE_QO_A.EO` with `Q_BackgroundColour_4.CNF` and thereby triggers `AND_QO.REQ`.



Summary

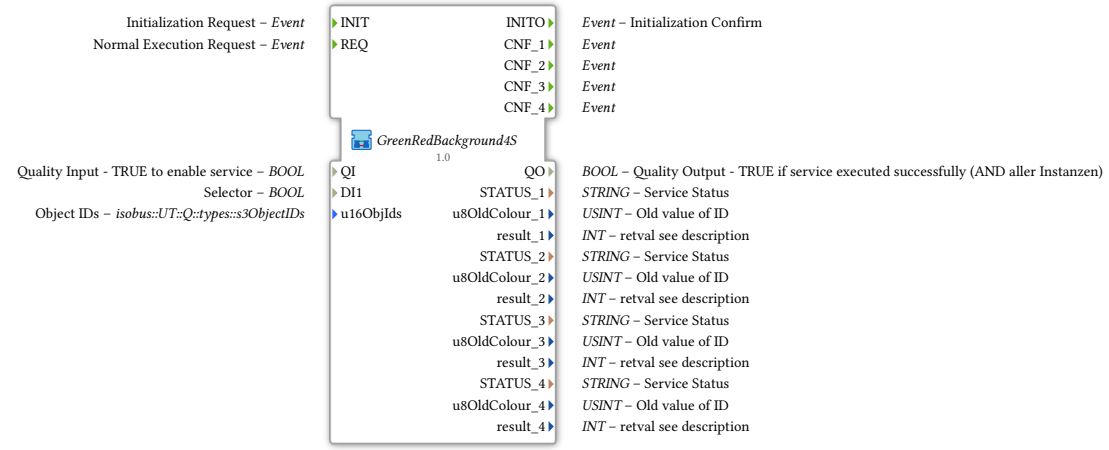
One of many variants in the background color block family: color pair Grün/Rot, 4 objects, BOOL selector.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

GreenRedBackground4S

• – ○ • – ○ • – ○ •



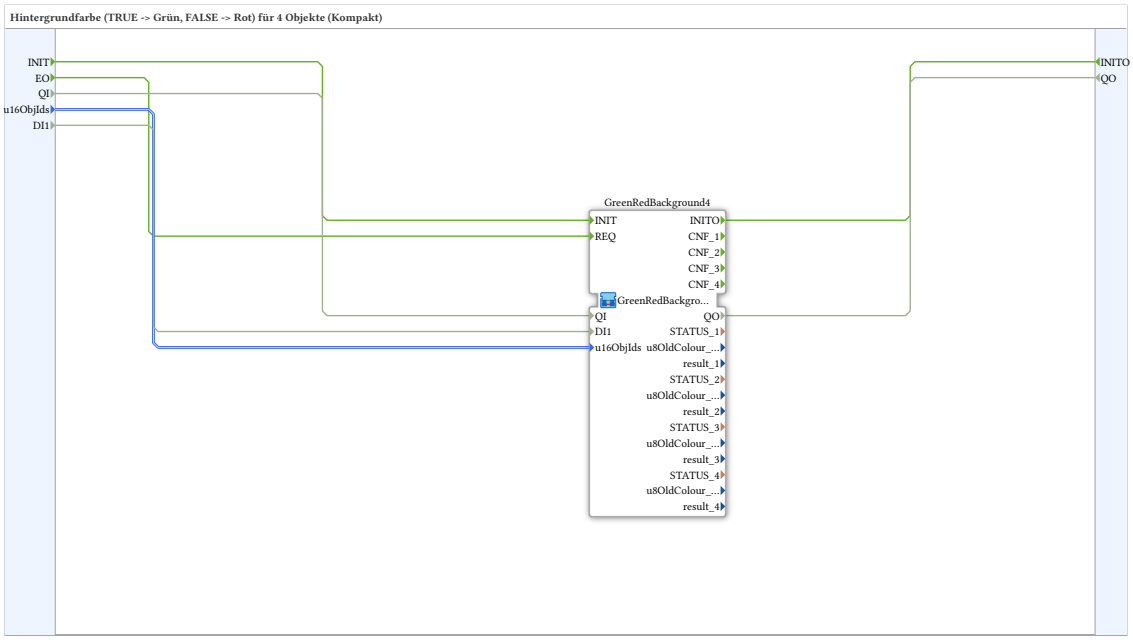
Introduction

`GreenRedBackground4S` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Rot**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

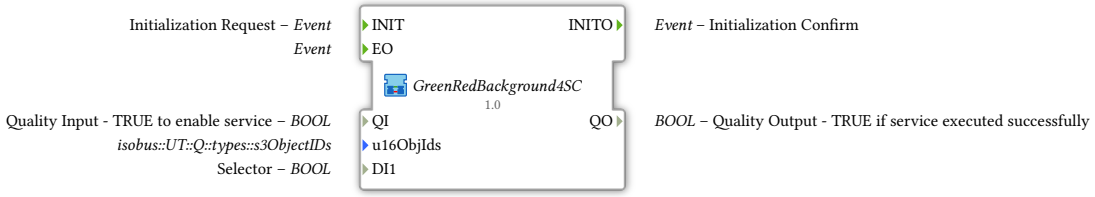
Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`F_MOVE.OUT.u16ObjIdB`	`Q_BackgroundColour` (regular object)

Interface (quality pattern): event input `INIT` and event output `INITO` (each `EInit`), data input `QI` (`BOOL`, default `TRUE`) and data output `QO` (`BOOL`, AND of all instances). Initialization: `INIT` ⟶ `Q_BackgroundColour_1.INIT`; `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`; `Q_BackgroundColour_3.INITO` ⟶ `Q_BackgroundColour_4.INIT`; `Q_BackgroundColour_4.INITO` ⟶ `INITO`. Quality: `QI` ⟶ `Q_BackgroundColour_1.QI`, `Q_BackgroundColour_2.QI`, `Q_BackgroundColour_3.QI`, `Q_BackgroundColour_4.QI`; `Q_BackgroundColour_1.QO`, `Q_BackgroundColour_2.QO`, `Q_BackgroundColour_3.QO`, `Q_BackgroundColour_4.QO` ⟶ `AND_QO.IN1` to `AND_QO.IN4` (`AND_QO`: `iec61131::booleanOperators::AND_BOOL_4`); `AND_QO.OUT` ⟶ `QO`. The trigger `AND_QO.REQ` comes via two merge blocks: `E_MERGE_QO_A` (`E_MERGE_4`) merges `Q_BackgroundColour_4.INITO` and the `CNF` of `Q_BackgroundColour_1` to `_3`, and `E_MERGE_QO` (`E_MERGE_2`) merges its output with `Q_BackgroundColour_4.CNF`; `E_MERGE_QO.EO` ⟶ `AND_QO.REQ`.

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).



Summary



One of many variants in the background color block family: color pair Grün/Rot, 4 objects, BOOL selector, struct. object ID.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

GreenRedBackground4SC

• – ○ • – ○ • – ○ •

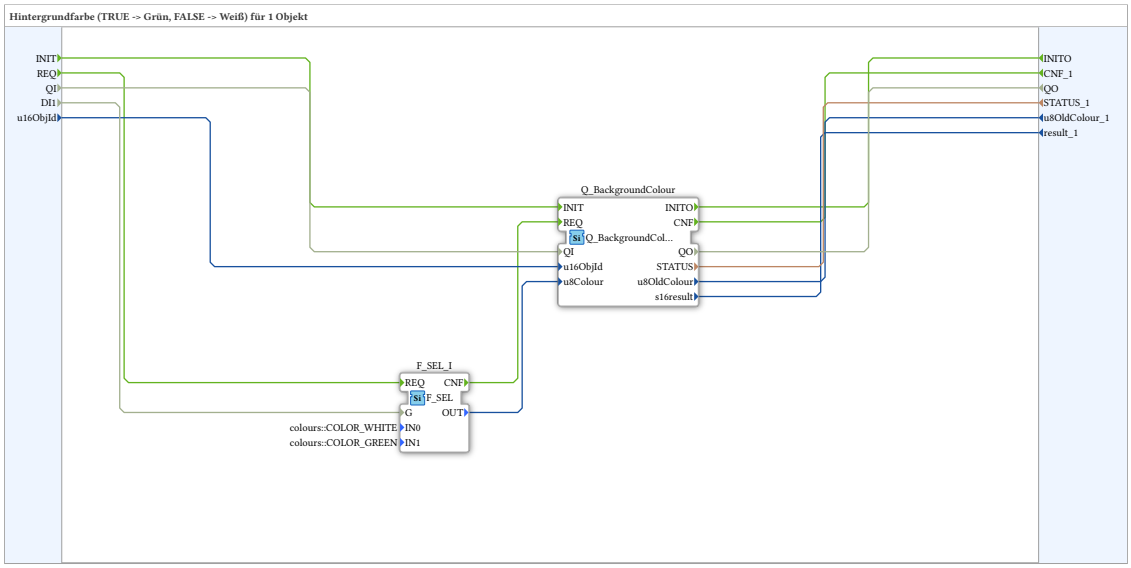
Introduction

`GreenRedBackground4SC` is a **compact wrapper** around `GreenRedBackground4S` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

For the shared pattern, see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `GreenRedBackground4.QI`
- **Data output** `QO` (`BOOL`, Quality Output): passed through from `GreenRedBackground4.QO`
- **Initialization chain**: `INIT` ⟶ `GreenRedBackground4.INIT`, `GreenRedBackground4.INITO` ⟶ `INITO`



Summary

A pure pass-through to `GreenRedBackground4S` for the common case where the diagnostic values aren't needed.

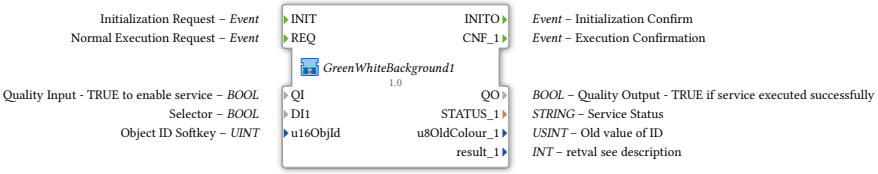
GreenWhiteBackground1



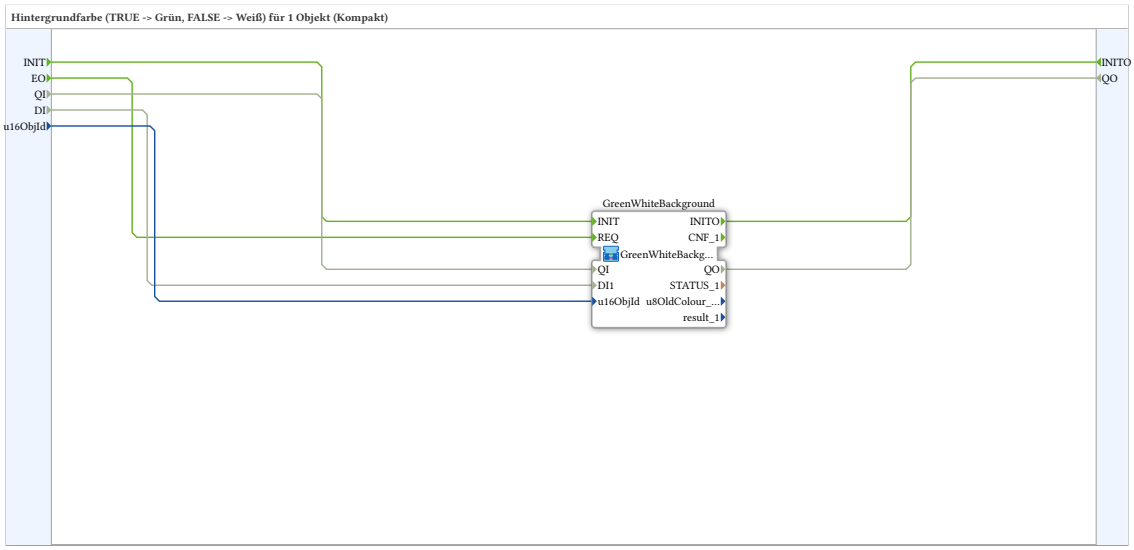
• — ○ • — ○ • — ○ •

Introduction

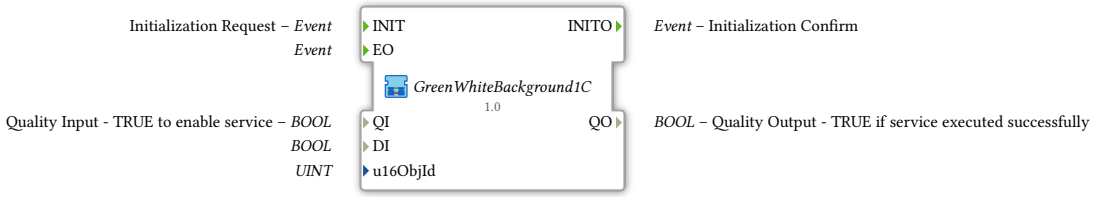
`GreenWhiteBackground1` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via input `u16ObjId`.

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Quality ports: The block additionally has the event `INIT` (input) and `INITO` (output), the data input `QI` (BOOL, default `TRUE`, "Quality Input - TRUE to enable service") and the data output `QO` (BOOL, "Quality Output - TRUE if service executed successfully"). `INIT` is passed on to `Q_BackgroundColour.INIT`, `Q_BackgroundColour.INITO` is passed to `INITO`; `QI` is connected to `Q_BackgroundColour.QI` and `Q_BackgroundColour.QO` to `QO`.



Summary



One of many variants in the background color block family: color pair Grün/Weiß, 1 object, BOOL selector.

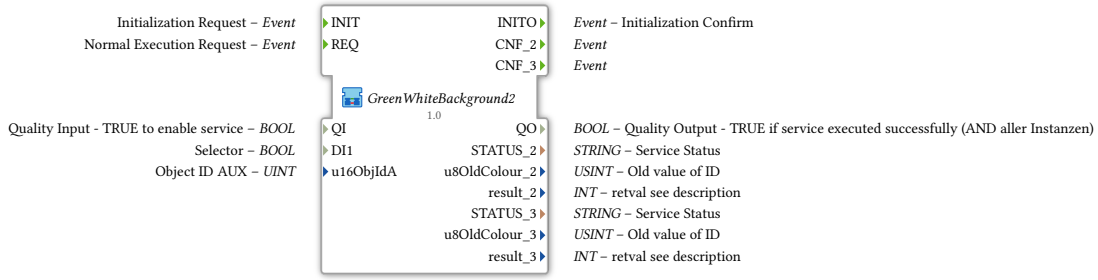
GreenWhiteBackground2



• — ○ • — ○ • — ○ •

Introduction

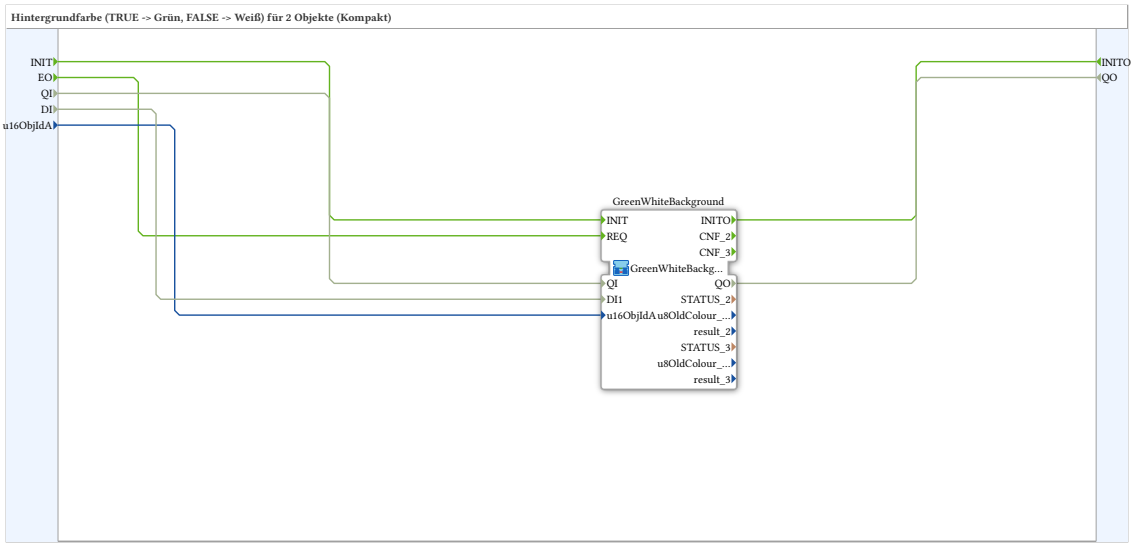
`GreenWhiteBackground2` switches the VT background color of 2 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via inputs `u16ObjIdA`.

Position	Object ID source	Block
1	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

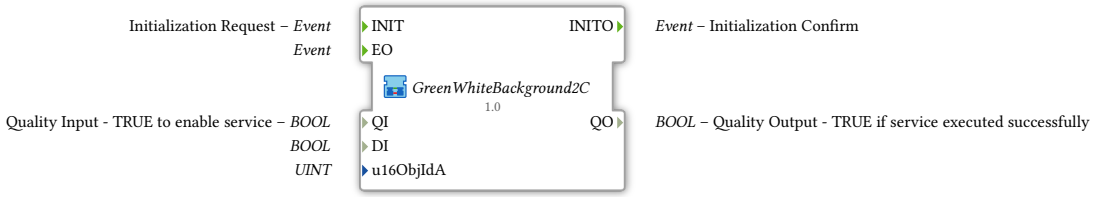
For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`): initialization is chained through the `Q_BackgroundColour` instances: `INIT` ⟶ `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`; `Q_BackgroundColour_3.INITO` ⟶ `INITO`.
- **Data input `QI`** (`BOOL`, default `TRUE`) is distributed to `.QI` of all instances (`Q_BackgroundColour_2`, `Q_BackgroundColour_3`).
- **Data output `QO`** (`BOOL`): AND of all instances via `AND_QO` (`iec61131::booleanOperators::AND_BOOL_2`): `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.
- `E_MERGE_QO` (`iec61499::events::E_MERGE_3`) merges `Q_BackgroundColour_3.INITO` and the `CNF` events of both instances (`Q_BackgroundColour_2.CNF`, `Q_BackgroundColour_3.CNF`) and thereby triggers `AND_QO.REQ`.



Summary



One of many variants in the background color block family: color pair Grün/Weiß, 2 objects, BOOL selector.

🌐 Related topic subpages on ms-muc-docs.de

GreenWhiteBackground2C

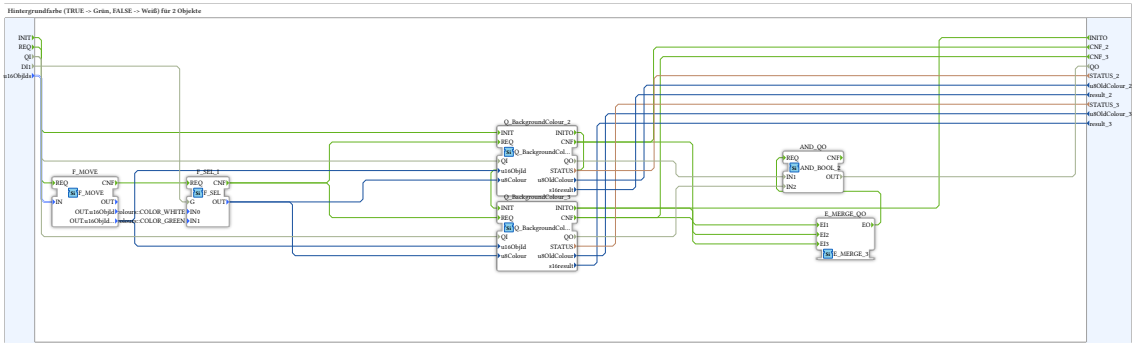
• – ○ • – ○ • – ○ •

Introduction

`GreenWhiteBackground2C` is a **compact wrapper** around `GreenWhiteBackground2` — passes `u16ObjId` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

Interface (quality pattern): The wrapper additionally has the event input `INIT` and the event output `INITO` (each `EInit`) as well as the data input `QI` (`BOOL`, default `TRUE`) and the data output `QO` (`BOOL`). They are passed straight through to the inner instance `GreenWhiteBackground`: `INIT` ⟶ `GreenWhiteBackground.INIT`, `GreenWhiteBackground.INITO` ⟶ `INITO`, `QI` ⟶ `GreenWhiteBackground.QI`, `GreenWhiteBackground.QO` ⟶ `QO`.

For the shared pattern, see Background Color Blocks (shared pattern).



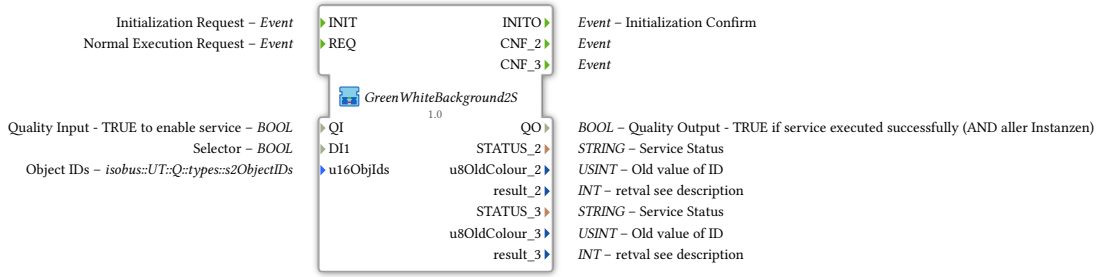
Summary

A pure pass-through to `GreenWhiteBackground2` for the common case where the diagnostic values aren't needed.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

GreenWhiteBackground2S



• – ○ • – ○ • – ○ •

Introduction

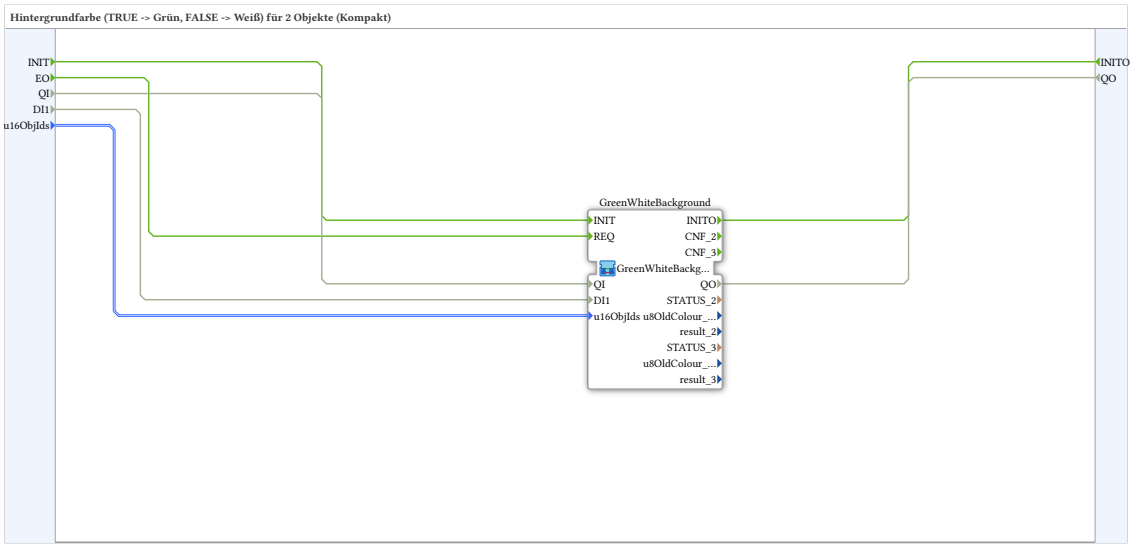
`GreenWhiteBackground2S` switches the VT background color of 2 objects based on a boolean selector signal: `TRUE` → **Grün**, `FALSE` → **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector → `AX_SEL`/`F_SEL` → `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `Q_BackgroundColour_2.QI` and `Q_BackgroundColour_3.QI`
- **Data output** `QO` (`BOOL`, Quality Output): AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_2`) of the `QO` outputs of `Q_BackgroundColour_2.QO` and `Q_BackgroundColour_3.QO`
- **Initialization chain**: `INIT` → `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` → `Q_BackgroundColour_3.INIT`, `Q_BackgroundColour_3.INITO` → `INITO`
- `E_MERGE_QO` (type `iec61499::events::E_MERGE_3`) merges `Q_BackgroundColour_3.INITO`, `Q_BackgroundColour_2.CNF` and `Q_BackgroundColour_3.CNF` and triggers `AND_QO.REQ`



Summary

One of many variants in the background color block family: color pair Grün/Weiß, 2 objects, BOOL selector, struct. object ID.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

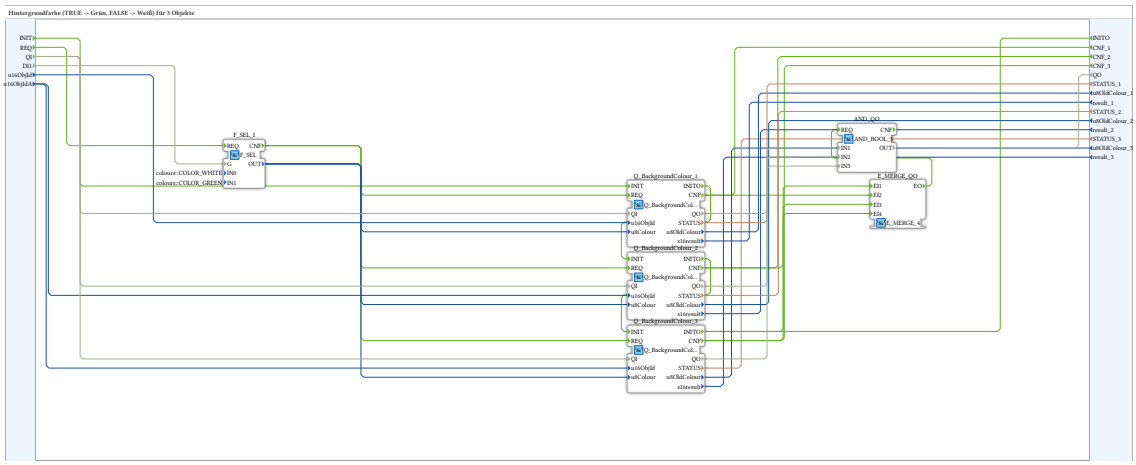
GreenWhiteBackground2SC

• – ○ • – ○ • – ○ •

Introduction

`GreenWhiteBackground2SC` is a **compact wrapper** around `GreenWhiteBackground2S` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`). In addition, `INIT` ⟶ `GreenWhiteBackground.INIT`, `GreenWhiteBackground.INITO` ⟶ `INITO`, `QI` ⟶ `GreenWhiteBackground.QI` (initial value `TRUE`) and `GreenWhiteBackground.QO` ⟶ `QO` are passed through.

For the shared pattern, see Background Color Blocks (shared pattern).



Summary

A pure pass-through to `GreenWhiteBackground2S` for the common case where the diagnostic values aren't needed.

🌐 Related topic subpages on ms-muc-docs.de

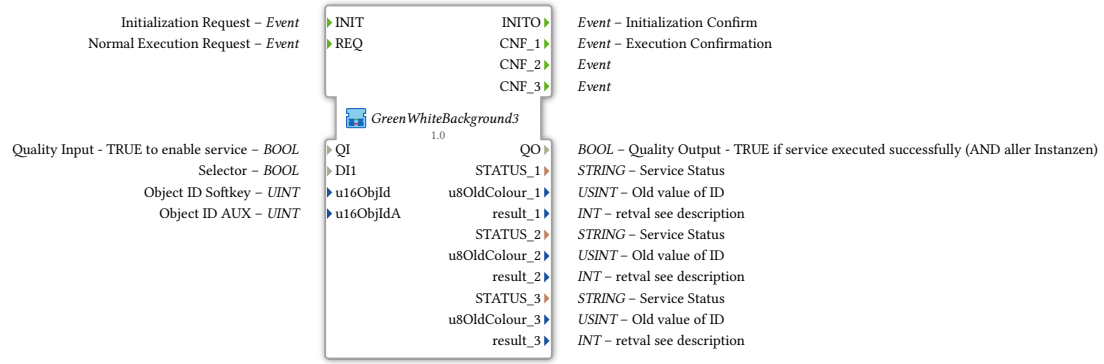
GreenWhiteBackground3

• – ○ • – ○ • – ○ •



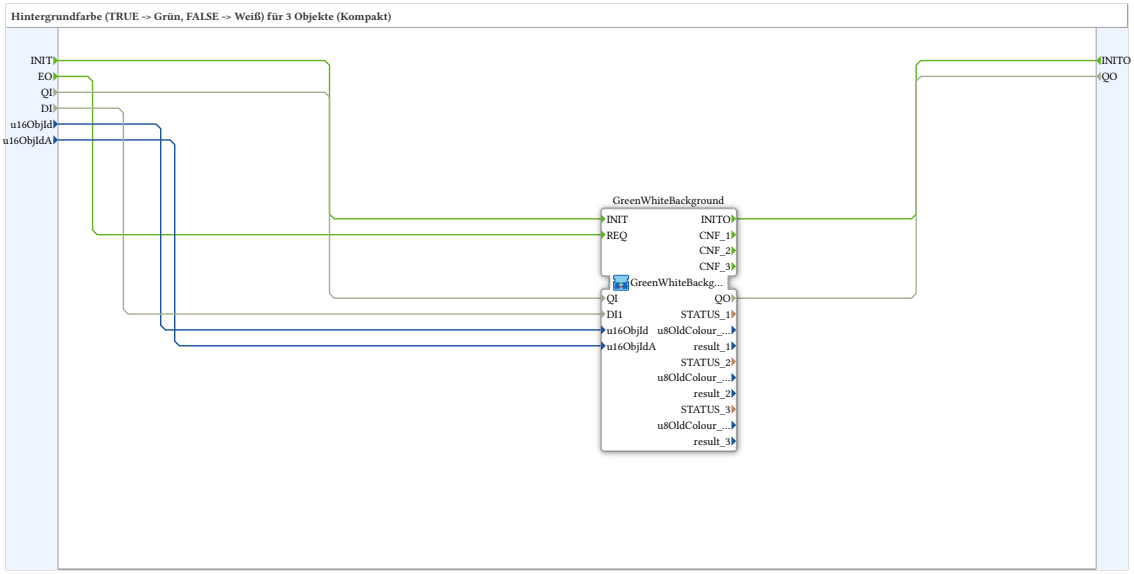
Introduction

`GreenWhiteBackground3` switches the VT background color of 3 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA`.

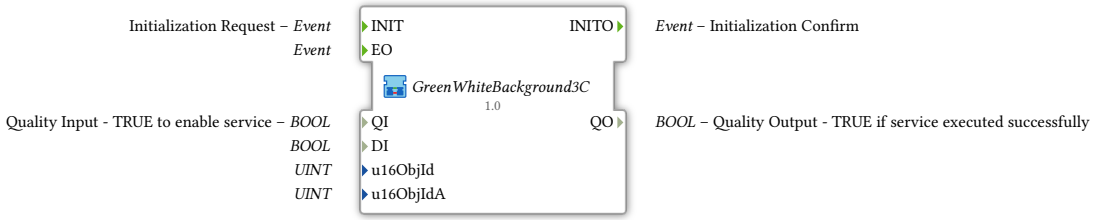
Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

Initialization and quality: In addition to the previous events, the block has the event input `INIT`, the event output `INITO`, as well as `QI` (BOOL, input, initial value `TRUE`) and `QO` (BOOL, output, AND of all instances). Init chain: `INIT` ⟶ `Q_BackgroundColour_1` ⟶ `Q_BackgroundColour_2` ⟶ `Q_BackgroundColour_3` ⟶ `INITO` (each `INITO` ⟶ next `INIT`). `QI` is passed on to all `Q_BackgroundColour_n.QI`. `QO` is formed by `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`): `Q_BackgroundColour_1.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN2`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN3`, `AND_QO.OUT` ⟶ `QO`. `E_MERGE_QO` (`E_MERGE_4`) merges `Q_BackgroundColour_3.INITO` and the `CNF` outputs `Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF`, `Q_BackgroundColour_3.CNF`; `E_MERGE_QO.EO` triggers `AND_QO.REQ`.

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).



Summary



One of many variants in the background color block family: color pair Grün/Weiß, 3 objects, BOOL selector.

GreenWhiteBackground3C

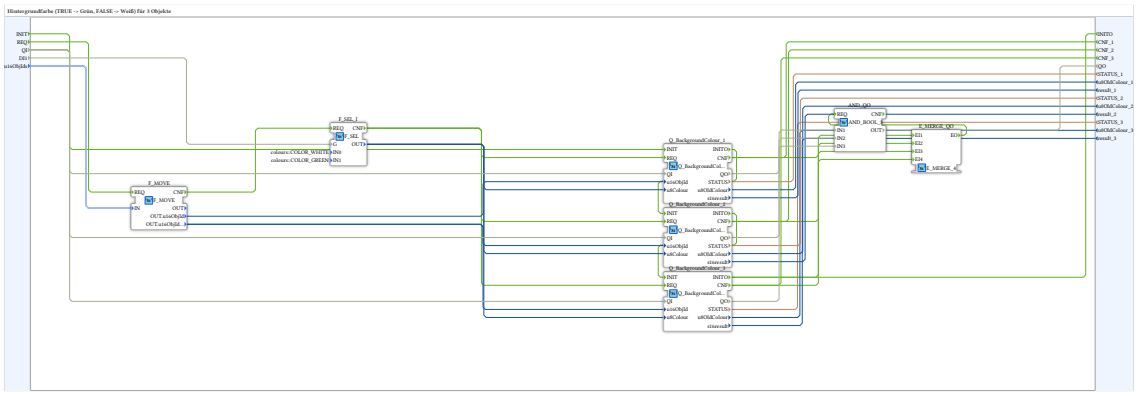
• – ○ • – ○ • – ○ •

Introduction

`GreenWhiteBackground3C` is a **compact wrapper** around `GreenWhiteBackground3` — passes `u16ObjId` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

For the shared pattern, see Background Color Blocks (shared pattern).

In addition, the wrapper exposes the initialization and quality interface: event input `INIT`, event output `INITO`, data input `QI` (`BOOL`, initial value `TRUE`) and data output `QO` (`BOOL`). They are passed 1:1 through to the inner instance `GreenWhiteBackground`: `INIT` ⟶ `GreenWhiteBackground.INIT`, `GreenWhiteBackground.INITO` ⟶ `INITO`, `QI` ⟶ `GreenWhiteBackground.QI`, `GreenWhiteBackground.QO` ⟶ `QO`.



Summary

A pure pass-through to `GreenWhiteBackground3` for the common case where the diagnostic values aren't needed.

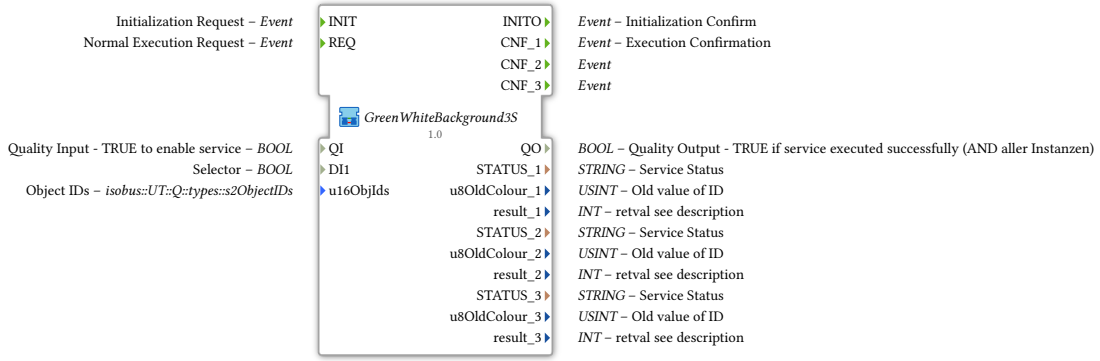
GreenWhiteBackground3S



• – ○ • – ○ • – ○ •

Introduction

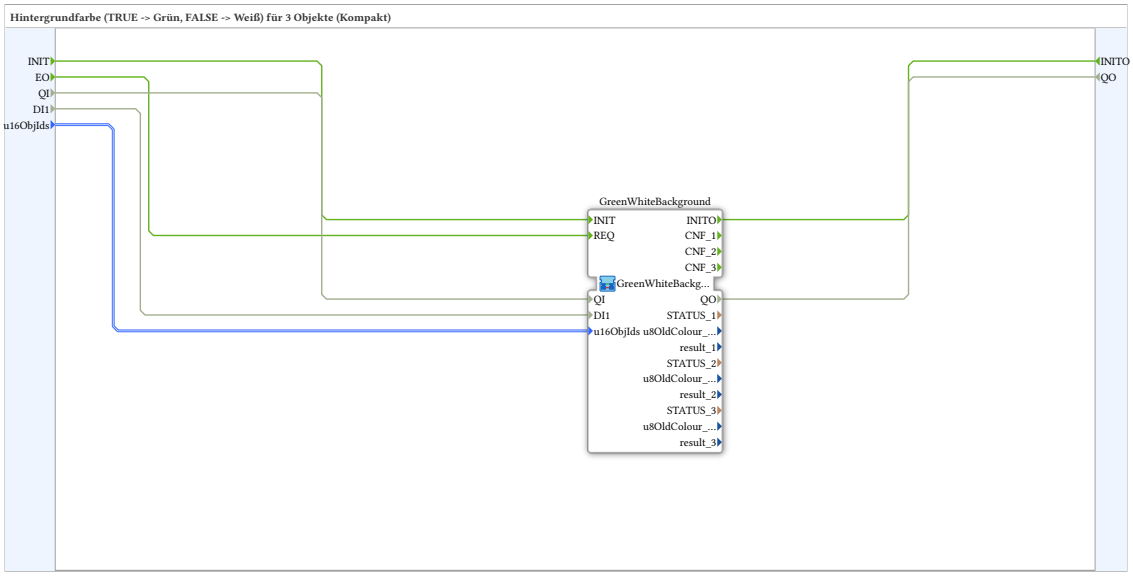
`GreenWhiteBackground3S` switches the VT background color of 3 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via the structured type `s2ObjectIDs` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`): initialization is chained through the `Q_BackgroundColour` instances: `INIT` ⟶ `Q_BackgroundColour_1.INIT`; `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`; `Q_BackgroundColour_3.INITO` ⟶ `INITO`.
- **Data input `QI`** (`BOOL`, default `TRUE`) is distributed to `.QI` of all instances (`Q_BackgroundColour_1`, `Q_BackgroundColour_2`, `Q_BackgroundColour_3`).
- **Data output `QO`** (`BOOL`): AND of all instances via `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`): `Q_BackgroundColour_1.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN2`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN3`; `AND_QO.OUT` ⟶ `QO`.
- `E_MERGE_QO` (`iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_3.INITO` and the `CNF` events of all three instances (`Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF`, `Q_BackgroundColour_3.CNF`) and thereby triggers `AND_QO.REQ`.



Summary

One of many variants in the background color block family: color pair Grün/Weiß, 3 objects, BOOL selector, struct. object ID.

GreenWhiteBackground3SC

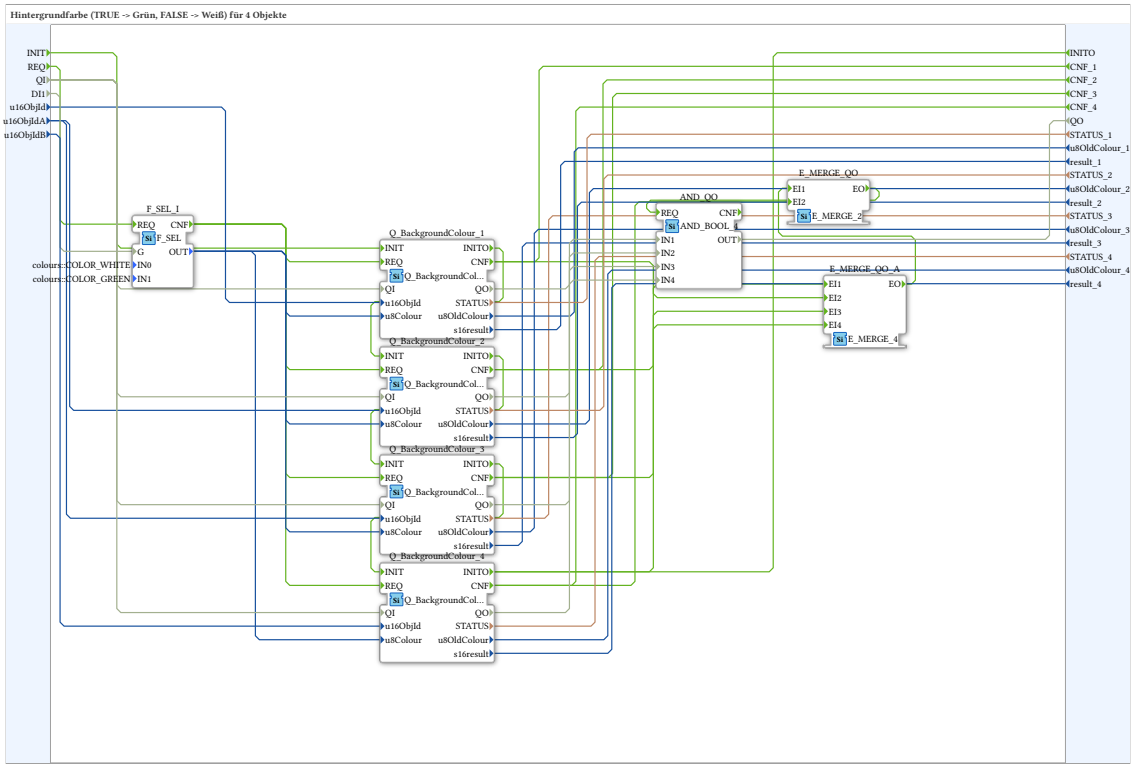
• – ○ • – ○ • – ○ •

Introduction

`GreenWhiteBackground3SC` is a **compact wrapper** around `GreenWhiteBackground3S` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

Interface (quality pattern): The wrapper additionally has the event input `INIT` and the event output `INITO` (each `EInit`) as well as the data input `QI` (`BOOL`, default `TRUE`) and the data output `QO` (`BOOL`). They are passed straight through to the inner instance `GreenWhiteBackground`: `INIT` ⟶ `GreenWhiteBackground.INIT`, `GreenWhiteBackground.INITO` ⟶ `INITO`, `QI` ⟶ `GreenWhiteBackground.QI`, `GreenWhiteBackground.QO` ⟶ `QO`.

For the shared pattern, see Background Color Blocks (shared pattern).



Summary

A pure pass-through to `GreenWhiteBackground3S` for the common case where the diagnostic values aren't needed.

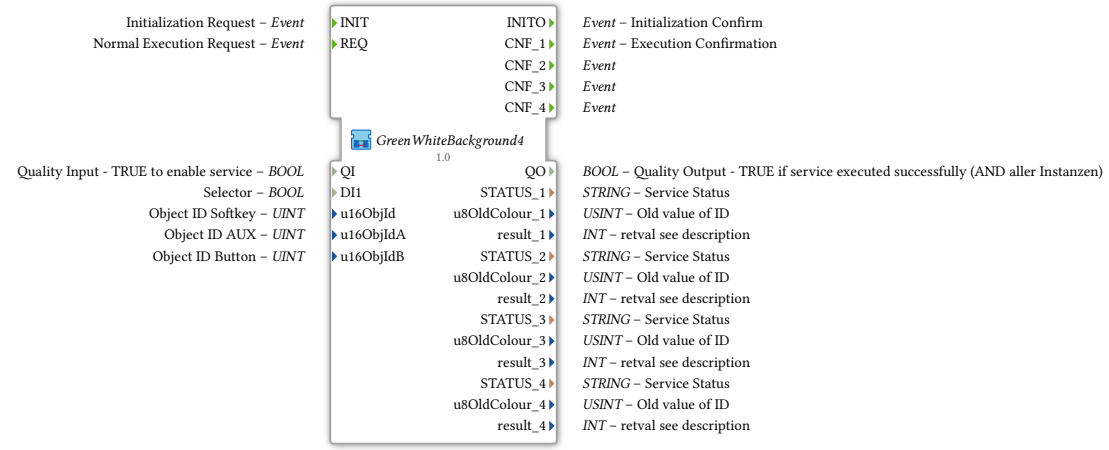
GreenWhiteBackground4



• — ○ • — ○ • — ○ •

Introduction

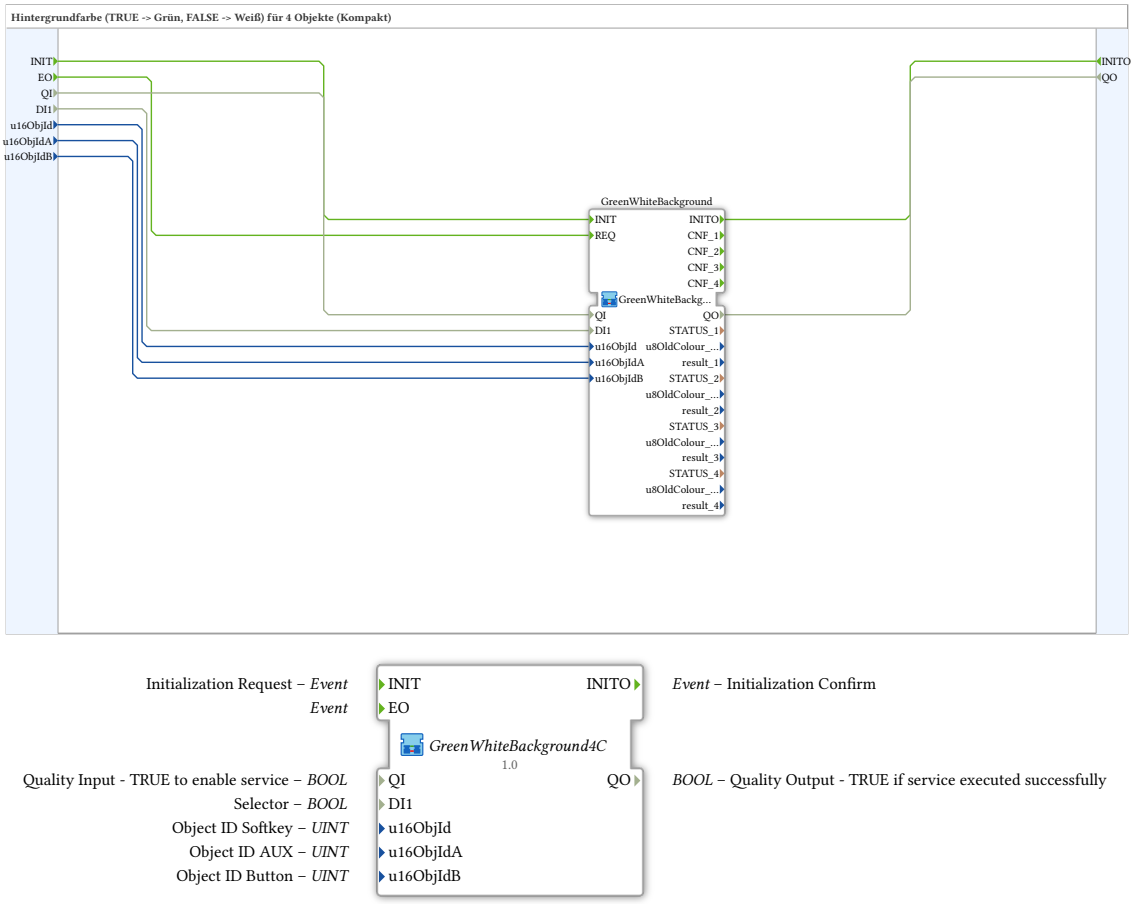
`GreenWhiteBackground4` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA, u16ObjIdB`.

Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`u16ObjIdB`	`Q_BackgroundColour` (regular object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `Q_BackgroundColour_1.QI`, `Q_BackgroundColour_2.QI`, `Q_BackgroundColour_3.QI` and `Q_BackgroundColour_4.QI`
- **Data output** `QO` (`BOOL`, Quality Output): AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_4`) of the `QO` outputs of `Q_BackgroundColour_1.QO`, `Q_BackgroundColour_2.QO`, `Q_BackgroundColour_3.QO` and `Q_BackgroundColour_4.QO`
- **Initialization chain**: `INIT` → `Q_BackgroundColour_1.INIT`, `Q_BackgroundColour_1.INITO` → `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` → `Q_BackgroundColour_3.INIT`, `Q_BackgroundColour_3.INITO` → `Q_BackgroundColour_4.INIT`, `Q_BackgroundColour_4.INITO` → `INITO`
- `E_MERGE_QO_A` (type `iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_4.INITO`, `Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF` and `Q_BackgroundColour_3.CNF` and passes the result to `E_MERGE_QO.EI1`
- `E_MERGE_QO` (type `iec61499::events::E_MERGE_2`) merges `E_MERGE_QO_A.EO` and `Q_BackgroundColour_4.CNF` and triggers `AND_QO.REQ`



Summary

One of many variants in the background color block family: color pair Grün/Weiß, 4 objects, BOOL selector.

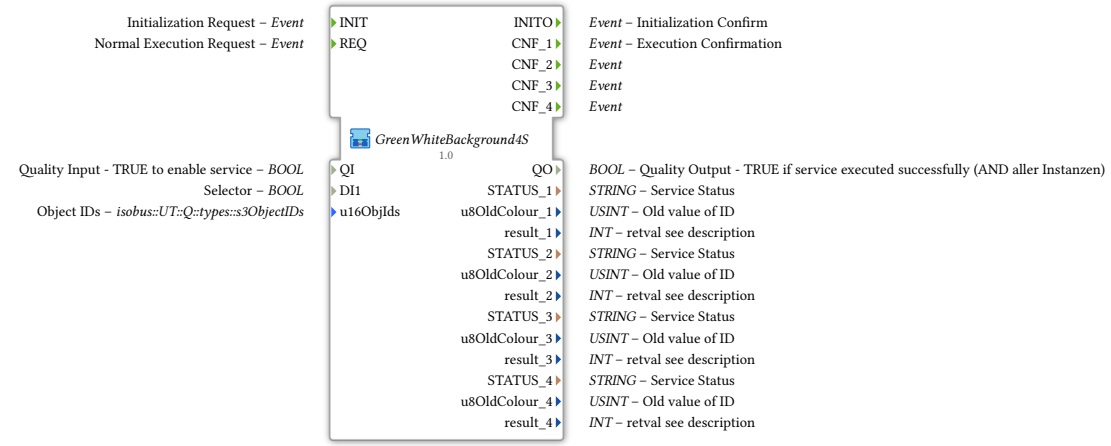
GreenWhiteBackground4S

• – ○ • – ○ • – ○ •

Introduction



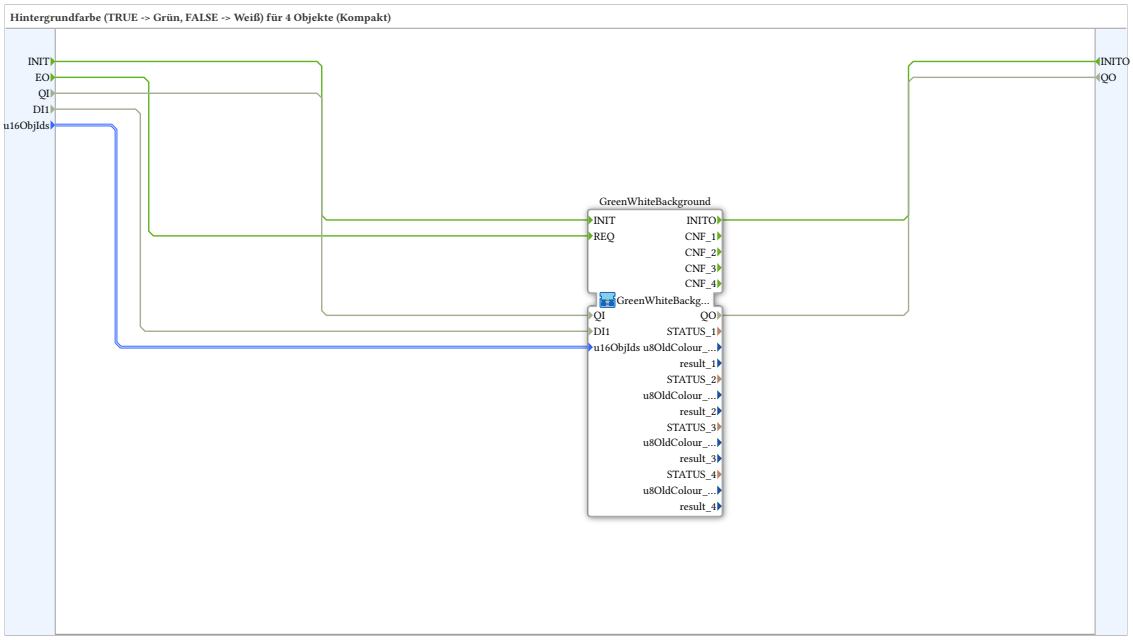
`GreenWhiteBackground4S` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` ⟶ **Grün**, `FALSE` ⟶ **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`F_MOVE.OUT.u16ObjIdB`	`Q_BackgroundColour` (regular object)

Initialization and quality: In addition to the previous events, the block has the event input `INIT`, the event output `INITO`, as well as `QI` (BOOL, input, initial value `TRUE`) and `QO` (BOOL, output, AND of all instances). Init chain: `INIT` ⟶ `Q_BackgroundColour_1` ⟶ `Q_BackgroundColour_2` ⟶ `Q_BackgroundColour_3` ⟶ `Q_BackgroundColour_4` ⟶ `INITO` (each `INITO` ⟶ next `INIT`). `QI` is passed on to all `Q_BackgroundColour_n.QI`. `QO` is formed by `AND_QO` (`iec61131::booleanOperators::AND_BOOL_4`): `Q_BackgroundColour_1.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN2`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN3`, `Q_BackgroundColour_4.QO` ⟶ `AND_QO.IN4`, `AND_QO.OUT` ⟶ `QO`. `E_MERGE_QO_A` (`E_MERGE_4`) merges

`Q_BackgroundColour_4.INITO` and the `CNF` outputs of `Q_BackgroundColour_1`, `Q_BackgroundColour_2` and `Q_BackgroundColour_3`, `E_MERGE_QO` (`E_MERGE_2`) adds `Q_BackgroundColour_4.CNF`; `E_MERGE_QO.EO` triggers `AND_QO.REQ`.

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).



Summary

One of many variants in the background color block family: color pair Grün/Weiß, 4 objects, BOOL selector, struct. object ID.

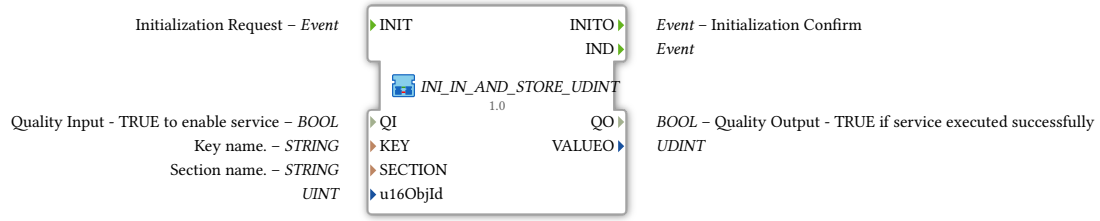
INI_IN_AND_STORE_UDINT

• – ○ • – ○ • – ○ •



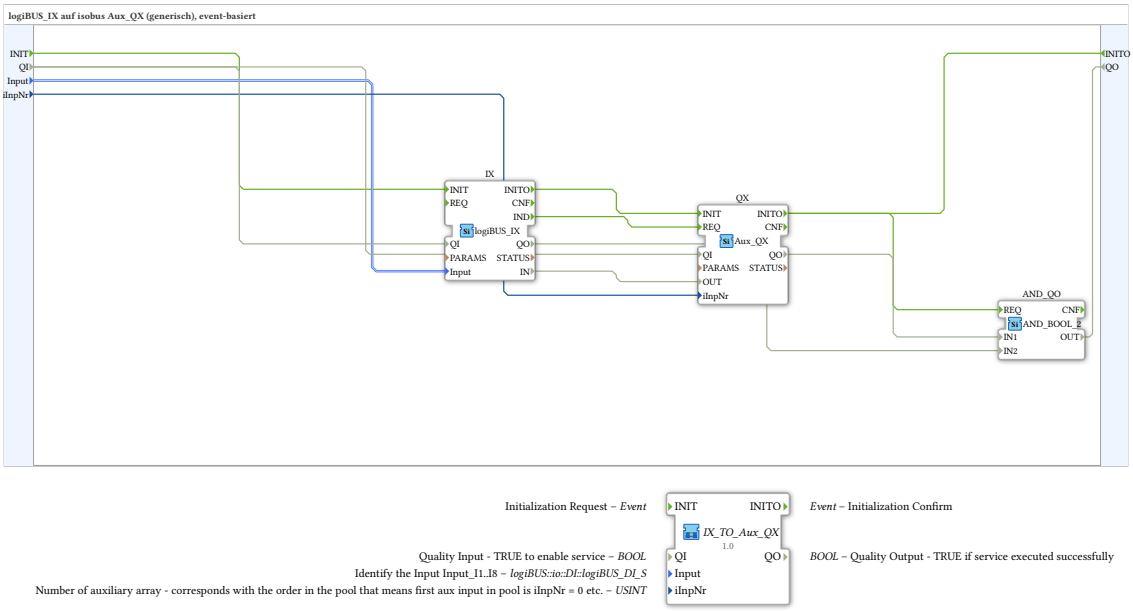
Introduction

`INI_IN_AND_STORE_UDINT` persistently stores a UDINT value entered via the VT in an INI file and automatically reloads it on deployment. This is the MyLib_B variant of the INI storage family known from MyLib_AX.

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

Quality ports: The block additionally has the data input `QI` (BOOL, default `TRUE`, "Quality Input - TRUE to enable service") and the data output `QO` (BOOL, "Quality Output - TRUE if service executed successfully"). `QI` is connected to `Q_NumericValue.QI`, `InputNumber_I1.QI` and `INI.QI`; `QO` is the AND (`AND_QO`, `iec61131::booleanOperators::AND_BOOL_3`) of `Q_NumericValue.QO`, `InputNumber_I1.QO` and `INI.QO`.

In addition, the block has the events `INIT` (input, `EInit`) and `INITO` (output, `EInit`); initialization is chained: `INIT` ⟶ `InputNumber_I1.INIT`; `InputNumber_I1.INITO` ⟶ `INI.INIT`; `INI.INITO` ⟶ `Q_NumericValue.INIT`; `Q_NumericValue.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`).



Summary

UDINT variant of the INI storage family (MyLib_B).

IX_TO_Aux_QX

• — ○ • — ○ • — ○ •

Introduction

The IX_TO_Aux_QX is an event-based subapplication designed to map digital inputs from a logiBUS (IX) to an isobus auxiliary output (Aux_QX). It provides a generic interface for converting logiBUS digital input signals into isobus auxiliary output requests, suitable for scenarios where auxiliary functions need to be controlled based on input signals. This subapplication encapsulates the logic to bridge the two different industrial communication systems, simplifying integration and promoting reusability.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; passed on to `IX.INIT`.

Event Outputs

- **INITO** (`EInit`): initialization confirm; comes from `QX.INITO`.

Data Inputs

- **Input** (Type: `logiBUS::io::DI::logiBUS_DI_S`): Identifies the logiBUS input signal (e.g., Input_I1 to Input_I8). The initial value is set to `Invalid`.
- **QI** (Type: `BOOL`): Quality input - TRUE enables the service. The initial value is `TRUE`.
- **iInpNr** (Type: `USINT`): Specifies the auxiliary array number, corresponding to the order in the pool. The first auxiliary input has an `iInpNr` of 0. The initial value is 0.

Data Outputs

- **QO** (Type: `BOOL`): Quality output - AND combination (`AND_QO`, `AND_BOOL_2`) of `QX.QO` and `IX.QO`. The processed data itself is used internally.

Adapters

- **None**: No adapters are defined in the subapplication interface.

Functionality

The IX_TO_Aux_QX subapplication encapsulates two primary function blocks: `logiBUS_IX` (IX) and `isobus::UT::io::Auxiliary::OUT::Aux_QX` (QX). It operates as follows:

- When the `logiBUS_IX` block receives a valid input signal, it triggers its `IND` event output.
- The `IND` event is connected to the `REQ` event input of the `Aux_QX` block, initiating a request to the isobus auxiliary output.
- Data mapping is performed via internal data connections:
  - The `Input` data variable is forwarded to `IX.Input`.
  - The `iInpNr` data variable is forwarded to `QX.iInpNr`.
  - The `IX.IN` output is internally connected to `QX.OUT`, although this does not expose a direct output from the subapplication.

Initialization and quality: `INIT` ⟶ `IX.INIT`; `IX.INITO` ⟶ `QX.INIT`; `QX.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`. `QI` is distributed to `IX.QI` and `QX.QI` (there is no hard-wired `QI` parameter any more); `QX.QO` ⟶ `AND_QO.IN1`, `IX.QO` ⟶ `AND_QO.IN2`, `AND_QO.OUT` ⟶ `QO`.

This structure allows the subapplication to process a logiBUS digital input and trigger an isobus auxiliary output request based on the configured input number and signal.

Technical Features

- **Event-driven Processing**: The subapplication uses an event-based mechanism to connect the input event from `IX` to the output request event of `QX`, ensuring timely response to input changes.
- **Parameterized Configuration**: The `Input` variable allows selection of specific logiBUS inputs (I1–I8), while `iInpNr` defines the order of the auxiliary array, enabling flexible setup.
- **Encapsulation**: By wrapping the function blocks, the subapplication provides a clean interface and hides the complexity of direct block wiring.
- **Reusability**: Designed as a generic solution, it can be reused across different projects requiring logiBUS-to-isobus bridging.
- **Internal Data Flow**: The data connection from `IX.IN` to `QX.OUT` indicates that the processed input data is passed internally, though not exposed externally.

State Overview

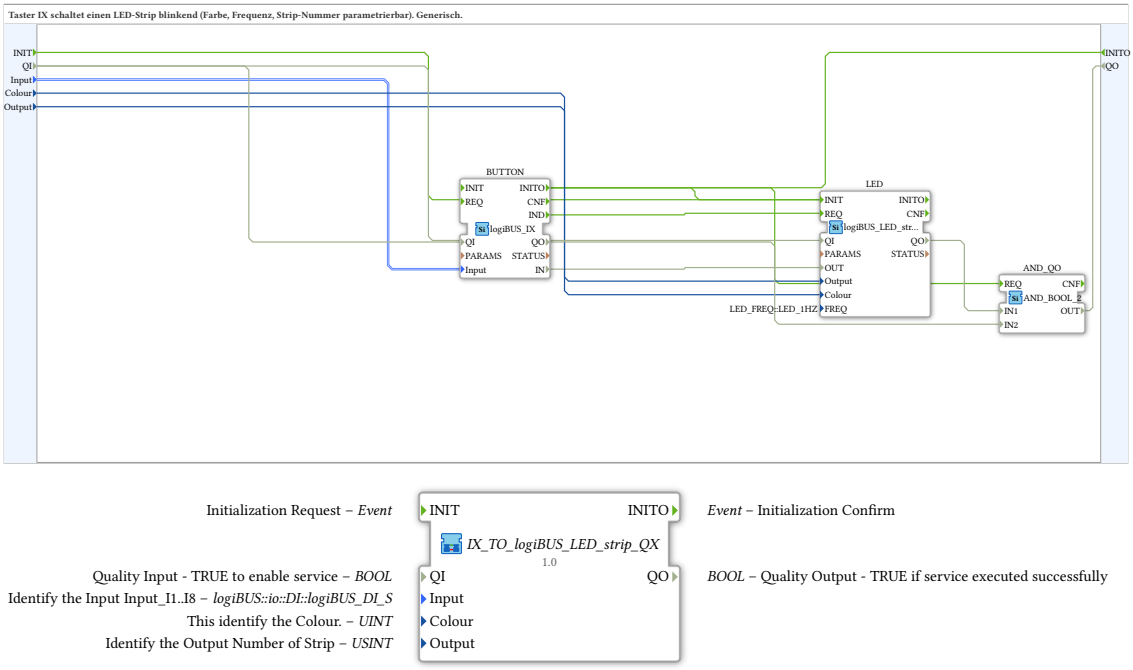
This subapplication does not implement a complex state machine. Instead, it relies on the behavior of its internal function blocks. The state is primarily event-driven, where the activation of the `IND` event in `IX` directly influences the `REQ` event in `QX`. The subapplication is stable in idle state until an input event occurs, at which point it processes the data and generates a corresponding output request.

Application Scenarios

- **Agricultural Machinery**: Used to convert physical digital inputs (e.g., switches on a control panel) into isobus auxiliary control commands, such as activating hydraulic functions or implement operations.
- **Industrial Automation**: Bridges logiBUS-based sensor inputs with isobus-controlled auxiliary devices in automated systems.
- **System Integration**: Provides a standardized interface for connecting logiBUS and isobus networks, reducing development effort and minimizing wiring errors.

Comparison with Similar Blocks

Compared to directly implementing `logiBUS_IX` and `Aux_QX` individually, the IX_TO_Aux_QX subapplication offers several advantages:



- **Simplified Interface**: Exposes only two data inputs, making it easier to configure than separately wiring multiple blocks.
- **Generic Design**: The subapplication is parameterized to support different input numbers and array indices, whereas manual wiring may require reconfiguration for each instance.
- **Reusability**: As a self-contained unit, it can be copied and integrated into different projects without additional modifications.
- **Maintainability**: Encapsulation improves code organization and simplifies debugging, as the internal logic is isolated.

Similar blocks might include direct block combinations or other bridging subapplications, but IX_TO_Aux_QX is specifically optimized for logiBUS to isobus auxiliary output conversion, offering a balance of flexibility and simplicity.

Conclusion

The IX_TO_Aux_QX subapplication is a valuable component for integrating logiBUS digital inputs with isobus auxiliary outputs. Its event-driven design, parameterized configuration, and encapsulated structure make it a practical solution for systems requiring efficient and reliable signal bridging. By simplifying the interface and promoting reusability, it enhances development productivity and system performance.

IX_TO_logiBUS_LED_strip_QX

Introduction

The `IX_TO_logiBUS_LED_strip_QX` is a generic subapplication that connects a logiBUS pushbutton input to a blinking LED strip output. It is designed for applications where a physical button should switch an LED strip on and off in a blinking mode. The color, the used input, and the target strip can be parameterized through the subapplication interface; initialization is exposed via `INIT`/`INITO` and the status via `QI`/`QO`.

The subapplication encapsulates the event handling and data routing, so it can be reused easily in larger 4diac-ide projects.

Interface Structure

Event Inputs

- `INIT` (`EInit`): Initialization Request

Apart from `INIT`, the subapplication does not expose any event inputs. The trigger is generated internally by the encapsulated pushbutton function block.

Event Outputs

- `INITO` (`EInit`): Initialization Confirm

Data Inputs

Name	Type	Initial Value	Description
`QI`	`BOOL`	`TRUE`	Quality Input - TRUE enables the service.
`Input`	`logiBUS::io::DI::logiBUS_DI_S`	`logiBUS::io::DI::logiBUS_DI::Invalid`	Identifies the physical input, e.g. `Input_I1` to `Input_I8`.

Colour	UINT	LED_COLOURS::LED_GREEN	Identifies the color of the LED strip.
Output	USINT	—	Identifies the output number of the LED strip.

Data Outputs

- QO (BOOL): Quality Output - TRUE if the service executed successfully (AND of LED.QO and BUTTON.QO, via the AND_QO block of type iec61131::booleanOperators::AND_BOOL_2).

Adapters

There are no adapters.

Functionality

The subapplication contains two internal function blocks:

- BUTTON of type logiBUS::io::DI::logiBUS_IX
- LED of type logiBUS::io::DO_LED::logiBUS_LED_strip_QX

The BUTTON block monitors the selected physical input. When this input detects a signal change, the event output IND triggers the event input REQ of the LED block.

The data flow is as follows:

- The subapplication input Input selects the physical input for BUTTON.Input.
- The button value BUTTON.IN is forwarded to LED.OUT.
- The subapplication input Output selects the target LED strip via LED.Output.
- The subapplication input Colour sets the color via LED.Colour.

Initialization runs as a chain INIT → LED.INIT, LED.INITO → BUTTON.INIT, BUTTON.INITO → INITO (and additionally → AND_QO.REQ). QI is forwarded to LED.QI and BUTTON.QI; LED.QO and BUTTON.QO are ANDed into QO.

The internal LED block is configured with FREQ = LED_FREQ::LED_1HZ, so the selected LED strip blinks at a frequency of 1 Hz when triggered.

Technical Features

- Generic subapplication for button-controlled blinking LED strips.
- Input selection via logiBUS_DI_S, with Invalid as a safe default.
- Color selection through UINT constants from LED_COLOURS.
- Output selection via USINT.
- Internal event connection: BUTTON.IND -> LED.REQ.
- Internal data forwarding is hidden in the subapplication network.
- Both internal blocks receive QI from the subapplication's QI input (default TRUE).
- Fixed blink frequency of 1 Hz.
- No external event wiring required apart from the optional INIT/INITO initialization chain.

State Overview

The subapplication itself does not define an explicit state machine. Its behavior is determined by the encapsulated function blocks and the event connection between them.

At the subapplication level, the control flow can be described conceptually:

- **Idle state:** The button input is monitored; no LED request is active.
- **Trigger state:** A button event occurs at BUTTON.IND and triggers LED.REQ.
- **Return state:** After the request is processed, the subapplication returns to the idle state.

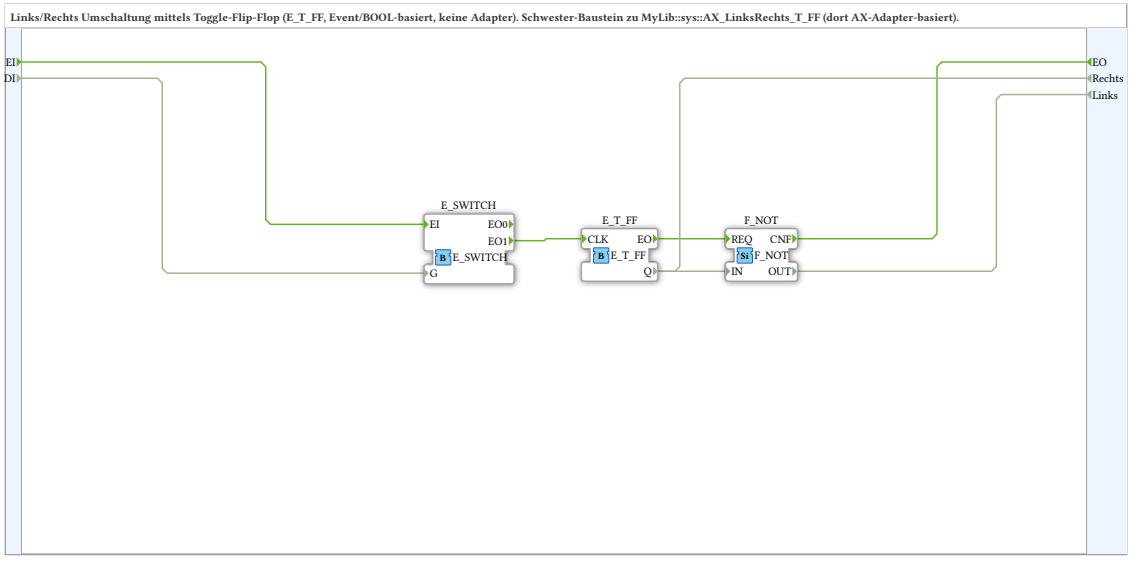
This simple event-driven behavior makes the subapplication easy to understand and integrate.

Application Scenarios

Typical use cases include:

- Controlling blinking LED strips with standard pushbutton inputs.
- Reusing the same logic for multiple inputs and outputs by parameterizing Input and Output.
- Setting different LED colors by using constants from LED_COLOURS.

- Building modular logiBUS-based lighting control applications in 4diac-ide.
- Encapsulating frequently used button-to-LED logic in a clean, reusable subapplication.



Comparison with Similar Blocks

Approach	Characteristics
Direct wiring of `logiBUS_IX` to `logiBUS_LED_strip_QX`	More wiring effort, manual event connection, no encapsulation.
Subapplication with exposed event inputs	Allows external triggering, but requires additional event handling.
Subapplication with adjustable frequency input	Offers configurable blink frequency, but has a larger interface.
`IX_TO_logiBUS_LED_strip_QX`	Self-contained button-triggered blinking LED strip with fixed 1 Hz frequency and configurable input, color, and output.

Conclusion

The `IX_TO_logiBUS_LED_strip_QX` subapplication provides a compact, generic solution for button-controlled blinking LED strips. It hides the internal event and data wiring, exposes only the necessary parameters, and can be reused in multiple places within a logiBUS-based automation project. It is especially useful when a simple pushbutton should reliably trigger a configurable LED strip output.

LinksRechts_T_FF_Event

Introduction

`LinksRechts_T_FF_Event` is a reusable IEC 61499 subapplication that implements a left/right toggle switch using an event-triggered T flip-flop. It provides two complementary boolean outputs, `Rechts` and `Links`, and can be used wherever a single event should alternately switch between two states.

The subapplication is built from standard function blocks: E_SWITCH, E_T_FF, and F_NOT. It uses only event and BOOL data connections and does not require any adapter interfaces. This makes it easy to integrate into plain event/BOOL-based automation networks.

Interface Structure

The subapplication has one event input, one event output, one BOOL data input, and two BOOL data outputs.

Event Inputs

Name	Type	Description
EI	Event	Master trigger event. If DI is TRUE, this event toggles the internal flip-flop. If DI is FALSE, the event is ignored.

Event Outputs

Name	Type	Description
EO	Event	Completion event. It is issued after the toggle operation has finished and both Rechts and Links have been updated.

Data Inputs

Name	Type	Description
DI	BOOL	Enable signal for the toggle. TRUE allows the next EI event to toggle the state. FALSE suppresses the toggle.

Data Outputs

Name	Type	Description
Rechts	BOOL	Direct output of the internal T flip-flop. It is TRUE when the toggle state is 1.
Links	BOOL	Inverted output of the internal T flip-flop. It is always the complement of Rechts.

Adapters

Name	Type	Description
None	-	This subapplication has no adapter sockets or plugs.

Functionality

The subapplication works as a gated toggle switch:

1. An event arrives at EI.
2. The internal E_SWITCH checks the DI signal:
   - If DI = TRUE, the event is passed to E_T_FF.CLK.
   - If DI = FALSE, the event is passed to the unconnected EO0 output of E_SWITCH and has no effect.
3. When E_T_FF receives the clock event, it toggles its internal state Q.
4. The new Q value is written directly to Rechts.
5. E_T_FF.EO triggers F_NOT.REQ, and F_NOT computes the inverted value of Q.
6. The inverted value is written to Links.
7. F_NOT.CNF issues the external event EO.

This event chain ensures that Rechts and Links are always complementary and are updated together during the same event handling cycle.

Technical Features

- Built entirely from standard 4diac/IEC 61499 function blocks: E_SWITCH, E_T_FF, and F_NOT.
- Pure event and BOOL-based data flow.

- No adapter interfaces required.
- Single event input for triggering and a single completion event output.
- Gating input `DI` enables or disables switching.
- Complementary outputs are generated automatically by the `F_NOT` block.
- Deterministic behavior: only one active event can cause a state change at a time.
- Suitable as a reusable subapplication in higher-level function block networks.

State Overview

The subapplication has no explicit ECC state machine, but it contains an internal memory state represented by the T flip-flop output `Q`.

Internal State `Q`	`Rechts`	`Links`
`FALSE`	`FALSE`	`TRUE`
`TRUE`	`TRUE`	`FALSE`

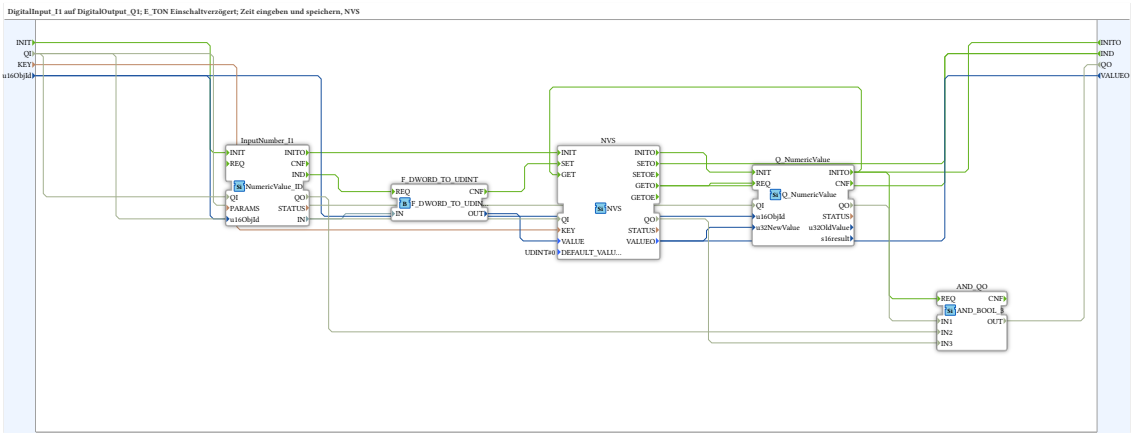
An active event, i.e. `EI` with `DI = TRUE`, toggles `Q` to the opposite state. The subapplication therefore alternates between the `Rechts` active state and the `Links` active state on each accepted trigger event.

If `DI = FALSE`, the state remains unchanged and no external completion event is generated.

Application Scenarios

- Direction control for motors, conveyors, or actuators where `Rechts` and `Links` represent clockwise/counterclockwise rotation.
- Single-button toggle with an additional enable signal, e.g. manual mode switching.
- Alternating between two operating modes using a single event source.
- Reusable subapplication for machine controls that require two mutually exclusive output signals.

Comparison with Similar Blocks



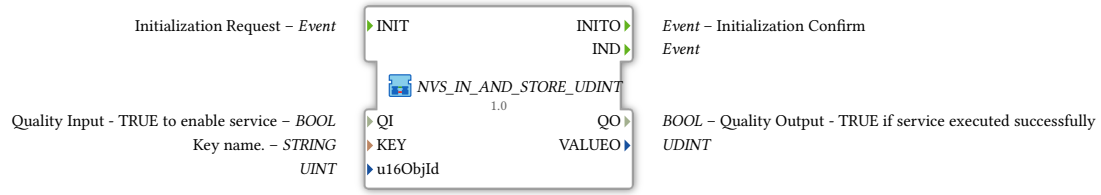
Block	Interface Type	Behavior
`LinksRechts_T_FF_Event`	Event/BOOL	Gated toggle with complementary `Rechts` and `Links` outputs.
`AX_LinksRechts_T_FF`	Adapter-based	Same left/right toggle concept, but uses an adapter interface.
Plain `E_T_FF`	Event/BOOL	Simple toggle flip-flop only; no input gating and no complement output.

Compared to a direct `E_T_FF`, this subapplication adds an enable path and complementary output generation. Compared to the adapter-based sister block, it uses a simpler interface and is therefore easier to embed in applications that do not need adapter abstraction.

Conclusion

`LinksRechts_T_FF_Event` is a compact and reliable subapplication for event-controlled left/right switching. It combines an event gate, a T flip-flop, and an inverter to produce two stable complementary outputs. Because it requires no adapters and uses only standard function blocks, it can be easily reused in a wide range of 4diac-based control applications.

NVS_IN_AND_STORE_UDINT



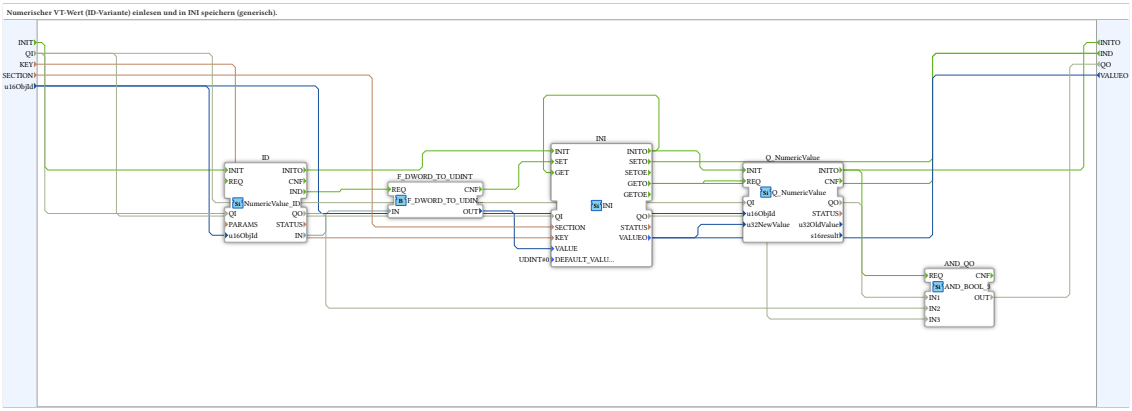
• – ○ • – ○ • – ○ •

Introduction

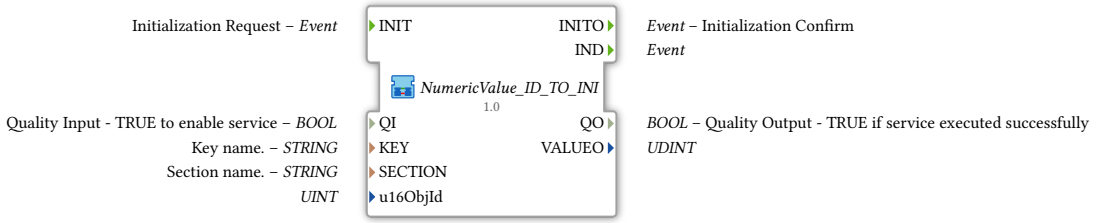
`NVS_IN_AND_STORE_UDINT` persistently stores a UDINT value entered via the VT in ESP32 flash (NVS) instead of an INI file — otherwise identical to `INI_IN_AND_STORE_UDINT`.

For the general pattern, see INI_IN_AND_STORE / NVS_IN_AND_STORE (shared pattern).

Quality ports: The block additionally has the data input `QI` (BOOL, default `TRUE`, "Quality Input - TRUE to enable service") and the data output `QO` (BOOL, "Quality Output - TRUE if service executed successfully"). `QI` is passed through to `Q_NumericValue.QI`, `InputNumber_I1.QI` and `NVS.QI` (the internal FBs no longer carry a fixed `QI=TRUE`). `QO` is the `AND` (`AND_QO`, `AND_BOOL_3`) of the `QO` outputs of `Q_NumericValue` (`IN1`), `InputNumber_I1` (`IN2`) and `NVS` (`IN3`); `AND_QO.REQ` is triggered by `Q_NumericValue.INITO` (in addition to `Q_NumericValue.INITO` ⟶ `INITO`).



Summary



NVS counterpart to `INI_IN_AND_STORE_UDINT` (MyLib_B).

NumericValue_ID_TO_INI

• – ◦ • – ◦ • – ◦ •

Introduction

The **NumericValue_ID_TO_INI** subapplication is a generic, reusable component that reads a numeric value from a Virtual Terminal (VT) using an ID-based variant and stores it persistently in an INI file. It combines the ISOBUS UT (Universal Terminal) NumericValue interface with IEC 61131 conversion functions and the Eclipse 4diac INI storage service. The subapplication is designed for scenarios where a numeric VT value, identified by a unique object ID, needs to be captured and saved to a configuration or data file, while also being queryable for further processing.

Interface Structure

Event Inputs

Name	Type	Description
`INIT`	`EInit`	Initialization request; starts the init chain at `ID.INIT`. Further activity is triggered internally via the internal NumericValue FB indication.

Event Outputs

Name	Type	Description
`INITO`	`EInit`	Initialization confirmation; comes from `Q_NumericValue.INITO`, the end of the init chain.
`IND`	Event	Indicates that a read, write, or initialization operation has completed. Emitted either after a successful INI SET operation, after a GET operation, or after querying the VT value.

Data Inputs

Name	Type	Initial Value	Description
`QI`	`BOOL`	`TRUE`	Quality Input - TRUE to enable service; passed through to `ID.QI`, `INI.QI` and `Q_NumericValue.QI`
`KEY`	`STRING`	—	The key (name) under which the numeric value is stored in the INI file.
`SECTION`	`STRING`	—	The section of the INI file where the key is located.
`u16ObjId`	`UINT`	`ID_NULL`	The object ID of the numeric VT value to be read (source identifier for the VT communication).

Data Outputs

Name	Type	Description
`QO`	`BOOL`	Quality Output - TRUE if service executed successfully; AND combination (`AND_QO`, `AND_BOOL_3`) of `Q_NumericValue.QO`, `ID.QO` and `INI.QO`
`VALUEO`	`UDINT`	The numeric value read from the VT and stored/retrieved from the INI file. This output is updated after a GET or SET operation.

Adapters

None.

Functionality

The subapp (including the added AND_QO block for the combined QO) provides a complete data path from a Virtual Terminal numeric object to persistent INI storage:

1. **VT Read**: The internal NumericValue_ID FB (isobus::UT::io::NumericValue::NumericValue_ID) reads the numeric value from the VT based on the provided u16ObjId. When the VT delivers the value, the FB raises its IND output event.
2. **Conversion**: The raw DWORD value from the VT is passed to the F_DWORD_TO_UDINT conversion FB, which converts it to a UDINT data type suitable for storage and further processing.
3. **Persistent Storage**: The converted value is written to the INI file via the INI FB (eclipse4diac::storage::INI). The parameters KEY and SECTION define the exact location in the file where the value is stored. After successful storage, the SETO event is emitted, which triggers the subapp's IND output.
4. **Initialization / Read-back**: Upon initialization, the INI FB performs a GET operation (via the internal connection from INITO to GET) to retrieve the previously stored value. After the GET completes, two actions occur:
   - The GETO event triggers the Q_NumericValue FB, which is used to query or set the VT numeric value with the retrieved stored value (ensuring synchronization).
   - The GETO event also propagates directly to the subapp's IND output, informing the external application that the read-back is complete.
5. **Output**: The retrieved value from the INI FB (VALUEO) is provided on the subapp's VALUEO output and simultaneously sent to the Q_NumericValue FB for VT synchronization.

Initialization and quality ports: The init chain is INIT → ID.INIT, ID.INITO → INI.INIT, INI.INITO → Q_NumericValue.INIT, Q_NumericValue.INITO → INITO and AND_QO.REQ (the connection INI.INITO → INI.GET remains in addition). QI (data input, BOOL, default TRUE) is passed to Q_NumericValue.QI, ID.QI and INI.QI; their QO outputs go to AND_QO.IN1 (Q_NumericValue), IN2 (ID) and IN3 (INI) of the block AND_QO (iec61131::booleanOperators::AND_BOOL_3), AND_QO.OUT → QO (BOOL). This lets the surrounding logic enable all three services and check their joint success.

Technical Features

- **Generic design**: The subapp is fully reusable and not bound to a specific application context – the KEY, SECTION, and u16ObjId parameters make it flexible for any numeric VT object.
- **DWORD → UDINT conversion**: Ensures type compatibility between the ISOBUS layer (which delivers DWORD) and the storage layer (which expects UDINT).
- **Self-initializing**: On startup, the INI FB automatically loads the last stored value via the internal INITO → GET connection.
- **Two-way synchronization**: After reading from the VT, the value is stored to INI; after reading from INI, the value is pushed to the VT via Q_NumericValue.
- **Single event output** (IND): Allows the calling application to react to any of the internal operations (SET, GET, or query) in a unified manner.
- **Direct output visibility**: The current value is always available on VALUEO, allowing external monitoring or further processing without additional event handling.
- **Use of standard libraries**: Relies on established ISOBUS UT, IEC 61131 conversion, and Eclipse 4diac storage functions, ensuring compatibility and maintainability.

State Overview

The subapp operates in a sequential, event-driven manner without explicit state variables. The internal event flow can be summarized as:

1. **Idle**: The subapp waits for an internal trigger (either a VT indication or initialization).
2. **VT Read State**: The NumericValue_ID FB receives a new value from the VT. Upon indication (IND), the value is forwarded to the conversion FB.
3. **Conversion State**: F_DWORD_TO_UDINT processes the value and issues a confirmation (CNF).

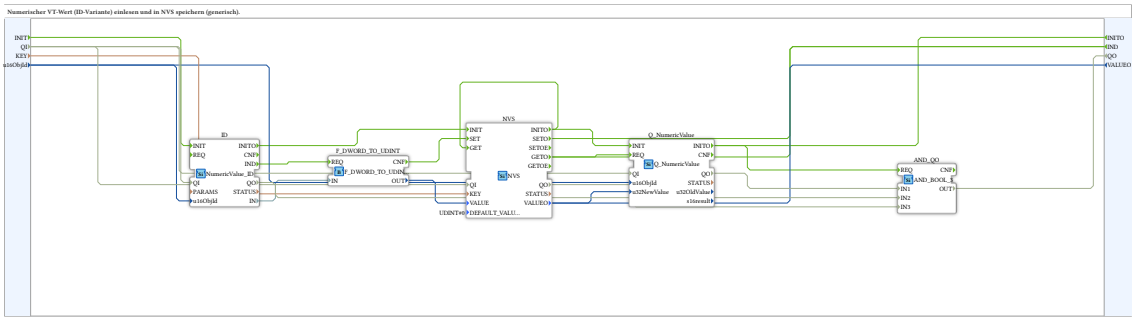
4. **Storage State**: The `INI` FB writes the converted value using `KEY`/`SECTION`. After the write completes, `SETO` is raised, and the subapp emits `IND`.
5. **Initialization / Read-back State**: On startup, the `INI` FB automatically issues a `GET`. When the value is retrieved (`GETO`), the `Q_NumericValue` FB is triggered to synchronize the VT, and `IND` is emitted simultaneously.

The use of implicit event chaining (via internal connections) ensures deterministic behavior without race conditions.

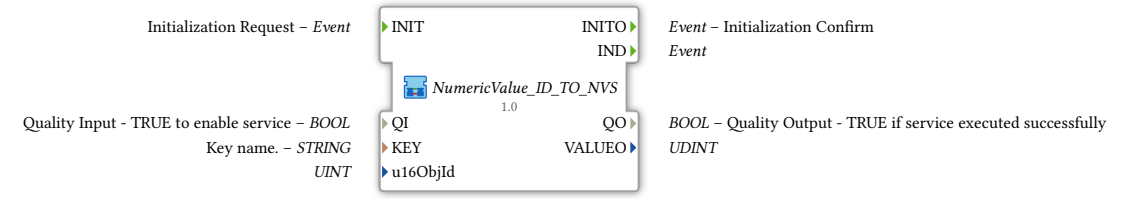
Application Scenarios

- **VT parameter persistence**: Storing operator-set numeric parameters (e.g., setpoints, machine limits) from an ISOBUS Virtual Terminal to a local INI file, so that values survive a power cycle.
- **Automated machine configuration**: Reading a numeric value from a VT object and writing it to a configuration file used by other automation components.
- **Data logging / audit trails**: Capturing numeric VT values (e.g., speed, temperature) and storing them in INI-based logs for later analysis.
- **System synchronization**: Using the INI file as a bridge between a VT and a control application – the subapp ensures both ends are updated consistently.
- **Reusable building block**: Since it was extracted from an existing application for reuse, it can be embedded in multiple FB networks without modification.

Comparison with Similar Blocks



Feature	NumericValue_ID_TO_INI	Direct NumericValue FB (e.g., `NumericValue_ID`)	INI Storage FB (standalone)
Reads from VT	Yes	Yes	No
Writes to INI	Yes	No	Yes
Type conversion	Automatic (DWORD→UDINT)	Not included	Not included
Initialization load	Yes (automatic GET)	No	No
VT synchronization after read	Yes (via `Q_NumericValue`)	No	No
Encapsulation	High – single subapp	Low – requires external wiring	Low – requires external wiring
Reusability	High (generic parameters)	Medium (requires setup)	Medium (requires setup)
Complexity	Moderate (internal logic hidden)	Low but manual effort needed	Low but manual effort needed



The main advantage of this subapp over using the individual blocks separately is the **complete integration** – the user does not have to wire the event/data connections, handle the initialization sequence, or manage the conversion logic. It provides a ready-to-use, self-contained solution.

Conclusion

The **NumericValue_ID_TO_INI** subapplication is a well-structured, generic component that bridges the gap between ISOBUS Virtual Terminal numeric values and persistent INI storage. It encapsulates a complete data flow – from VT reading, through type conversion, to file storage and back-synchronization – within a single, easy-to-use interface. With only three configuration inputs (plus `QI`) and the event outputs `IND` and `INITO`, it is both simple to integrate and highly reusable. The automatic initialization behavior and the implicit synchronization with the VT make it particularly suitable for applications requiring persistent, consistent numeric parameters. Its design follows established standards (IEC 61499-2, IEC 61131) and leverages proven library components, ensuring reliability and maintainability in industrial automation environments.

NumericValue_ID_TO_NVS

• – ○ • – ○ • – ○ •

Introduction

NumericValue_ID_TO_NVS is a generic IEC 61499 subapplication that reads a numeric value identified by an object ID and stores or retrieves that value in the non-volatile storage (NVS) of an ESP32. It combines an ISOBUS-compatible numeric value input block, a data type conversion function block, and an NVS storage block into a reusable component. The subapplication exposes a simple interface with one event output, two data inputs, and one data output.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request; goes to `ID.INIT` and starts the initialization chain

Event Outputs

Event	Comment
`IND`	Indicates that either a SET or GET operation on the NVS has been completed.
`INITO`	Initialization confirm; comes from `Q_NumericValue.INITO`, the end of the chain `ID` ⟶ `NVS` ⟶ `Q_NumericValue`.

Data Inputs

Name	Type	Initial Value	Comment
`QI`	`BOOL`	`TRUE`	Quality Input - TRUE to enable service; passed through to `ID.QI`, `NVS.QI` and `Q_NumericValue.QI`
`KEY`	`STRING`	—	Key name used in the NVS storage.
`u16ObjId`	`UINT`	`ID_NULL`	Object ID of the numeric value to be processed.

Data Outputs

Name	Type	Comment
`QO`	`BOOL`	Quality Output - TRUE if service executed successfully; AND of `Q_NumericValue.QO`, `ID.QO` and `NVS.QO`
`VALUEO`	`UDINT`	Numeric value that is currently stored in the NVS.

Adapters

None.

Functionality

The subapplication internally uses three main function blocks:

1. `NumericValue_ID`
   Reads a numeric value associated with the input `u16ObjId`. Its event output `IND` triggers the following processing steps.
2. `F_DWORD_TO_UDINT`
   Converts the incoming numeric value from `DWORD` to `UDINT`. This ensures that the value is stored in the NVS in a consistent unsigned double integer format.
3. `NVS`
   Stores the converted value under the key provided by `KEY` and makes it available again on the output `VALUEO`.

The internal event flow works as follows:

- When the `NumericValue_ID` block produces an `IND` event, the conversion block is triggered via `REQ`.
- After conversion, the `CNF` event triggers the NVS block to perform a `SET` operation.
- A completed SET operation is reported on `SETO`, which is propagated to the subapplication output `IND`.
- On initialization, the NVS block performs a GET operation automatically after its `INITO` event. The retrieved value is then assigned to `VALUEO` and also passed to the internal `Q_NumericValue` block.

Initialization and quality ports: `INIT` → `ID.INIT`, `ID.INITO` → `NVS.INIT`, `NVS.INITO` → `Q_NumericValue.INIT`, `Q_NumericValue.INITO` → `INITO` (and → `AND_QO.REQ`); in addition `NVS.INITO` still triggers `NVS.GET`. `QI` (data input, BOOL, default `TRUE`) is passed on to `ID.QI`, `NVS.QI` and `Q_NumericValue.QI`. The output `QO` (BOOL) is the output of the instance `AND_QO` (`iec61131::booleanOperators::AND_BOOL_3`), which combines `Q_NumericValue.QO`, `ID.QO` and `NVS.QO`. This lets the surrounding logic enable the service and check whether it succeeded.

Technical Features

- Generic NVS key handling through the `KEY` input.
- Object-ID-based value selection through `u16ObjId`.
- Automatic conversion from `DWORD` to `UDINT` before storage.
- NVS default value configured as `UDINT#0`.
- Initial object ID default is `ID_NULL`, imported from `isobus::UT::Q::const::IDs`.
- All internal event sequencing is self-contained; no external event input is required.
- Provides a simple completion signal via the `IND` event output.
- This subapplication is suitable for reuse in larger ISOBUS or ESP32-based systems.

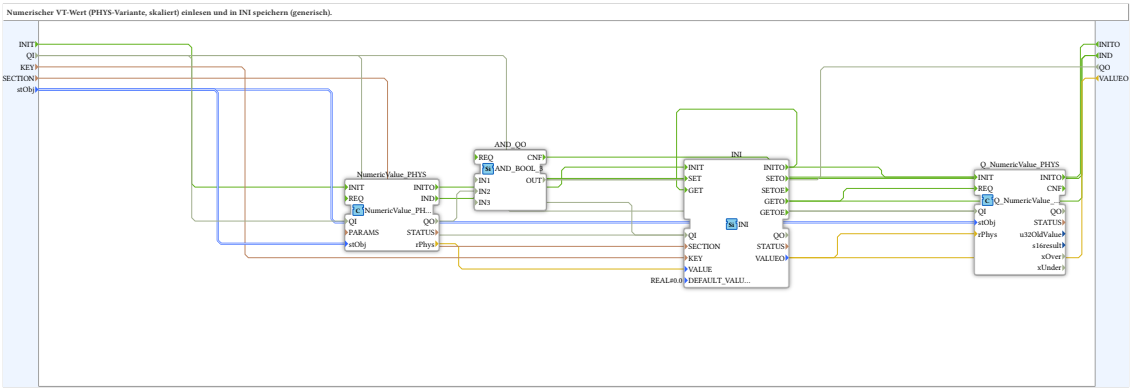
State Overview

The subapplication can be described by the following internal operating states:

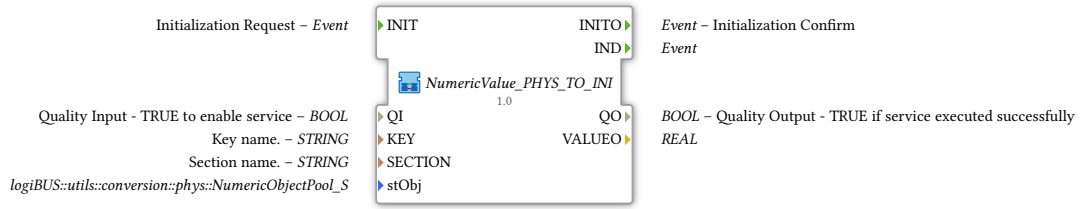
1. **Initialization State**
   After startup, the NVS block initializes. Its `INITO` event automatically triggers a GET request.
2. **GET State**
   The NVS reads the value associated with `KEY`. When completed, the retrieved value is written to `VALUEO` and the `IND` event is emitted.
3. **Value Update State**
   When a new numeric value is read from the `NumericValue_ID` block, it is converted and then stored in the NVS via a SET operation.
4. **Completion State**
   After the SET operation finishes, the `SETO` event propagates to the external world through `IND`.

Application Scenarios

- Storing ISOBUS numeric implement values in ESP32 non-volatile memory.
- Persisting calibration values or configuration parameters that are addressed by object IDs.
- Building reusable components for V3 / ISOBUS object pool applications.
- Replacing direct manual handling of NVS storage with a generic, event-driven storage pattern.



Comparison with Similar Blocks



- Compared to a straightforward connection between `NumericValue_ID` and `NVS`, this subapplication encapsulates the required data conversion and event handling, reducing wiring complexity.
- Compared to non-ID numeric storage blocks, this variant selects values by `u16ObjId`, making it suitable for ISOBUS-related data.
- Compared to blocks that only read or only write, this subapplication supports both reading and writing while exposing a single completion event.

Conclusion

NumericValue_ID_TO_NVS is a compact and reusable subapplication for reading numeric values by object ID and persisting them in ESP32 NVS storage. It simplifies integration by hiding conversion, initialization, and event sequencing behind a small interface. It is especially useful in ISOBUS-based systems where numeric values need to be preserved across power cycles.

NumericValue_PHYS_TO_INI

• — ○ • — ○ • — ○ •

Introduction

The `NumericValue_PHYS_TO_INI` subapplication provides a generic, reusable mechanism for reading a scaled numeric process or device value (the PHYS variant) and persistently storing it in an INI storage. It combines a physical-value acquisition block, an INI storage block, and a query-conversion block to deliver a complete read-and-persist chain. The entity is designed to be parameterized via a key, a section name, and a numeric object-pool descriptor that carries scaling, offset, and decimal-place information.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialization request. The further internal processing is triggered by the embedded function blocks.

Event Outputs

Name	Type	Description
`INITO`	EInit	Initialization confirmation (from `Q_NumericValue_PHYS.INITO`).
`IND`	Event	Indicates that a value has been successfully stored in or retrieved from the INI storage.

Data Inputs

Name	Type	Description
QI	BOOL	Quality Input - TRUE to enable service; distributed to Q_NumericValue_PHYS.QI, NumericValue_PHYS.QI and INI.QI
KEY	STRING	Key name under which the value is stored in the INI file.
SECTION	STRING	Section name within the INI file used for grouping the key.
stObj	I4CBUS::utils::conversion::phys::NumericObjectPool_t	Object-pool descriptor containing the numeric object ID, scale factor, offset, and number of decimals. Initial value: (u16ObjId := ID_NULL, r32Scale := 1.0, i32Offset := 0, u8Decimals := 0).

Data Outputs

Name	Type	Description
QO	BOOL	Quality Output - TRUE if service executed successfully; AND of Q_NumericValue_PHYS.QO, NumericValue_PHYS.QO and INI.QO
VALUEO	REAL	The current value that has been stored or retrieved from the INI storage.

Adapters

None.

Functionality

The subapplication orchestrates four internal function blocks:

- NumericValue_PHYS – acquires a raw process value and converts it into a scaled physical REAL value using the parameters contained in stObj.
- INI – stores and retrieves that REAL value in an INI file, addressed by KEY and SECTION.
- Q_NumericValue_PHYS – a query function that reconstructs the physical representation from the stored numeric value, using the same object-pool descriptor.
- AND_QO (iec61131::booleanOperators::AND_BOOL_3) – combines Q_NumericValue_PHYS.QO (IN1), NumericValue_PHYS.QO (IN2) and INI.QO (IN3) into the subapplication output QO.

The operational sequence is as follows:

1. Upon initialization, the INI block performs an automatic GET operation (INITO → GET) to load any previously persisted value for the given key and section.
2. When a new value is available, NumericValue_PHYS emits an IND event, triggering the INI.SET operation. The converted physical value (rPhys) is written to the INI storage.
3. Both the completion of a SET and the completion of a GET operation propagate an IND event to the subapplication output.
4. On every GETO, the retrieved value is forwarded to the query block Q_NumericValue_PHYS for further conversion, and simultaneously made available as VALUEO.

The internal data connections ensure that the same stObj descriptor is used consistently by both the acquisition block (for scaling while reading) and the query block (for reverse scaling), while KEY and SECTION only reference the INI storage.

Quality ports: QI (data input, BOOL, default TRUE) is distributed to Q_NumericValue_PHYS.QI, NumericValue_PHYS.QI and INI.QI; the output QO (BOOL) is the AND of the QO outputs of these three blocks (AND_QO). This lets the surrounding logic enable the service and check whether it succeeded.

Initialization: `INIT` → `NumericValue_PHYS.INIT`; `NumericValue_PHYS.INITO` → `INI.INIT`; `INI.INITO` → `Q_NumericValue_PHYS.INIT` (and internally → `INI.GET`); `Q_NumericValue_PHYS.INITO` → `INITO` and → `AND_QO.REQ`.

Technical Features

- **Generic parameterization** – The subapplication does not hard-code any key, section, or object ID. All addressing and scaling information is supplied through the data inputs.
- **Scaling support** – The `stObj` descriptor allows arbitrary `REAL` scaling (`r32Scale`, `i32Offset`) and decimal rounding (`u8Decimals`), making the block suitable for engineering-unit conversions.
- **Non-volatile persistence** – Values are stored in an INI file, surviving restarts of the runtime environment.
- **Default initial value** – If no stored value exists, the `INI` block falls back to a default value of `REAL#0.0`.
- **Automatic init-read** – On start-up the stored value is fetched automatically, so the `VALUEO` output reflects the persisted state without an explicit external trigger.

State Overview

The internal `INI` function block follows this state transition pattern:

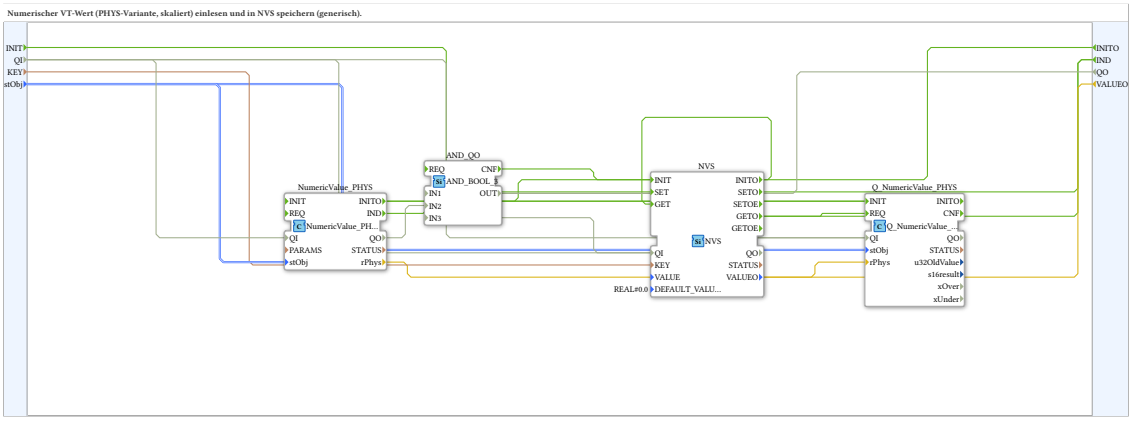
- **Uninitialized** – After power-up or before `INIT` is accepted.
- **Initializing** – On receiving the `INI.INITO` event, the block immediately issues a `GET` operation to load the stored value.
- **Operational (Set/Get)** – In this state, the block alternates between `SET` (triggered by `NumericValue_PHYS.IND`) and `GET` operations, each producing a corresponding `SETO` or `GETO` confirmation event.
- **Fault** – If a storage access fails, the `INI` block raises an error condition; the error handling is external to this subapplication and must be monitored via the standard `QO`/`EO` signals of the INI block (not exposed at this level).

The `NumericValue_PHYS` acquisition block operates independently and is enabled via the `QI` of the subapplication; it continuously acquires and converts values as they arrive.

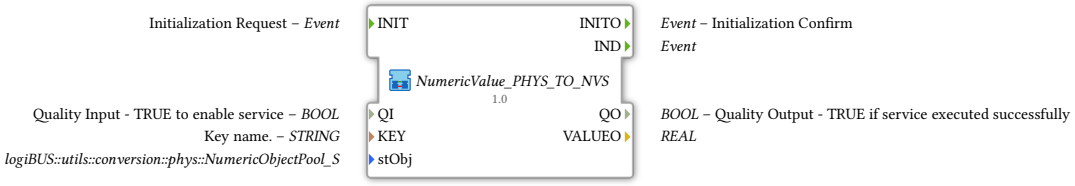
Application Scenarios

- **Machine parameter persistence** – Storing calibrated sensor values or scaled setpoints in an INI configuration file so they remain valid after a controller restart.
- **Data logging with scaling** – Saving scaled engineering values (e.g., temperatures, pressures, flow rates) in a compact textual format, where the original unit conversion is defined by the object-pool descriptor.
- **System configuration exchange** – Using a standardized INI section/key structure to export/import process values between different plant components or HMI layers.
- **Generic library reuse** – Because the subapplication is fully generic, it can be instantiated multiple times within a larger application, each instance configured with its own key, section, and scaling descriptor, without code changes.

Comparison with Similar Blocks



Aspect	`NumericValue_PHYS_TO_INI`	`NumericValue` (raw, no storage)	`NumericValue_TO_INI` (non-phys variant)
Value scaling	Yes – through `stObj` (scale, offset, decimals)	No – raw value only	No – raw value only
Persistence in INI	Yes	No	Yes
Automatic init-read	Yes	N/A	Yes
Required external data	`KEY`, `SECTION`, `stObj`	None (only acquisition parameters)	`KEY`, `SECTION`
Output behavior	`VALUEO` is the stored/retrieved value	Output is the live raw value	Output is the stored raw value



The distinctive advantage of this subapplication is the combination of scaling and persistence in a single reusable component, which reduces wiring effort and ensures consistent conversion parameters between acquisition and storage.

Conclusion

`NumericValue_PHYS_TO_INI` is a compact and generic subapplication that solves the recurring task of reading a scaled physical process value and making it persistable in an INI storage. Its well-defined interface, automatic initialization behavior, and built-in scaling support make it a suitable building block for larger automation projects that require configuration persistence with engineering-unit correctness. The block is particularly valuable in environments where multiple measured values must be archived or restored across restarts without redundant application logic.

NumericValue_PHYS_TO_NVS

• – ○ • – ○ • – ○ •

Introduction

The **NumericValue_PHYS_TO_NVS** subapplication is a generic, reusable component that integrates a physical numeric value sensor (scaled variant) with non-volatile storage (NVS). It reads a physical value using the `NumericValue_PHYS` function block, stores the result into an NVS key, and provides the stored value as an output. The subapp is designed for embedded systems where calibration data or process values need to be persisted across power cycles.

This subapp decouples the scaling logic (performed by `NumericValue_PHYS`) from the storage management (handled by `NVS`), offering a clean interface that exposes only the key name, scaling parameters, and the current stored value.

Interface Structure

Event Outputs

Event	Description
`INITO`	Initialization confirm (EInit). Comes from `NVS.INITO` (end of the initialization chain).
`IND`	Indicates that a storage or retrieval operation has been completed. This event is emitted after a successful `SET` or `GET` operation from the internal NVS block.

Event Inputs

- **INIT** (EInit): Initialization request. Passed on to `Q_NumericValue_PHYS.INIT`, which starts the chain `Q_NumericValue_PHYS` ⟶ `NumericValue_PHYS` ⟶ `NVS`.

Data Inputs

Name	Type	Description
QI	BOOL	Quality Input - TRUE to enable service; distributed to Q_NumericValue_PHYS.QI, NumericValue_PHYS.QI and NVS.QI
KEY	STRING	The unique identifier (key name) under which the value is stored in NVS.
stObj	iomBUS::utils::conversion::phys::NumericObjectPScaling	Scaling and formatting parameters (object ID, scaling factor, offset, decimals). Default: (u16ObjId := ID_NULL, r32Scale := 1.0, i32Offset := 0, u8Decimals := 0).

Data Outputs

Name	Type	Description
QO	BOOL	Quality Output - TRUE if service executed successfully; AND combination (AND_QO, AND_BOOL_3) of Q_NumericValue_PHYS.QO, NumericValue_PHYS.QO and NVS.QO
VALUEO	REAL	The current value stored in NVS (read back after initialization or after a write operation).

Adapters

None.

Functionality

The subapp operates internally with three main components and an AND block for the quality output:

1. **NumericValue_PHYS** – Converts a raw physical input into a scaled REAL value (rPhys) using the scaling parameters from stObj. It receives QI from the subapp input, so it is ready to process by default.
2. **NVS** – A non-volatile storage block that handles SET, GET, and INIT operations. It receives QI from the subapp input and has a default value of 0.0.
3. **Q_NumericValue_PHYS** – A query block that reconstructs the physical value from the stored data, making it available for further processing. It receives INIT and QI from outside; its INITO starts NumericValue_PHYS, and its QO feeds AND_QO.IN1.
4. **AND_QO** (iec61131::booleanOperators::AND_BOOL_3) – combines Q_NumericValue_PHYS.QO (IN1), NumericValue_PHYS.QO (IN2) and NVS.QO (IN3) into QO.

Data flow:

- The scaled physical value (rPhys) from NumericValue_PHYS is fed to the VALUE input of NVS.
- The event IND from NumericValue_PHYS triggers the SET operation of NVS, storing the current value under KEY.
- Upon successful SETO (or GETO), the subapp emits an IND event to inform the outside world.
- The subapp event INIT is forwarded to Q_NumericValue_PHYS.INIT; Q_NumericValue_PHYS.INITO → NumericValue_PHYS.INIT; NumericValue_PHYS.INITO → NVS.INIT; NVS.INITO is emitted as the subapp's INITO and also triggers AND_QO.REQ. QI is distributed to Q_NumericValue_PHYS.QI, NumericValue_PHYS.QI and NVS.QI, and AND_QO.OUT is output as the subapp's QO.
- Independently, after the NVS block's initialization (NVS.INITO), it performs a GET operation, retrieving the previously stored value. This value is then output via VALUEO and also passed to Q_NumericValue_PHYS for scaling/interpretation.

The subapp therefore keeps the stored value up-to-date whenever a new physical reading is available and also allows the stored value to be read back after a restart.

Quality ports: QI (data input, BOOL, default TRUE) is distributed to Q_NumericValue_PHYS.QI, NumericValue_PHYS.QI and NVS.QI; the output QO (BOOL) is the AND combination (AND_QO) of the three QO outputs. This lets the surrounding logic enable the service and check whether it succeeded.

Technical Features

- **Generic scalability** – The `stObj` parameter encapsulates all scaling and formatting information, making the subapp reusable for different sensor types or units.
- **Persistent storage** – Leverages the NVS mechanism of the ESP32 platform to retain data across power cycles.
- **Automatic initialization** – On startup, the subapp reads the stored value from NVS and exposes it via `VALUE0`.
- **Minimal external interface** – Only one key name and the scaling object are required as inputs, keeping integration simple.
- **Modular design** – Uses well-defined function blocks from the `isobus` and `logiBUS` libraries, promoting code reuse and maintainability.

State Overview

The subapp does not explicitly define a state machine. Instead, it relies on the built-in behavior of the internal NVS block, which has the following typical states:

- **Uninitialized** – Before `INIT0` is processed.
- **Idle** – Waiting for a `SET` or `GET` request.
- **Busy** – During a read/write operation.
- **Error** – If a storage operation fails (handled internally by the NVS block).

The subapp's output `IND` is emitted after each completed operation, providing a simple handshake mechanism for external logic.

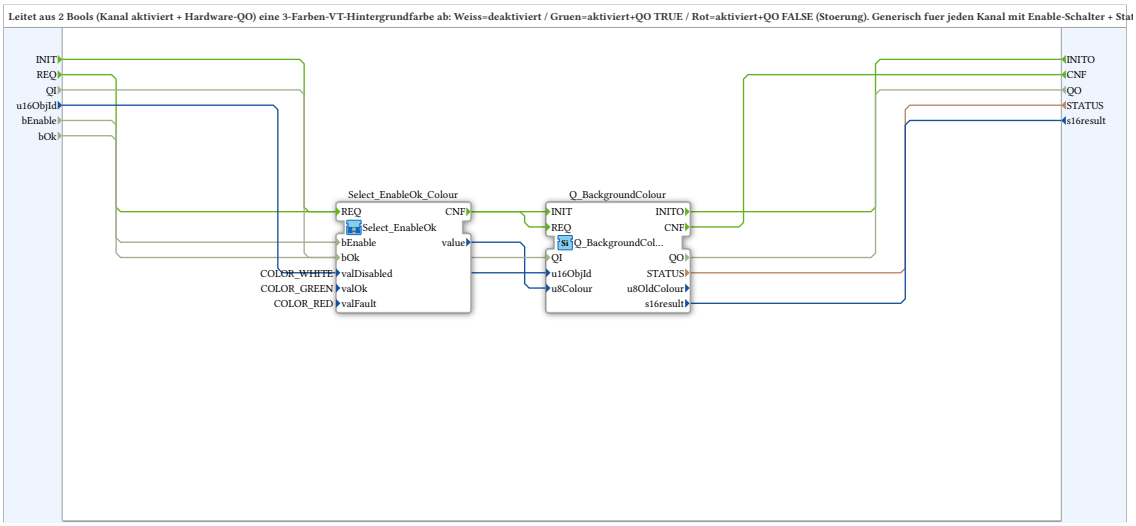
Application Scenarios

- **Calibration data storage** – Store calibration constants or correction factors for analog inputs.
- **Setpoint persistence** – Save user-configured setpoints in an industrial control system.
- **Data logging** – Periodically capture a physical measurement and keep the last value in non-volatile memory.
- **Fail-safe recovery** – Restore the last known good value after a system reboot.

The subapp is particularly useful in IoT devices, smart sensors, and embedded controllers where configuration or measurement data must survive power loss.

Comparison with Similar Blocks

There are other subapplications that handle NVS storage (e.g., a raw value store without scaling or a store with a fixed scaling). The distinguishing feature of **NumericValue_PHYS_TO_NVS** is its tight integration with the physical scaling layer. Unlike a simple `NVS` wrapper, this block:



- Automatically applies scaling factors and offsets via `NumericValue_PHYS`.
- Provides a query path (`Q_NumericValue_PHYS`) to convert the stored raw data back to a physical value.
- Combines storage and conversion in a single, configurable component.

Other blocks might require the user to manage scaling separately, increasing complexity and the risk of inconsistencies.

Conclusion

The **NumericValue_PHYS_TO_NVS** subapplication offers a compact and efficient solution for persisting scaled numeric values in non-volatile storage. Its generic interface and internal modularity make it suitable for a wide range of embedded applications. By encapsulating scaling, storage, and retrieval, it simplifies the development of robust systems that require reliable data retention.

Q_BackgroundColour_EnableOk

• — ○ • — ○ • — ○ •

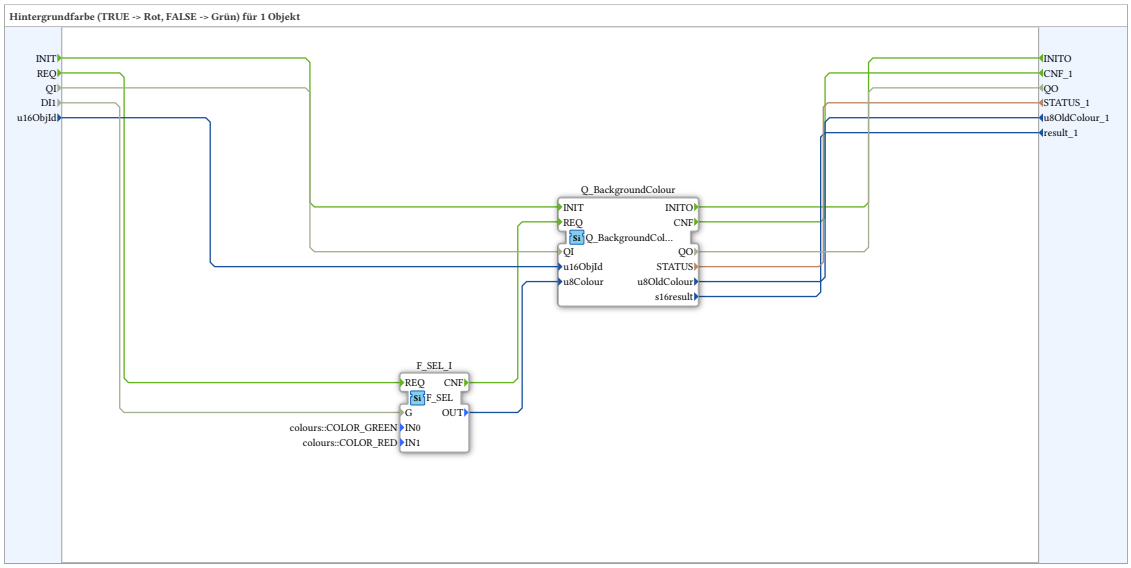
Introduction

`Q_BackgroundColour_EnableOk` derives a 3-color VT background color from 2 bools (channel enabled + hardware QO): white = disabled, green = enabled and QO TRUE, red = enabled and QO FALSE (fault). Generic for any channel with an enable switch + status LED (PWM, PI, ...). The pure selection logic now lives in `Select_EnableOk` this block just instantiates it with the 3 colors as parameters and attaches `Q_BackgroundColour`.

Quality ports: The block additionally has the event `INIT` (input) and `INITO` (output), the data input `QI` (BOOL, default `TRUE`, “Quality Input - TRUE to enable service”) and the data output `QO` (BOOL, “Quality Output - TRUE if service executed successfully”). `INIT` is passed on to `Q_BackgroundColour.INIT`, `Q_BackgroundColour.INITO` is passed to `INITO`; `QI` is connected to `Q_BackgroundColour.QI` and `Q_BackgroundColour.QO` to `QO`.

Function blocks used

- **Select_EnableOk_Colour** (SubApp, type `MyLib::sys::Select_EnableOk`): `valDisabled=COLOR_WHITE`, `valOk=COLOR_GREEN`, `valFault=COLOR_RED`.
- **Q_BackgroundColour** (`isobus::UT::Q::Q_BackgroundColour`): writes the computed color to `u16ObjId`.



Summary

Ready-parameterized color logic (white/green/red) for enable+ok status displays, built on the generic `Select_EnableOk` selection.

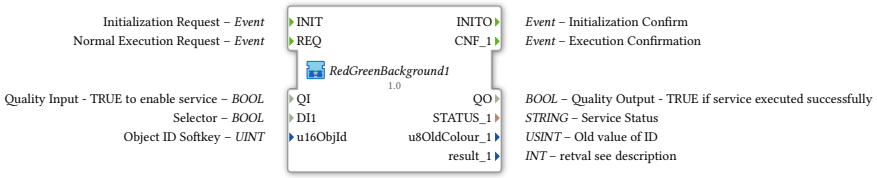
RedGreenBackground1



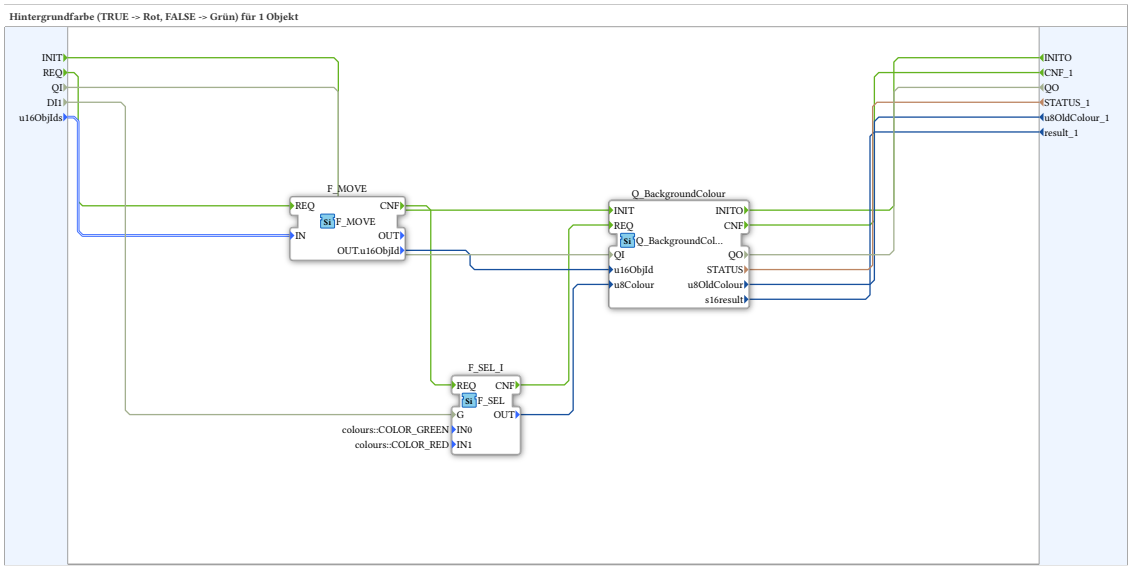
• — ○ • — ○ • — ○ •

Introduction

`RedGreenBackground1` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Grün**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via input `u16ObjId`.

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Quality ports: The block additionally has the event `INIT` (input) and `INITO` (output), the data input `QI` (BOOL, default `TRUE`, "Quality Input - TRUE to enable service") and the data output `QO` (BOOL, "Quality Output - TRUE if service executed successfully"). `INIT` is passed on to `Q_BackgroundColour.INIT`, `Q_BackgroundColour.INITO` is passed to `INITO`; `QI` is connected to `Q_BackgroundColour.QI` and `Q_BackgroundColour.QO` to `QO`.



Summary

One of many variants in the background color block family: color pair Rot/Grün, 1 object, BOOL selector.

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

RedGreenBackground1S

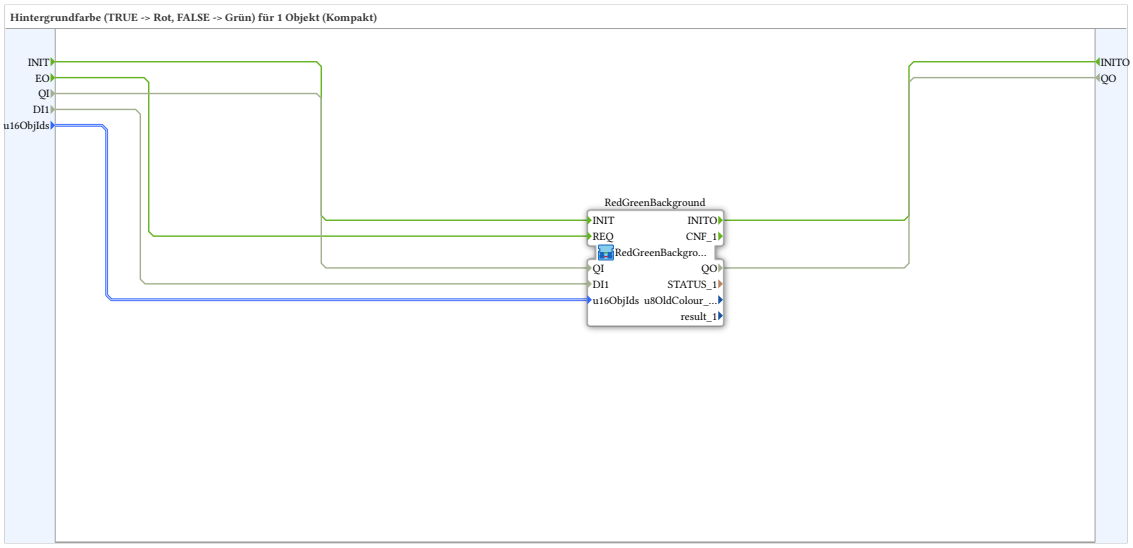
• – ○ • – ○ • – ○ •

Introduction

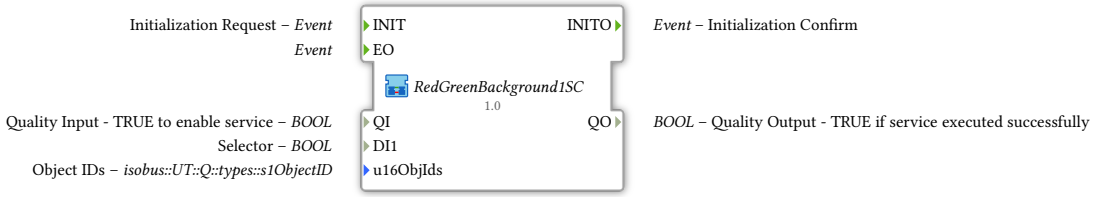
`RedGreenBackground1S` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Grün**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via the structured type `s1ObjectID` (`u16ObjIds`).

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Quality ports: The block additionally has the event `INIT` (input) and `INITO` (output), the data input `QI` (BOOL, default `TRUE`, "Quality Input - TRUE to enable service") and the data output `QO` (BOOL, "Quality Output - TRUE if service executed successfully"). `INIT` is passed on to `Q_BackgroundColour.INIT`, `Q_BackgroundColour.INITO` is passed to `INITO`; `QI` is connected to `Q_BackgroundColour.QI` and `Q_BackgroundColour.QO` to `QO`.



Summary



One of many variants in the background color block family: color pair Rot/Grün, 1 object, BOOL selector, struct. object ID.

RedGreenBackground1SC

• – ○ • – ○ • – ○ •

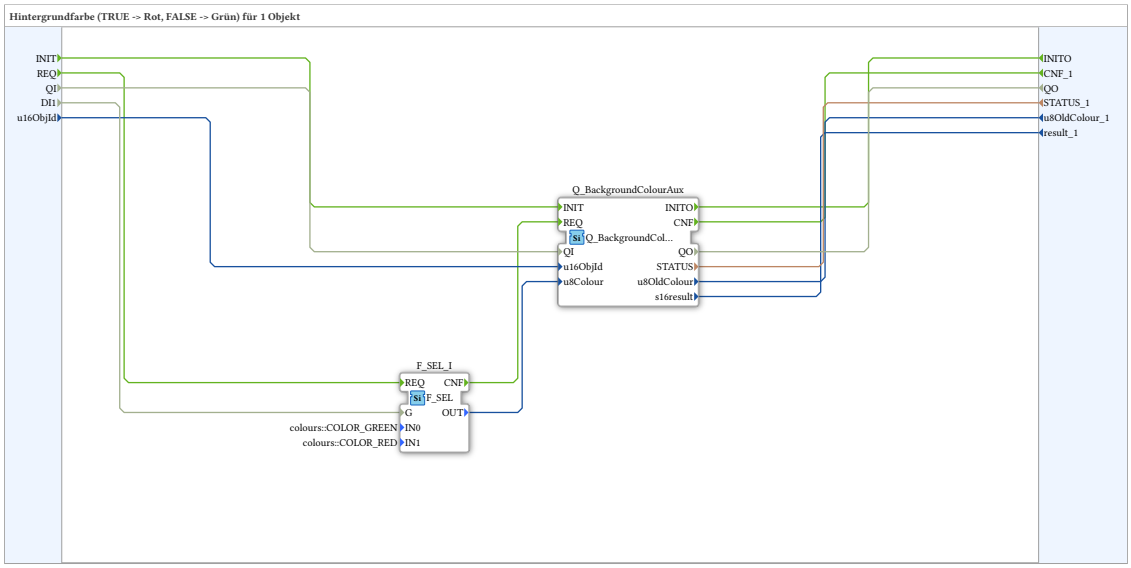
Introduction

`RedGreenBackground1SC` is a **compact wrapper** around `RedGreenBackground1S` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

For the shared pattern, see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `RedGreenBackground.QI`
- **Data output** `QO` (`BOOL`, Quality Output): passed through from `RedGreenBackground.QO`
- **Initialization chain**: `INIT` ⟶ `RedGreenBackground.INIT`, `RedGreenBackground.INITO` ⟶ `INITO`



Summary

A pure pass-through to `RedGreenBackground1S` for the common case where the diagnostic values aren't needed.

RedGreenBackground1_aux

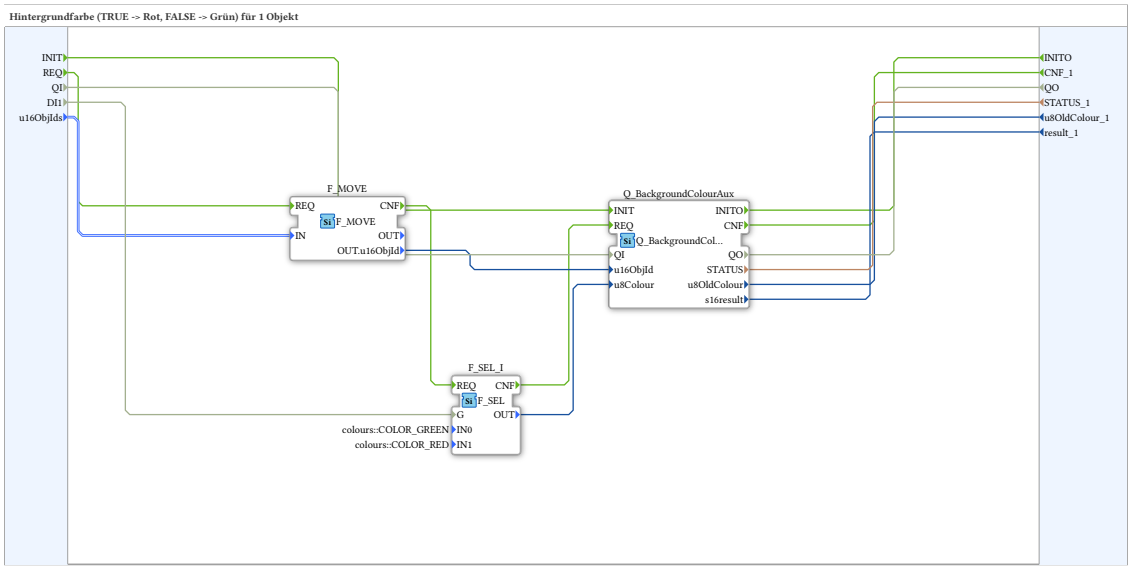
• — ○ • — ○ • — ○ •

Introduction

`RedGreenBackground1_aux` switches the VT background color of one object based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Grün**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via input `u16ObjId`.

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Quality ports: The block additionally has the event `INIT` (input) and `INITO` (output), the data input `QI` (BOOL, default `TRUE`, "Quality Input - TRUE to enable service") and the data output `QO` (BOOL, "Quality Output - TRUE if service executed successfully"). `INIT` is passed on to `Q_BackgroundColourAux.INIT`, `Q_BackgroundColourAux.INITO` is passed to `INITO`; `QI` is connected to `Q_BackgroundColourAux.QI` and `Q_BackgroundColourAux.QO` to `QO`.



Summary

One of many variants in the background color block family: color pair Rot/Grün, 1 object, BOOL selector.

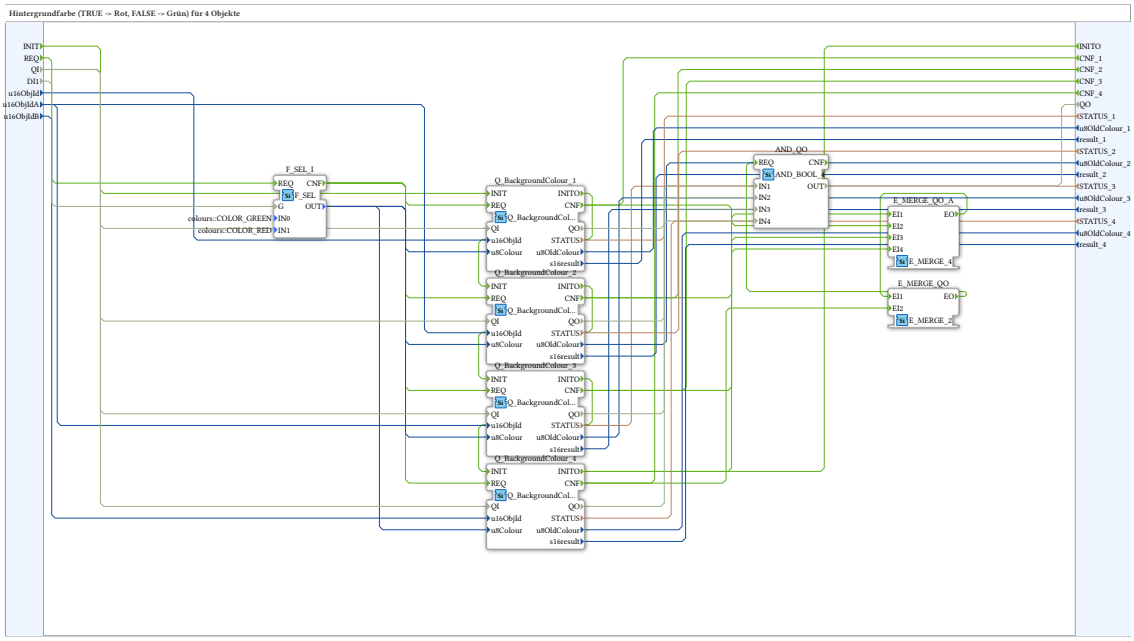
RedGreenBackground1_auxSC

• — ○ • — ○ • — ○ •

Introduction

`RedGreenBackground1_auxSC` is a **compact wrapper** around `RedGreenBackground1_auxS` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`). In addition, `INIT` ⟶ `RedGreenBackground.INIT`, `RedGreenBackground.INITO` ⟶ `INITO`, `QI` ⟶ `RedGreenBackground.QI` (initial value `TRUE`) and `RedGreenBackground.QO` ⟶ `QO` are passed through.

For the shared pattern, see Background Color Blocks (shared pattern).



Summary

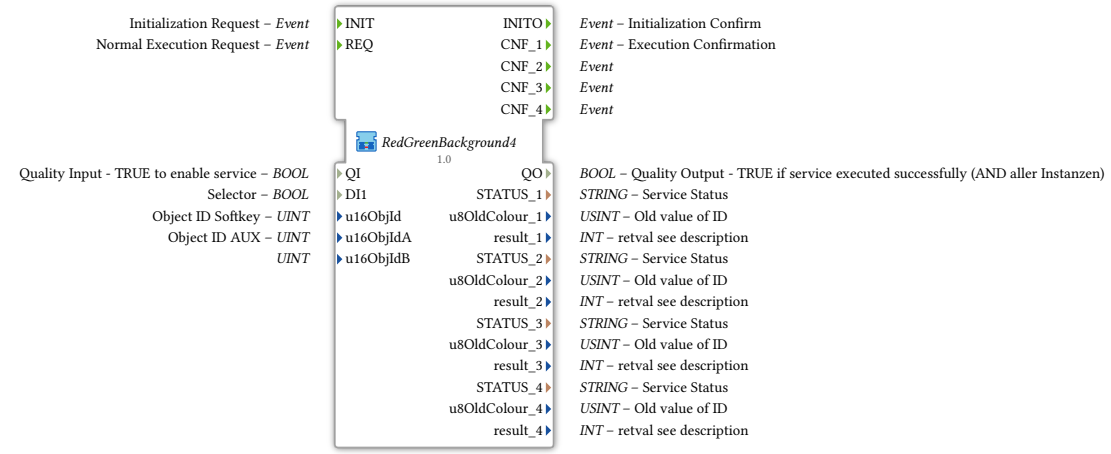
A pure pass-through to `RedGreenBackground1_auxS` for the common case where the diagnostic values aren't needed.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

RedGreenBackground4

• — ○ • — ○ • — ○ •



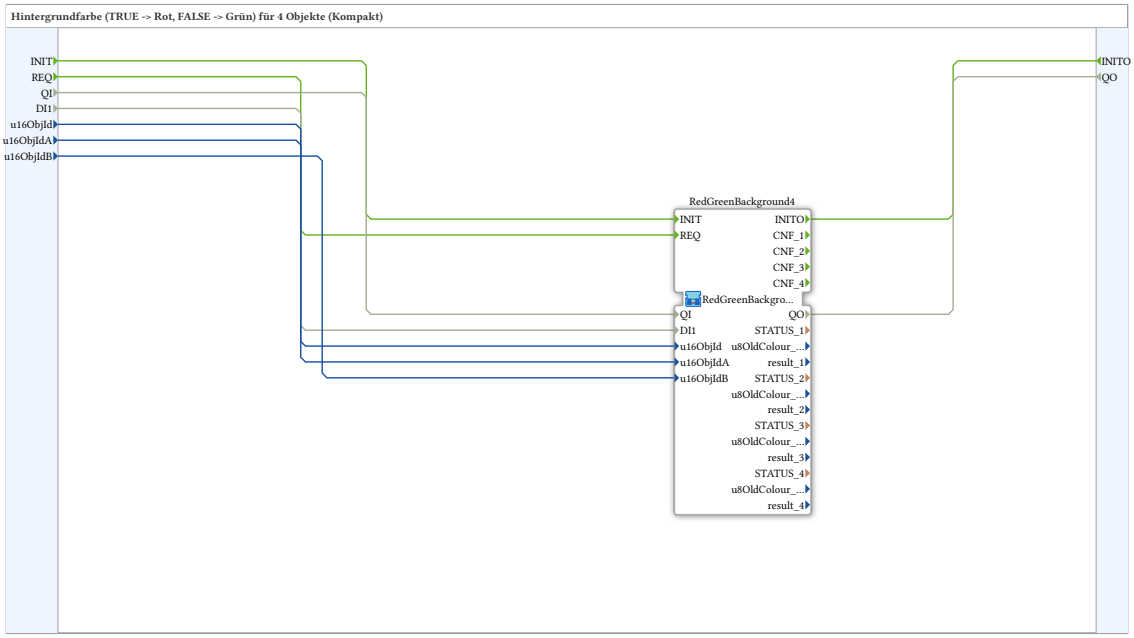
Introduction

`RedGreenBackground4` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Grün**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA, u16ObjIdB`.

Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`u16ObjIdB`	`Q_BackgroundColour` (regular object)

Initialization and quality: In addition to the previous events, the block has the event input `INIT`, the event output `INITO`, as well as `QI` (BOOL, input, initial value `TRUE`) and `QO` (BOOL, output, AND of all instances). Init chain: `INIT` ⟶ `Q_BackgroundColour_1` ⟶ `Q_BackgroundColour_2` ⟶ `Q_BackgroundColour_3` ⟶ `Q_BackgroundColour_4` ⟶ `INITO` (each `INITO` ⟶ next `INIT`). `QI` is passed on to all `Q_BackgroundColour_n.QI`. `QO` is formed by `AND_QO` (`iec61131::booleanOperators::AND_BOOL_4`): `Q_BackgroundColour_1.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN2`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN3`, `Q_BackgroundColour_4.QO` ⟶ `AND_QO.IN4`, `AND_QO.OUT` ⟶ `QO`. `E_MERGE_QO_A` (`E_MERGE_4`) merges `Q_BackgroundColour_4.INITO` and the `CNF` outputs of `Q_BackgroundColour_1`, `Q_BackgroundColour_2` and `Q_BackgroundColour_3`, `E_MERGE_QO` (`E_MERGE_2`) adds `Q_BackgroundColour_4.CNF`; `E_MERGE_QO.EO` triggers `AND_QO.REQ`.

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).



Summary

One of many variants in the background color block family: color pair Rot/Grün, 4 objects, BOOL selector.

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

RedGreenBackground4C

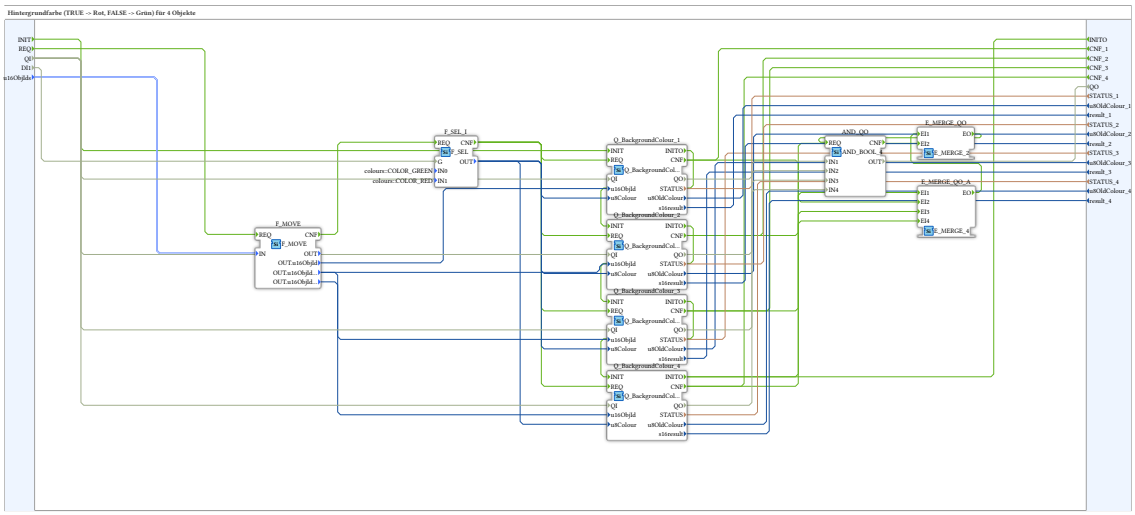
• – ○ • – ○ • – ○ •

Introduction

`RedGreenBackground4C` is a **compact wrapper** around `RedGreenBackground4` — passes `u16ObjId` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

For the shared pattern, see Background Color Blocks (shared pattern).

In addition, the wrapper exposes the initialization and quality interface: event input `INIT`, event output `INITO`, data input `QI` (`BOOL`, initial value `TRUE`) and data output `QO` (`BOOL`). They are passed 1:1 through to the inner instance `RedGreenBackground4`: `INIT` ⟶ `RedGreenBackground4.INIT`, `RedGreenBackground4.INITO` ⟶ `INITO`, `QI` ⟶ `RedGreenBackground4.QI`, `RedGreenBackground4.QO` ⟶ `QO`.



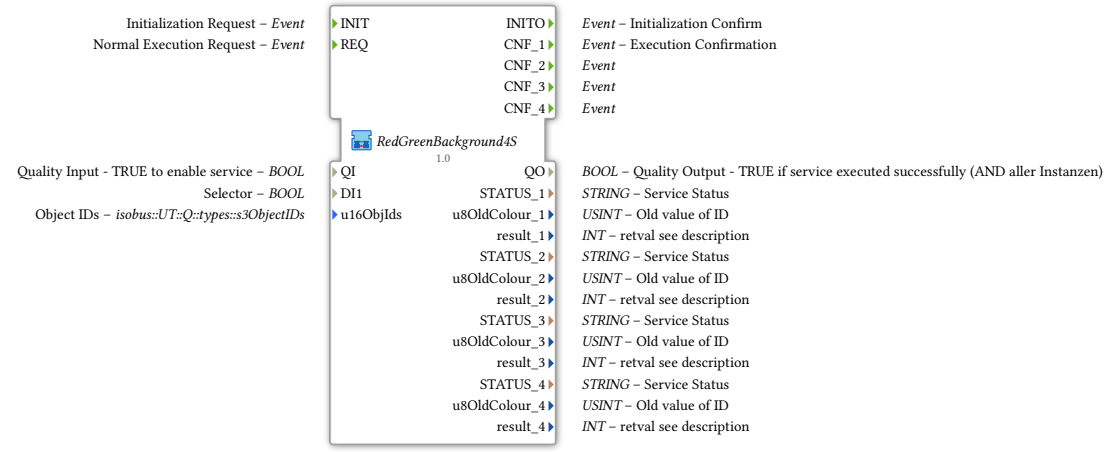
Summary

A pure pass-through to `RedGreenBackground4` for the common case where the diagnostic values aren't needed.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

RedGreenBackground4S



• — ○ • — ○ • — ○ •

Introduction

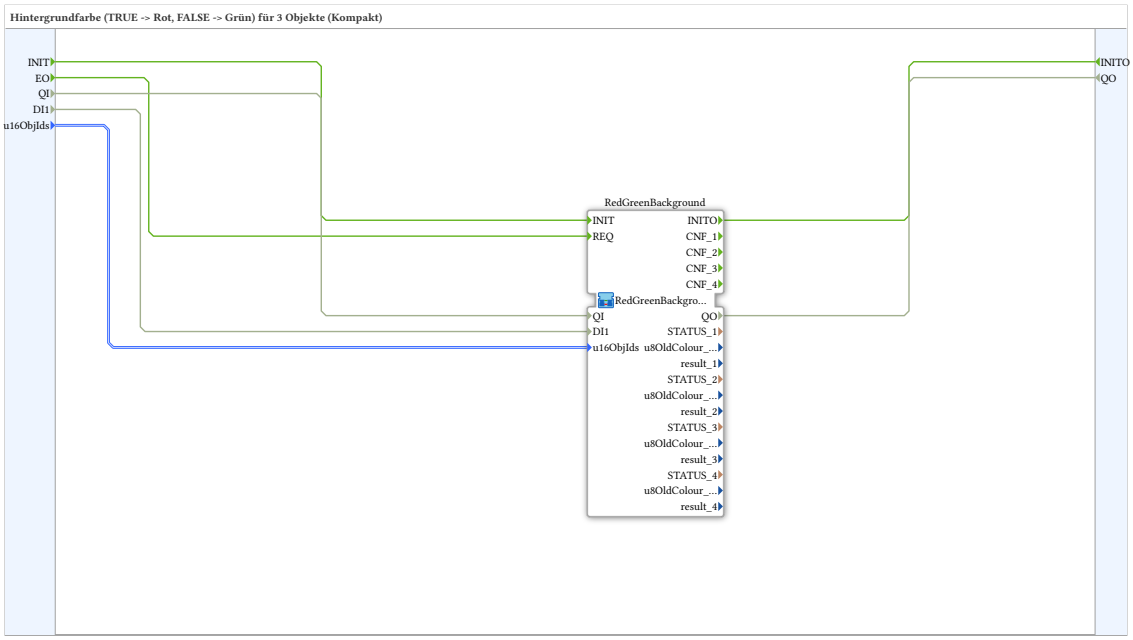
`RedGreenBackground4S` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Grün**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via the structured type `s3ObjectIDs` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`F_MOVE.OUT.u16ObjIdB`	`Q_BackgroundColour` (regular object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`): initialization is chained through the `Q_BackgroundColour` instances: `INIT` → `Q_BackgroundColour_1.INIT`; `Q_BackgroundColour_1.INITO` → `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` → `Q_BackgroundColour_3.INIT`; `Q_BackgroundColour_3.INITO` → `Q_BackgroundColour_4.INIT`; `Q_BackgroundColour_4.INITO` → `INITO`.
- **Data input `QI`** (`BOOL`, default `TRUE`) is distributed to `.QI` of all instances (`Q_BackgroundColour_1`, `Q_BackgroundColour_2`, `Q_BackgroundColour_3`, `Q_BackgroundColour_4`).
- **Data output `QO`** (`BOOL`): AND of all instances via `AND_QO` (`iec61131::booleanOperators::AND_BOOL_4`): `Q_BackgroundColour_1.QO` → `AND_QO.IN1`, `Q_BackgroundColour_2.QO` → `AND_QO.IN2`, `Q_BackgroundColour_3.QO` → `AND_QO.IN3`, `Q_BackgroundColour_4.QO` → `AND_QO.IN4`; `AND_QO.OUT` → `QO`.
- `E_MERGE_QO_A` (`iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_4.INITO` and the `CNF` events of instances 1 to 3; `E_MERGE_QO` (`iec61499::events::E_MERGE_2`) merges its output `E_MERGE_QO_A.EO` with `Q_BackgroundColour_4.CNF` and thereby triggers `AND_QO.REQ`.



Summary

One of many variants in the background color block family: color pair Rot/Grün, 4 objects, BOOL selector, struct. object ID.

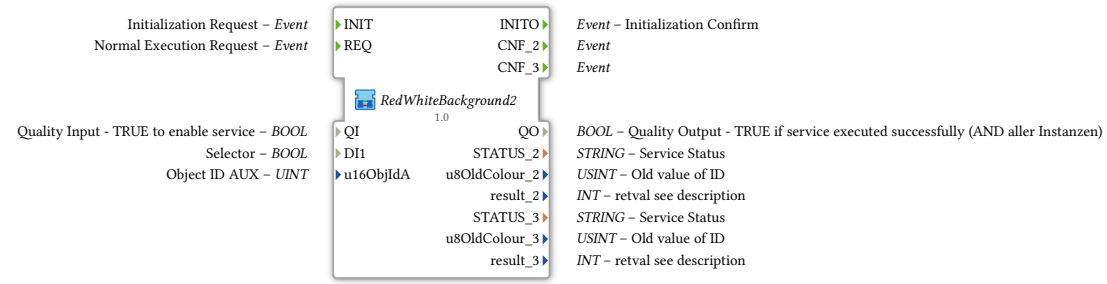
RedWhiteBackground2

• – ○ • – ○ • – ○ •



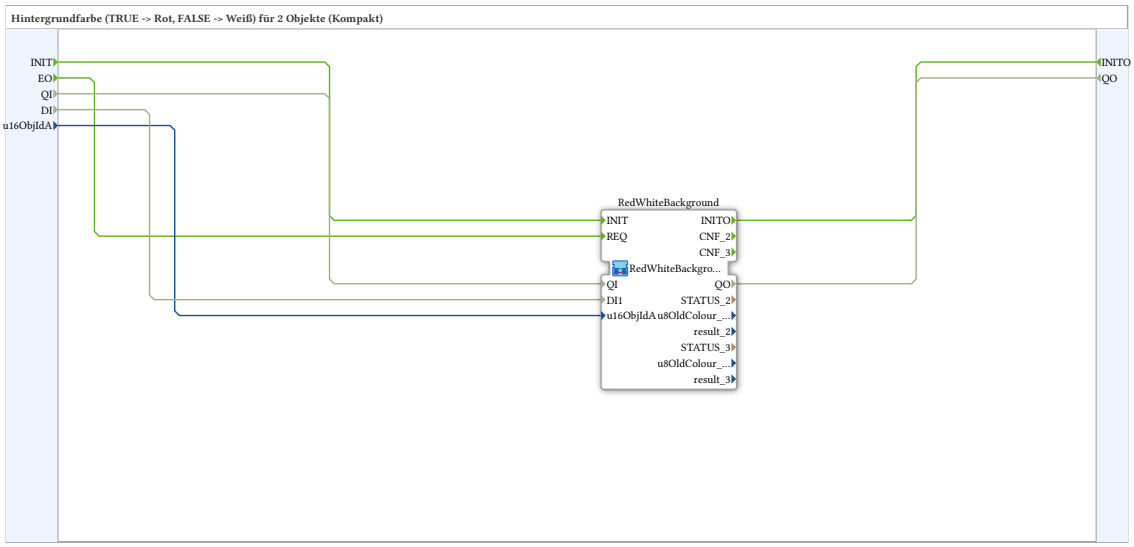
Introduction

`RedWhiteBackground2` switches the VT background color of 2 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via inputs `u16ObjIdA`.

Position	Object ID source	Block
1	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

Initialization and quality: In addition to the previous events, the block has the event input `INIT`, the event output `INITO`, as well as `QI` (BOOL, input, initial value `TRUE`) and `QO` (BOOL, output, AND of all instances). Init chain: `INIT` ⟶ `Q_BackgroundColour_2` ⟶ `Q_BackgroundColour_3` ⟶ `INITO` (each `INITO` ⟶ next `INIT`). `QI` is passed on to all `Q_BackgroundColour_n.QI`. `QO` is formed by `AND_QO` (`iec61131::booleanOperators::AND_BOOL_2`): `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN2`, `AND_QO.OUT` ⟶ `QO`. `E_MERGE_QO` (`E_MERGE_3`) merges `Q_BackgroundColour_3.INITO` and the `CNF` outputs `Q_BackgroundColour_2.CNF`, `Q_BackgroundColour_3.CNF`; `E_MERGE_QO.EO` triggers `AND_QO.REQ`.

For the general pattern (selector ⟶ `AX_SEL/F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).



Summary

One of many variants in the background color block family: color pair Rot/Weiß, 2 objects, BOOL selector.

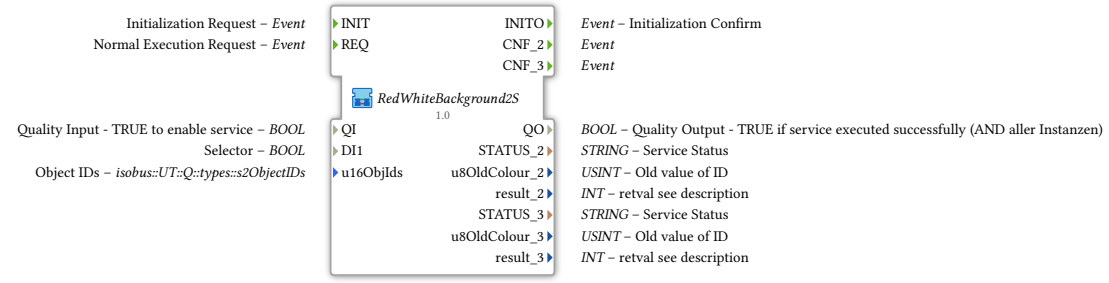
RedWhiteBackground2S



• – ○ • – ○ • – ○ •

Introduction

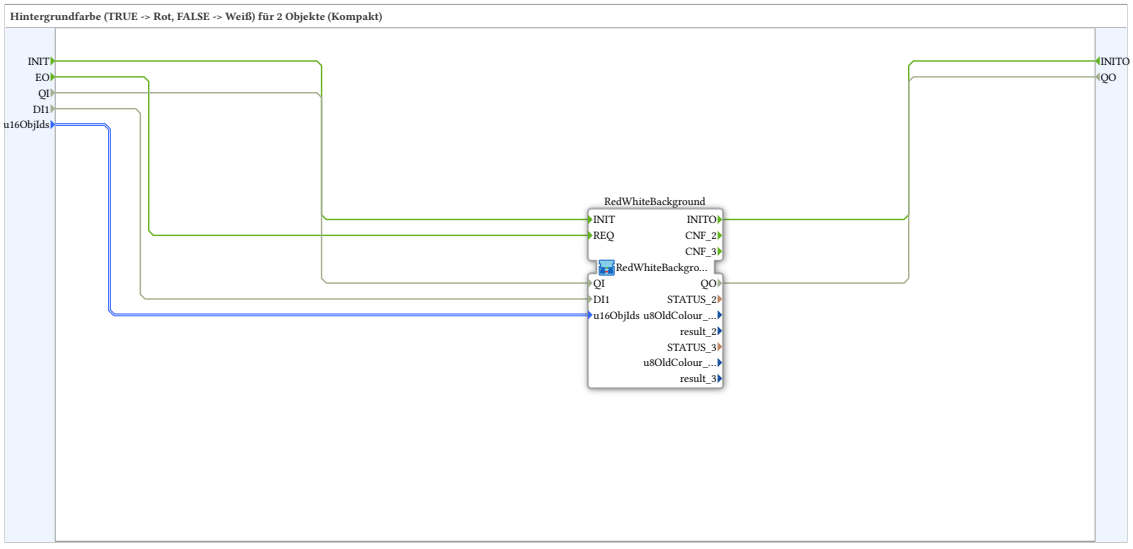
`RedWhiteBackground2S` switches the VT background color of 2 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via the structured type `s2ObjectIDs` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`): initialization is chained through the `Q_BackgroundColour` instances: `INIT` ⟶ `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`; `Q_BackgroundColour_3.INITO` ⟶ `INITO`.
- **Data input `QI`** (`BOOL`, default `TRUE`) is distributed to `.QI` of all instances (`Q_BackgroundColour_2`, `Q_BackgroundColour_3`).
- **Data output `QO`** (`BOOL`): AND of all instances via `AND_QO` (`iec61131::booleanOperators::AND_BOOL_2`): `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.
- `E_MERGE_QO` (`iec61499::events::E_MERGE_3`) merges `Q_BackgroundColour_3.INITO` and the `CNF` events of both instances (`Q_BackgroundColour_2.CNF`, `Q_BackgroundColour_3.CNF`) and thereby triggers `AND_QO.REQ`.



Summary

One of many variants in the background color block family: color pair Rot/Weiß, 2 objects, BOOL selector, struct. object ID.

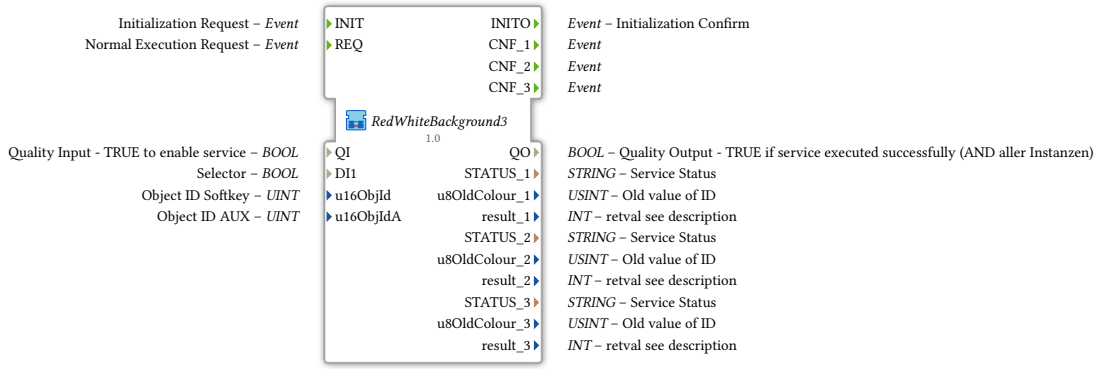
RedWhiteBackground3



• – ○ • – ○ • – ○ •

Introduction

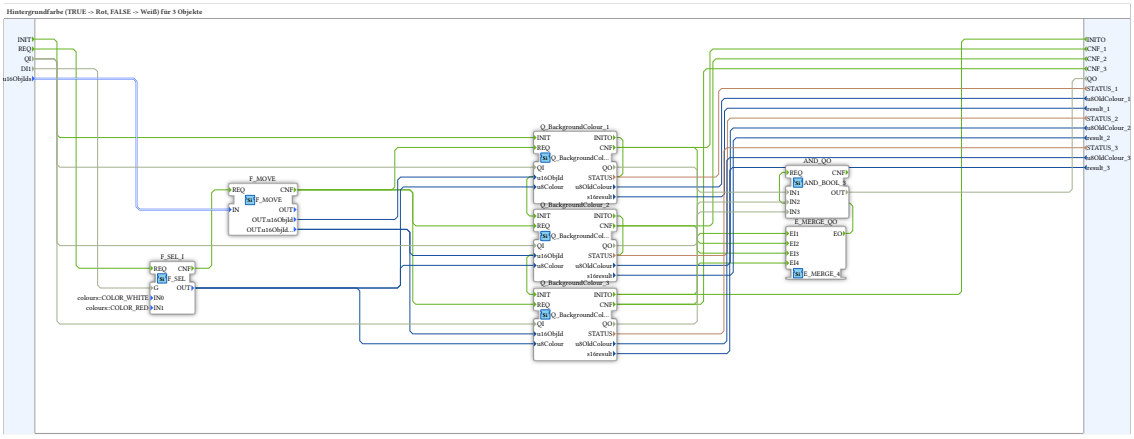
`RedWhiteBackground3` switches the VT background color of 3 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA`.

Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`, Initialization Request) and **event output** `INITO` (`EInit`, Initialization Confirm)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `Q_BackgroundColour_1.QI`, `Q_BackgroundColour_2.QI` and `Q_BackgroundColour_3.QI`
- **Data output** `QO` (`BOOL`, Quality Output): AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_3`) of the `QO` outputs of `Q_BackgroundColour_1.QO`, `Q_BackgroundColour_2.QO` and `Q_BackgroundColour_3.QO`
- **Initialization chain**: `INIT` → `Q_BackgroundColour_1.INIT`, `Q_BackgroundColour_1.INITO` → `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` → `Q_BackgroundColour_3.INIT`, `Q_BackgroundColour_3.INITO` → `INITO`
- `E_MERGE_QO` (type `iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_3.INITO`, `Q_BackgroundColour_1.CNF`, `Q_BackgroundColour_2.CNF` and `Q_BackgroundColour_3.CNF` and triggers `AND_QO.REQ`



Summary

One of many variants in the background color block family: color pair Rot/Weiß, 3 objects, BOOL selector.

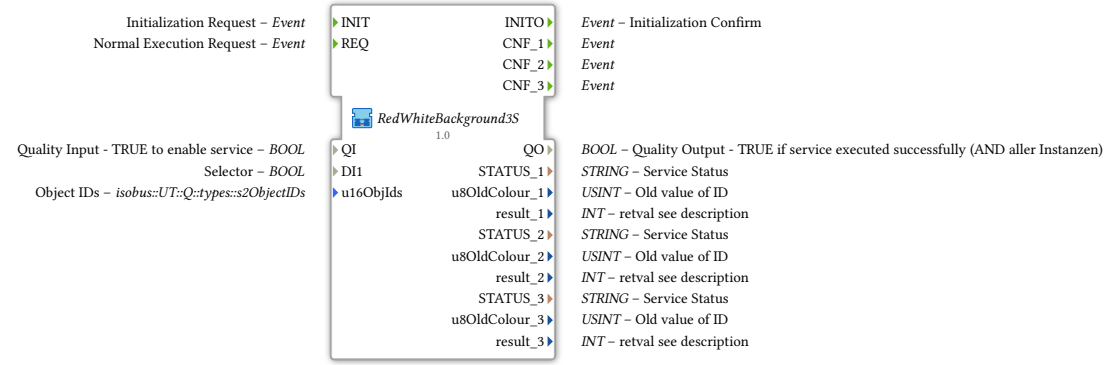
RedWhiteBackground3S

• – ○ • – ○ • – ○ •



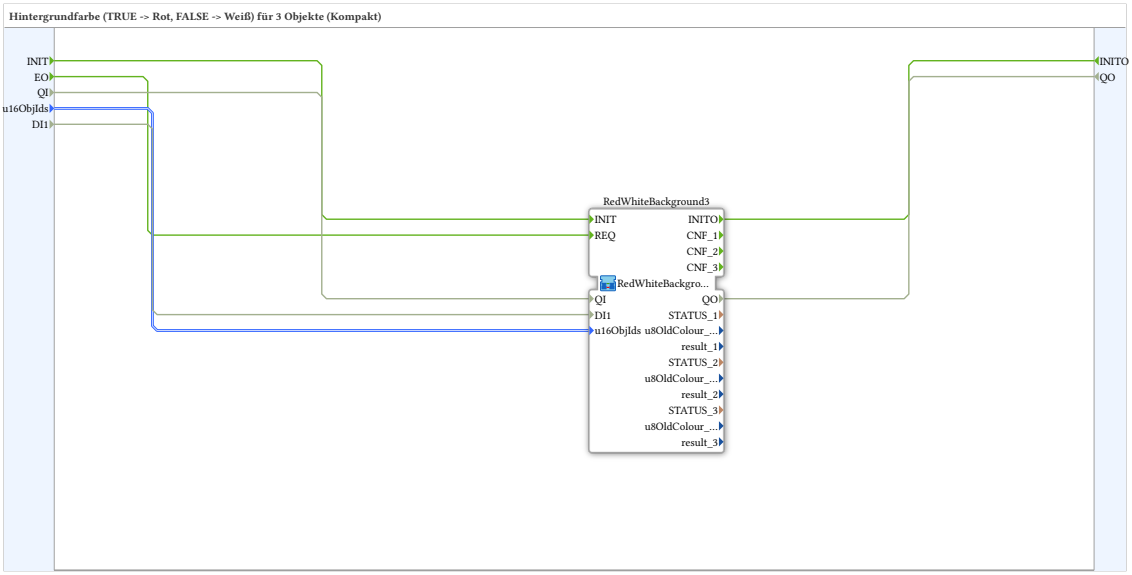
Introduction

`RedWhiteBackground3S` switches the VT background color of 3 objects based on a boolean selector signal: `TRUE` → **Rot**, `FALSE` → **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via the structured type `s2ObjectIDs` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and quality: The SubApp has `INIT`/`INITO` and `QI`/`QO`. `INIT` ⟶ `Q_BackgroundColour_1.INIT` ⟶ `Q_BackgroundColour_2.INIT` ⟶ `Q_BackgroundColour_3.INIT` (each via `INITO`), `Q_BackgroundColour_3.INITO` ⟶ `INITO`. `QI` goes to all three instances. `QO` is the `AND` (`AND_QO`, `AND_BOOL_3`) of the three `QO` outputs; `AND_QO.REQ` is triggered via `E_MERGE_QO` (`E_MERGE_4`: `Q_BackgroundColour_3.INITO`, `Q_BackgroundColour_1.CNF`, `_2.CNF`, `_3.CNF`).



Summary

One of many variants in the background color block family: color pair Rot/Weiß, 3 objects, BOOL selector, struct. object ID.

RedWhiteBackground3SC

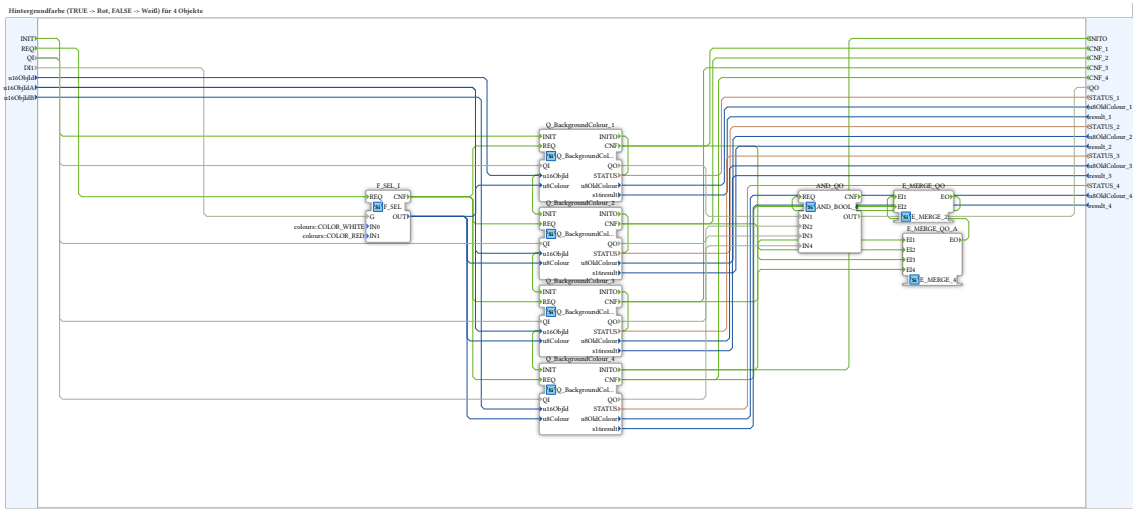
• — ○ • — ○ • — ○ •

Introduction

`RedWhiteBackground3SC` is a **compact wrapper** around `RedWhiteBackground3S` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

In addition, initialization and quality are passed through: `INIT` ⟶ `RedWhiteBackground3.INIT`, `RedWhiteBackground3.INITO` ⟶ `INITO`, `QI` (initial value `TRUE`) ⟶ `RedWhiteBackground3.QI` and `RedWhiteBackground3.QO` ⟶ `QO`.

For the shared pattern, see Background Color Blocks (shared pattern).



Summary

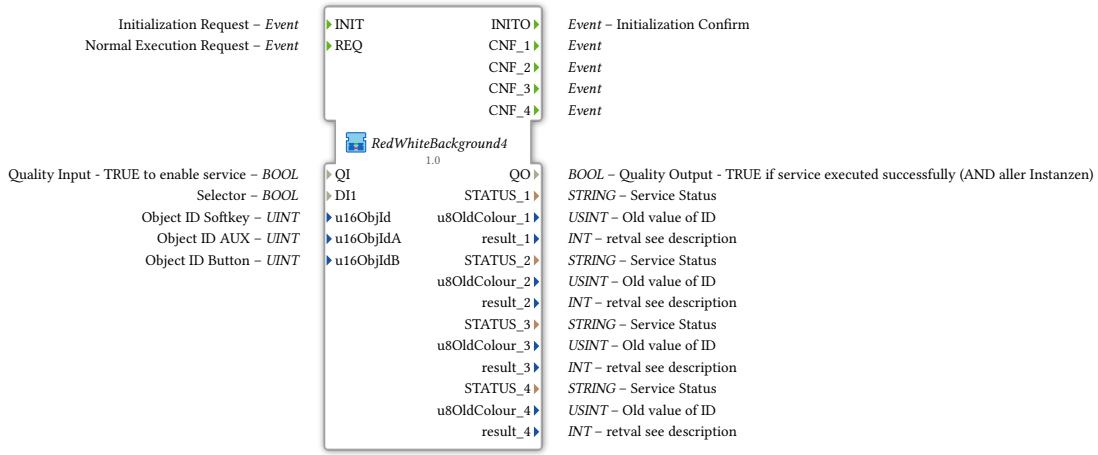
A pure pass-through to `RedWhiteBackground3S` for the common case where the diagnostic values aren't needed.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

RedWhiteBackground4

• — ○ • — ○ • — ○ •



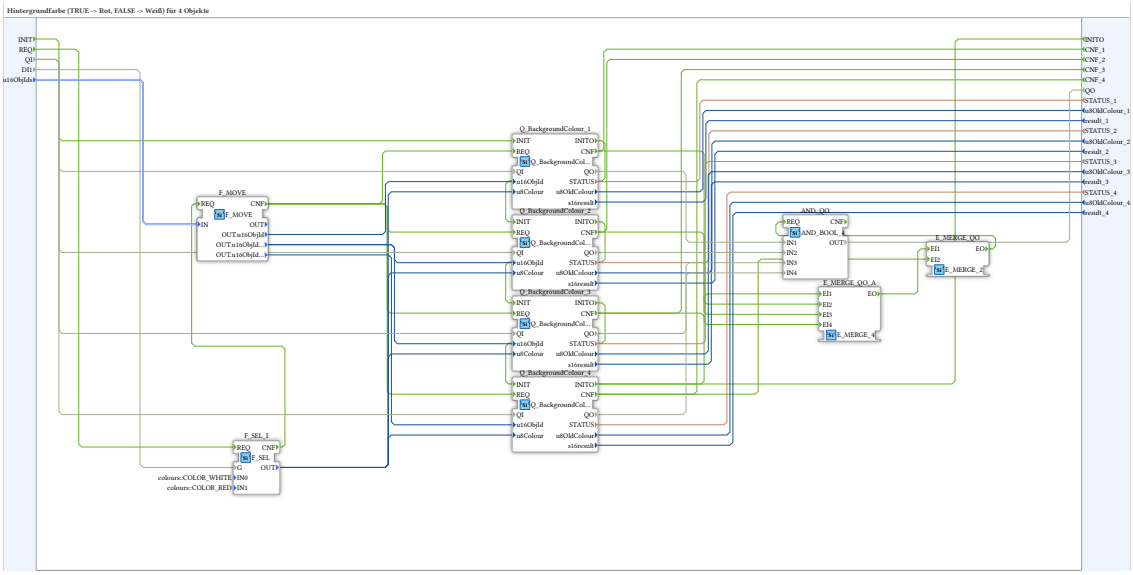
Introduction

`RedWhiteBackground4` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via inputs `u16ObjId, u16ObjIdA, u16ObjIdB`.

Position	Object ID source	Block
1	`u16ObjId`	`Q_BackgroundColour` (regular object)
2	`u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`u16ObjIdB`	`Q_BackgroundColour` (regular object)

For the general pattern (selector → `AX_SEL/F_SEL` → `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

In addition, the block has the initialization and quality interface: event input `INIT`, event output `INITO`, data input `QI` (`BOOL`, initial value `TRUE`) and data output `QO` (`BOOL`). `INIT` → `Q_BackgroundColour_1.INIT`, `Q_BackgroundColour_1.INITO` → `Q_BackgroundColour_2.INIT`, `Q_BackgroundColour_2.INITO` → `Q_BackgroundColour_3.INIT`, `Q_BackgroundColour_3.INITO` → `Q_BackgroundColour_4.INIT`, `Q_BackgroundColour_4.INITO` → `INITO` (so the four instances are initialized one after another). `QI` is passed to `QI` of all four instances. `QO` is the output of the instance `AND_QO` (`iec61131::booleanOperators::AND_BOOL_4`), which combines the `QO` of the four instances. Its `REQ` is triggered by `E_MERGE_QO` (`E_MERGE_2`), which merges the output of `E_MERGE_QO_A` (`E_MERGE_4`: `Q_BackgroundColour_4.INITO` and the `CNF` of `Q_BackgroundColour_1` to `_3`) and `Q_BackgroundColour_4.CNF`.



Summary

One of many variants in the background color block family: color pair Rot/Weiß, 4 objects, BOOL selector.

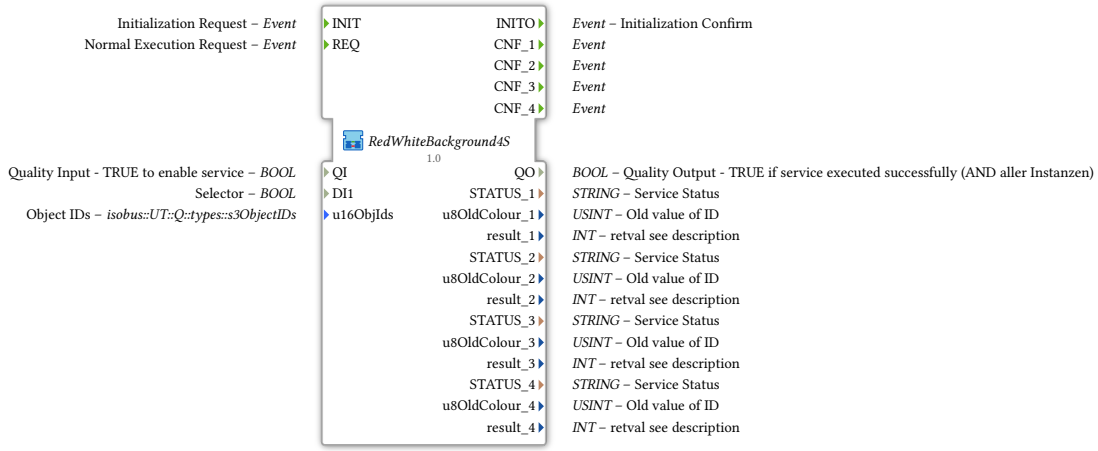
- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

RedWhiteBackground4S



• – ○ • – ○ • – ○ •

Introduction

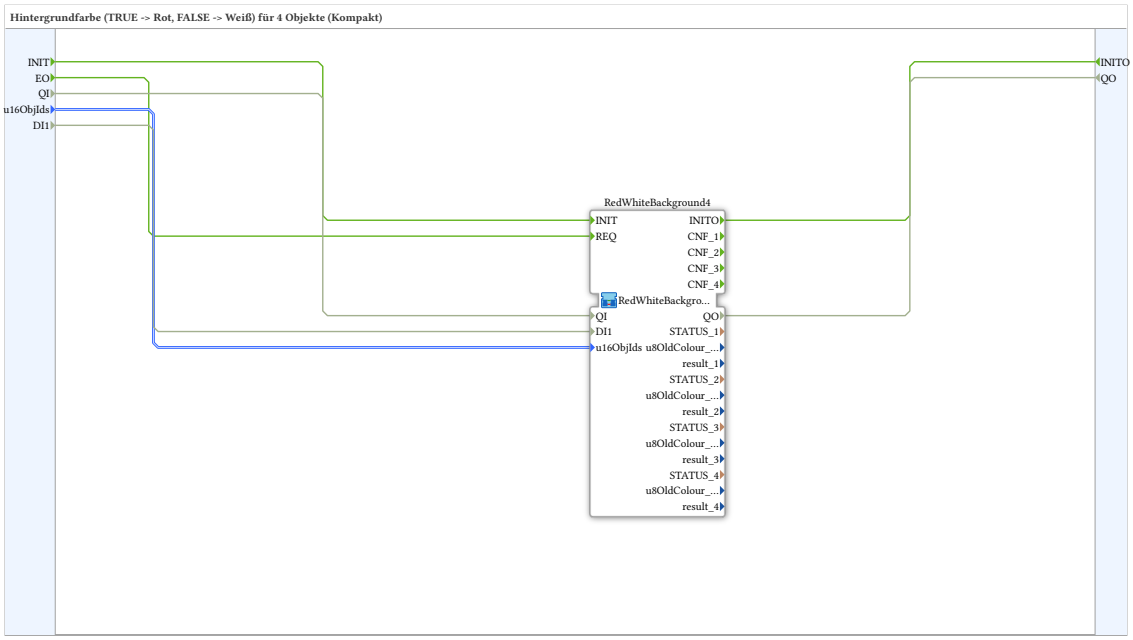
`RedWhiteBackground4S` switches the VT background color of 4 objects based on a boolean selector signal: `TRUE` ⟶ **Rot**, `FALSE` ⟶ **Weiß**. The selector signal arrives as a plain `BOOL` data input (`DI1`). The object ID is passed via the structured type `s3ObjectIDs` (`u16ObjIds`).

Position	Object ID source	Block
1	`F_MOVE.OUT.u16ObjId`	`Q_BackgroundColour` (regular object)
2	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColour` (regular object)
3	`F_MOVE.OUT.u16ObjIdA`	`Q_BackgroundColourAux` (auxiliary function object)
4	`F_MOVE.OUT.u16ObjIdB`	`Q_BackgroundColour` (regular object)

For the general pattern (selector ⟶ `AX_SEL`/`F_SEL` ⟶ `Q_BackgroundColour`), see Background Color Blocks (shared pattern).

Initialization and Quality

- **Event input `INIT`** (`EInit`) and **event output `INITO`** (`EInit`): initialization is chained through the `Q_BackgroundColour` instances: `INIT` ⟶ `Q_BackgroundColour_1.INIT`; `Q_BackgroundColour_1.INITO` ⟶ `Q_BackgroundColour_2.INIT`; `Q_BackgroundColour_2.INITO` ⟶ `Q_BackgroundColour_3.INIT`; `Q_BackgroundColour_3.INITO` ⟶ `Q_BackgroundColour_4.INIT`; `Q_BackgroundColour_4.INITO` ⟶ `INITO`.
- **Data input `QI`** (`BOOL`, default `TRUE`) is distributed to `.QI` of all instances (`Q_BackgroundColour_1`, `Q_BackgroundColour_2`, `Q_BackgroundColour_3`, `Q_BackgroundColour_4`).
- **Data output `QO`** (`BOOL`): AND of all instances via `AND_QO` (`iec61131::booleanOperators::AND_BOOL_4`): `Q_BackgroundColour_1.QO` ⟶ `AND_QO.IN1`, `Q_BackgroundColour_2.QO` ⟶ `AND_QO.IN2`, `Q_BackgroundColour_3.QO` ⟶ `AND_QO.IN3`, `Q_BackgroundColour_4.QO` ⟶ `AND_QO.IN4`; `AND_QO.OUT` ⟶ `QO`.
- `E_MERGE_QO_A` (`iec61499::events::E_MERGE_4`) merges `Q_BackgroundColour_4.INITO` and the `CNF` events of instances 1 to 3; `E_MERGE_QO` (`iec61499::events::E_MERGE_2`) merges its output `E_MERGE_QO_A.EO` with `Q_BackgroundColour_4.CNF` and thereby triggers `AND_QO.REQ`.



Summary

One of many variants in the background color block family: color pair Rot/Weiß, 4 objects, BOOL selector, struct. object ID.

RedWhiteBackground4SC

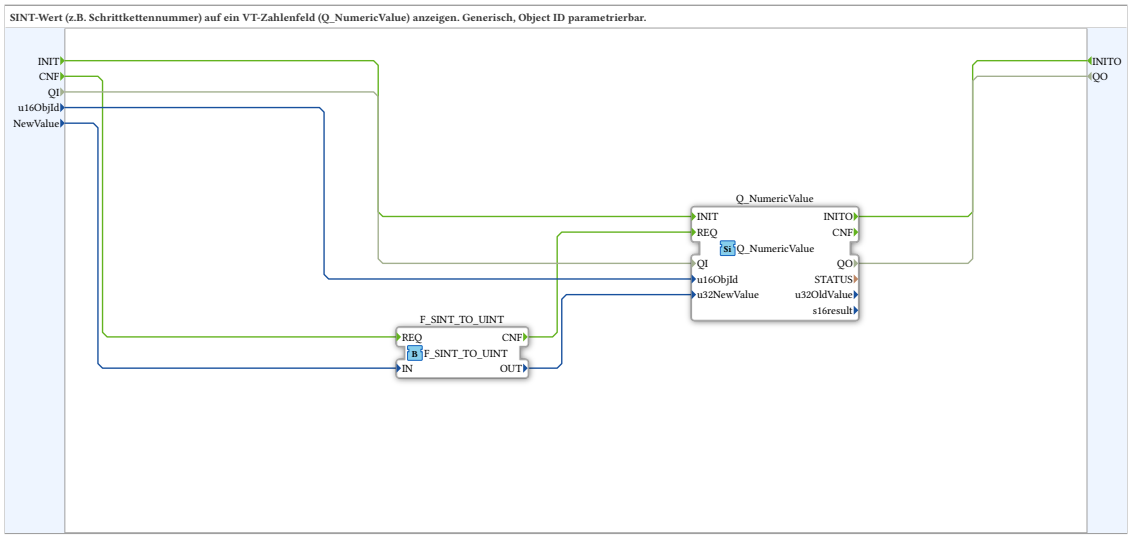
• – ○ • – ○ • – ○ •

Introduction

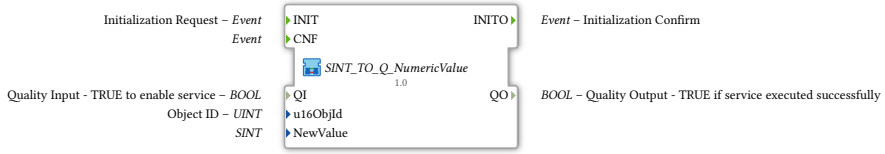
`RedWhiteBackground4SC` is a **compact wrapper** around `RedWhiteBackground4S` — passes `u16ObjIds` and the selector straight through, without exposing the `CNF` event outputs and diagnostic values (`STATUS_n`, `u8OldColour_n`, `result_n`).

Interface (quality pattern): The wrapper additionally has the event input `INIT` and the event output `INITO` (each `EInit`) as well as the data input `QI` (`BOOL`, default `TRUE`) and the data output `QO` (`BOOL`). They are passed straight through to the inner instance `RedWhiteBackground4`: `INIT` ⟶ `RedWhiteBackground4.INIT`, `RedWhiteBackground4.INITO` ⟶ `INITO`, `QI` ⟶ `RedWhiteBackground4.QI`, `RedWhiteBackground4.QO` ⟶ `QO`.

For the shared pattern, see Background Color Blocks (shared pattern).



Summary



A pure pass-through to `RedWhiteBackground4S` for the common case where the diagnostic values aren't needed.

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

SINT_TO_Q_NumericValue

• – ○ • – ○ • – ○ •

Introduction

The **SINT_TO_Q_NumericValue** subapplication provides a generic and reusable solution for displaying a signed 8-bit integer value (e.g., a step number in a sequence) on a numeric visualization field (Q_NumericValue) within a VT (Visualization Terminal). The object ID of the target display element is parameterizable, making the block adaptable to different HMI layouts without internal modification. It decouples the source data type (SINT) from the display element's expected input type (UINT) by performing a conversion internally.

Interface Structure

Event Inputs

Event	Description
`INIT`	Initialization request; forwarded to `Q_NumericValue.INIT`.
`CNF`	Triggers the conversion and subsequent update of the numeric display field.

Event Outputs

Event	Description
`INITO`	Initialization confirm from `Q_NumericValue.INITO`.

Data Inputs

Data Name	Type	Initial Value	Description
`QI`	BOOL	`TRUE`	Quality Input - TRUE to enable service; passed through to `Q_NumericValue.QI`.
`u16ObjId`	UINT	`ID_NULL`	Object ID of the target Q_NumericValue element on the visualization screen.

NewValue	SINT	–	Signed 8-bit value to be converted and displayed.

Data Outputs

Data Name	Type	Description
QO	BOOL	Quality Output - TRUE if the service executed successfully; taken from Q_NumericValue.QO.

Adapters

None.

Functionality

The INIT event is forwarded to Q_NumericValue.INIT, and its INITO is output at INITO. QI is passed through to Q_NumericValue.QI, and Q_NumericValue.QO is passed through to QO. Upon receiving an event at the CNF input, the subapplication performs the following operations internally:

1. The value on NewValue (SINT) is passed to the conversion function block **F_SINT_TO_UINT** (IEC 61131-3 compliant) via the IN input.
2. The conversion block produces the corresponding unsigned 32-bit representation on its OUT output.
3. This converted value is routed to the u32NewValue input of the **Q_NumericValue** function block, which represents the target visualization element.
4. Simultaneously, the u16ObjId input is forwarded to the u16ObjId input of **Q_NumericValue**, telling the visualization which display field to update.
5. The function block Q_NumericValue is then triggered by the REQ event (sourced from the completion of the conversion, CNF of F_SINT_TO_UINT), causing it to update the display with the new numeric value.

The entire process is combinational – there is no internal state storage; each CNF event produces one display update.

Technical Features

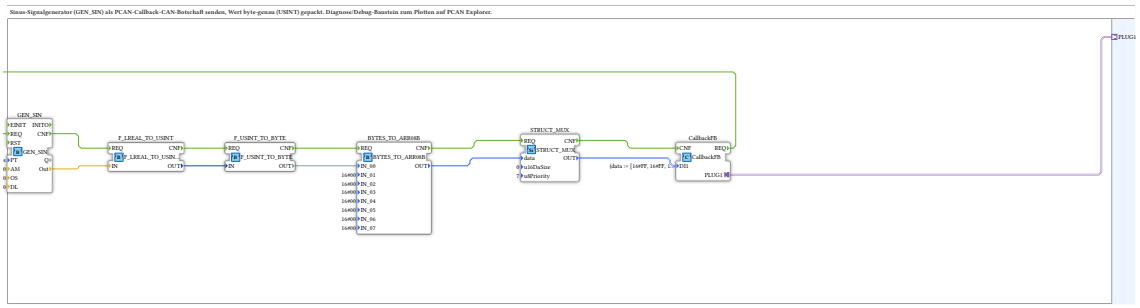
- **Data Type Conversion** – Uses a standard IEC 61131-3 conversion block (F_SINT_TO_UINT) to safely map the signed 8-bit input to an unsigned 32-bit value.
- **Parameterizable Object ID** – The u16ObjId input allows the user to specify which numeric field on the HMI should be updated, enabling reuse of the subapplication across multiple screens and elements.
- **Generic Design** – The block is completely independent of the specific step sequence or machine logic; it only provides the interface and conversion logic.
- **No Internal State** – Because no data is stored, the block is stateless and can be used in cyclic or event-driven environments without concerns about stale data.
- **Compact and Reusable** – Encapsulates common conversion and display logic, reducing duplication in larger projects.

State Overview

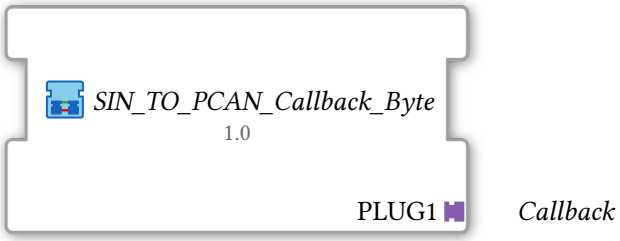
This subapplication does not contain any state memory or sequential logic. Every activation of the CNF event immediately leads to a fresh conversion and update of the display field. Therefore, no state diagram is applicable; the behavior is purely event-driven and deterministic.

Application Scenarios

- **Step Number Display** – In a sequential control system (e.g., a packaging machine), a SINT step counter can be shown on an HMI numeric field.
- **Parameter Value Visualization** – Any signed 8-bit parameter (temperature offset, speed correction, etc.) that needs to be presented on a VT.
- **Generic HMI Binding** – When multiple numeric fields are used, each can be connected to a separate instance of this subapplication with a different u16ObjId.
- **Modular Automation Projects** – Used as a building block in larger subapplications or FBs, where conversion and display logic is required repeatably.



Comparison with Similar Blocks



- **Direct Q_NumericValue usage** – Without this subapplication, one would have to connect a UINT source directly to Q_NumericValue and handle the conversion externally. This block encapsulates the conversion, reducing wiring and potential errors.
- **Other conversion blocks** – Standard conversion FBs (e.g., F_SINT_TO_DINT) could be used, but this subapplication combines conversion with HMI communication, offering a higher-level interface tailored to visualization tasks.
- **Custom display logic** – Writing custom code for each display element would be error-prone and not reusable; this subapplication provides a uniform, parameterized solution.

Conclusion

The **SINT_TO_Q_NumericValue** subapplication is a focused, non-intrusive utility that bridges the gap between a signed 8-bit data source and a numeric HMI display. By integrating type conversion and display addressing into a single, stateless block, it simplifies project engineering, improves maintainability, and promotes reuse across different automation systems. Its generic object ID parameter ensures flexibility, while its straightforward event interface makes it easy to integrate into any IEC 61499-based control application.

SIN_TO_PCAN_Callback_Byte

• – ○ • – ○ • – ○ •

Introduction

The **SIN_TO_PCAN_Callback_Byte** subapplication is a diagnostic and debugging tool designed to generate a sinusoidal signal and transmit it as a CAN message via PCAN, using a callback-based adapter interface. The signal value is converted into a single unsigned byte (USINT) and packed into a CAN frame, making it suitable for real-time plotting and analysis in tools such as PCAN Explorer. This subapplication encapsulates the entire signal generation, conversion, and transmission chain into a reusable component.

Interface Structure

The subapplication exposes only one external interface: a plug adapter for the CAN callback. It has no direct event or data inputs/outputs; all control and data flow is handled internally.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Name	Type	Description
PLUG1	isobus::pgn::tx::Callback	Callback interface to send CAN messages (e.g., to PCAN) upon request. This adapter is used to pass the structured CAN message prepared by the internal CallbackFB function block.

Functionality

The subapplication performs the following steps in a continuous loop:

1. **Signal Generation**: The GEN_SIN function block (from the OSCAT library) creates a sinusoidal waveform with the given parameters (period PT, amplitude AM, offset OS, and dead level DL). In this configuration, the period is 10 seconds, amplitude 10.0, and offset 5.0, producing a sine wave oscillating between −5.0 and 15.0.
2. **Conversion to USINT**: The F_LREAL_TO_USINT conversion block transforms the LREAL output from GEN_SIN into an USINT (unsigned 8-bit integer) value.
3. **Byte Conversion**: The F_USINT_TO_BYTE block converts the USINT value into a byte representation.
4. **Array Assembly**: The BYTES_TO_ARR08B block places the converted byte into the first byte of an 8-byte array. This block also supports byte reversal (reversing order) and is configured with initial placeholder values for the remaining seven bytes (all set to 16#00).
5. **Message Structuring**: The STRUCT_MUX block packs the byte array into a structured CAN message of type isobus::pgn::CAN_MSG. It also sets the payload size (u16DaSize) to 0 and the default priority (u8Priority) to 7.
6. **Transmission**: The CallbackFB function block receives the structured CAN message and, when triggered, sends it via the PLUG1 adapter (connected to a callback interface, typically a PCAN driver).

The event chain is: CallbackFB.REQ → GEN_SIN.REQ → GEN_SIN.CNF → F_LREAL_TO_USINT.REQ → F_LREAL_TO_USINT.CNF → F_USINT_TO_BYTE.REQ → F_USINT_TO_BYTE.CNF → BYTES_TO_ARR08B.REQ → BYTES_TO_ARR08B.CNF → STRUCT_MUX.REQ → STRUCT_MUX.CNF → CallbackFB.CNF. Each step passes the required data along the corresponding data connections.

Technical Features

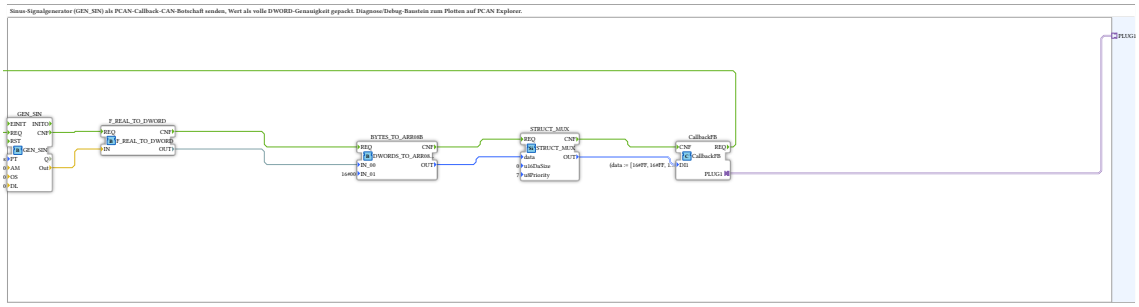
- **Sinusoidal Generation**: Configurable via parameters PT, AM, OS, and DL to adapt the signal characteristics.
- **Precision Conversion**: The signal value is rounded to an unsigned 8-bit integer, ensuring byte-level accuracy.
- **CAN Message Formatting**: Uses a structured type isobus::pgn::CAN_MSG for compatibility with ISO 11783 (ISOBUS) PGN transmission.
- **Callback-based Transmission**: The output adapter PLUG1 uses a callback interface, allowing integration with event-driven PCAN drivers.
- **Reusable Design**: The subapplication can be instantiated multiple times with different parameters or data sources.
- **Debug Friendly**: The byte-only representation simplifies plotting and analysis in external tools.

State Overview

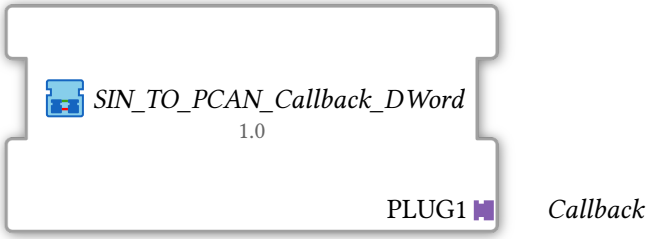
This subapplication does not maintain any internal state machine. It operates purely as a data-flow pipeline, where each function block processes its input and produces an output in a single scan cycle. The only dynamic behavior is the continuous generation of sinusoidal values by GEN_SIN, which is driven by the event request from CallbackFB. All conversions and message assembly are combinatorial in nature.

Application Scenarios

- **Real-time Signal Visualization**: Use the sinusoidal output to test or calibrate CAN-based measurement systems.
- **Function Testing of PCAN Interfaces**: Verify correct data packing and transmission in a PCAN environment.
- **Educational Tool**: Demonstrate how to generate, convert, and send analog signals over CAN in an industrial automation context.
- **Prototyping**: Quickly create a CAN node that broadcasts a sinusoidal test signal for development purposes.



Comparison with Similar Blocks



Unlike a standard analog-to-CAN converter that may send floating-point values, this subapplication specifically packs the signal into a single byte, sacrificing resolution for simplicity and compactness. It also uses a callback-based adapter rather than a direct CAN output, making it more flexible for different bus interfaces. Compared to a generic `GEN_SIN` block used standalone, this subapplication integrates the conversion and CAN transmission chain into a single ready-to-use component. It is similar in purpose to dedicated signal generator modules but is optimized for debugging and analysis via PCAN tools.

Conclusion

The **SIN_TO_PCAN_Callback_Byte** subapplication is a compact and reusable component for generating sinusoidal signals and transmitting them as CAN messages with byte-level precision. Its modular design, based on standard 4diac-IDE function blocks, ensures easy integration into larger projects. The clear separation of signal generation, conversion, and transmission makes it an ideal choice for diagnostic tasks, prototype development, and educational use in industrial automation environments.

SIN_TO_PCAN_Callback_DWord

• – ○ • – ○ • – ○ •

Introduction

The **SIN_TO_PCAN_Callback_DWord** subapplication is a diagnostic and debugging oriented function block that generates a sinusoidal signal and transmits it as a CAN message through a PCAN callback adapter. The generated signal value is packed into the CAN data field with full DWORD (32-bit) precision, using a reversed byte order for proper little-endian interpretation on the receiving side. The primary purpose of this block is to provide a real-time, easily plottable signal stream for tools such as PCAN Explorer, allowing engineers to visualize and verify the sine wave directly on the CAN bus.

Interface Structure

The subapplication exposes a single adapter interface and no direct event or data ports. All interaction with the outside world is performed through this adapter.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Adapter Name	Type	Direction	Description
PLUG1	`isobus::pgn::tx::Callback`	Plug	Callback-based CAN transmission interface. Provides the mechanism to send CAN messages to the connected PCAN channel via the callback system.

Functionality

The subapplication implements a self-contained signal-generation and CAN-forwarding pipeline. The functional flow is initiated when the callback adapter receives a request from the connected partner (typically the PCAN callback driver). Upon this trigger, the following processing chain is executed:

1. **Trigger generation** – The `CallbackFB` receives the adapter request and forwards it as an event to the sine generator.
2. **Sine wave synthesis** – The `GEN_SIN` function block produces a sinusoidal output value with the configured parameters: a period of 10 seconds, an amplitude of 10.0, an offset of 5.0, and no dead time.
3. **Data type conversion** – The floating-point sine value is converted to a DWORD (32-bit unsigned integer) using the `F_REAL_TO_DWORD` conversion block, preserving the full bit pattern of the REAL value.
4. **Byte array transformation** – The DWORD is converted into an 8-byte array with reversed byte order (`DWORDS_TO_ARR08B`). This ensures that the DWORD is placed in the least significant four bytes in a little-endian (reversed) arrangement, while the upper four bytes are padded with zero.
5. **Message structure assembly** – The byte array is packed into a `CAN_MSG` structured type using `STRUCT_MUX`. The message is configured with priority 7 and a data size field set to 0, which represents a standard CAN frame with an 8-byte data payload.
6. **Transmission** – The assembled CAN message is handed back to the `CallbackFB`, which sends it over the adapter to the PCAN bus.

Technical Features

- **Full DWORD precision**: The sine value is transported as a raw 32-bit IEEE 754 representation, preserving all decimal places and enabling high-resolution plotting on the receiver side.
- **Reversed byte order**: The DWORD is placed into the first four data bytes in reversed order (byte 3, 2, 1, 0), which matches the little-endian memory layout used by many CAN visualization tools.
- **Parameterizable sine wave**: The generator allows configuration of period (`PT`), amplitude (`AM`), offset (`OS`), and dead time (`DL`), making the block adaptable to various test and debug scenarios.
- **Deterministic event chain**: The functional flow is strictly event-driven, ensuring that each CAN message is only generated when the callback adapter requests a new transmission.
- **Standard CAN message layout**: The output adheres to a common CAN frame structure with priority, data size, and an 8-byte payload, making it compatible with standard CAN analysis tools.

State Overview

The subapplication is essentially an event-driven pipeline with no internal persistent state beyond the standard function block request/confirmation handshakes. The operational sequence follows a linear state progression:

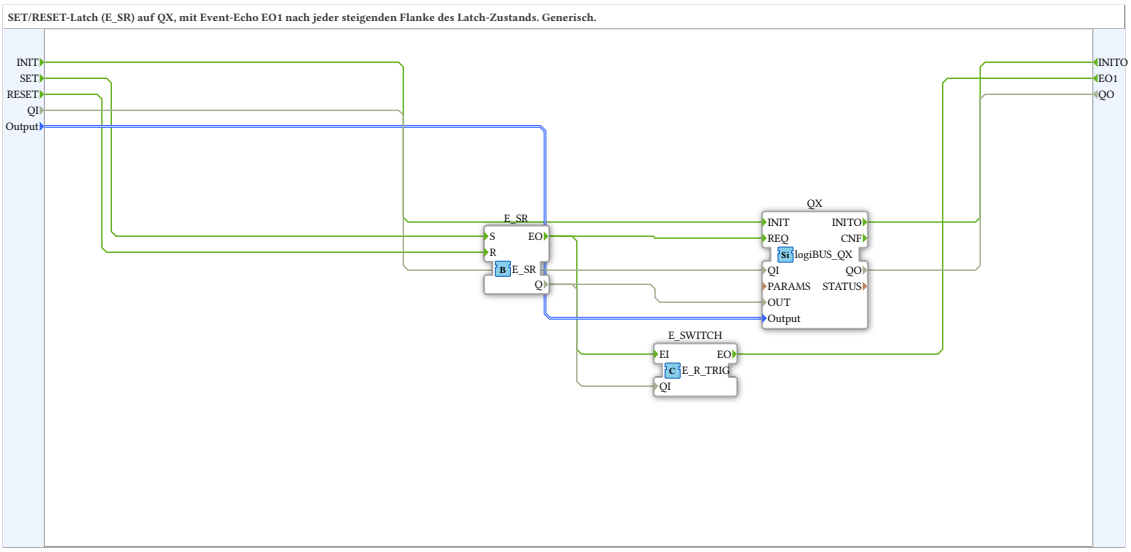
1. **Idle** – Waiting for a request from the callback adapter (`CallbackFB` idle).
2. **Signal Generation** – On request, `GEN_SIN` is activated and produces the sine output.

3. **Conversion** – The REAL value is converted to DWORD.
4. **Byte Packing** – The DWORD is transformed into the reversed byte array and subsequently wrapped into the CAN message structure.
5. **Transmission** – The completed message is forwarded to the callback adapter for transmission on the PCAN bus, after which the block returns to the idle state.

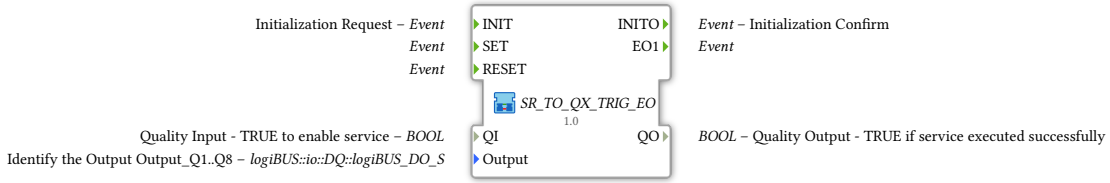
There are no error or exceptional states because the conversion and packing operations are deterministic and do not depend on external conditions other than the availability of the callback adapter.

Application Scenarios

- **PCAN Explorer visualization**: The block provides a continuous, high-precision sine stream that can be directly plotted in PCAN Explorer, allowing engineers to monitor signal quality and timing without additional hardware.
- **CAN bus testing and validation**: As a diagnostic block, it can inject a known sinusoidal signal into a CAN network to verify the correct operation of receivers, data logging, or filter configurations.
- **Signal generator for simulation**: When developing or debugging CAN-based control systems, this block serves as a stable and repeatable signal source, replacing manual or external signal generators.
- **End-to-end data integrity checks**: By comparing the received sine values with the expected parameters (period, amplitude, offset), users can confirm that the CAN transmission chain preserves data integrity.



Comparison with Similar Blocks



Feature	SIN_TO_PCAN_Callback_DWord	Direct GEN_SIN to CAN (without conversion)	SIN_TO_PCAN with 16-bit precision
Signal precision	Full DWORD (32-bit IEEE 754)	Not directly possible (type mismatch)	Reduced to 16-bit, loses precision
Byte ordering handled internally	Yes (reversed, little-endian)	Manual or external handling required	Manual handling required
Configuration effort	Low (parameters preset in block)	High (multiple conversion steps needed)	Moderate (additional scaling required)
Suitability for high-resolution plotting	Excellent	Not applicable	Limited for values with many decimal places
Dependencies on external functions	Only the callback adapter	Requires additional custom conversion FB	Requires scaling and type conversion FB

Conclusion

The **SIN_TO_PCAN_Callback_DWord** subapplication is a robust and practical solution for generating and transmitting sinusoidal CAN signals with full numerical precision. By integrating the sine generator, REAL-to-DWORD conversion, byte-order reversal, and message assembly into a single encapsulated block, it significantly reduces development effort and improves reliability. Its event-driven design ensures deterministic message generation in response to callback requests, while the parameterized sine configuration offers flexibility across a wide range of diagnostic and testing applications. This block is particularly well suited for engineers working with PCAN Explorer and similar CAN analysis tools who require a dependable, high-resolution signal source.

SR_TO_QX_TRIG_EO

• — ○ • — ○ • — ○ •

Introduction

The **SR_TO_QX_TRIG_EO** subapplication combines a set/reset latch (E_SR) with a digital output (logiBUS_QX) and a rising-edge trigger (E_R_TRIG). It provides a reusable, event-controlled digital output stage that emits an echo event (EO1) whenever the latched output state transitions from false to true. The block is designed as a generic solution: the target physical output (Q1…Q8) is selected via a dedicated data input.

Interface Structure

Event Inputs

Name	Description
`INIT`	Initialization Request (`EInit`); passed on to `QX.INIT`.
`SET`	Event input that sets the internal latch, driving the output Q to `TRUE`.
`RESET`	Event input that resets the internal latch, driving the output Q to `FALSE`.

Event Outputs

Name	Description
`INITO`	Initialization Confirm (`EInit`); passed through from `QX.INITO`.
`EO1`	Echo event emitted on the rising edge of the latch output (transition `FALSE` ⟶ `TRUE`).

Data Inputs

Name	Type	Initial Value	Description
`QI`	`BOOL`	`TRUE`	Quality Input - TRUE enables the service; passed on to `QX.QI`.

Output	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Identifies the physical digital output to be driven (Output_Q1...Q8).

Data Outputs

Name	Type	Description
QO	BOOL	Quality Output - TRUE if the service executed successfully; passed through from QX.QO.

Adapters

None.

Functionality

The subapplication implements a classic latch-and-drive pattern:

1. On SET, the internal E_SR latch is set (Q = TRUE). On RESET, the latch is cleared (Q = FALSE).
2. After every latch update (whether SET or RESET), the Q value is transferred to the logiBUS_QX digital output block, which writes the value to the physical output specified by the Output data input.
3. The same Q signal is also fed to a rising-edge detector (E_R_TRIG). When Q changes from FALSE to TRUE, the detector fires the EO1 event output.

INIT is passed on to QX.INIT, QX.INITO is output as INITO, QI is forwarded to QX.QI and QX.QO is output as QO.

Thus, EO1 acts as an acknowledgment that the latch has been turned on, while the physical output is refreshed on every state change.

Technical Features

- **Event-driven Design** – No cyclic polling; all operations are triggered by events.
- **Generic Output Selection** – The Output data input allows mapping to any logiBUS DQ channel (Q1...Q8) without modification.
- **Rising-Edge Echo** – EO1 only fires when the latched output turns on, providing a clean positive-transition notification.
- **Integrated Output Stage** – Combines latch, physical output, and edge detection in a single reusable unit.
- **Non-Blocking** – Suitable for distributed control applications following the IEC 61499 execution model.

State Overview

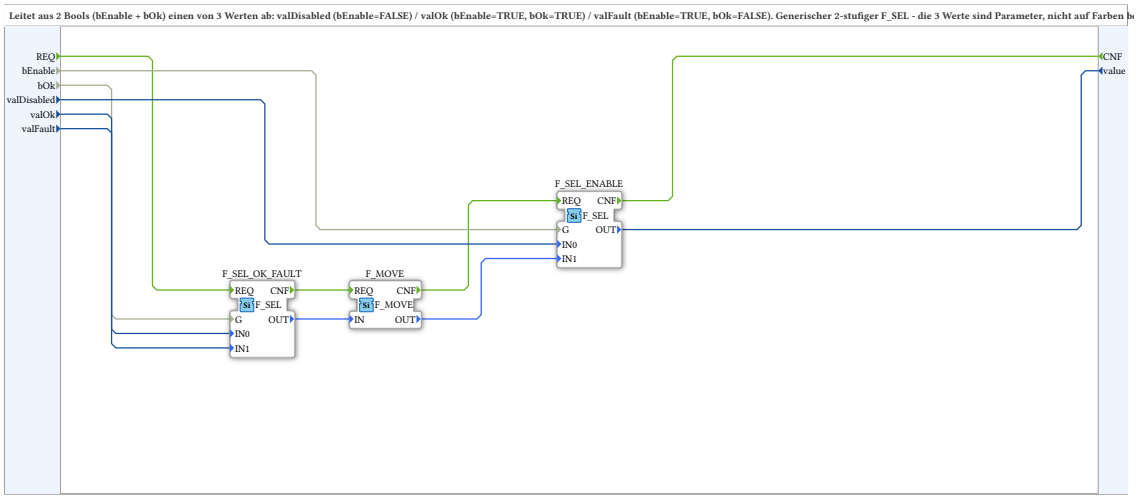
The internal latch has two stable states:

State	Output Q	EO1 Emission
Reset (default)	FALSE	No
Set	TRUE	Emitted on rise to TRUE

The EO1 event is only produced during the FALSE ⟶ TRUE transition; RESET operations do not trigger EO1.

Application Scenarios

- **Discrete Output Control** – Switching a digital actuator (e.g., valve, lamp, motor starter) on and off via events.
- **Acknowledgment Signaling** – Providing a confirmation event to a supervisory controller when the output has been successfully switched on.
- **Reusable Library Component** – The block can be instantiated multiple times in a system, each bound to a different output channel.
- **Training / Educational Use** – Suitable for IEC 61499 and 4diac demonstrations of latch, edge detection, and output mapping concepts.

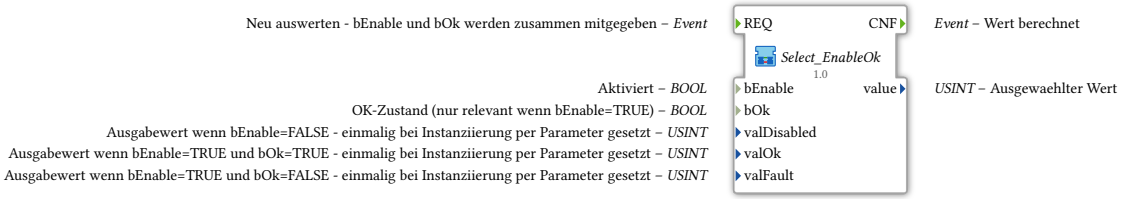


Comparison with Similar Blocks

Block	Key Difference
E_SR (standalone)	Only provides latch functionality without integrated output or echo.
E_RS	Uses a reset-dominant latch behavior; no rising-edge echo or output stage.
logiBUS_QX (direct)	Writes an output directly but lacks latch memory and event echo.
SR_TO_QX_TRIG_EO	Combines latch, physical output update, and rising-edge echo in one block; self-contained and reusable.

Conclusion

The **SR_TO_QX_TRIG_EO** subapplication is a compact, reusable building block for event-based digital output control with latch semantics and a rising-edge acknowledgment event. Its generic output selection makes it flexible for a wide range of logiBUS-based applications, while its clean event interface integrates seamlessly into IEC 61499 systems. By bundling latch, output driver, and edge detection, it reduces wiring effort and improves maintainability.



Select_EnableOk

• — ○ • — ○ • — ○ •

Introduction

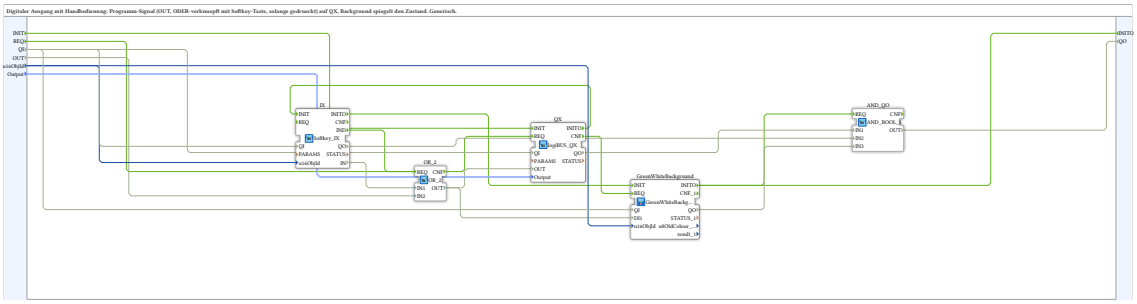
`Select_EnableOk` derives one of 3 parameterized USINT values from 2 bools (`bEnable`, `bOk`): `valDisabled` (bEnable=FALSE), `valOk` (bEnable=TRUE and bOk=TRUE), `valFault` (bEnable=TRUE and bOk=FALSE). A generic 2-stage `F_SEL`, not limited to colors - per the source comment, extracted from `Q_BackgroundColour_EnableOk` to decouple the pure selection logic from the VT background-color application.

Function blocks used

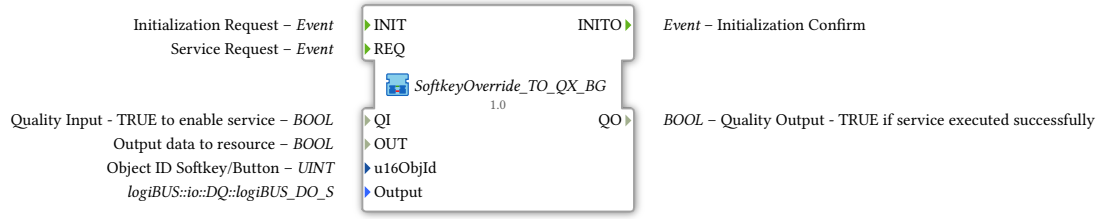
- **F_SEL_OK_FAULT** (`iec61131::selection::F_SEL`): selects between `valFault`/`valOk` based on `bOk`.
- **F_MOVE** (`iec61131::selection::F_MOVE`, `DataType=USINT`): passes the intermediate value through unchanged (sequencing the two selection stages).
- **F_SEL_ENABLE** (`iec61131::selection::F_SEL`): selects between `valDisabled`/intermediate result based on `bEnable`.

Program flow and connections

`REQ -> F_SEL_OK_FAULT.REQ -> F_MOVE.REQ -> F_SEL_ENABLE.REQ -> CNF`. On the data side: `bOk`/`valFault`/`valOk` -> `F_SEL_OK_FAULT` -> `F_MOVE` -> `F_SEL_ENABLE.IN1`, in parallel `bEnable`/`valDisabled` -> `F_SEL_ENABLE.IN0`/`.G` -> `value`.



Summary



Generic 2-bool-to-1-of-3-values selection, reusable beyond background colors (e.g. for any enable/ok status display).

• – ○ • – ○ • – ○ •

Introduction

`SoftkeyOverride_TO_QX_BG` is a reusable IEC 61499 subapplication that combines a program signal with a manual softkey input and writes the result to a digital output of type `logiBUS_QX`. It is designed for digital outputs that need both automatic program control and manual hand operation. The OR combination ensures that the output can be forced active while the softkey is pressed, even if the program signal is inactive. A background visualization subapplication mirrors the output state for HMI purposes.

Interface Structure

Event Inputs

Name	Type	Comment
`INIT`	EInit	Initialization request; starts the chain `QX` ⟶ `IX` ⟶ `GreenWhiteBackground`.
`REQ`	Event	Service Request; triggers evaluation and output update.

Event Outputs

Name	Type	Comment
`INITO`	EInit	Initialization confirmation; comes from `GreenWhiteBackground.INITO`.

There are no other event outputs.

Data Inputs

Name	Type	Initial Value	Comment
QI	BOOL	TRUE	Quality input, service enable; passed on to QX, IX and GreenWhiteBackground.
OUT	BOOL	—	Output data to resource.
u16ObjId	UINT	ID_NULL	Object ID Softkey/Button.
Output	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Selection of the physical/logical digital output.

Data Outputs

Name	Type	Comment
QO	BOOL	Quality output, AND of the QO outputs of QX, IX and GreenWhiteBackground (via AND_QO, AND_BOOL_3).

The actual output goes through the embedded QX block to the physical channel.

Adapters

There are no adapters.

Functionality

The subapplication implements a digital output stage with manual override capability:

- The program signal OUT is combined with the softkey input IX.IN through an OR_2 function block.
- The softkey input is read by an internal Softkey_IX block, which delivers the current key state and emits an event when the key state changes.
- The external REQ event also triggers the OR evaluation, so the output can be updated cyclically or on demand.
- The result of the OR operation is written to the QX digital output.
- The same result is sent to an internal GreenWhiteBackground subapplication, so the HMI background reflects the current output state.
- The QX.CNF event triggers the background update after the output has been written successfully.
- Initialization and quality: INIT → QX.INIT; QX.INITO → IX.INIT; IX.INITO → GreenWhiteBackground.INIT; GreenWhiteBackground.INITO → INITO and → AND_QO.REQ. QI → QX.QI, IX.QI and GreenWhiteBackground.QI (no fixed QI=TRUE any more on QX and IX); QX.QO → AND_QO.IN1, IX.QO → AND_QO.IN2, GreenWhiteBackground.QO → AND_QO.IN3; AND_QO.OUT → QO.

The behavior is purely combinatorial with respect to the data values: the output is active if either the program signal OUT is true OR the softkey is currently pressed. There is no latching or memory.

Technical Features

- Generic design: the same subapplication can be reused with different softkey object IDs and different digital output channels.
- Parameterizable softkey address via u16ObjId.
- Parameterizable output channel via Output.
- Supports event-driven processing through REQ.
- The softkey block can trigger processing independently via its internal event output.
- Output and background visualization are updated consistently.
- Uses standard logic block OR_2 from IEC 61131 bitwise operators.
- The subapplication is packaged as an IEC 61499 subapplication type and can be embedded in larger applications.

State Overview

The subapplication has no internal state machine, but the output state can be described by the following combinations:

OUT	Softkey pressed	QX output	Background
FALSE	FALSE	FALSE	Inactive
TRUE	FALSE	TRUE	Active
FALSE	TRUE	TRUE	Active
TRUE	TRUE	TRUE	Active

The manual softkey therefore acts as an “on” override. It can force the output to be active while pressed, but it cannot force the output off when the program signal is active.

Application Scenarios

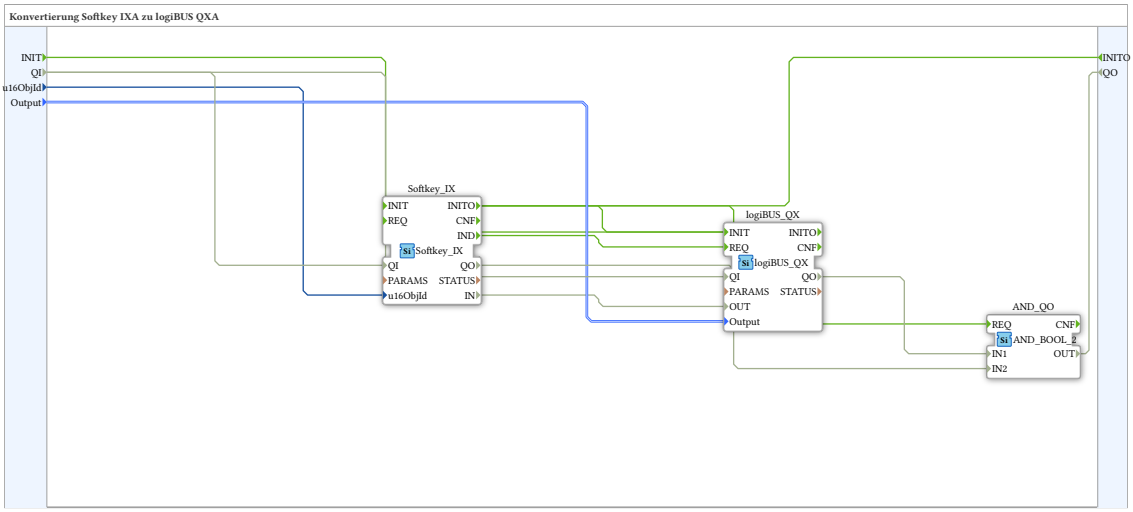
Typical use cases include:

- Digital actuators that must be operable both from a PLC program and from a local HMI softkey.
- Manual test or service functions for machine outputs.
- Lamp, relay, or valve control with operator override.
- HMI background elements that visualize whether an output is active.
- Generic output stages where the same logic must be reused for multiple channels.

Comparison with Similar Blocks

Compared with a simple direct connection from `OUT` to a digital output, this subapplication adds:

- Manual softkey override capability.
- Event-driven softkey processing.
- HMI background mirroring.



Compared with a flip-flop or latch-based manual override, this subapplication does not store the manual command. The output remains active only while the softkey is pressed. When the softkey is released and `OUT` is false, the output returns to false.

Compared with an AND-based inhibit logic, this subapplication uses an OR combination, so it supports forced activation rather than forced deactivation. If manual off is required, a different logic structure would be needed.

Conclusion

`SoftkeyOverride_TO_QX_BG` is a compact and reusable subapplication for digital outputs requiring both program control and manual hand operation. It combines a softkey input with a program signal using OR logic, writes the result to a `logiBUS_QX` output, and mirrors the state to an HMI background. Its generic parameters make it suitable for many output channels and softkey configurations in IEC 61499-based systems.

Softkey_IX_TO_logiBUS_QX

• – ○ • – ○ • – ○ •

Introduction

`Softkey_IX_TO_logiBUS_QX` is the test_B counterpart to `Softkey_IXA_TO_logiBUS_QXA` — a VT softkey (`Softkey_IX`) directly switches a physical output (`logiBUS_QX`), without adapters.

Function Blocks (FBs) Used

Sub-blocks: Softkey_IX_TO_logiBUS_QX

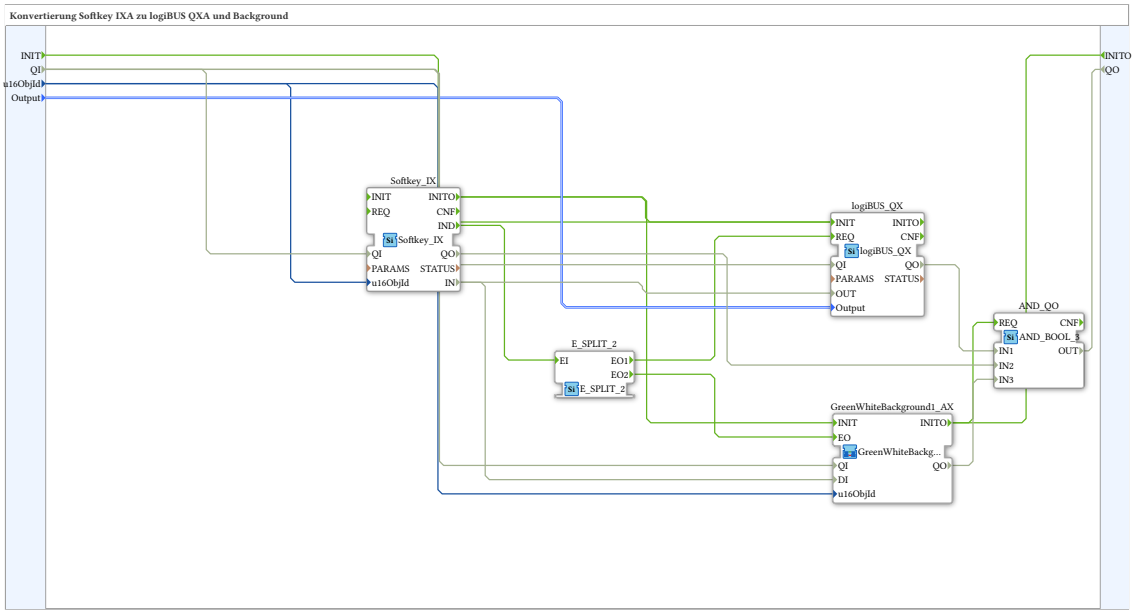
- **Type**: SubAppType
- **Internal FBs used**:
  - **Softkey_IX**: `isobus::UT::io::Softkey::Softkey_IX` — VT softkey (non-adapter variant).
  - **logiBUS_QX**: `logiBUS::io::DQ::logiBUS_QX` — physical digital output.
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` — combines `logiBUS_QX.QO` and `Softkey_IX.QO` into the output `QO`.
- **Functionality**: `Softkey_IX.IND` triggers `logiBUS_QX.REQ`; `Softkey_IX.IN` is wired directly to `logiBUS_QX.OUT`. The SubApp interface additionally has the events `INIT`/`INITO` as well as `QI` (BOOL, initial value `TRUE`) and `QO` (BOOL).

Program Flow and Connections

1. `u16ObjId` ⟶ `Softkey_IX.u16ObjId`; `Output` ⟶ `logiBUS_QX.Output`.
2. `Softkey_IX.IND` ⟶ `logiBUS_QX.REQ`; `Softkey_IX.IN` ⟶ `logiBUS_QX.OUT`.
3. Initialization chain: `INIT` ⟶ `logiBUS_QX.INIT`, `logiBUS_QX.INITO` ⟶ `Softkey_IX.INIT`, `Softkey_IX.INITO` ⟶ `INITO` and `AND_QO.REQ`.
4. Quality: `QI` ⟶ `logiBUS_QX.QI` and `Softkey_IX.QI`; `logiBUS_QX.QO` ⟶ `AND_QO.IN1`; `Softkey_IX.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.

Application Scenarios

- Minimal softkey-to-output block for test_B.



Summary

test_B counterpart to `Softkey_IXA_TO_logiBUS_QXA`.

Softkey_IX_TO_logiBUS_QX_BG

• – ○ • – ○ • – ○ •

Introduction

`Softkey_IX_TO_logiBUS_QX_BG` extends `Softkey_IX_TO_logiBUS_QX` with a VT status color — the test_B counterpart to `Softkey_IXA_TO_logiBUS_QXA_BG`.

Function Blocks (FBs) Used

Sub-blocks: Softkey_IX_TO_logiBUS_QX_BG

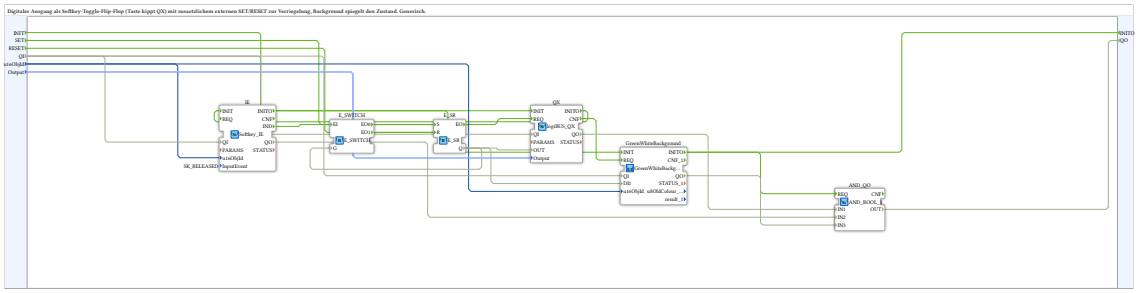
- **Type**: SubAppType
- **Internal FBs used**:
  - **Softkey_IX**: `isobus::UT::io::Softkey::Softkey_IX` — VT softkey.
  - **logiBUS_QX**: `logiBUS::io::DQ::logiBUS_QX` — physical digital output.
  - **E_SPLIT_2**: `iec61499::events::E_SPLIT_2` — splits the softkey event.
  - **Color block** (compact background variant, see Background Color Blocks): sets the status color.
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_3` — combines the `QO` of `logiBUS_QX`, `Softkey_IX` and the color block.
- **Functionality**: `Softkey_IX.IND` is distributed via `E_SPLIT_2` to `logiBUS_QX.REQ` and the color block; `Softkey_IX.IN` feeds `logiBUS_QX.OUT` and the color block.

Program Flow and Connections

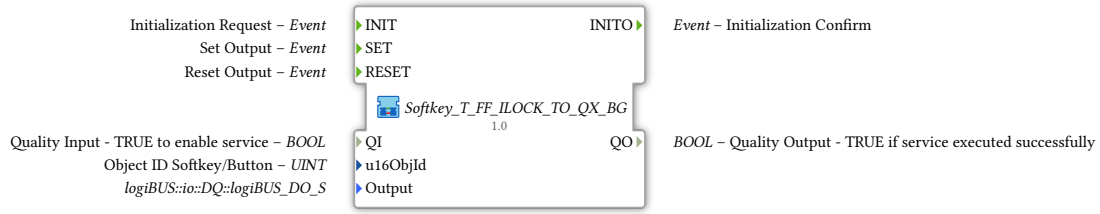
1. `u16ObjId` ⟶ `Softkey_IX.u16ObjId` and the color block's `.u16ObjId`; `Output` ⟶ `logiBUS_QX.Output`.
2. `Softkey_IX.IND` ⟶ `E_SPLIT_2.EI` ⟶ `EO1` ⟶ `logiBUS_QX.REQ`, `EO2` ⟶ color block `.EO`.
3. `Softkey_IX.IN` ⟶ `logiBUS_QX.OUT` and ⟶ color block `.DI`.
4. Initialization: event input `INIT` ⟶ `logiBUS_QX.INIT`, `logiBUS_QX.INITO` ⟶ `Softkey_IX.INIT`, `Softkey_IX.INITO` ⟶ color block `.INIT` (instance `GreenWhiteBackground1_AX`), whose `INITO` ⟶ event output `INITO` and ⟶ `AND_QO.REQ`.
5. Quality: data input `QI` (`BOOL`, default `TRUE`) ⟶ `logiBUS_QX.QI`, `Softkey_IX.QI` and color block `.QI`; `logiBUS_QX.QO` ⟶ `AND_QO.IN1`, `Softkey_IX.QO` ⟶ `AND_QO.IN2`, color block `.QO` ⟶ `AND_QO.IN3`; `AND_QO.OUT` ⟶ data output `QO`.

Application Scenarios

- VT softkey with visual status feedback for test_B, without OPC-UA.



Summary



test_B counterpart to `Softkey_IXA_TO_logiBUS_QXA_BG`.

🌐 Related topic subpages on ms-muc-docs.de

Softkey_T_FF_ILOCK_TO_QX_BG

• — ○ • — ○ • — ○ •

Introduction

Softkey_T_FF_ILOCK_TO_QX_BG is a generic subapplication that implements a digital output driven by a softkey (button) toggle flip-flop. Each released key press toggles the state of a logiBUS_QX digital output. In addition, external SET and RESET event inputs allow overriding or locking the flip-flop independently of the key. The internal background visualization reflects the current output state (green/white), providing an immediate visual feedback in the HMI.

Interface Structure

Event Inputs

Name	Description
INIT	Initialization request (`EInit`)
SET	Sets the internal flip-flop output to TRUE
RESET	Resets the internal flip-flop output to FALSE

Event Outputs

Name	Description
INITO	Initialization confirmation (`EInit`, from `GreenWhiteBackground.INITO`)

Data Inputs

Name	Type	Initial Value	Description

QI	BOOL	TRUE	Quality Input, TRUE enables the service
u16ObjId	UINT	ID_NULL	Object ID of the softkey/button
Output	logiBUS::io::DQ::logiBUS_DO_S	logiBUS_DO::Invalid	Digital output configuration (type/address)

Data Outputs

Name	Type	Description
QO	BOOL	Quality Output, AND of `QX.QO`, `IE.QO` and `GreenWhiteBackground.QO` (`AND_QO`, `iec61131::booleanOperators::AND_BOOL_3`)

Adapters

None.

Functionality

The subapplication combines a softkey input event handler, a Set/Reset flip-flop and a digital output function block:

1. The softkey event block (Softkey_IE) monitors the assigned softkey (identified by `u16ObjId`) and generates an event on every key release (`SK_RELEASED`).
2. The E_SWITCH block routes this event either to the Set input or to the Reset input of the E_SR flip-flop, depending on the current state `Q` (routed to the switch control input `G`):
   - If `Q = FALSE` (`G = FALSE`), the event is routed to `E_SR.S` ⟶ the output becomes TRUE.
   - If `Q = TRUE` (`G = TRUE`), the event is routed to `E_SR.R` ⟶ the output becomes FALSE. This yields a toggle behavior: every softkey release inverts the flip-flop state.
3. The external event inputs `SET` and `RESET` are connected directly to the `S` and `R` inputs of the E_SR flip-flop. They take precedence over the key events and can be used to lock the output to a defined state or to override the toggle.
4. The flip-flop output `Q` drives the `QX` function block, which writes the digital output (e.g., logiBUS output module). The value `Output` (data input) defines the output module and channel configuration.
5. The `GreenWhiteBackground` subapplication is triggered after every completed output write (`QX.CNF`) and receives both the object ID and the current state `Q` as `DI1`, so the background color indicates the output state (green = active, white = inactive).
6. `QI` is distributed to `QX.QI`, `IE.QI` and `GreenWhiteBackground.QI` (no longer hard-wired to `TRUE`). Initialization is chained: `INIT` ⟶ `QX.INIT`; `QX.INITO` ⟶ `IE.INIT`; `IE.INITO` ⟶ `GreenWhiteBackground.INIT`; `GreenWhiteBackground.INITO` ⟶ `INITO` (and ⟶ `AND_QO.REQ`). `QX.QO` ⟶ `AND_QO.IN1`; `IE.QO` ⟶ `AND_QO.IN2`; `GreenWhiteBackground.QO` ⟶ `AND_QO.IN3`; `AND_QO.OUT` ⟶ `QO`.

Technical Features

- Generic design: works with any softkey object ID and any logiBUS digital output configuration.
- Toggle flip-flop based on edge-triggered softkey release events, debounce handled by the softkey driver.
- External SET/RESET override inputs allow interlocking or forced control.
- Integrated background visualization (green/white) for direct HMI feedback.
- Uses standard 61499 blocks (E_SR, E_SWITCH) and logiBUS function blocks (logiBUS_QX, Softkey_IE).
- Combines event-driven logic with a synchronous data flow for state propagation.

State Overview

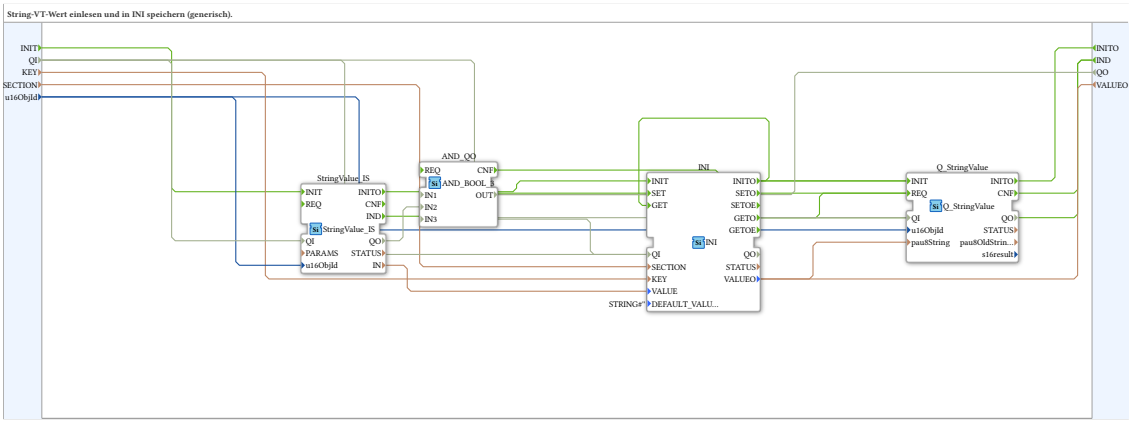
The E_SR flip-flop defines the central state:

State	Output QX	Background	Trigger to leave state
FALSE	inactive	white	Softkey release (toggle) or external SET
TRUE	active	green	Softkey release (toggle) or external RESET

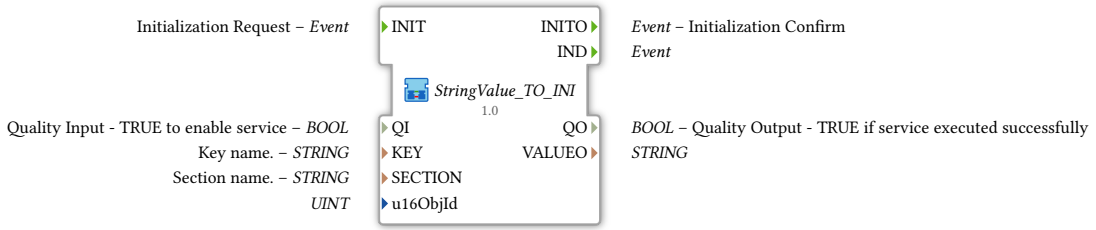
The E_SWITCH uses the current state `Q` as its switching signal `G`, ensuring the correct event path for the next softkey press.

Application Scenarios

- **Machine operator panel**: A physical softkey toggles a digital output (e.g., lamp, valve, motor) while a PLC program can lock the output via SET/RESET during safety conditions.
- **Manual/Auto override**: The output can be forced to a defined state by the control system even if the operator presses the key.
- **Visual feedback on HMI**: The background of the corresponding HMI element turns green when the output is active, making the state visible at a glance.
- **Reusable subapplication**: Can be instantiated multiple times for different softkeys and output channels within the same project.



Comparison with Similar Blocks



Feature	Softkey_T_FF_ILOCK_TO_QX_BG	Simple Softkey-to-QX (without flip-flop)	Softkey with separate Set/Reset inputs
Toggle on key press	Yes (flip-flop toggles)	No (output follows key)	No
External override	Yes (SET/RESET events)	No	Yes
Background visualization	Yes (green/white)	Optional	Optional
Generic object ID	Yes (`u16ObjId`)	Yes	Yes

Conclusion

Softkey_T_FF_ILOCK_TO_QX_BG is a versatile, generic subapplication that combines a toggle flip-flop softkey logic with external override capability and integrated background visualization. It offers a clean separation between operator input, interlocking logic, and output driving, making it suitable for a wide range of control and visualization tasks in automation systems based on 4diac/logiBUS.

StringValue_TO_INI

• – ○ • – ○ • – ○ •

Introduction

The StringValue_TO_INI subapplication is a generic IEC 61499 component that reads a string value from an ISOBUS Virtual Terminal (VT) object and persistently stores it in an INI-based storage system. It

provides both storage and retrieval functionality, making it suitable for scenarios where VT input values need to be persisted across sessions or used by other parts of a control application.

Interface Structure

Event Inputs

Event	Description
INIT	Initialization request (EInit); starts the initialization chain `StringValue_IS` ⟶ `INI` ⟶ `Q_StringValue`.

Event Outputs

Event	Description
INITO	Initialization confirm (EInit); comes from `Q_StringValue.INITO` (end of the chain).
IND	Indicates that a SET or GET operation on the INI storage has completed successfully.

Data Inputs

Data	Type	Description
QI	BOOL	Quality Input - TRUE to enable service (initial value TRUE); distributed to StringValue_IS.QI, INI.QI and Q_StringValue.QI.
KEY	STRING	The key name under which the value is stored in the INI file.
SECTION	STRING	The section name in the INI file where the key resides.
u16ObjId	UINT	The object identifier of the string object within the ISOBUS Virtual Terminal. Initialized to ID_NULL.

Data Outputs

Data	Type	Description
QO	BOOL	Quality Output - TRUE if the service executed successfully; AND combination (`AND_QO`, `AND_BOOL_3`) of Q_StringValue.QO, StringValue_IS.QO and INI.QO.
VALUEO	STRING	The string value read from the INI storage after a GET operation.

Adapters

None.

Functionality

The StringValue_TO_INI subapplication combines three functional building blocks (plus an AND block `AND_QO`, `iec61131::booleanOperators::AND_BOOL_3`, for the quality output) to perform the following operations:

1. **Read from VT**: The internal StringValue_IS FB reads a string value from the ISOBUS VT object specified by u16ObjId. When this value is available, it triggers the INI SET operation.
2. **Store in INI**: The internal INI FB stores the received string value under the KEY within the SECTION of the INI storage. This allows the value to be persisted and retrieved later.
3. **Retrieve and Queue**: On initialization, the subapplication automatically performs a GET operation to read the stored value. This value is then output via VALUEO and also forwarded to the internal Q_StringValue queue for further processing.

Initialization: `INIT` ⟶ `StringValue_IS.INIT`; `StringValue_IS.INITO` ⟶ `INI.INIT`; `INI.INITO` ⟶ `Q_StringValue.INIT`; `Q_StringValue.INITO` ⟶ `INITO` and ⟶ `AND_QO.REQ`. Quality: `QI` is distributed to `StringValue_IS.QI` and `INI.QI` (and `Q_StringValue.QI`); `Q_StringValue.QO` ⟶ `AND_QO.IN1`,

`StringValue_IS.QO` ⟶ `AND_QO.IN2`, `INI.QO` ⟶ `AND_QO.IN3`; `AND_QO.OUT` ⟶ `QO`. The internal `GET` trigger after `INI.INITO` is unchanged.

The event flow is as follows:

- When the INI storage initializes, a GET operation is automatically triggered.
- Upon completion of a GET operation, the retrieved value appears at VALUEO and is queued via Q_StringValue, and the IND event is emitted.
- When a VT string value is read (StringValue_IS.IND), it is written to the INI storage via a SET operation, and the IND event is emitted upon completion.

Technical Features

- **Generic INI Storage**: Uses the eclipse4diac INI storage FB, making the storage format compatible with standard INI file conventions.
- **ISOBUS VT Integration**: Reads string values from ISOBUS Virtual Terminal objects using the isobus::UT::io::StringValue FB, enabling interaction with operator terminals.
- **Automatic Initialization**: The subapplication performs an initial GET operation during startup to load the persisted value.
- **Queue Support**: The internal Q_StringValue block queues string values, allowing for ordered processing in downstream logic.
- **Configurable Keys**: Both KEY and SECTION are configurable data inputs, making the subapplication reusable for different INI entries.
- **Default Value Handling**: The INI FB uses a default empty string when no value exists in storage.

State Overview

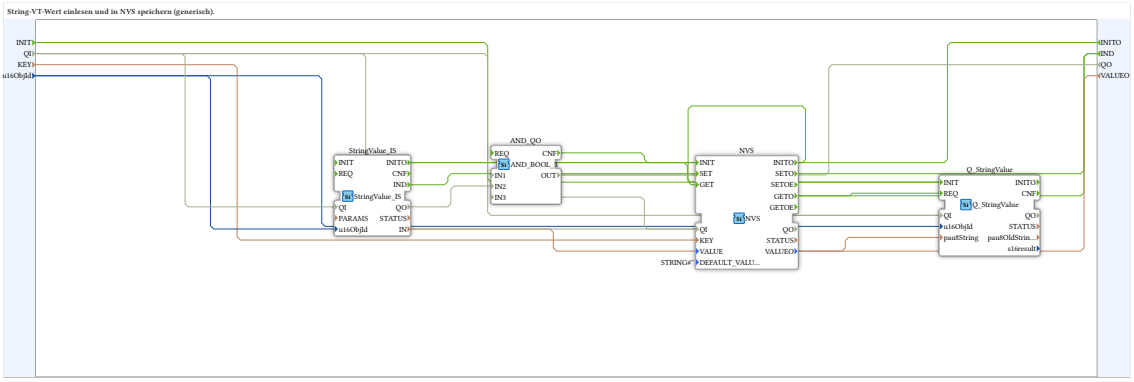
The subapplication exhibits the following operational states:

State	Description
Initialization	During startup, the INI storage initializes. The INITO output triggers a GET operation to retrieve the stored value.
GET Operation	Retrieves the string value associated with KEY/SECTION from the INI storage. Upon completion (GETO), the value is output and queued, and the IND event is issued.
SET Operation	Stores a new string value received from the VT object into INI storage. Triggered by StringValue_IS.IND. Upon completion (SETO), the IND event is issued.
Idle	Waiting for either a VT value to arrive (triggering SET) or for external requests that cause further GET operations.

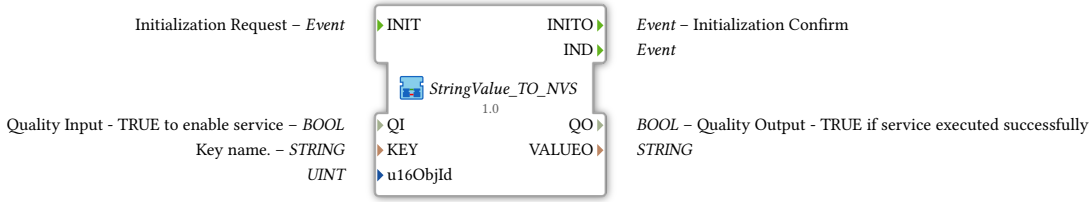
Application Scenarios

- **Machine Operator Preferences**: Store operator-entered string values (e.g., machine names, batch identifiers) from a VT terminal into persistent INI storage.
- **Configuration Persistence**: Save configuration strings entered via a VT terminal so they are retained across power cycles.
- **Data Exchange Between Applications**: Write VT string values to a shared INI file that other applications can read.
- **Queued Processing**: Use the Q_StringValue queue to process multiple string values in order, e.g., for logging or sequential command execution.

Comparison with Similar Blocks



Feature	StringValue_TO_INI	Standard String Store FB	INI Direct Access
VT interface	Yes (reads from ISOBUS VT)	Usually no	No
Persistent storage	Yes (INI file)	Depends on implementation	Yes
Queue support	Yes (Q_StringValue)	No	No
Configurable key/section	Yes	Limited	Yes



Generic reuse	High	Medium	Low

Conclusion

The StringValue_TO_INI subapplication provides a compact and reusable solution for bridging ISOBUS Virtual Terminal string inputs with persistent INI storage. Its automatic initialization, queue support, and configurable keys make it a versatile building block for industrial automation applications that require both operator interaction and data persistence.

StringValue_TO_NVS

• – ◦ • – ◦ • – ◦ •

Introduction

The **StringValue_TO_NVS** subapplication provides a generic solution for reading a String-VT value and persisting it into the non-volatile storage (NVS) of an ESP32. It combines the `isobus::UT::io::StringValue::StringValue_IS` function block for input acquisition with the `logiBUS::storage::esp32_nvs::NVS` function block for durable storage. The subapplication also exposes the stored value on its output interface. It was extracted from a larger exercise project to be reused as a standalone, generic component.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization request; starts the initialization chain (`Q_StringValue` ⟶ `StringValue_IS` ⟶ `NVS`).

Event Outputs

- **INITO** (EInit): Initialization confirm from `NVS.INITO` (end of the initialization chain).
- **IND** (Event): Emitted after a read or write operation completes, indicating that a new value has been stored or retrieved.

Data Inputs

- **QI** (BOOL): Quality Input - TRUE to enable service (initial value `TRUE`); passed through to `Q_StringValue.QI`, `StringValue_IS.QI` and `NVS.QI`.
- **KEY** (STRING): The key name under which the value is stored in the NVS.
- **u16ObjId** (UINT): The object identifier for the String-VT value. Defaults to `ID_NULL`.

Data Outputs

- **QO** (BOOL): Quality Output - TRUE if the service executed successfully; AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_3`) of the `QO` of `Q_StringValue`, `StringValue_IS` and `NVS`.
- **VALUEO** (STRING): The current string value that has been read from the NVS or acquired from the input.

Adapters

The subapplication does not expose any adapter interfaces.

Functionality

The subapplication operates as follows. In addition, the initialization chain runs `INIT` → `Q_StringValue.INIT`, `Q_StringValue.INITO` → `StringValue_IS.INIT`, `StringValue_IS.INITO` → `NVS.INIT`, `NVS.INITO` → `INITO` and → `AND_QO.REQ`; `QI` goes to `Q_StringValue.QI`, `StringValue_IS.QI` and `NVS.QI`, and their `QO` outputs are ANDed by the `AND_QO` block (`AND_BOOL_3`) into `QO`.

1. **Initialization**: On startup, the internal `NVS` function block performs its initialization. The resulting `INITO` event is immediately routed to the `GET` event of the same block, causing the currently stored value to be read from the NVS.
2. **Value acquisition**: The `StringValue_IS` function block acquires a String-VT value based on the provided `u16ObjId`. When a new value is available, its `IND` output event triggers the `NVS.SET` event.
3. **Storage**: The acquired string value (from `StringValue_IS.IN`) is written to the NVS under the configured `KEY`. After a successful write operation (`NVS.SETO`), the subapplication emits the `IND` output event to signal completion.
4. **Read/Query**: The `GETO` event from the `NVS` block is forwarded to the `Q_StringValue` query function block, which converts the internal representation (`pau8String`) into a proper String-VT format. Simultaneously, `GETO` is also routed to the subapplication's `IND` output.
5. **Output**: The `VALUEO` output continuously reflects the value stored in the NVS. It is updated after each `SET` or `GET` operation.

Technical Features

- **Generic NVS key**: The storage key is configurable via the `KEY` input.
- **Object ID binding**: The `u16ObjId` input selects the correct String-VT object in the ISOBUS context.
- **Automatic initialization**: On startup, the NVS block is initialized and the stored value is read automatically without external triggering.
- **Default value handling**: The NVS block is configured with an empty default value (`STRING#''`) for the first-time retrieval.
- **Event acknowledgment**: The `IND` event output signals successful read or write operations.
- **Internal wiring encapsulated**: All event and data connections between the internal function blocks are hidden behind the subapplication interface, simplifying reuse.

State Overview

The internal state machine is primarily managed by the `NVS` function block from the `logiBUS` library. The typical states are:

1. **Initialization (INIT)**: The NVS block initializes the underlying storage backend.
2. **Get (GET)**: Reads the value from the NVS and makes it available on `VALUEO`.
3. **Set (SET)**: Writes the input value to the NVS under the configured key.

The internal event paths are:

- `NVS.INITO → NVS.GET` (auto-read stored value after initialization)
- `StringValue_IS.IND → NVS.SET` (store a newly acquired value)
- `NVS.GETO → Q_StringValue.REQ` and `NVS.GETO → IND` (query and indication)

Application Scenarios

- **IoT device configuration**: Storing sensor values, device names, or user-adjustable parameters that must survive a reboot or power loss.
- **ISOBUS integration**: Working with ISO 11783 String-VT objects to persist display strings, diagnostic messages, or configuration data in agricultural automation systems.
- **Generic reuse**: Because both the key and object ID are parameterizable, the subapplication can be instantiated multiple times within a project for storing different values.

- **Parameter snapshotting**: Saving runtime states or calibration values for later retrieval during development or commissioning.

Comparison with Similar Blocks

Feature	StringValue_TO_NVS	NVS (storage only)	StringValue_IS (input only)
Reads a String-VT value	✅	❌	✅
Stores value in NVS	✅	✅	❌
Exposes stored value as output	✅	✅	❌
Handles initialization automatically	✅	✅ (via INIT)	❌
Provides query response via Q_StringValue	✅	❌	❌
Encapsulates event wiring	✅	❌	❌

Compared to using the `NVS` and `StringValue_IS` function blocks separately, this subapplication bundles the necessary event wiring, initialization sequence, and query logic into a single reusable component, reducing integration effort and the risk of wiring errors.

Conclusion

The `StringValue_TO_NVS` subapplication is a well-structured, generic solution for reading a String-VT value and persisting it in the ESP32 NVS. It simplifies project integration by encapsulating initialization, storage, and query behavior behind a clean interface. The exposed `IND` event and `VALUE0` output make it straightforward to incorporate into larger IEC 61499 applications, and its parameterizable inputs provide the flexibility needed for reuse across different contexts.

SwitchPic(Col) Building Blocks: Common Pattern

• – ◦ • – ◦ • – ◦ •

Introduction

`MyLib::sys` (test_B) contains a family of building blocks that **display a different VT image (object pointer target) and/or a different background color depending on the state** — e.g., a slider/valve animation with the states Unknown/Closed/Opening/Opened/Closing. This page explains the common pattern; the individual pages only list the specific variations.

Naming Scheme

`SwitchPic[Col]_<Zustände>_<Variante>[_aux]`

Component	Meaning
`Col` (optional)	In addition to changing the image, also toggles a background color (`Q_BackgroundColour`) to match the state, not just the image (`Q_NumericValue`).
States (`2` or `5`)	`2` = Boolean selector `DI1` (`up/down`, type `s2x1ObjectIDs/s2x2ObjectIDs`); `5` = `iSTATE`-Selector (`USINT`, slider state machine Unknown/Closed/Opening/Opened/Closing, type `SchieberStruct/SchieberAuxInStruct`), evaluated via `F_MUX_5`.
Variant (`1/2/3`, only with `SwitchPic`)	Number/Type of VT objects updated simultaneously: `1` = only a normal VT object (Softkey/DataMask), `2` = additionally an AUX object, `3` = additionally an AUX object AND a second normal object (“Button”).

_aux	Only AUX object(s) are switched, no normal VT object (counterpart to variant 1, but exclusively for Auxiliary Function objects).

Functionality

1. A structure `pictures/Sets` (type depends on state/variant) contains the corresponding object ID(s) (image and, if applicable, color) for each possible state.
2. `F_MOVE` unpacks this structure into individual values.
3. A multiplexer (`F_SEL` for 2 states, `F_MUX_5` for 5 states, controlled by `DI1` or `iSTATE`) selects the values matching the current state.
4. `Q_NumericValue/Q_NumericValueAux` sets the selected object pointer value to the VT object identified by `Picture/PictureA/PictureB`; for `Col` variants, `Q_BackgroundColour/Q_BackgroundColourAux` additionally sets the background color to the object identified by `Color`.
5. For multiple target objects (variant 2/3), several `Q_NumericValue(Aux)` instances are chained together in a fixed INIT sequence (each triggers the next via `INITO`) before `INITO` is reported externally.

Summary

A multiplexer pattern: State ⟶ Structure lookup (`F_MOVE`) ⟶ Selection (`F_SEL`/`F_MUX_5`) ⟶ one or more `Q_NumericValue(Aux)`/`Q_BackgroundColour(Aux)` targets. The variant number (1/2/3) and `Col`/`_aux` determine only how many targets of which type (normal/AUX, image/color) are updated simultaneously.

SwitchPic(Col) Blocks: Shared Pattern

• – ◦ • – ◦ • – ◦ •

Introduction

`MyLib::sys` (test_B) contains a family of blocks that **display a different VT picture (object-pointer target) and/or a different background color depending on state** — e.g. a slide-valve animation with the states Unknown/Closed/Opening/Opened/Closing. This page explains the shared pattern; the individual pages only state the concrete differences.

Naming Scheme

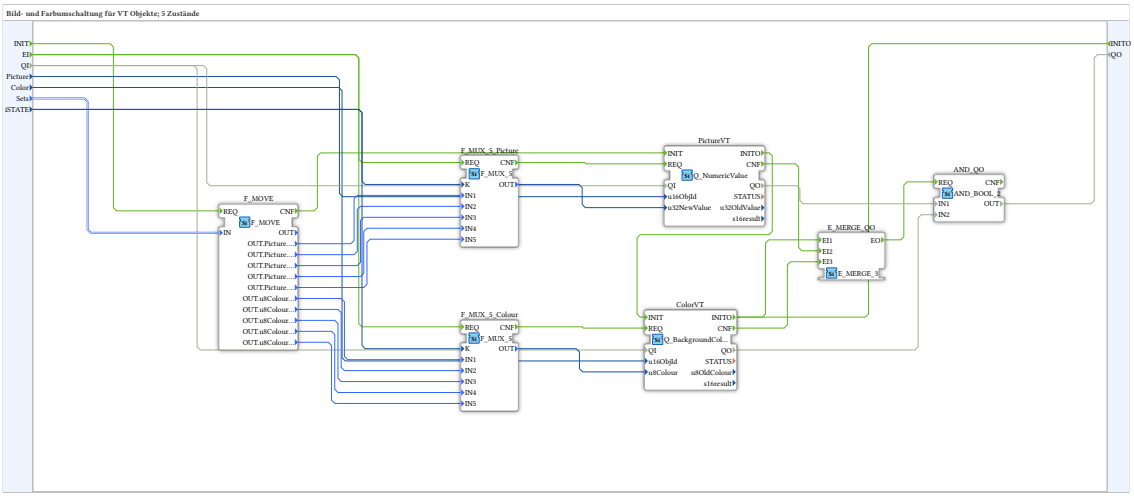
`SwitchPic[Col]_<states>_<variant>[_aux]`

Component	Meaning
Col (optional)	In addition to the picture, also switches a background color (`Q_BackgroundColour`) to match the state, not just a picture (`Q_NumericValue`).
States (2 or 5)	`2` = boolean selector `DI1` (up/down, type `s2x1ObjectIDs`/`s2x2ObjectIDs`); `5` = `iSTATE` selector (`USINT`, slide-valve state machine Unknown/Closed/Opening/Opened/Closing, type `SchieberStruct/SchieberAuxInStruct`), evaluated via `F_MUX_5`.
Variant (1/2/3, `SwitchPic` only)	Number/kind of VT objects updated simultaneously: `1`=regular VT object only (softkey/data mask), `2`=plus an AUX object, `3`=plus an AUX object AND a second regular object (“button”).
_aux	Only AUX object(s) are switched, no regular VT object (counterpart to variant 1, but exclusively for auxiliary function objects).

Functionality

1. A structure `pictures/Sets` (type depending on states/variant) holds, for every possible state, the associated object ID(s) (picture and, where applicable, color).

2. F_MOVE unpacks this structure into individual values.
3. A multiplexer (F_SEL for 2 states, F_MUX_5 for 5 states, driven by DI1 or iSTATE) selects the values matching the current state.
4. Q_NumericValue/Q_NumericValueAux sets the selected object-pointer value on the VT object identified by Picture/PictureA/PictureB; Col variants additionally set Q_BackgroundColour/Q_BackgroundColourAux's background color on the object identified by Color.
5. With multiple target objects (variant 2/3), several Q_NumericValue(Aux) instances are chained in a fixed INIT sequence (each triggers the next via INITO) before INITO is reported outward.



Summary

A multiplexer pattern: state → struct lookup (F_MOVE) → selection (F_SEL/F_MUX_5) → one or more Q_NumericValue(Aux)/Q_BackgroundColour(Aux) targets. The variant number (1/2/3) and Col/_aux only determine how many targets of which kind (regular/AUX, picture/color) get updated simultaneously.

SwitchPicCol_5_1

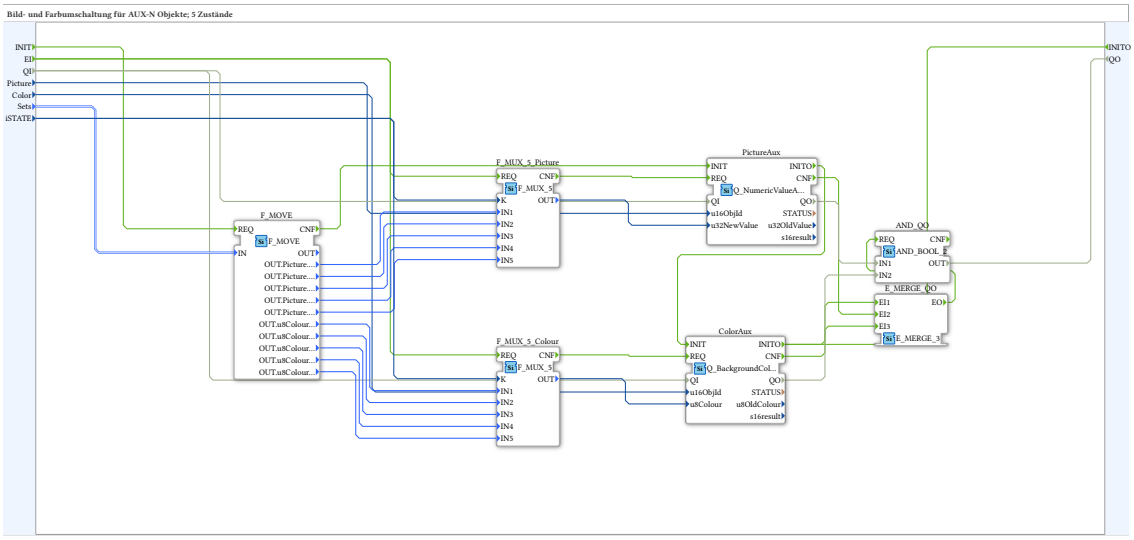
• – ○ • – ○ • – ○ •

Introduction

SwitchPicCol_5_1 switches both a VT picture (Picture, via Q_NumericValue) **and** a VT background color (Color, via Q_BackgroundColour) between 5 states (slide-valve animation) — two parallel F_MUX_5 multiplexers (one for picture IDs, one for color values), both driven by the same iSTATE value, targeting regular (non-AUX) objects.

For the general pattern, see SwitchPic(Col) Blocks (shared pattern).

Initialization and quality: INIT → F_MOVE.REQ; F_MOVE.CNF → PictureVT.INIT; PictureVT.INITO → ColorVT.INIT; ColorVT.INITO → INITO. New are QI (BOOL, default TRUE), which goes to PictureVT.QI and ColorVT.QI, and QO (BOOL): AND (AND_QO, AND_BOOL_2) of PictureVT.QO and ColorVT.QO. AND_QO.REQ is triggered via E_MERGE_QO (E_MERGE_3: ColorVT.INITO, PictureVT.CNF, ColorVT.CNF).



Summary

Combines picture and color switching (Col) for 5 states on regular VT objects.

SwitchPicCol_5_1_aux

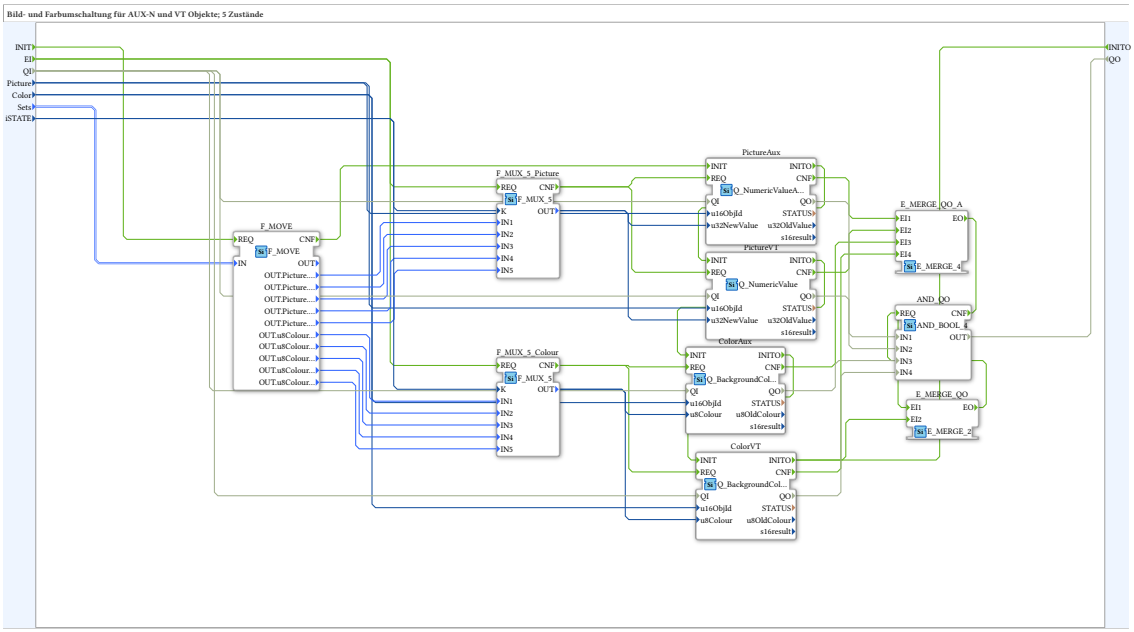
• – ○ • – ○ • – ○ •

Introduction

`SwitchPicCol_5_1_aux` switches both a picture and a background color between 5 states — like `SwitchPicCol_5_1`, but exclusively for **auxiliary function** objects (`Q_NumericValueAux`/ `Q_BackgroundColourAux`) instead of regular VT objects.

Initialization and quality: The SubApp has the event inputs `INIT` and `EI`, the event output `INITO` as well as `QI` (BOOL, initial value `TRUE`) and `QO` (BOOL). Init chain: `INIT` ⟶ `F_MOVE.REQ`, `F_MOVE.CNF` ⟶ `PictureAux.INIT`, `PictureAux.INITO` ⟶ `ColorAux.INIT`, `ColorAux.INITO` ⟶ `INITO`. `QI` is passed on to `PictureAux.QI` and `ColorAux.QI`; their `QO` outputs go to `AND_QO.IN1` and `AND_QO.IN2` respectively (`iec61131::booleanOperators::AND_BOOL_2`), `AND_QO.OUT` ⟶ `QO`. `AND_QO.REQ` is triggered by `E_MERGE_QO` (`E_MERGE_3`), which merges `ColorAux.INITO`, `PictureAux.CNF` and `ColorAux.CNF`.

For the general pattern, see SwitchPic(Col) Blocks (shared pattern).



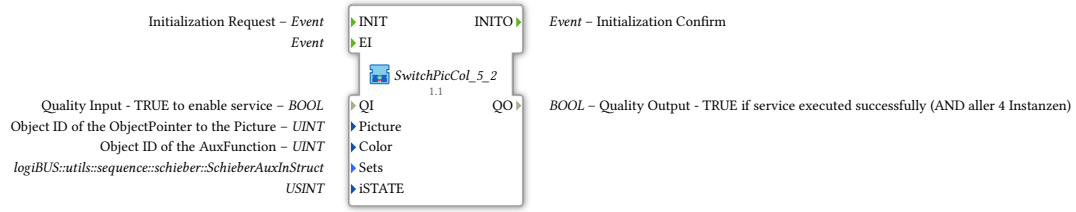
Summary

AUX counterpart to `SwitchPicCol_5_1`.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

SwitchPicCol_5_2



• – ○ • – ○ • – ○ •

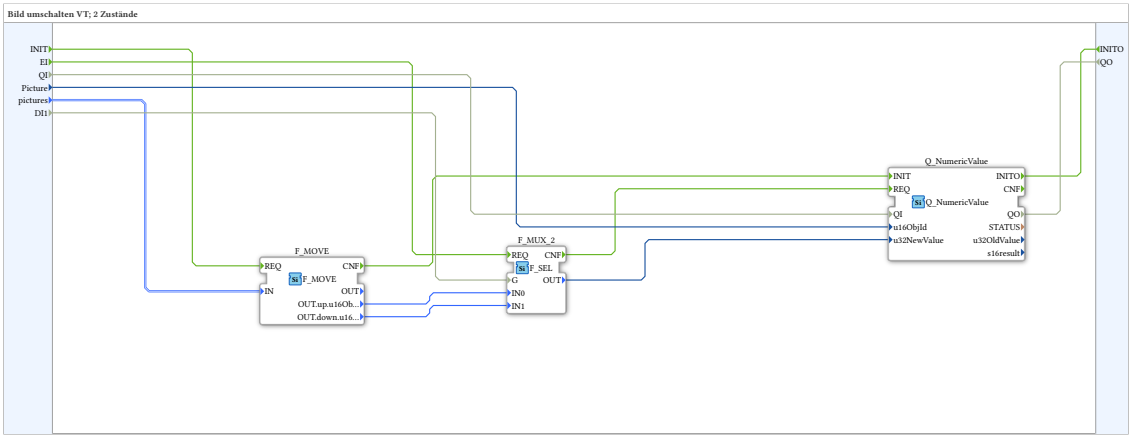
Introduction

`SwitchPicCol_5_2` switches both picture and background color between 5 states — on **four** targets at once: a regular picture object (`PictureVT`), an AUX picture object (`PictureAux`), a regular color object (`ColorVT`), and an AUX color object (`ColorAux`), all driven by the same two `F_MUX_5` multiplexers (picture/color).

For the general pattern, see SwitchPic(Col) Blocks (shared pattern).

Initialization and quality

The block has the event input `INIT`, the event output `INITO` (both `EInit`), the data input `QI` (`BOOL`, default `TRUE`) and the data output `QO` (`BOOL`). Initialization runs as a chain: `INIT` ⟶ `F_MOVE.REQ`, `F_MOVE.CNF` ⟶ `PictureAux.INIT`, `PictureAux.INITO` ⟶ `PictureVT.INIT`, `PictureVT.INITO` ⟶ `ColorAux.INIT`, `ColorAux.INITO` ⟶ `ColorVT.INIT`, `ColorVT.INITO` ⟶ `INITO`. `QI` is passed to `PictureAux`, `PictureVT`, `ColorAux` and `ColorVT`. `QO` is the output of the instance `AND_QO` (`iec61131::booleanOperators::AND_BOOL_4`), which combines their four `QO`. Its `REQ` is triggered by `E_MERGE_QO` (`E_MERGE_2`), which merges the output of `E_MERGE_QO_A` (`E_MERGE_4`, merges the `CNF` of `PictureAux`, `PictureVT`, `ColorAux` and `ColorVT`) and `ColorVT.INITO`.



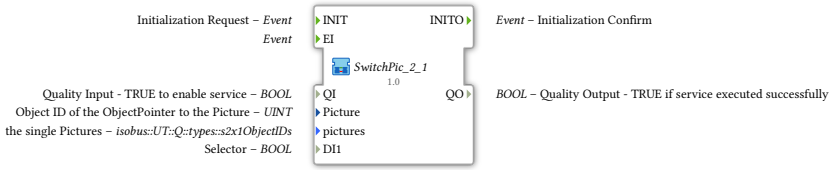
Summary

Extends `SwitchPicCol_5_1` with the AUX objects for both picture and color at once — the most extensive variant in the `SwitchPicCol` series.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

SwitchPic_2_1



• – ○ • – ○ • – ○ •

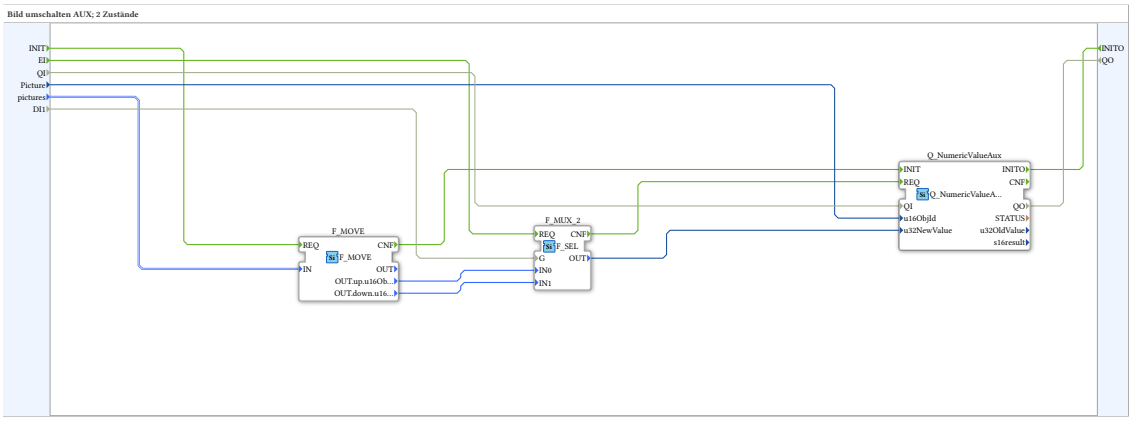
Introduction

`SwitchPic_2_1` switches a VT picture (object pointer) between 2 states (`up`/`down`) based on a boolean selector (`DI1`) — only the regular VT object (`Picture`, via `Q_NumericValue`), no AUX object.

For the general pattern, see SwitchPic(Col) Blocks (shared pattern).

Interface (QI/QO)

The block has the data input `QI` (`BOOL`, default `TRUE`, Quality Input) and the data output `QO` (`BOOL`, Quality Output). `QI` is passed through directly to `Q_NumericValue.QI`, and `Q_NumericValue.QO` directly to `QO`.



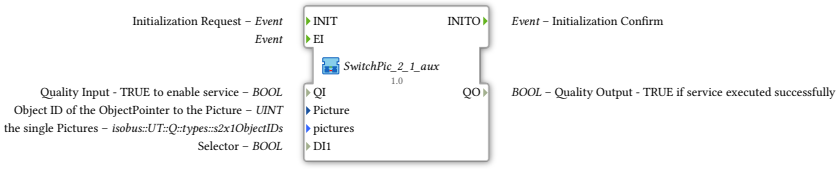
Summary

Variant “1” (regular object only) of the 2-state picture switch.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

SwitchPic_2_1_aux



• – ○ • – ○ • – ○ •

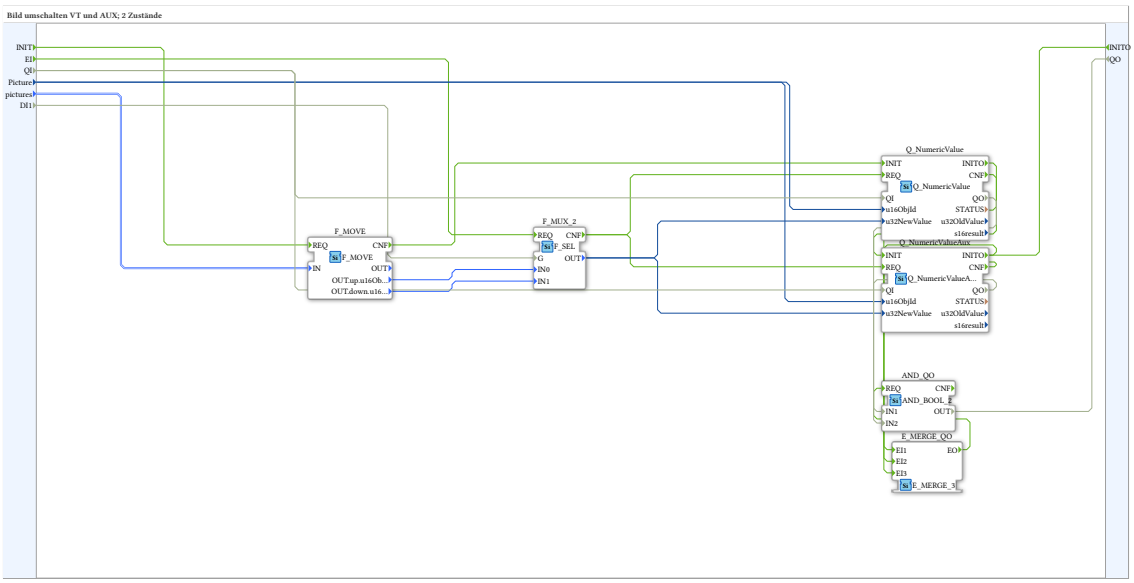
Introduction

`SwitchPic_2_1_aux` switches a VT picture between 2 states (`up/down`) based on a boolean selector (`DI1`) — exclusively for an **auxiliary function** object (`Q_NumericValueAux`), no regular VT object.

For the general pattern, see SwitchPic(Col) Blocks (shared pattern).

Interface (QI/QO)

The block has the data input `QI` (`BOOL`, default `TRUE`, Quality Input) and the data output `QO` (`BOOL`, Quality Output). `QI` is passed through directly to `Q_NumericValueAux.QI`, and `Q_NumericValueAux.QO` directly to `QO`.



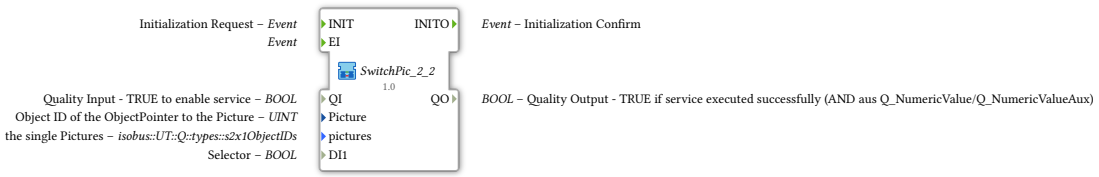
Summary

AUX counterpart to `SwitchPic_2_1`: same 2-state logic, but for an AUX object instead of a regular VT object.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

SwitchPic_2_2



• — ○ • — ○ • — ○ •

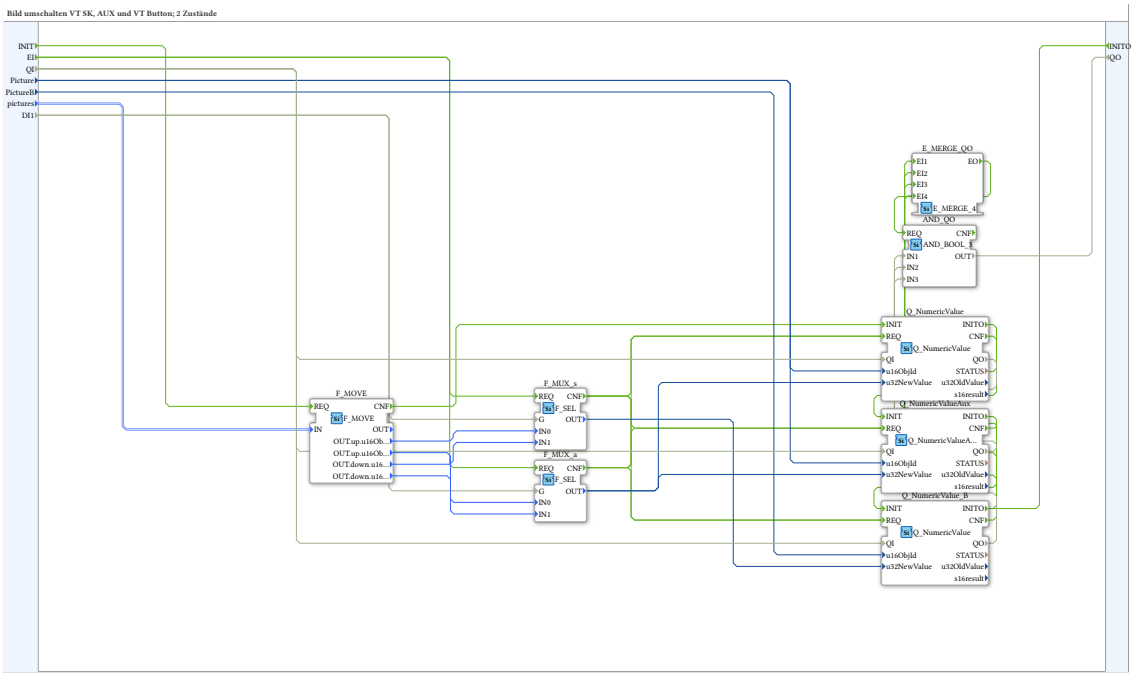
Introduction

`SwitchPic_2_2` switches a VT picture between 2 states (`up/down`) based on a boolean selector (`DI1`) — on both a regular VT object (`Picture`, `Q_NumericValue`) and simultaneously an **auxiliary function** object (`Q_NumericValueAux`), both sharing the same object ID (`Picture`).

For the general pattern, see SwitchPic(Col) Blocks (shared pattern).

Initialization and Quality

- **Event inputs** `INIT` (`EInit`) and `EI` (switch request); **event output** `INITO` (`EInit`).
- **Data input** **`QI`** (`BOOL`, default `TRUE`) ⟶ `Q_NumericValue.QI` and `Q_NumericValueAux.QI`; **data output** **`QO`** (`BOOL`): AND of `Q_NumericValue.QO` and `Q_NumericValueAux.QO` (`AND_QO`, `iec61131::booleanOperators::AND_BOOL_2`).
- Initialization: `INIT` ⟶ `F_MOVE.REQ`; `F_MOVE.CNF` ⟶ `Q_NumericValue.INIT`; `Q_NumericValue.INITO` ⟶ `Q_NumericValueAux.INIT`; `Q_NumericValueAux.INITO` ⟶ `INITO`.
- The `AND_QO.REQ` trigger comes from `E_MERGE_QO` (`iec61499::events::E_MERGE_3`), which merges `Q_NumericValueAux.INITO`, `Q_NumericValue.CNF` and `Q_NumericValueAux.CNF`.



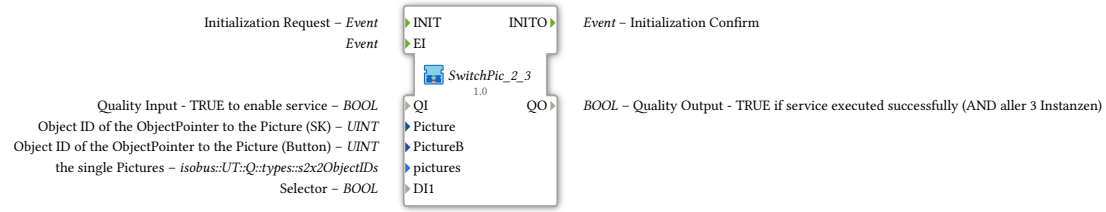
Summary

Variant “2” (regular object + AUX object) of the 2-state picture switch.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

SwitchPic_2_3



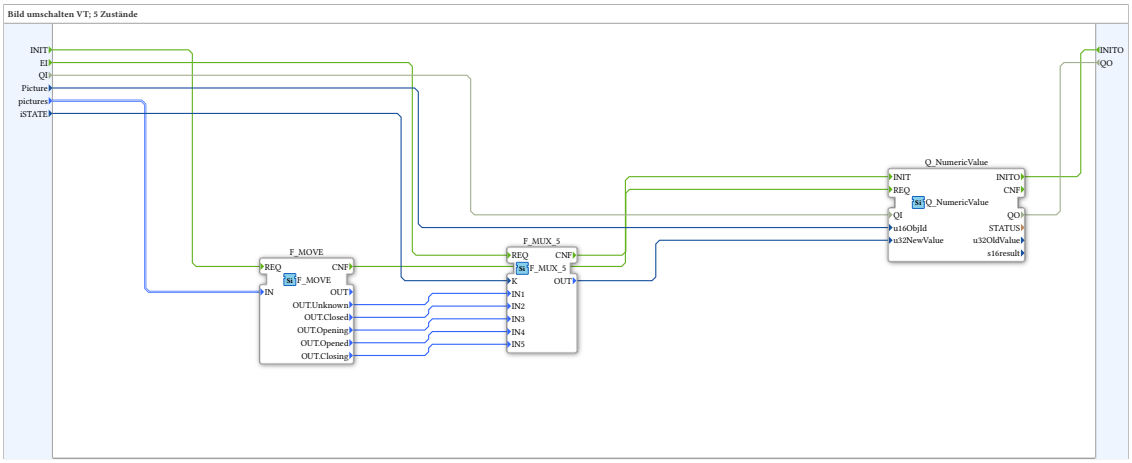
• — ○ • — ○ • — ○ •

Introduction

`SwitchPic_2_3` switches a VT picture between 2 states (up/down) based on a boolean selector (`DI1`) — on three targets at once: a regular softkey object (`Picture`), an AUX object (same ID `Picture`), and a second, independent regular object (“button”, `PictureB`, its own object-ID sub-field `u16ObjIdA` in the structure).

Interface (quality pattern): the data input `QI` (`BOOL`, default `TRUE`) is distributed to `Q_NumericValue`, `Q_NumericValueAux` and `Q_NumericValue_B`; the data output `QO` (`BOOL`) is the AND combination (`AND_QO`: `iec61131::booleanOperators::AND_BOOL_3`) of the `QO` outputs of these three instances (`IN1` to `IN3` in this order). The trigger `AND_QO.REQ` is supplied by `E_MERGE_QO` (`E_MERGE_4`), which merges `Q_NumericValue_B.INITO` and the `CNF` of `Q_NumericValue`, `Q_NumericValueAux` and `Q_NumericValue_B`.

For the general pattern, see SwitchPic(Col) Blocks (shared pattern).



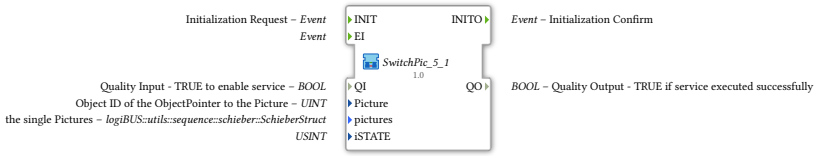
Summary

Variant “3” (regular softkey object + AUX object + second regular button object) of the 2-state picture switch — the most extensive variant in the `SwitchPic_2_*` series.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

SwitchPic_5_1



• – ○ • – ○ • – ○ •

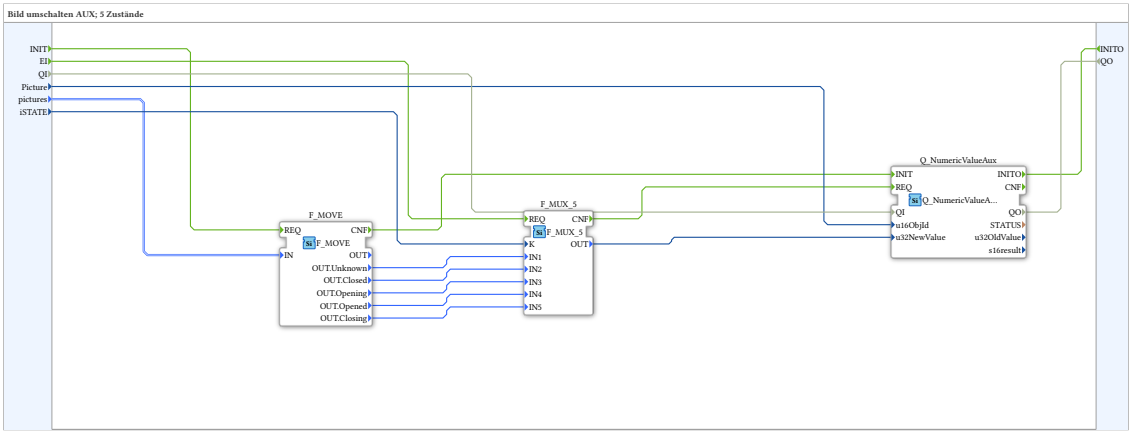
Introduction

`SwitchPic_5_1` switches a VT picture between 5 states (slide-valve animation: `Unknown`, `Closed`, `Opening`, `Opened`, `Closing`) based on an `iSTATE` value (`USINT`) — only the regular VT object (`Picture`, via `Q_NumericValue`), no AUX object.

For the general pattern, see SwitchPic(Col) Blocks (shared pattern).

Interface (QI/QO)

The block has the data input `QI` (`BOOL`, default `TRUE`, Quality Input) and the data output `QO` (`BOOL`, Quality Output). `QI` is passed through directly to `Q_NumericValue.QI`, and `Q_NumericValue.QO` directly to `QO`.



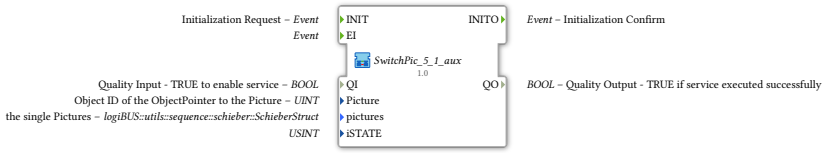
Summary

Variant “1” (regular object only) of the 5-state picture switch — the 5-state counterpart to `SwitchPic_2_1`.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

SwitchPic_5_1_aux



• – ○ • – ○ • – ○ •

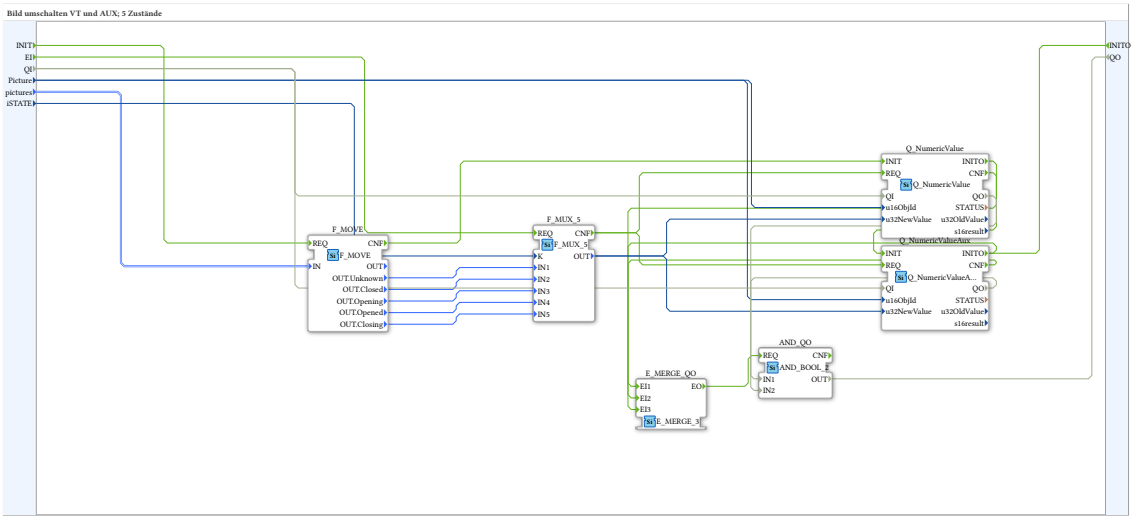
Introduction

`SwitchPic_5_1_aux` switches a VT picture between 5 states (slide-valve animation) based on an `iSTATE` value — exclusively for an **auxiliary function** object (`Q_NumericValueAux`), no regular VT object.

For the general pattern, see SwitchPic(Col) Blocks (shared pattern).

Interface (QI/QO)

The block has the data input `QI` (`BOOL`, default `TRUE`, Quality Input) and the data output `QO` (`BOOL`, Quality Output). `QI` is passed through directly to `Q_NumericValueAux.QI`, and `Q_NumericValueAux.QO` directly to `QO`.



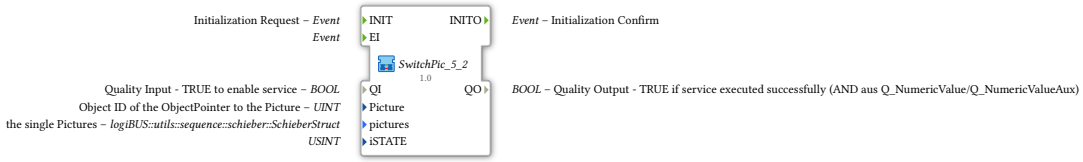
Summary

AUX counterpart to `SwitchPic_5_1`.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

SwitchPic_5_2



• – ○ • – ○ • – ○ •

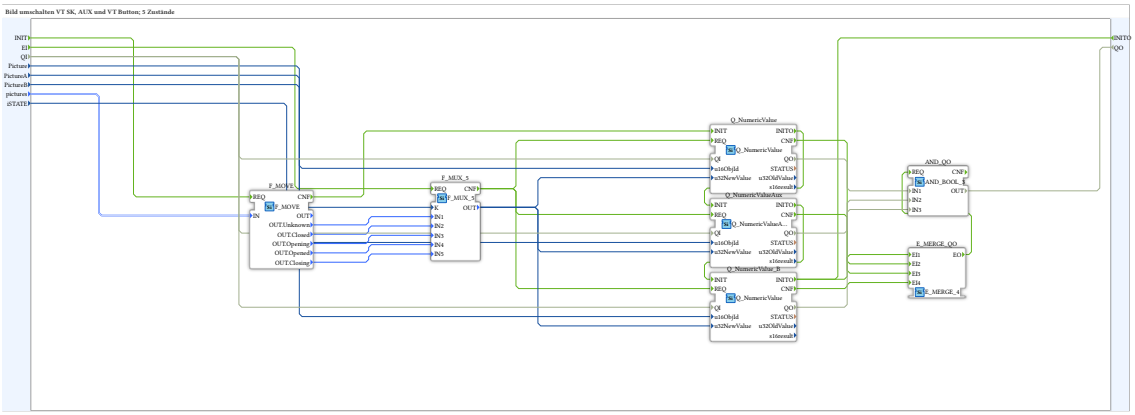
Introduction

`SwitchPic_5_2` switches a VT picture between 5 states (slide-valve animation) based on an `iSTATE` value — on both a regular VT object (`Picture`) and simultaneously an AUX object (same ID `Picture`).

For the general pattern, see SwitchPic(Col) Blocks (shared pattern).

Initialization and Status (INIT/INITO, QI/QO)

- **Event input** `INIT` (`EInit`) and **event output** `INITO` (`EInit`)
- **Data input** `QI` (`BOOL`, default `TRUE`, Quality Input) is forwarded to `Q_NumericValue.QI` and `Q_NumericValueAux.QI`
- **Data output** `QO` (`BOOL`, Quality Output): AND (`AND_QO`, type `iec61131::booleanOperators::AND_BOOL_2`) of the `QO` outputs of `Q_NumericValue` and `Q_NumericValueAux`
- **Initialization chain**: `INIT` ⟶ `F_MOVE.REQ`, `F_MOVE.CNF` ⟶ `Q_NumericValue.INIT`, `Q_NumericValue.INITO` ⟶ `Q_NumericValueAux.INIT`, `Q_NumericValueAux.INITO` ⟶ `INITO`
- `E_MERGE_QO` (type `iec61499::events::E_MERGE_3`) merges `Q_NumericValueAux.INITO`, `Q_NumericValue.CNF` and `Q_NumericValueAux.CNF` and triggers `AND_QO.REQ`



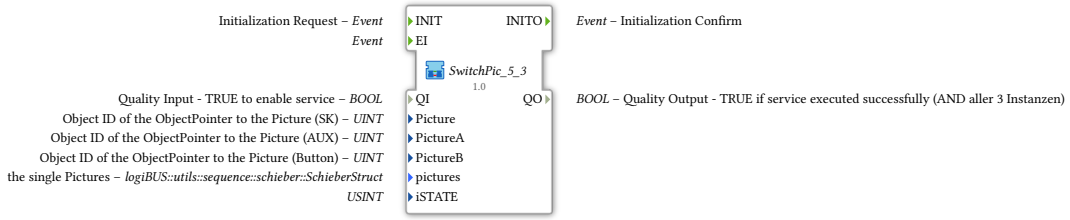
Summary

5-state counterpart to `SwitchPic_2_2`.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

SwitchPic_5_3



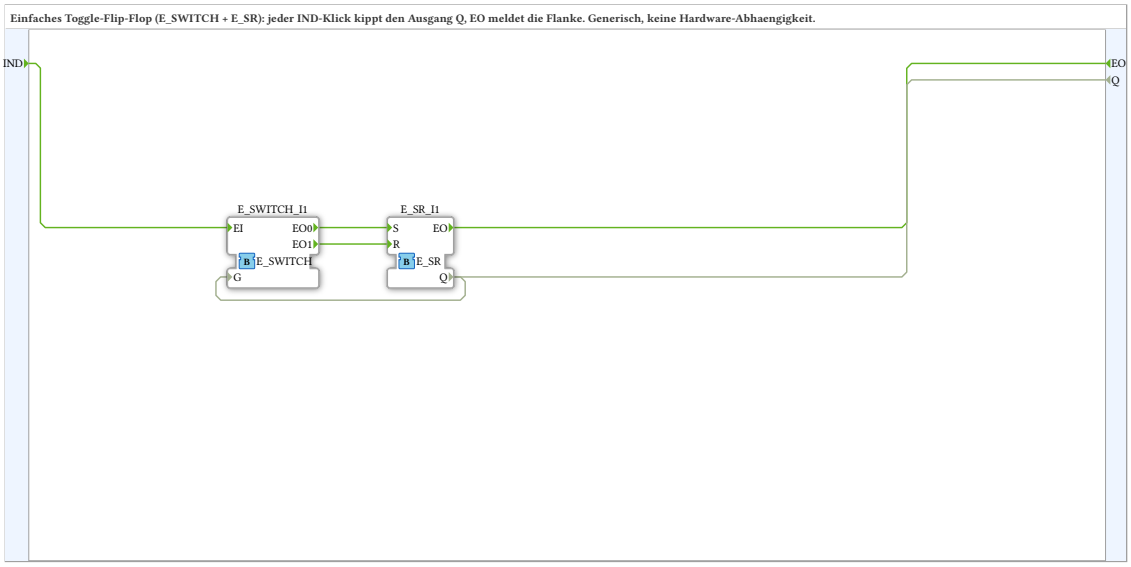
• – ○ • – ○ • – ○ •

Introduction

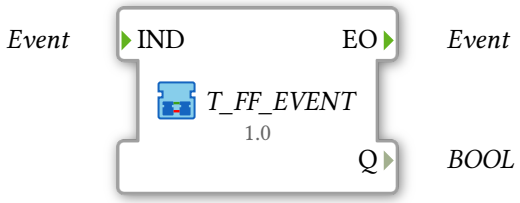
`SwitchPic_5_3` switches a VT picture between 5 states (slide-valve animation) based on an `iSTATE` value — on three independent targets at once: a regular softkey object (`Picture`), an AUX object (`PictureA`), and a second regular button object (`PictureB`), each with its own object ID.

For the general pattern, see SwitchPic(Col) Blocks (shared pattern).

Initialization and quality: `INIT` ⟶ `F_MOVE.REQ`; `F_MOVE.CNF` ⟶ `Q_NumericValue.INIT` ⟶ `Q_NumericValueAux.INIT` ⟶ `Q_NumericValue_B.INIT` (each via `INITO`); `Q_NumericValue_B.INITO` ⟶ `INITO`. New are `QI` (`BOOL`, default `TRUE`), which goes to all three `Q_NumericValue` instances, and `QO` (`BOOL`): `AND` (`AND_QO`, `AND_BOOL_3`) of the three `QO` outputs. `AND_QO.REQ` is triggered via `E_MERGE_QO` (`E_MERGE_4`: `Q_NumericValue_B.INITO`, `Q_NumericValue.CNF`, `Q_NumericValueAux.CNF`, `Q_NumericValue_B.CNF`).



Summary



5-state counterpart to `SwitchPic_2_3` — the most extensive variant in the `SwitchPic_5_*` series.

🌐 Related topic subpages on ms-muc-docs.de

T_FF_EVENT

• – ○ • – ○ • – ○ •

Introduction

T_FF_EVENT is a generic toggle flip-flop subapplication implemented by combining an `E_SWITCH` and an `E_SR` function block. It provides a simple, event-driven mechanism where every activation of the `IND` event input toggles the boolean output `Q`. A corresponding `EO` event is emitted whenever the state changes, making the block suitable for edge detection and state-based control logic. The subapplication is fully generic and does not depend on any specific hardware platform.

Interface Structure

Event Inputs

Name	Type	Description

IND	Event	Input event that triggers the toggle operation. Each occurrence of this event flips the internal state and updates Q.

Event Outputs

Name	Type	Description
EO	Event	Output event fired after the internal state has changed. It signals that a toggle has occurred and Q has been updated.

Data Inputs

No data inputs are available for this subapplication.

Data Outputs

Name	Type	Description
Q	BOOL	Current state of the toggle flip-flop. It alternates between FALSE and TRUE with each IND event.

Adapters

No adapters are present in this subapplication.

Functionality

The internal network consists of an E_SWITCH block (named E_SWITCH_I1) and an E_SR block (named E_SR_I1), interconnected as follows:

1. The incoming IND event is routed to the EI input of E_SWITCH_I1.
2. The G (gate) input of E_SWITCH_I1 is driven by the current output Q of E_SR_I1.
3. When IND occurs, E_SWITCH_I1 evaluates its gate:
   - If G = FALSE (i.e., Q = FALSE), it issues an event on output EO0, which is connected to the S (set) input of E_SR_I1. This sets Q to TRUE.
   - If G = TRUE (i.e., Q = TRUE), it issues an event on output EO1, which is connected to the R (reset) input of E_SR_I1. This resets Q to FALSE.
4. After the state change, E_SR_I1 emits its EO output event, which is forwarded to the subapplication's EO output.

Thus, every IND event flips the state of Q, and the EO event confirms that the toggle has been completed.

Technical Features

- **Event-driven toggle**: The flip-flop changes state only when an IND event is received, not on a continuous level signal.
- **Generic implementation**: Built from standard IEC 61499 function blocks (E_SWITCH and E_SR), which are part of the basic event function block library.
- **No hardware dependency**: The logic is purely algorithmic and can be applied in any IEC 61499 runtime environment.
- **Single output**: The only data output is the boolean state Q, while the EO event provides a change notification.
- **No data inputs**: The subapplication requires no configuration parameters or external data to operate.

State Overview

The toggle flip-flop has two stable states, determined by the output Q:

State	Q Value	Description
OFF (Reset)	FALSE	Initial state. The next IND event will set Q to TRUE.
ON (Set)	TRUE	Toggled state. The next IND event will reset Q to FALSE.

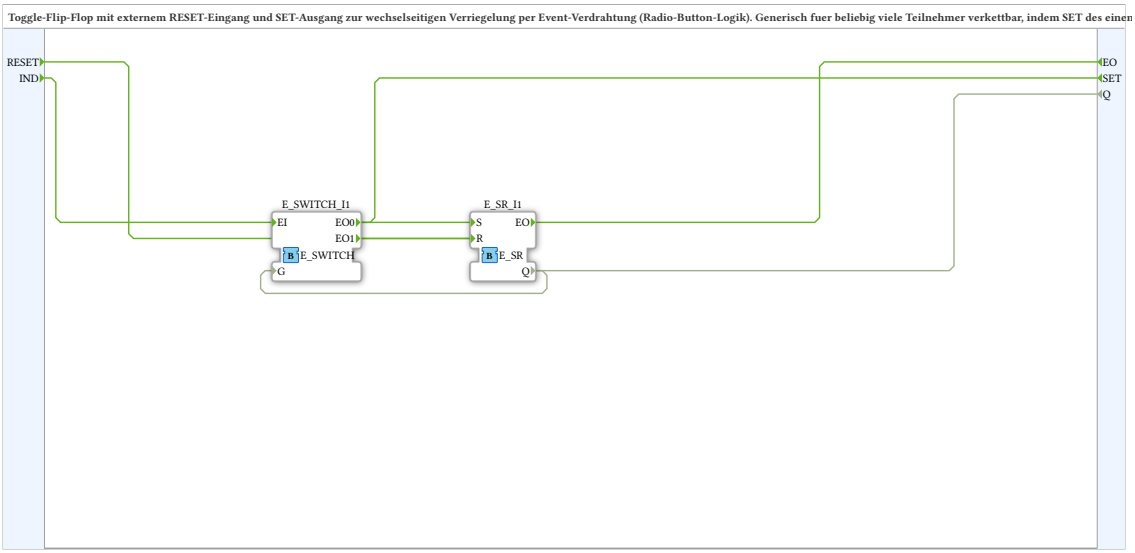
The transition between states is strictly sequential: each IND event moves the block from one state to the other, and EO is emitted on every transition. There is no hold, debounce, or delay logic inside the block; the toggle is immediate and synchronous with the input event.

Application Scenarios

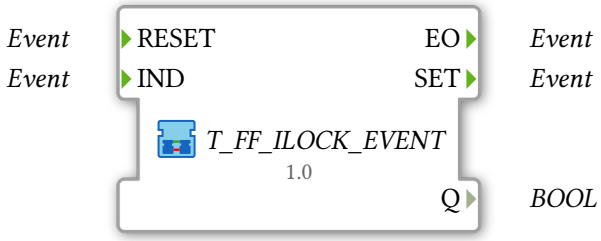
T_FF_EVENT is well suited for a variety of use cases where a binary state must be toggled by an event signal:

- **Push-button toggling**: Turning a light or actuator on and off with a momentary pushbutton, where each press generates an `IND` event.
- **Mode switching**: Alternating between two operating modes (e.g., automatic/manual) in a control application.
- **Edge detection and reporting**: Using `EO` to notify other parts of the system that the state has changed, e.g., to trigger logging or further processing.
- **State-based sequencing**: As a building block in larger subapplications where a binary flag needs to be inverted under event control.

Because the block is generic and hardware-independent, it can be reused across different projects, from simple logic exercises to industrial control systems.



Comparison with Similar Blocks



- **E_SR / E_RS (Set-Reset flip-flops)**: These blocks require two separate event inputs (`S` and `R`, or `R` and `S`) to set or reset the output. T_FF_EVENT is different because it requires only a single event input and automatically alternates between set and reset. It is equivalent to an E_SR with its set/reset inputs fed from an E_SWITCH controlled by its own output.
- **SR (data-level flip-flop)**: A standard SR latch uses level signals rather than events. T_FF_EVENT is event-driven and has no data input, so it cannot be forced to a particular state from outside; it always toggles from its current state.
- **T-flip-flop (binary counter)**: A classic T-flip-flop toggles on each active clock edge. T_FF_EVENT implements exactly this behavior using IEC 61499 events, but without a separate clock input; the `IND` event itself acts as the toggle trigger.

Conclusion

T_FF_EVENT is a compact and reusable subapplication that provides a simple toggle behavior with an event output for change notification. By combining an `E_SWITCH` and an `E_SR` in a feedback configuration, it achieves a clean, edge-triggered toggle flip-flop without external dependencies. Its generic design, minimal interface, and clearly defined state behavior make it an ideal building block for event-driven control systems, batch processing, and state management applications.

T_FF_ILOCK_EVENT

• – ◦ • – ◦ • – ◦ •

Introduction

T_FF_ILOCK_EVENT is a reusable IEC 61499 subapplication that implements an event-driven toggle flip-flop with an external reset input and a dedicated SET output for interlocking. It is designed for radio-button style mutual exclusion: when one instance becomes active, its SET event can be connected to the RESET input of another instance. Multiple instances can be chained this way to form an interlocked group.

Interface Structure

Event Inputs

Name	Type	Description
IND	Event	Toggle trigger. Each event toggles the internal state Q.
RESET	Event	Forces Q to FALSE and produces EO.

Event Outputs

Name	Type	Description
EO	Event	Acknowledgment output after an IND or RESET event has been processed.
SET	Event	Emitted only when Q changes from FALSE to TRUE; used to reset other participants.

Data Inputs

This subapplication has no data inputs.

Data Outputs

Name	Type	Description
Q	BOOL	Current state. TRUE means the participant is active.

Adapters

This subapplication exposes no adapters.

Functionality

Internally, T_FF_ILOCK_EVENT uses an E_SR flip-flop and an E_SWITCH event router.

When an IND event arrives, E_SWITCH uses the current state Q to decide whether to set or reset the internal flip-flop:

- If Q = FALSE, the event is routed to the Set input of E_SR. Q becomes TRUE and the SET output is emitted.
- If Q = TRUE, the event is routed to the Reset input of E_SR. Q becomes FALSE and no SET output is emitted.

The external RESET event is connected directly to the Reset input of E_SR. This allows an external event, or the SET output of another participant, to force the block into the inactive state.

After every accepted IND or RESET event, the EO output is emitted.

Technical Features

- Pure event-driven operation; no polling or cyclic execution is required.
- Uses only standard IEC 61499 event and data connections.
- One BOOL output Q for state indication.
- SET output provides a clean pulse for interlocking or resetting other participants.
- RESET input supports master reset and daisy-chain interlocking.
- No data inputs, so no additional configuration is required.
- Scales to any number of participants by connecting SET of one instance to RESET of the next.

State Overview

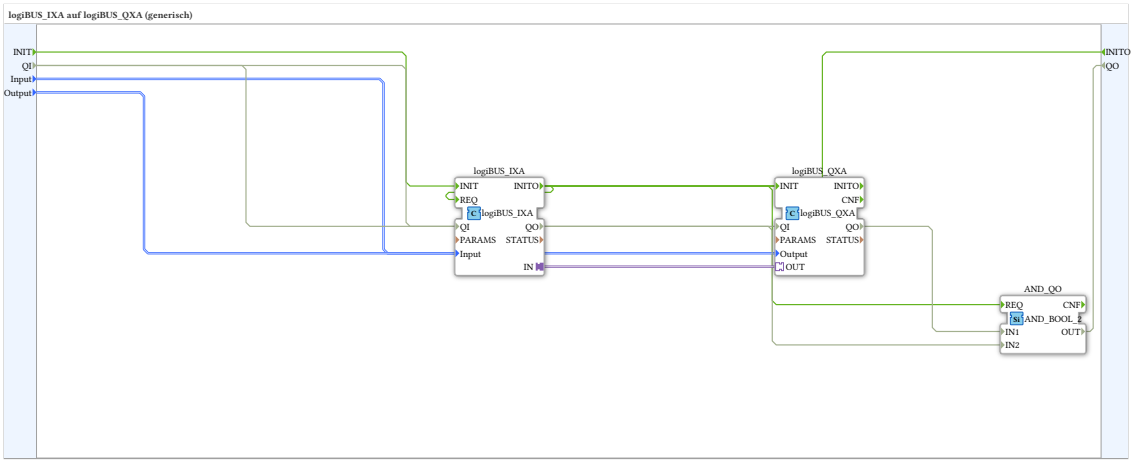
Current Q	Event	Resulting Q	Output Events
FALSE	IND	TRUE	SET, EO
TRUE	IND	FALSE	EO
FALSE	RESET	FALSE	EO
TRUE	RESET	FALSE	EO

This behavior creates a toggle switch: each IND toggles the local state, while RESET guarantees a defined inactive state.

Application Scenarios

- **Radio-button control groups:** Selecting a new participant automatically deselects the previously active one by connecting SET to the previous participant's RESET.
- **Exclusive modes in machines:** Use one instance per mode, e.g. Auto, Manual, Setup, and chain the SET outputs to the other RESET inputs.
- **Toggle pushbuttons:** Use IND from a button to create a latching toggle output, with RESET available for emergency off or master reset.
- **Multi-station interlocking:** Chain any number of instances for arbitration between stations, recipes, or active states.

Comparison with Similar Blocks

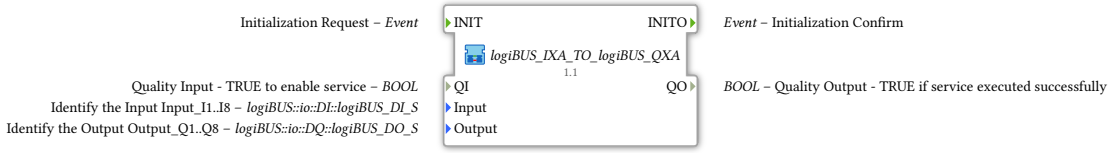


- **E_SR:** A plain set/reset flip-flop requires separate set and reset events. It has no toggle behavior and no interlocking SET output.
- **E_SWITCH:** Routes events based on a selector input but has no memory and cannot store the selected state.
- **A generic T-FF:** Toggles on each input event, but does not provide a dedicated SET output, external reset support, or event-based interlocking convenience.

T_FF_ILOCK_EVENT combines the memory of an E_SR with the routing capability of an E_SWITCH and adds an interlock-oriented SET output, making it especially suitable for event-based radio-button logic.

Conclusion

T_FF_ILOCK_EVENT is a compact, reusable, event-driven interlock subapplication. It provides toggle behavior, external reset, state output, and a SET pulse for daisy-chaining mutual exclusion groups. Because it requires no data inputs and no additional wiring logic, it can be used consistently in HMI panels, control applications, and multi-station systems.



logiBUS_IXA_TO_logiBUS_QXA

• – ○ • – ○ • – ○ •

Introduction

`logiBUS_IXA_TO_logiBUS_QXA` wires a physical digital input (`logiBUS_IXA`) directly to a physical digital output (`logiBUS_QXA`) — a pure hardware pass-through with no VT involvement, adapter-based (acyclic with confirmation, `QI` comes from the input `QI`). For the event-driven variant without an adapter, see `logiBUS_IX_TO_logiBUS_QX`.

Function Blocks Used

Sub-blocks: logiBUS_IXA_TO_logiBUS_QXA

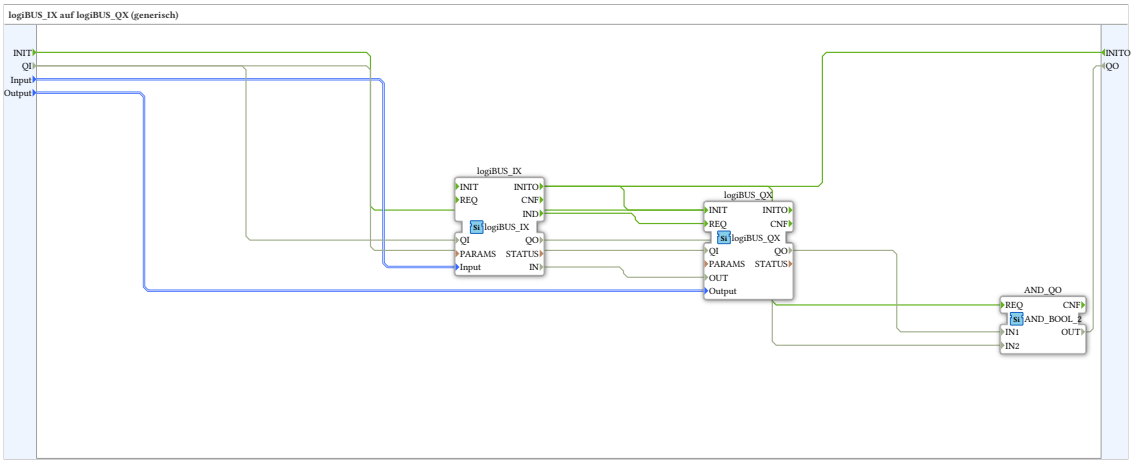
- **Type**: SubAppType
- **Internal FBs used**:
  - **logiBUS_IXA**: `logiBUS::io::DI::logiBUS_IXA` — physical digital input, adapter output `IN`, `QI` comes from the input `QI`.
  - **logiBUS_QXA**: `logiBUS::io::DQ::logiBUS_QXA` — physical digital output, adapter input `OUT`, `QI` comes from the input `QI`.
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` — combines `logiBUS_QXA.QO` and `logiBUS_IXA.QO` into the output `QO`.
- **Operation**: The input's adapter output is wired directly to the output's adapter input — no intermediate logic, no VT connection. The SubApp interface additionally has the events `INIT`/`INITO` as well as `QI` (BOOL, initial value `TRUE`) and `QO` (BOOL).

Program Flow and Connections

1. `Input` ⟶ `logiBUS_IXA.Input`; `Output` ⟶ `logiBUS_QXA.Output`.
2. `logiBUS_IXA.IN` (adapter) ⟶ `logiBUS_QXA.OUT` (adapter) — direct pass-through.
3. Initialization chain: `INIT` ⟶ `logiBUS_QXA.INIT`, `logiBUS_QXA.INITO` ⟶ `logiBUS_IXA.INIT`, `logiBUS_IXA.INITO` ⟶ `INITO` and `AND_QO.REQ` (in addition `logiBUS_IXA.INITO` ⟶ `logiBUS_IXA.REQ`).
4. Quality: `QI` ⟶ `logiBUS_QXA.QI` and `logiBUS_IXA.QI`; `logiBUS_QXA.QO` ⟶ `AND_QO.IN1`; `logiBUS_IXA.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ `QO`.

Application Scenarios

- Pure hardware-to-hardware wiring, e.g. for a physical emergency-stop contact or a fixed interlock that must work independently of the VT.



Summary

Adapter-based direct wiring of a physical input to a physical output, with no VT or event logic.

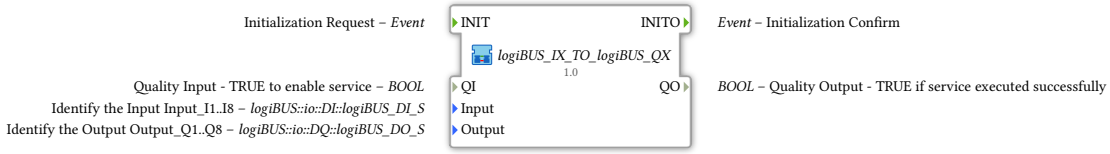
- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



logiBUS_IX_TO_logiBUS_QX

• – ○ • – ○ • – ○ •

Introduction

`logiBUS_IX_TO_logiBUS_QX` wires a physical digital input (`logiBUS_IX`) directly to a physical digital output (`logiBUS_QX`) — functionally equivalent to `logiBUS_IXA_TO_logiBUS_QXA`, but using the non-adapter-based `logiBUS_IX`/`logiBUS_QX` variants: the connection is made via an explicit event connection plus a data connection instead of an adapter.

Function Blocks Used

Sub-blocks: logiBUS_IX_TO_logiBUS_QX

- **Type**: SubAppType
- **Internal FBs used**:
  - **logiBUS_IX**: `logiBUS::io::DI::logiBUS_IX` — physical digital input, fires `IND` on state change.
  - **logiBUS_QX**: `logiBUS::io::DQ::logiBUS_QX` — physical digital output, driven via `REQ`.
  - **AND_QO**: `iec61131::booleanOperators::AND_BOOL_2` — combines the `QO` of `logiBUS_QX` and `logiBUS_IX`.
- **Operation**: The input event `IND` directly triggers `REQ` on the output; the current state is passed through in parallel via a data connection from `IN` to `OUT`.

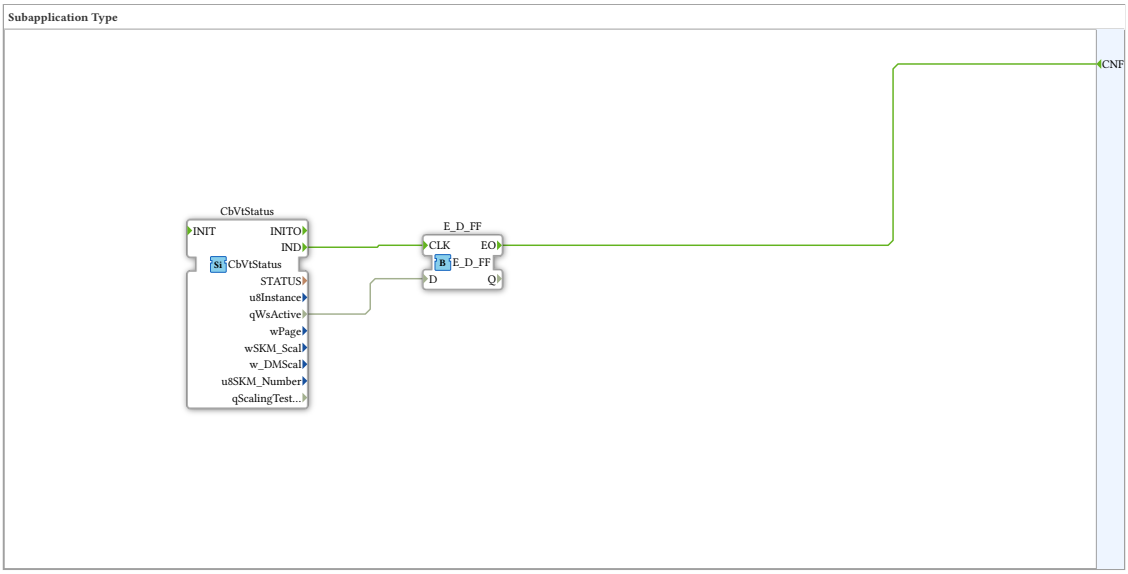
Program Flow and Connections

1. `Input` ⟶ `logiBUS_IX.Input`; `Output` ⟶ `logiBUS_QX.Output`.
2. `logiBUS_IX.IND` ⟶ `logiBUS_QX.REQ` (event connection).
3. `logiBUS_IX.IN` ⟶ `logiBUS_QX.OUT` (data connection).
4. Initialization: event input `INIT` ⟶ `logiBUS_QX.INIT`, `logiBUS_QX.INITO` ⟶ `logiBUS_IX.INIT`, `logiBUS_IX.INITO` ⟶ event output `INITO` and ⟶ `AND_QO.REQ`.
5. Quality: data input `QI` (`BOOL`, default `TRUE`) ⟶ `logiBUS_QX.QI` and `logiBUS_IX.QI`; `logiBUS_QX.QO` ⟶ `AND_QO.IN1`, `logiBUS_IX.QO` ⟶ `AND_QO.IN2`; `AND_QO.OUT` ⟶ data output `QO`.

Application Scenarios

- Hardware-to-hardware pass-through in training systems that (unlike `test_AX`) rely on the non-adapter-based I/O blocks `logiBUS_IX`/`logiBUS_QX`.

Summary



Non-adapter-based counterpart to `logiBUS_IXA_TO_logiBUS_QXA`: same function, explicit event/data connection instead of adapter coupling.

page

Event – Execution Confirmation

• – ○ • – ○ • – ○ •

Introduction

The `page` subapplication is a compact IEC 61499 composite type that encapsulates an ISOBUS status monitoring block together with an event-triggered D flip-flop. It exposes a single event output `CNF` and provides no external data interface. Internally, the subapplication uses the `CbVtStatus` block from the ISOBUS UT status library to detect a status indication and the standard `E_D_FF` block to sample a boolean value at exactly the moment the indication occurs.

Interface Structure

The subapplication interface is intentionally minimal: it only exposes one event output. All data and event processing is done inside the encapsulated network.

Event Inputs

- None

Event Outputs

- `CNF` : Execution Confirmation
  This event is emitted after the internal event chain has been completed. It confirms that the status indication has been processed and the associated boolean value has been latched.

Data Inputs

- None

Data Outputs

- None

Adapters

- None

Functionality

Internally, the subapplication contains two function blocks:

1. `CbVtStatus` of type `isobus::UT::status::CbVtStatus`
   This block monitors an ISOBUS UT status condition. When a status indication occurs, it produces the event `IND`. It also provides the boolean data output `qWsActive`, which represents the current working-set-active state.
2. `E_D_FF` of type `iec61499::events::E_D_FF`
   This is an event-triggered D flip-flop. It uses the event input `CLK` to sample the boolean value present at its data input `D`. When the clock event occurs, the flip-flop latches the value of `D` and emits the event output `EO`.

The internal connections perform the following task:

- `CbVtStatus.IND` is connected to `E_D_FF.CLK`, so every status indication triggers the flip-flop.
- `CbVtStatus.qWsActive` is connected to `E_D_FF.D`, so the current working-set-active value is used as the data input.
- `E_D_FF.EO` is connected to the subapplication output `CNF`, so the confirmation event is emitted after the value has been latched.

In effect, the subapplication captures the boolean status value exactly at the time of the indication and produces a confirmation event for the surrounding application.

Technical Features

- Encapsulated subapplication with no exposed event or data inputs.
- Single event output `CNF` for handshake-based integration.
- Internal event flow: `CbVtStatus.IND` ⟶ `E_D_FF.CLK` ⟶ `E_D_FF.EO` ⟶ `CNF`.
- Internal data flow: `CbVtStatus.qWsActive` ⟶ `E_D_FF.D`.
- Uses standard IEC 61499 components from the `iec61499::events` library.
- Uses an ISOBUS-specific status block from the `isobus::UT::status` library.
- The externally visible behavior is event-driven and synchronous: one status indication results in one confirmation event.

State Overview

The internal `E_D_FF` block can be considered as having two stable states:

State	Latched Value	Description
Reset	`false`	`qWsActive` was `false` at the last `CLK` event
Set	`true`	`qWsActive` was `true` at the last `CLK` event

The state is held internally and is not exposed through the subapplication data interface. The only visible effect is that each `CLK` event causes the `EO` event to be emitted, which is forwarded as `CNF`.

Application Scenarios

This subapplication is suitable for event-driven ISOBUS applications where the controller must be informed whenever a VT status indication occurs. Typical use cases include:

- Monitoring the working-set-active status of an ISOBUS Universal Terminal.
- Capturing a boolean status value at a precise event boundary.
- Generating a confirmation event for use in a larger function block network.
- Synchronizing status evaluation with downstream event-triggered logic.

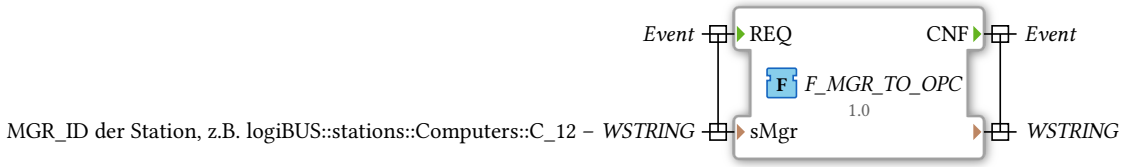
Because the subapplication exposes only a confirmation event, it can be integrated cleanly into systems where data transfer is not required or where the status value is evaluated further inside another composite block.

Comparison with Similar Blocks

Compared with a simple direct connection from `CbVtStatus.IND` to the subapplication output, this subapplication additionally samples and latches the `qWsActive` data value. That makes the captured state stable and independent of later changes to `qWsActive`.

Compared with an `E_RS_FF`-based solution, the `E_D_FF` approach uses a data input to define the next state instead of separate set and reset event paths. This is better suited for situations where the state should follow a sampled boolean signal.

Compared with a pure combinatorial event-forwarding block, the internal flip-flop ensures that the data value is consistent with the event that triggered the confirmation.



Conclusion

The `page` subapplication is a small but useful reusable component. It combines ISOBUS VT status indication with a D-type event latch to provide a single confirmation event. Its minimal interface makes it easy to embed in larger 4diac applications, while the internal flip-flop guarantees that the associated boolean value is captured at the correct moment.

2.1.7 MyLib_OPC

- F_MGR_TO_OPC
- F_OPC_LOCAL
- F_OPC_REMOTE

2.1.7.1 F_MGR_TO_OPC: Function (IEC 61499 Function)

• – ◦ • – ◦ • – ◦ •

Introduction

`F_MGR_TO_OPC` is not a SubApp but a function type (`.fct`, standard 61499-1) in the package `MyLib_OPC` with the comment “OPC-UA endpoint from MGR_ID: 192.168.1.12:61499 -> opc.tcp:

Function Interface

Instance	Type	Parameters	Explanation
`REQ`	`Event (event input)`	`With = sMgr`	Execution request.
`CNF`	`Event (event output)`	`With` = (unnamed variable)	Confirmation; delivers the return value.
`sMgr`	`WSTRING (input variable)`	- constant (`logiBUS::stations::Computers::C_12` has the value `"192.168.1.12:61499"`).	MGR_ID of the station in the format `host:port`, e.g. `"192.168.1.12:61499"`. This is the value of a station
(unnamed)	`WSTRING (output variable)`	-	Return value `F_MGR_TO_OPC` (empty output name).

Program Flow and Connections

The body is written in Structured Text:

```
PACKAGE MyLib_OPC;

(* OPC-UA-Endpunkt aus MGR_ID: 192.168.1.12:61499 -> opc.tcp://192.168.1.12:4840 *)
FUNCTION F_MGR_TO_OPC : WSTRING

VAR_INPUT
    sMgr : WSTRING; // MGR_ID der Station, z.B. logiBUS::stations::Computers::C_12
END_VAR

F_MGR_TO_OPC := CONCAT("opc.tcp://", LEFT(sMgr, FIND(sMgr, ":")), "4840");

END_FUNCTION
```

Note: The source comment `// MGR_ID der Station, z.B. logiBUS::stations::Computers::C_12` names the station constant. `sMgr` receives its value in the format `host:port` (here `"192.168.1.12:61499"`); a hierarchical name without a colon would not give a valid endpoint.

1. `FIND(sMgr, ":")` returns the position of the first colon.
2. `LEFT(sMgr, ...)` cuts the text up to and including this colon (`192.168.1.12:`); the MGR port `61499` is dropped.
3. `CONCAT` joins `opc.tcp://`, this part and the fixed OPC-UA port `4840`.

Example

Call and result:

```
MyLib_OPC::F_MGR_TO_OPC("192.168.1.12:61499")  ->  opc.tcp://192.168.1.12:4840
```

Usage

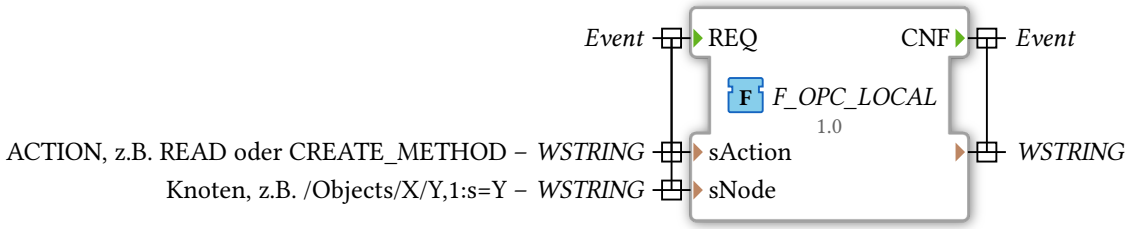
Used in `myOpcUaAddresses.gcf` (project `test_VV`, folder `const/OPC_UA`, described in `OPC_UA_Adressen.md`) as the `InitialValue` of a WSTRING constant:

```
InitialValue="MyLib_OPC::F_MGR_TO_OPC(PC_A)"
```

`PC_A_OPC` and `PC_B_OPC` get the OPC-UA endpoint of the respective station via `MyLib_OPC::F_MGR_TO_OPC(PC_A)` and `MyLib_OPC::F_MGR_TO_OPC(PC_B)`.

The expression is evaluated at export time; the boot file therefore contains only the finished strings, no function calls.

Note: The arguments must be constants (literals or other constants of the `.gcf`), because evaluation happens at export time, not at runtime.



Summary

`F_MGR_TO_OPC` is a small IEC 61499 function of the library `MyLib_OPC` that derives the OPC-UA endpoint from a MGR_ID.

2.1.7.2 F_OPC_LOCAL: Function (IEC 61499 Function)

• – ◦ • – ◦ • – ◦ •

Introduction

F_OPC_LOCAL is not a SubApp but a function type (.fct, standard 61499-1) in the package MyLib_OPC with the comment "OPC-UA ID for a local node: opc_ua[ACTION;NODE]". It has one event input REQ, one event output CNF and a Structured Text body; there are no function block instances and no connections.

Function Interface

Instance	Type	Parameters	Explanation
REQ	Event (event input)	With = sAction, sNode	Execution request.
CNF	Event (event output)	With = (unnamed variable)	Confirmation; delivers the return value.
sAction	WSTRING (input variable)	-	ACTION, e.g. READ or CREATE_METHOD
sNode	WSTRING (input variable)	-	Node, e.g. /Objects/X/Y,1:s=Y
(unnamed)	WSTRING (output variable)	-	Return value F_OPC_LOCAL (empty output name).

Program Flow and Connections

The body is written in Structured Text:

```
PACKAGE MyLib_OPC;

(* OPC-UA-ID fuer einen lokalen Knoten: opc_ua[ACTION;NODE] *)
FUNCTION F_OPC_LOCAL : WSTRING

VAR_INPUT
    sAction : WSTRING; // ACTION, z.B. READ oder CREATE_METHOD
    sNode : WSTRING; // Knoten, z.B. /Objects/X/Y,1:s=Y
END_VAR

F_OPC_LOCAL := CONCAT("opc_ua[", sAction, ";", sNode, "]");

END_FUNCTION
```

1. CONCAT joins opc_ua[, sAction, ;, sNode and].

Example

Call and result:

```
MyLib_OPC::F_OPC_LOCAL("READ", "/Objects/X/Y,1:s=Y")  ->  opc_ua[READ;/Objects/X/
Y,1:s=Y]
```

Usage

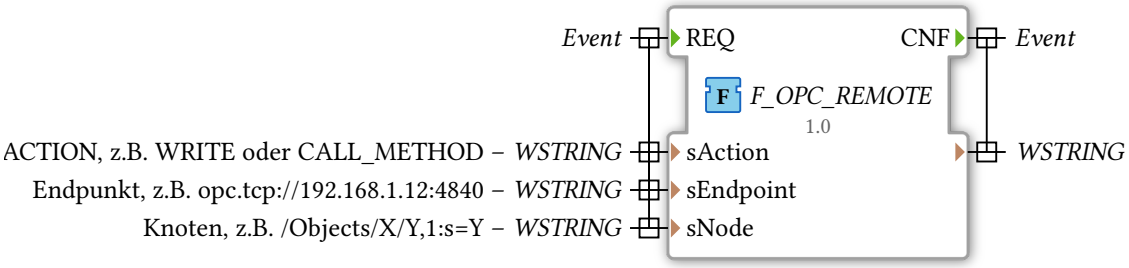
Used in myOpcUaAddresses.gcf (project test_VV, folder const/OPC_UA, described in OPC_UA_Adressen.md) as the InitialValue of a WSTRING constant:

```
InitialValue="MyLib_OPC::F_OPC_LOCAL(&amp;quot;READ&amp;quot;, Q1_NODE)"
```

Q1_LOCAL_READ and FF1_TRIGGER_LOCAL_METHOD (local on station B) use MyLib_OPC::F_OPC_LOCAL("READ", Q1_NODE) and MyLib_OPC::F_OPC_LOCAL("CREATE_METHOD", FF1_TRIGGER_NODE).

The expression is evaluated at export time; the boot file therefore contains only the finished strings, no function calls.

Note: The arguments must be constants (literals or other constants of the .gcf), because evaluation happens at export time, not at runtime.



Summary

F_OPC_LOCAL is a small IEC 61499 function of the library MyLib_OPC that assembles the OPC-UA ID for a local node.

2.1.7.3 F_OPC_REMOTE: Function (IEC 61499 Function)

• – ◦ • – ◦ • – ◦ •

Introduction

`F_OPC_REMOTE` is not a SubApp but a function type (`.fct`, standard 61499-1) in the package `MyLib_OPC` with the comment "OPC-UA ID for a node on another station: opc_ua[ACTION;ENDPOINT#;NODE]". It has one event input `REQ`, one event output `CNF` and a Structured Text body; there are no function block instances and no connections.

Function Interface

Instance	Type	Parameters	Explanation
`REQ`	`Event (event input)`	`With = sAction, sEndpoint, sNode`	Execution request.
`CNF`	`Event (event output)`	`With` = (unnamed variable)	Confirmation; delivers the return value.
`sAction`	`WSTRING (input variable)`	-	ACTION, e.g. `WRITE` or `CALL_METHOD`
`sEndpoint`	`WSTRING (input variable)`	-	Endpoint, e.g. `opc.tcp://192.168.1.12:4840`
`sNode`	`WSTRING (input variable)`	-	Node, e.g. `/Objects/X/Y,1:s=Y`
(unnamed)	`WSTRING (output variable)`	-	Return value `F_OPC_REMOTE` (empty output name).

Program Flow and Connections

The body is written in Structured Text:

```
PACKAGE MyLib_OPC;

(* OPC-UA-ID fuer einen Knoten auf einer anderen Station: opc_ua[ACTION;ENDPOINT#;NODE]
*)
FUNCTION F_OPC_REMOTE : WSTRING

VAR_INPUT
    sAction : WSTRING; // ACTION, z.B. WRITE oder CALL_METHOD
    sEndpoint : WSTRING; // Endpunkt, z.B. opc.tcp://192.168.1.12:4840
    sNode : WSTRING; // Knoten, z.B. /Objects/X/Y,1:s=Y
END_VAR

F_OPC_REMOTE := CONCAT("opc_ua[", sAction, ";", sEndpoint, "#;", sNode, "]");

END_FUNCTION
```

1. `CONCAT` joins `opc_ua[`, `sAction`, `;`, `sEndpoint`, `#;`, `sNode` and `]`; the `#` terminates the endpoint.

Example

Call and result:

```
MyLib_OPC::F_OPC_REMOTE("WRITE", "opc.tcp://192.168.1.12:4840", "/Objects/X/Y,1:s=Y")  -
>  opc_ua[WRITE;opc.tcp://192.168.1.12:4840#;/Objects/X/Y,1:s=Y]
```

Usage

Used in `myOpcUaAddresses.gcf` (project `test_VV`, folder `const/OPC_UA`, described in `OPC_UA_Adressen.md`) as the `InitialValue` of a WSTRING constant:
`InitialValue="MyLib_OPC::F_OPC_REMOTE("WRITE", PC_B_OPC, Q1_NODE)"`
`Q1_REMOTE_WRITE` (station A writes to station B) uses `MyLib_OPC::F_OPC_REMOTE("WRITE", PC_B_OPC, Q1_NODE)`; the endpoint `PC_B_OPC` comes from `F_MGR_TO_OPC`.

The expression is evaluated at export time; the boot file therefore contains only the finished strings, no function calls.

Note: The arguments must be constants (literals or other constants of the `.gcf`), because evaluation happens at export time, not at runtime.

Summary

`F_OPC_REMOTE` is a small IEC 61499 function of the library `MyLib_OPC` that assembles the OPC-UA ID for a node on another station.

CTRL_OUT

Control Output with Limit and Manual Override CTRL_OUT adds to the CI input the value of OFFSET and returns the result to Y if MANUAL = FALSE. If MANUAL is TRUE at output Y the input value of MAN_IN + OFFSET is issued. Y is always limited to the boundaries defined by LIM_L and LIM_H. If Y reaches one of the limits, then the output LIM is TRUE. CTRL_OUT can be used to build your own rule modules.

CTRL_PI

FT_PI is a PI controller with manual functionality. version 2.0 June 30, 2008 programmer hugo tested by oscat The PID controller works according to the fomula Y = e *(KP+ KI * INTEG(e)) + offset, while e = set_point - actual. a rst will reset all internal data, while a switch to manual will cause the controller to follow the function Y = manual_in + offset. limit_h and Limit_l set the possible output range of Y. The output flags lim will signal that the output limits are active and overflow will signal that the integrator has reached its limits.

since rev 1.1 the “trapezoid rule is used for more accuracy. rev 1.2 added selective integratin which means the integrative component is only active within a small range of the target value this avoids the integrator to go to limits while an input setpoint change happened and is only causing overshoots. the int_band is by default 100 which means the int is active all the time and if set to for example to 0.1 the integrator is only active while the input is between 0.9 and 1.1 of the set_point value.

default values for KP = 1, TN = 1, TV = 1, LIMIT_L = −1000, LIMIT_H = +1000.

CTRL_PID_AR

• – ○ • – ○ • – ○ •

Introduction

`CTRL_PID_AR` is an AR adapter wrapper around the OSCAT PID controller `CTRL_PID` (`OSCAT::Basic::POUs::Engineering::Control::CTRL_PID`) and bridges between adapters and the OSCAT controller. Actual value, set point, manual switch, manual value, controller parameters as well as noise suppression, offset and limits are all implemented as adapter sockets - in the same order as the input variables of the wrapped `CTRL_PID`. No explicit `REQ` is needed, since each socket triggers `CTRL_PID.REQ` itself when a new value arrives.

Interface Structure

Event Inputs

- **RST**: Reset of the integrator (passed through to `CTRL_PID.RST`)

Event Outputs

No direct event outputs - events run via the adapter plugs

Data Inputs

No data inputs - all inputs are adapter sockets

Data Outputs

No data outputs - all outputs are adapter plugs

Adapters

Sockets (inputs); `E1` triggers `CTRL_PID.REQ`, `D1` supplies the value:

- **AR_ACT** (`AR`): Actual value (REAL)
- **SET** (`AR`): Set point (REAL, dynamically calculated)
- **SUP** (`AR`): Noise suppression (REAL, dynamic)
- **OFS** (`AR`): Offset (REAL, dynamic)
- **M_I** (`AR`): Manual value (REAL, dynamic)
- **AX_MAN** (`AX`): Manual mode switch (BOOL/event, optional)
- **KP** (`AR`): Proportional gain (REAL, dynamic)
- **TN** (`AR`): Integral time (REAL, dynamic)
- **TV** (`AR`): Derivative time (REAL, dynamic)
- **LL** (`AR`): Lower limit (REAL, dynamic)
- **LH** (`AR`): Upper limit (REAL, dynamic)

Plugs (outputs):

- **AR_Y** (`AR`): Control output (REAL)
- **AR_DIFF** (`AR`): Control error (`DIFF = SET - ACT`, REAL)
- **AB_LIM** (`AB`): Limit active flag (`LIM`, BOOL)

Function Blocks (FBs) Used

- **CTRL_PID**: `OSCAT::Basic::POUs::Engineering::Control::CTRL_PID`
- **E_D_FF_ANY**: `iec61499::events::E_D_FF_ANY_3` - 3-fold data latch for `Y`, `DIFF`, `LIM`

Program Flow and Connections

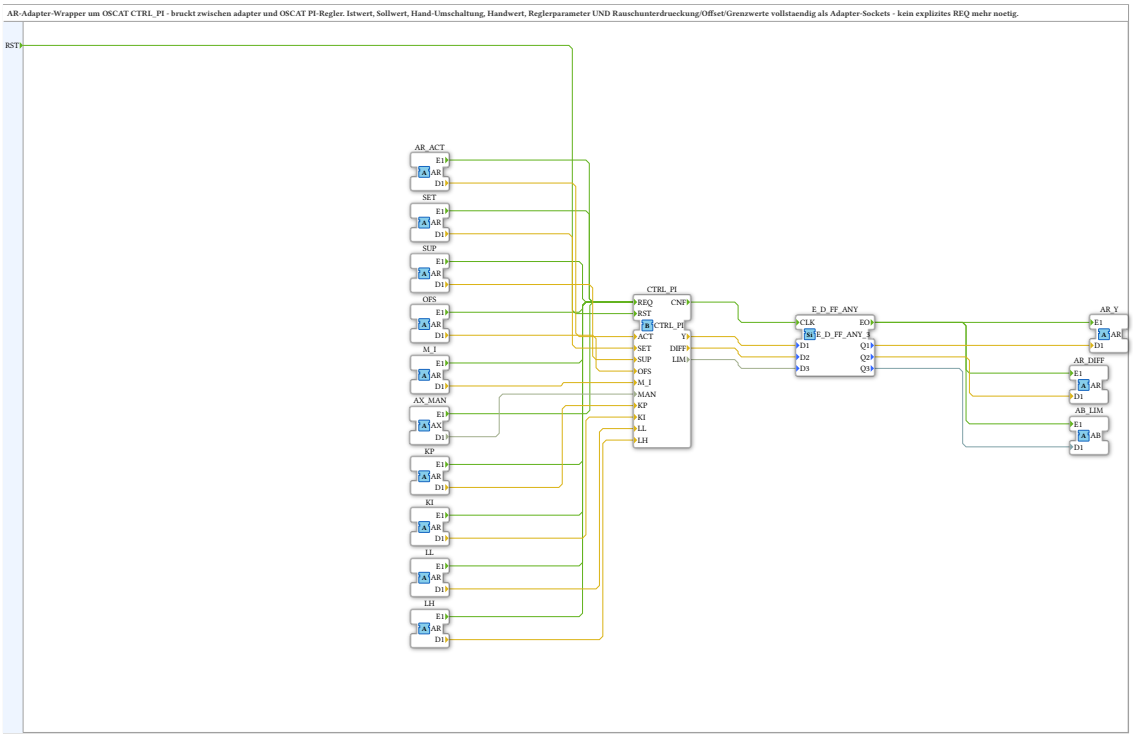
1. Every `E1` of the sockets `AR_ACT`, `SET`, `SUP`, `OFS`, `M_I`, `AX_MAN`, `KP`, `TN`, `TV`, `LL`, `LH` ⟶ `CTRL_PID.REQ`.
2. `D1` of the sockets ⟶ same-named input of `CTRL_PID` (`AR_ACT.D1` ⟶ `ACT`, `AX_MAN.D1` ⟶ `MAN`, otherwise identical names).
3. `RST` ⟶ `CTRL_PID.RST`.
4. `CTRL_PID.CNF` ⟶ `E_D_FF_ANY.CLK`; `CTRL_PID.Y/DIFF/LIM` ⟶ `E_D_FF_ANY.D1/D2/D3`.
5. `E_D_FF_ANY.EO` ⟶ `AR_Y.E1`, `AR_DIFF.E1`, `AB_LIM.E1`; `Q1/Q2/Q3` ⟶ `AR_Y.D1`, `AR_DIFF.D1`, `AB_LIM.D1`.

Technical Details

- The latch (`E_D_FF_ANY`) triggers the outputs only after the controller's `CNF`; there is no external `CNF` event any more.
- Each input socket triggers a calculation; if several values change simultaneously, multiple `REQ` occur.
- The sockets are sorted in the order of the `InputVars` of `CTRL_PID` (version 1.4).

Application Scenarios

- PID control in adapter networks, e.g. speed control of the pickup with a dynamically calculated set point and `AX_MAN` from an automatic/manual toggle

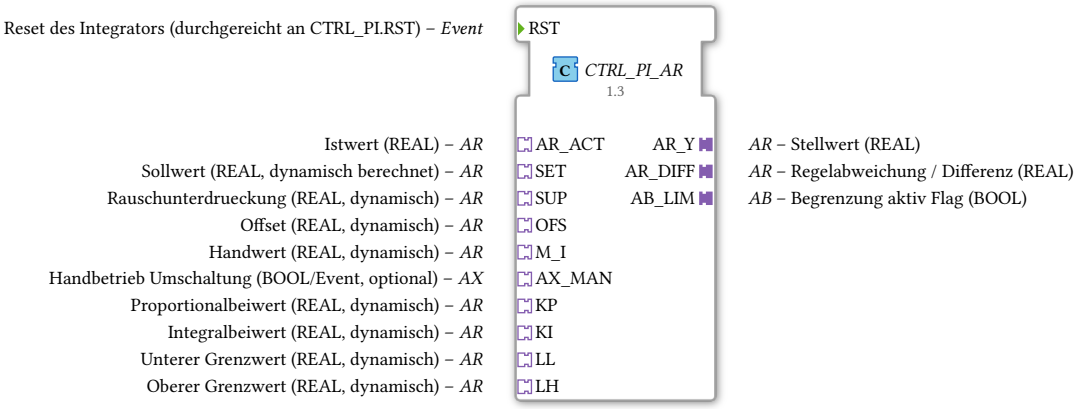


🛠️ Related Exercises

- Uebung_153_AX

Summary

`CTRL_PID_AR` connects the OSCAT PID controller entirely via AR/AX adapters, so that values flow only through adapter connections and no explicit `REQ` is needed.



CTRL_PI_AR

• – ○ • – ○ • – ○ •

Introduction

`CTRL_PI_AR` is an AR adapter wrapper around the OSCAT PI controller `OSCAT::Basic::POUs::Engineering::Control::CTRL_PI`. It bridges between adapters and OSCAT without either base library depending on the other. Actual value, set point, noise suppression, offset, manual value, manual mode switch, controller parameters and limits are all implemented as adapter sockets; an explicit `REQ` is no longer needed because every socket triggers the controller itself.

Interface Structure

Event Inputs

- **RST**: reset of the integrator (passed on to `CTRL_PI.RST`)

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AR_ACT** (socket, AR): actual value (REAL)
- **SET** (socket, AR): set point (REAL, dynamically calculated)
- **SUP** (socket, AR): noise suppression (REAL, dynamic)
- **OFS** (socket, AR): offset (REAL, dynamic)
- **M_I** (socket, AR): manual value (REAL, dynamic)
- **AX_MAN** (socket, AX): switch to manual mode (optional)
- **KP** (socket, AR): proportional gain (REAL, dynamic)
- **KI** (socket, AR): integral gain (REAL, dynamic)
- **LL** (socket, AR): lower limit (REAL, dynamic)
- **LH** (socket, AR): upper limit (REAL, dynamic)
- **AR_Y** (plug, AR): control output (REAL)
- **AR_DIFF** (plug, AR): control error `DIFF = SET - ACT` (REAL)
- **AB_LIM** (plug, AB): flag 'limiting active' (BOOL)

Functionality

The network consists of the controller `CTRL_PI` (`OSCAT::Basic::POUs::Engineering::Control::CTRL_PI`) and a change filter `E_D_FF_ANY` (`iec61499::events::E_D_FF_ANY_3`):

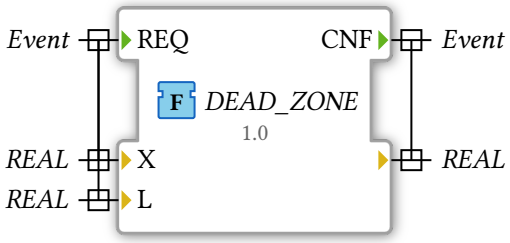
- **Triggering**: the event `E1` of every socket (`AR_ACT`, `SET`, `SUP`, `OFS`, `M_I`, `AX_MAN`, `KP`, `KI`, `LL`, `LH`) goes to `CTRL_PI.REQ`. `RST` goes to `CTRL_PI.RST`.
- **Data**: `AR_ACT.D1` ⟶ `ACT`, `SET.D1` ⟶ `SET`, `SUP.D1` ⟶ `SUP`, `OFS.D1` ⟶ `OFS`, `M_I.D1` ⟶ `M_I`, `AX_MAN.D1` ⟶ `MAN`, `KP.D1` ⟶ `KP`, `KI.D1` ⟶ `KI`, `LL.D1` ⟶ `LL`, `LH.D1` ⟶ `LH` of the controller.
- **Output**: `CTRL_PI.CNF` ⟶ `E_D_FF_ANY.CLK`; `CTRL_PI.Y`, `CTRL_PI.DIFF` and `CTRL_PI.LIM` go to `E_D_FF_ANY.D1..D3`. Only if at least one of the three values changes does `E_D_FF_ANY.EO` emit the event to `AR_Y.E1`, `AR_DIFF.E1` and `AB_LIM.E1`, and `Q1..Q3` go to `AR_Y.D1`, `AR_DIFF.D1` and `AB_LIM.D1`.

Technical Details

- The `CNF` event of the controller is now internal only (for the latch of `Y/DIFF/LIM`); there is no external `REQ/CNF` any more
- Every socket triggers the controller, so several controller runs are possible when several values arrive at the same time
- The sockets are sorted in the order of the `CTRL_PI` input variables: `AR_ACT`, `SET`, `SUP`, `OFS`, `M_I`, `AX_MAN`, `KP`, `KI`, `LL`, `LH`
- The adapter bridge resides in the library `OSCAT_adapter`, which depends on `adapter` and `OSCAT`; thus these two need not depend on each other

Application Scenarios

- PI control in purely adapter-based networks, e.g. speed or rotational speed control with a dynamically calculated set point
- Controllers whose parameters (KP, KI) and limits can be changed at runtime via VT/OPC-UA



🛠️ Related Exercises

- Uebung_152_AX

Conclusion

`CTRL_PI_AR` makes the OSCAT PI controller adapter-capable: all inputs and outputs are AR/AX/AB adapters, every input triggers the calculation, and results are output only on change.

FT_DERIV_10_AR

• – ○ • – ○ • – ○ •

Introduction

`FT_DERIV_10_AR` is an AR adapter wrapper around the OSCAT block `OSCAT::Basic::POUs::Engineering::Control::FT_DERIV_10` (derivative with a selectable window of 1 to 10 periods). It bridges adapters and OSCAT without either base library depending on the other. Compared to `FT_DERIV_AR`, the window `K` is a dynamic `AUI` adapter socket. `Faktor` and `run` remain plain input variables.

Interface Structure

Event Inputs

- **INIT** (`EInit`): Service initialization (passed through to `FT_DERIV_10.EINIT`)
- **REQ**: explicit execution request (passed through to `FT_DERIV_10.REQ`, in addition to `AR_IN.E1`/`K.E1`)
  - **Associated data**: `Faktor`, `run`
- **RST**: Reset of the derivative history (passed through to `FT_DERIV_10.RST`)

Event Outputs

- **INITO** (`EInit`): Initialization confirmation (from `FT_DERIV_10.INITO`)

Data Inputs

- **Faktor** (`REAL`, initial value `1.0`): Multiplication factor (passed through to `FT_DERIV_10.Faktor`)
- **run** (`BOOL`, initial value `TRUE`): Calculation active (passed through to `FT_DERIV_10.run`)

Data Outputs

None. All result values are output via adapter plugs.

Adapters

Interface	Direction	Adapter type	Data type	Description
AR_IN	Socket	AR	REAL	Input signal
K	Socket	AUI	UINT	Window select (dynamic): 0 = 1 period, 9 = 10 periods
AR_OUT	Plug	AR	REAL	Calculated derivative (FT_DERIV_10.out, based on K)
AR_DELTA_IN	Plug	AR	REAL	Input signal difference over 1 period (DI_0)
AUDI_DELTA_T	Plug	AUDI	UDINT	Time difference in microseconds over 1 period (DT_0)
AB_VALID	Plug	AB	BOOL	Measurement validity (FT_DERIV_10.valid)

Function Blocks (FBs) Used

- **FT_DERIV_10** (OSCAT::Basic::POUs::Engineering::Control::FT_DERIV_10): derivative calculation, see FT_DERIV_10
- **E_D_FF_ANY** (iec61499::events::E_D_FF_ANY_4): four-channel change filter/synchronisation of the results

How it works

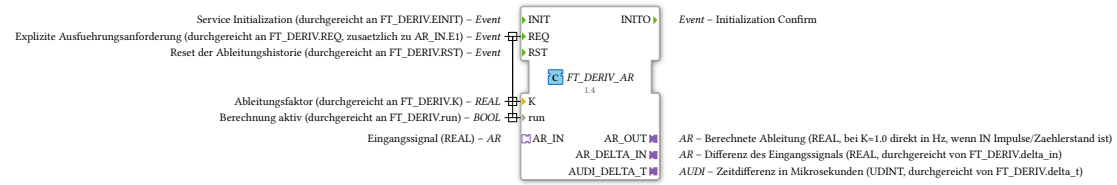
- AR_IN.E1, K.E1 and REQ all lead to FT_DERIV_10.REQ
- AR_IN.D1 → FT_DERIV_10.in; K.D1 → FT_DERIV_10.K; Faktor → FT_DERIV_10.Faktor; run → FT_DERIV_10.run
- INIT → FT_DERIV_10.EINIT; FT_DERIV_10.INITO → INITO; RST → FT_DERIV_10.RST
- FT_DERIV_10.CNF → E_D_FF_ANY.CLK; the results out, DT_0, DI_0, valid go to E_D_FF_ANY.D1 to D4
- E_D_FF_ANY.Q1...Q4 → AR_OUT.D1, AUDI_DELTA_T.D1, AR_DELTA_IN.D1, AB_VALID.D1; E_D_FF_ANY.EO triggers E1 of all four plugs

Technical Details

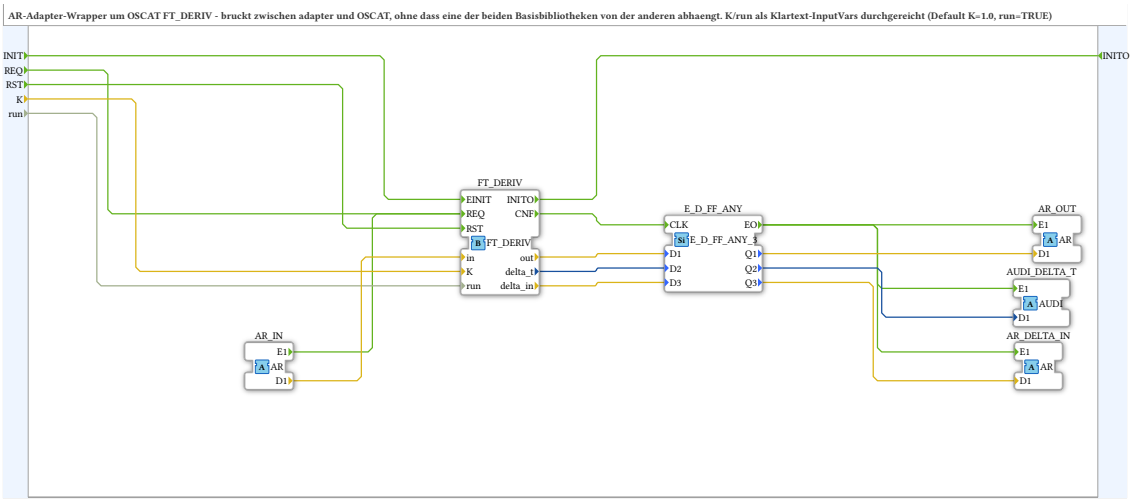
- **Pure adapter boundary**: All main outputs of FT_DERIV_10 are output as dedicated adapters; no plain event/data leaves the block (except INITO)
- **K as adapter** (version 1.2, 2026-10-03): K.E1 triggers a calculation just like AR_IN.E1, K.D1 supplies the value; K is therefore no longer bound to REQ via With
- **Explicit REQ** (version 1.1, 2026-09-20): bugfix so that Faktor and run are read reliably via a With binding (per IEC 61499, unbound variables are not read reliably); it also allows manual or periodic execution
- FT_DERIV_10 is a pure OSCAT function without an adapter interface; the bridge lives in the third library project OSCAT_adapter

Application Scenarios

- Frequency/speed calculation from a pulse counter value (AR_IN, e.g. from AD_TO_AR_NUM.AR_OUT) with a window selectable at runtime
- Passing the derivative on, e.g. to CTRL_PID_AR.AR_ACT



Summary



FT_DERIV_10_AR encapsulates FT_DERIV_10 behind a pure adapter interface with a dynamically selectable window K and provides derivative, input difference, time difference and validity as adapters.

FT_DERIV_AR

• — ○ • — ○ • — ○ •

Introduction

`FT_DERIV_AR` is an adapter wrapper around the OSCAT function block `OSCAT::Basic::POUs::Engineering::Control::FT_DERIV`. It provides a clean adapter-based interface for the derivative calculation so that the block can be used in subapplications that communicate through unidirectional `AR` / `AUDI` adapters.

The input signal is received through an `AR_IN` socket. The calculated derivative and the internal intermediate values are exposed through three adapter plugs. The configuration values `K` and `run` are kept as plain input variables so that they can be set as parameters when the block is instantiated.

The wrapper also solves a library-coupling problem: the generic `adapter` library and the `OSCAT` library can remain independent, while the bridge itself is encapsulated in a dedicated wrapper type.

Interface Structure

Event Inputs

Event	Type	Description
`INIT`	`EInit`	Initialization request; passed through to `FT_DERIV.EINIT`.
`RST`	`Event`	Resets the derivative history; passed through to `FT_DERIV.RST`.

Event Outputs

Event	Type	Description
`INITO`	`EInit`	Initialization confirmation; passed back from `FT_DERIV.INITO`.

Data Inputs

Name	Type	Initial Value	Description
`K`	`REAL`	`1.0`	Derivation factor; passed through to `FT_DERIV.K`.
`run`	`BOOL`	`TRUE`	Calculation enable; passed through to `FT_DERIV.run`.

Data Outputs

This block has no plain data outputs. All calculation results are exposed through adapter plugs.

Adapters

Kind	Name	Adapter Type	Description
Socket	AR_IN	adapter::types::unidirectional::AR	REAL input signal; E1 triggers the calculation and D1 carries the input value.
Plug	AR_OUT	adapter::types::unidirectional::AR	Calculated derivative (out, REAL).
Plug	AR_DELTA_IN	adapter::types::unidirectional::AR	Difference of the input signal (delta_in, REAL).
Plug	AUDI_DELTA_T	adapter::types::unidirectional::AUDI	Time difference in microseconds (delta_t, UDINT).

Functionality

The internal network consists of the OSCAT FB FT_DERIV and a three-channel D flip-flop E_D_FF_ANY_3. The wrapper orchestrates the event and data flow as follows:

1. **Initialization** – INIT is forwarded to FT_DERIV.EINIT. The internal block performs its initialization and returns INITO. If INIT is left unconnected, the EInit event fires automatically once at deployment.
2. **Input request** – When the AR_IN adapter receives an event (AR_IN.E1), the corresponding REAL value (AR_IN.D1) is written to FT_DERIV.in, and FT_DERIV.REQ is triggered.
3. **Derivative calculation** – The internal FT_DERIV calculates the derivative using the current input, the configured factor K, and the enable flag run.
4. **Output latching** – When FT_DERIV.CNF is emitted, the internal E_D_FF_ANY_3 latches out, delta_t, and delta_in into its three channels. The flip-flop then emits its output event EO, which is routed to all three plugs: AR_OUT.E1, AR_DELTA_IN.E1, and AUDI_DELTA_T.E1. The corresponding D1 values are taken from the latched Q1, Q2, and Q3 outputs.
5. **Reset** – RST is passed through to FT_DERIV.RST, clearing the internal derivative history.

Because all three values are latched from the same CNF event, downstream consumers receive a consistent snapshot of the calculation cycle.

Technical Features

- **Adapter-based result boundary** – The three calculation results are available only through AR / AUDI plugs; no plain data output is needed.
- **Composite implementation** – Contains OSCAT::Basic::POUs::Engineering::Control::FT_DERIV and iec61499::events::E_D_FF_ANY_3.
- **Simultaneous output update** – The internal three-channel D flip-flop ensures that AR_OUT, AR_DELTA_IN, and AUDI_DELTA_T are updated together.
- **Decoupled library design** – The wrapper is placed in a dedicated library project that depends on both adapter and OSCAT, avoiding a direct dependency between the two base libraries.
- **Pass-through lifecycle/reset** – INIT, INITO, and RST behave exactly like the underlying FT_DERIV interface.
- **Configuration inputs** – K and run are plain InputVars with default values 1.0 and TRUE.
- **Adapter-based wiring** – The block can be connected to other AR / AUDI blocks using ordinary AdapterConnections; no raw .E1 / .D1 access from a parent network is needed.

State Overview

FT_DERIV_AR is a composite FB type, so it does not define an explicit ECC state diagram. Its runtime behavior can be described by the following phases:

Phase	Description
Initialization	INIT is forwarded to FT_DERIV.EINIT; INITO confirms completion.
Ready / Waiting	The block is idle and waits for an AR_IN.E1 event.

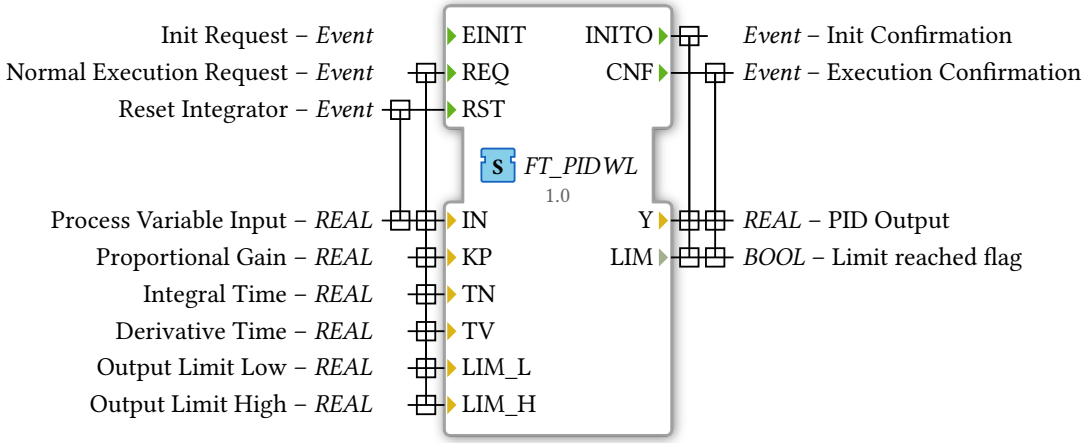
Calculating	FT_DERIV.REQ is active; the internal derivative calculation has not yet completed.
Output Update	FT_DERIV.CNF arrives and the flip-flop latches/emits out, delta_t, and delta_in to the adapter plugs.
Reset	RST clears the internal input/time history stored in FT_DERIV.

When run is FALSE, the internal calculation is disabled and the output plugs are not updated with a new derivative.

Application Scenarios

- **Frequency / rate measurement** – If the input AR_IN receives a pulse counter or incremental counter value, AR_OUT delivers the derivative directly in Hz when K = 1.0.
- **Rate-of-change monitoring** – The block can monitor the velocity of a process value such as pressure, temperature, or fill level and make the result available to adapter-based alarm or supervision blocks.
- **Adapter-based subapplications** – In compositions that already use AR / AUDI adapters, FT_DERIV_AR can be integrated without falling back to plain event/data connections.
- **Plain value conversion** – If a downstream block requires a plain REAL value instead of an adapter, the AR_OUT plug can be connected to a generic conversion block such as adapter::conversion::unidirectional::AR_R_TO_REAL.
- **Batch or mode changes** – RST can be used to clear the derivative history when the process is restarted or when a new operating mode begins.

Comparison with Similar Blocks



Block	Interface	Outputs	Typical Use
FT_DERIV	Plain events/data, no adapters	out, delta_t, delta_in	OSCAT-native networks where adapter boundaries are not required
FT_DERIV_AR	Adapter-based result boundary	AR_OUT, AR_DELTA_IN, AUDI_DELTA_T	Adapter-oriented 4diac subapplications and library decoupling

FT_DERIV_AR does not provide a new differentiation algorithm; it is a connectivity wrapper around the FT_DERIV calculation. Compared with using FT_DERIV directly, it adds adapter compatibility, output latching, and a clean separation between the adapter and OSCAT libraries.

Conclusion

FT_DERIV_AR is a practical adapter wrapper for the OSCAT FT_DERIV function block. It preserves the original calculation semantics while offering an adapter-friendly interface, consistent output latching, and clean library decoupling. This makes it well suited for modern 4diac subapplication designs that rely on unidirectional AR / AUDI adapters and want to avoid mixing raw .E1 / .D1 access or plain data pins across library boundaries.

FT_PIDWL

PI Controller with Anti-Windup version 1.3 November 13th 2009 programmer hugo tested by tobias FT_PIDWL is a PID controller with dynamic wind_up reset. FT_PT1

• – ◦ • – ◦ • – ◦ •

Introduction

`FT_PT1` is a first-order low-pass filter (PT1 element) from the OSCAT library. It is used to smooth analog signals and reduce noise with a programmable time constant `TM` and gain factor `K`.

The block is implemented as a `SimpleFB` (stateful function block with `EINIT`/`REQ`/`RST`) and performs discrete-time integration according to the PT1 transfer function:

$$T_M \cdot \frac{dy}{dt} + y(t) = K \cdot x(t) \tag{2.1}$$

Interface Structure

Event Inputs

Name	Type	Description	With Data
`EINIT`	`Event`	Service initialization of the filter	
`REQ`	`Event`	Execution request for a new calculation cycle	`in`, `TM`, `K`
`RST`	`Event`	Invalidates initialization state (`init = FALSE`) for re-seeding on next `REQ`	

Event Outputs

Name	Type	Description	With Data
`INITO`	`Event`	Initialization confirmation	
`CNF`	`Event`	Execution confirmation after calculation	`delta_t`, `out`

Input Vars

Name	Type	Initial Value	Description
`in`	`REAL`	`0.0`	Analog input signal
`TM`	`TIME`	`T#0s`	Filter time constant. If `TM = T#0s`, filtering is bypassed and `out = K * in`.
`K`	`REAL`	`1.0`	Gain factor (proportional coefficient)

Output Vars

Name	Type	Description
`delta_t`	`UDINT`	Elapsed time since last call in microseconds (μs)
`out`	`REAL`	Filtered output value

How It Works

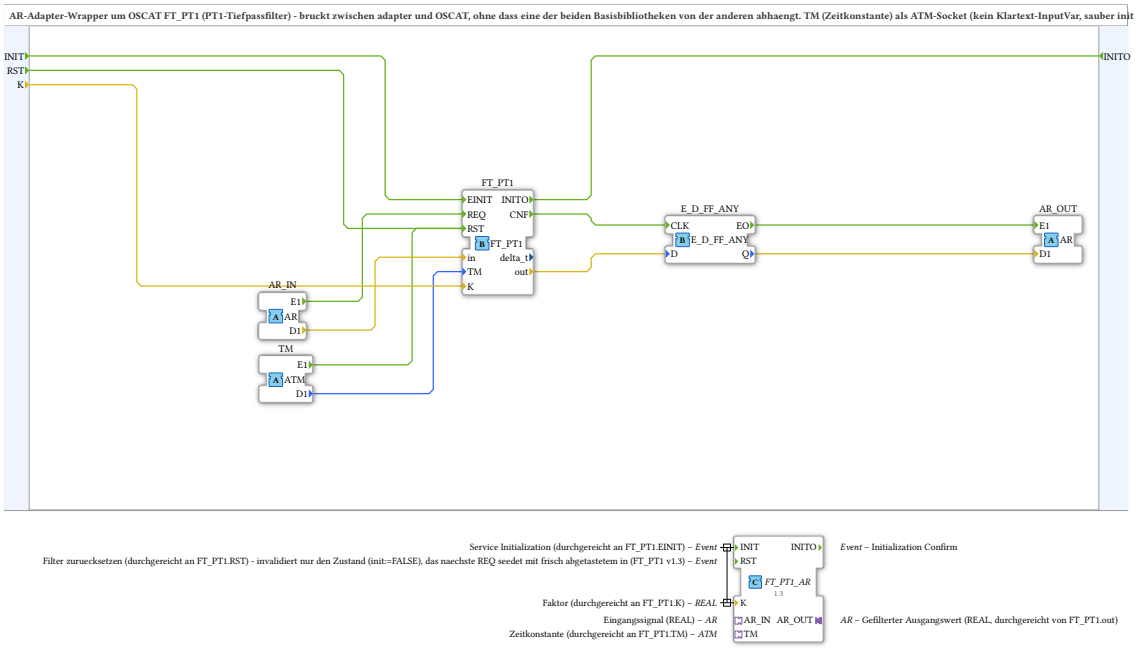
1. **Initialization (`EINIT`)**:
   Resets initialization state, sets `out = 0.0`, and signals readiness via `INITO`.
2. **Cyclic Calculation (`REQ`)**:
   On each `REQ` event, the block calculates elapsed time since the last call (Δt) in microseconds using `T_PLC_US()`.
   - If the block is not yet initialized (`init = FALSE`) or `TM = T#0s`, the filter state is (re)initialized: `init := TRUE`, `out := K * in` is seeded directly using fresh input data, `delta_t := 0`, and the timestamp baseline `last` is refreshed.
   - For `TM > T#0s`, the new output value is calculated according to:

$$\text{out}_{\text{new}} = \text{out}_{\text{old}} + (K \cdot \text{in} - \text{out}_{\text{old}}) \cdot \frac{\Delta t}{T_{\text{eff}}} \tag{2.2}$$

     where $\Delta t = \text{delta_t} \cdot 10^{-6}\,\text{s}$ is the measured call interval in seconds (from `T_PLC_US()`), $T_M = \text{TIME_TO_REAL}\ (TM)$ is the filter time constant in seconds, and $T_{\text{eff}} = \max(T_M, \Delta t)$ is the effective time constant in seconds. When the call interval Δt exceeds the configured filter time T_M, T_{eff} is clamped to Δt, capping the weighting factor $\frac{\Delta t}{T_{\text{eff}}}$ to at most 1.0.
   - To prevent denormalized float underruns, values $|out| < 1.0 \times 10^{-20}$ are automatically zeroed.
3. **Filter Reset (`RST`)**:
   Invalidates the initialization state (sets `init := FALSE`) without modifying `out` or timestamps immediately. This defers seeding until the next `REQ` event, ensuring fresh input data is sampled (rather than stale or default `0.0` values) and refreshing the timebase baseline.

Technical Features

- **Cycle-Independent Timebase**: Time differences are measured in microseconds via `T_PLC_US()`, compensating for call cycle variations.
- **Clamped Effective Filter Time Constant ($T_{\text{eff}} = \max(T_M, \Delta t)$)**: If call interval Δt exceeds filter time T_M, the block caps the discretization factor $\frac{\Delta t}{T_{\text{eff}}}$ to at most 1.0. This prevents Euler instability and overshoot when call cycles occur slower than T_M.
- **Filter Bypass at `TM = 0`**: When `TM = T#0s`, damping is disabled and the input signal is passed through scaled by `K`.
- **Clean Reset Recovery**: `RST` invalidates the initialization state (`init := FALSE`) without immediate output overwrite. The subsequent `REQ` event samples fresh input data, seeds `out := K * in`, and resets the timing baseline `last`, preventing spurious step jumps from stale input values.
- **Project-Specific Time Conversion**: Uses the project-specific helper function `TIME_TO_REAL.fct` for clean conversion of `TIME` input `TM` to seconds (`REAL`).



Application Scenarios

- Smoothing fluctuating sensor readings (e.g., pressure, temperature, speed).
- Noise reduction for control loop inputs.
- Soft start/ramp adjustment for setpoints.

See Also

- `FT_PT1_AR` – AR adapter wrapper for `FT_PT1`.
- `FT_PT2` – Second-order low-pass filter.
- `TIME_TO_REAL` – Time conversion helper function.

FT_PT1_AR

Introduction

`FT_PT1_AR` is an AR adapter wrapper around the OSCAT low-pass filter block `FT_PT1`. It encapsulates first-order low-pass filtering behind a purely adapter-based interface for IEC 61499 applications.

The time constant `TM` is provided as an `ATM` socket (per section 13 of the `iec61499-creator` skill), while gain factor `K` remains a plain `InputVar`. Internally, the block uses an `E_D_FF_ANY` D flip-flop to detect changes in the filtered value and fire adapter events only upon initial evaluation or when an actual change occurs.

Interface Structure

Event Inputs

Name	Type	Description
`INIT`	`EInit`	Service initialization, passed to `FT_PT1.INIT`
`RST`	`Event`	Invalidates filter state via `FT_PT1.RST` (`init := FALSE`)

Event Outputs

Name	Type	Description
`INITO`	`EInit`	Initialization confirmation from `FT_PT1`

Input Vars

Name	Type	Initial Value	Description
`K`	`REAL`	`1.0`	Gain factor, passed to `FT_PT1.K`

Output Vars

None. Output is provided exclusively through the adapter plug `AR_OUT`.

Adapters

Interface	Direction	Adapter Type	Data Type	Description

AR_IN	Socket	AR	REAL	Input signal to be filtered
TM	Socket	ATM	TIME	Filter time constant (TM.D1 passed to FT_PT1.TM)
AR_OUT	Plug	AR	REAL	Filtered output value (FT_PT1.out via E_D_FF_ANY)

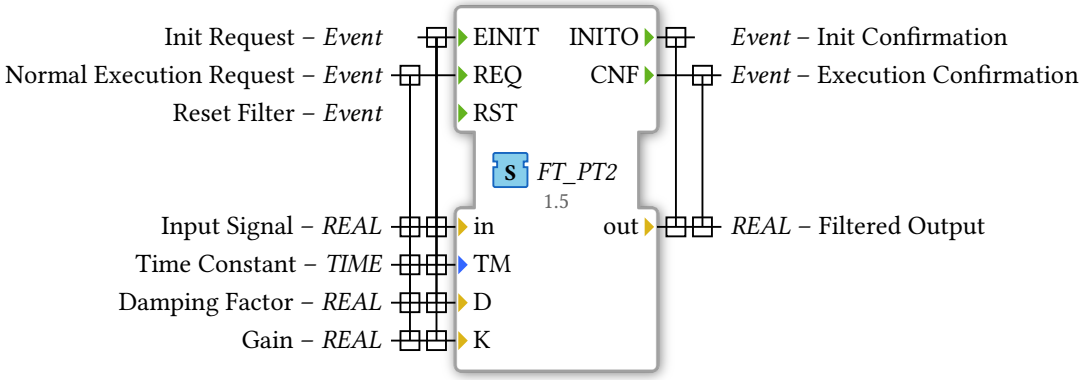
How It Works

The block connects FT_PT1 (OSCAT) and E_D_FF_ANY in an internal network:

1. **Signal Processing**:
   An event on AR_IN.E1 triggers FT_PT1.REQ. AR_IN.D1 supplies the raw analog value.
2. **Time Constant & Re-initialization**:
   The filter time TM.D1 is supplied by the ATM socket and passed to FT_PT1.TM. An event on TM.E1 also directly triggers FT_PT1.RST internally, invalidating the filter state (init := FALSE) so that the subsequent AR_IN.E1 request reinitializes the filter (out := K * in) using fresh input data and the updated time constant.
3. **Change Detection & Decoupling (E_D_FF_ANY)**:
   After calculation, FT_PT1.CNF triggers CLK on internal E_D_FF_ANY. The flip-flop emits the initial output value on the first clock after start. On subsequent cycles, AR_OUT.E1 and AR_OUT.D1 are updated **only** when a value change occurs.
4. **Reset & Initialization**:
   - INIT controls FT_PT1.INIT and confirms via INITO. Unconnected INIT events auto-fire once upon deployment.
   - RST as well as any incoming TM.E1 event are passed to FT_PT1.RST to invalidate the filter state (init := FALSE). The next AR_IN.E1 request performs clean re-initialization.

Technical Features

- **Clean Adapter Boundary**: Prevents direct accessing of internal .E1/.D1 structures across SubApp networks.
- **Automatic Filter Re-initialization on TM Change**: Receiving a TM.E1 event internally triggers FT_PT1.RST (setting init := FALSE). The subsequent AR_IN.E1 request reinitializes out := K * in with fresh input data and resets the timing baseline, so modified time constants take effect cleanly without jump artifacts or stale seeding.
- **Event Traffic Reduction**: E_D_FF_ANY prevents unnecessary event flooding down the processing chain for unchanged values.
- **ATM Socket Convention**: Timing parameters are routed via ATM sockets rather than bare variables (fed at instantiation site e.g., via initval_ATM).



Application Scenarios

- Smoothing analog sensor readings (e.g., pressure, temperature, speed) in adapter-based SubApp architectures.
- Noise filtering prior to thresholding or hysteresis blocks (AR_D_FF_HYS_TMIN).

FT_PT2_AR

Introduction

`FT_PT2_AR` is an AR adapter wrapper around the OSCAT 2nd-order low-pass filter block `FT_PT2`. It enables 2nd-order low-pass filtering with configurable time constant `TM`, damping `D`, and gain `K` within purely adapter-based IEC 61499 applications.

The time constant `TM` is provided via an `ATM` adapter socket (per section 13 of the `iec61499-creator` skill), while damping `D` and gain `K` remain plain `InputVars`. An internal `E_D_FF_ANY` D flip-flop ensures that output event `AR_OUT.E1` is fired unconditionally on the first cycle and subsequently only when an actual value change occurs.

Interface Structure

Event Inputs

Name	Type	Description
`INIT`	`EInit`	Service initialization, passed to `FT_PT2.INIT`
`RST`	`Event`	Resets the filter output via `FT_PT2.RST`

Event Outputs

Name	Type	Description
`INITO`	`EInit`	Initialization confirmation from `FT_PT2`

Input Vars

Name	Type	Initial Value	Description
`D`	`REAL`	`0.0`	Filter damping factor (e.g., 0.707 for Butterworth response)
`K`	`REAL`	`1.0`	Gain factor

Output Vars

None. Output is provided exclusively through the adapter plug `AR_OUT`.

Adapters

Interface	Direction	Adapter Type	Data Type	Description
`AR_IN`	Socket	`AR`	`REAL`	Input signal to be filtered
`TM`	Socket	`ATM`	`TIME`	Filter time constant (`TM.D1` passed to `FT_PT2.TM`)
`AR_OUT`	Plug	`AR`	`REAL`	Filtered output value (`FT_PT2.out` via `E_D_FF_ANY`)

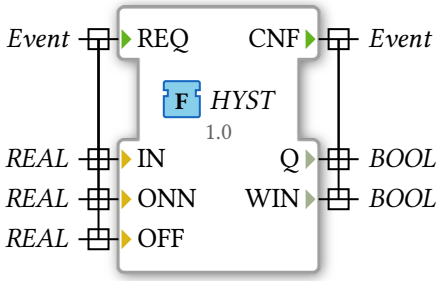
How It Works

The block embeds `FT_PT2` inside an internal FB network:

1. **Signal Processing**:
   An event on `AR_IN.E1` triggers `FT_PT2.REQ`. `AR_IN.D1` is supplied to `FT_PT2.in`.
2. **Parameterization**:
   `TM.D1` is read from the `ATM` socket. `D` and `K` are supplied as parameters.
3. **2nd-Order Stateful Integration**:
   `FT_PT2` filters the signal internally through two cascaded integration stages (`INTEGRATE`).
4. **Change Filtering (`E_D_FF_ANY`)**:
   `FT_PT2.CNF` drives internal `E_D_FF_ANY`. The flip-flop forwards the computed output value to `AR_OUT` unconditionally on the first cycle. On subsequent cycles, `AR_OUT.E1` and `AR_OUT.D1` are updated only when the computed filter value differs from the previous value.
5. **Reset & Initialization**:
   `INIT` controls `FT_PT2.INIT`. `RST` clears the internal memory of both integrator stages.

Technical Features

- **2nd-Order Response**: Provides steeper attenuation of high-frequency noise (12 dB/octave roll-off) compared to a PT1 filter.
- **Integrated Event Decoupling**: Eliminates redundant adapter events in downstream SubApps.
- **`ATM` Socket for Timing**: Adheres to project design rules for timing constants.



Application Scenarios

- High-frequency noise suppression on analog signals (e.g., force, pressure, or ground speed).
- Vibration damping in closed-loop control systems.

TIME_TO_REAL

Introduction

`TIME_TO_REAL` is a project-specific helper function (`FunctionType`) that converts a time duration of type `TIME` into a floating-point value (`REAL`). The return value represents the duration in **seconds**.

This function is utilized within OSCAT control and filter blocks (such as `FT_PT1`) to format PLC time quantities for mathematical differential and integration formulas.

Interface Structure

Inputs

Name	Type	Description
`IN`	`TIME`	Input time duration

Outputs

Name	Type	Description
(Return)	`REAL`	Calculated time duration in seconds

How It Works

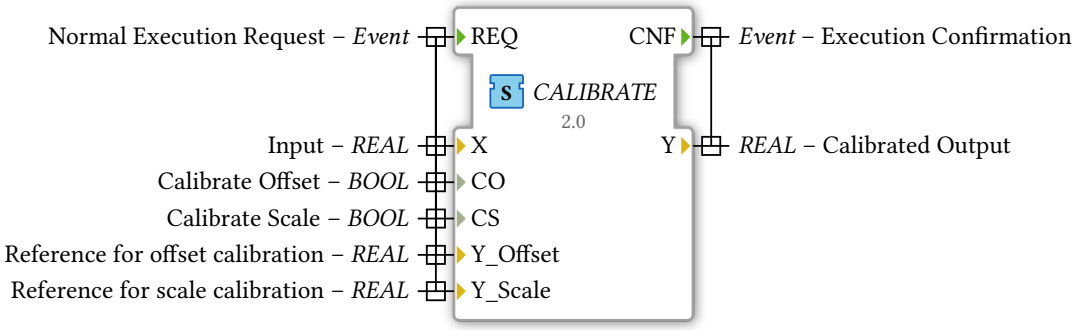
The function converts the internal millisecond representation of the `TIME` input into seconds:

$$\text{Return} = \text{TIME_TO_UDINT}\ (\text{IN}) \cdot 1.0 \times 10^{-3} \tag{2.3}$$

Examples:

- `IN = T#1s` → `Return = 1.0`
- `IN = T#500ms` → `Return = 0.5`
- `IN = T#2m30s` → `Return = 150.0`

Technical Features



- **Project-Specific Extension**: `TIME_TO_REAL` is not a standard OSCAT library function, but a local IEC 61499 conversion helper.
- **Scaling Precision**: Uses explicit floating-point scaling (1.0×10^{-3}) to prevent integer truncation errors during division.

See Also

- `FT_PT1` – First-order low-pass filter (uses `TIME_TO_REAL`).
- `FT_PT2` – Second-order low-pass filter.

measurements

CALIBRATE

• – ◦ • – ◦ • – ◦ •

Introduction

`CALIBRATE` performs a two-point calibration (offset & scale) of an analog input signal: `Y = (X + OFFSET) * SCALE`. Calibration is not triggered by dedicated events but by the Boolean inputs `CO`/`CS`, which are checked on every `REQ`. For an event-driven variant see E_CALIBRATE. For details on the calibration procedure, see Two- and Three-Point Calibration Procedures.

Interface Structure

Event Inputs

- **REQ**: normal execution request, carries `X`, `CO`, `CS`, `Y_Offset`, `Y_Scale`, `OFFSET`, `SCALE`. Recomputes `Y` on every call and, where applicable, performs a calibration step (see Functionality).

Event Outputs

- **CNF**: confirms execution, carries `Y`, `OFFSET` and `SCALE`.

Data Inputs

- **X** (REAL): raw input value.
- **CO** (BOOL): when `TRUE`, triggers offset calibration.
- **CS** (BOOL): when `TRUE`, triggers scale calibration (only meaningful once `CO` has run first).
- **Y_Offset** (REAL): target value for `Y` at the low reference point (offset calibration).
- **Y_Scale** (REAL): target value for `Y` at the high reference point (scale calibration).

Data Outputs

- **Y** (REAL): calibrated output value.

In/Out Variables

- **OFFSET** (REAL, initial `0.0`): stored offset value – recalculated on `CO`, otherwise held persistently by the caller.
- **SCALE** (REAL, initial `1.0`): stored scale factor – recalculated on `CS`, otherwise held persistently by the caller.

Functionality

On every `REQ`, `CALIBRATE` first checks `CO` and `CS` (as an `ELSIF` chain, so at most one calibration step per call):

- If `CO = TRUE`: `OFFSET := Y_Offset - X` – shifts `X` so that `Y = Y_Offset` at the current reference (only correct when `SCALE = 1`).
- Else if `CS = TRUE`: `SCALE := Y_Scale / (X + OFFSET)` – scales so that `Y = Y_Scale` at the current reference. Requires `OFFSET` to already have been determined via `CO`.

`Y := (X + OFFSET) * SCALE` is then computed either way and output via `CNF`.

Two-point calibration procedure:

1. Apply the low reference, set `Y_Offset` to the desired output, set `CO = TRUE` – yields `OFFSET`.
2. Apply the high reference, set `Y_Scale` to the desired output, set `CS = TRUE` – yields `SCALE`.

Example (4-20 mA pressure sensor via logiBUS, normalized to `0.0..1.0`, desired output range `0.0..500.0`):

Step	Action	Result
1	Apply 4 mA (`X=0.0`), `Y_Offset=0.0`, `CO=TRUE`	`OFFSET = 0`
2	Apply 20 mA (`X=1.0`), `Y_Scale=500.0`, `CS=TRUE`	`SCALE = 500`

Result: `Y = (X + 0) * 500 = X * 500 = 0..500`.

Technical Details

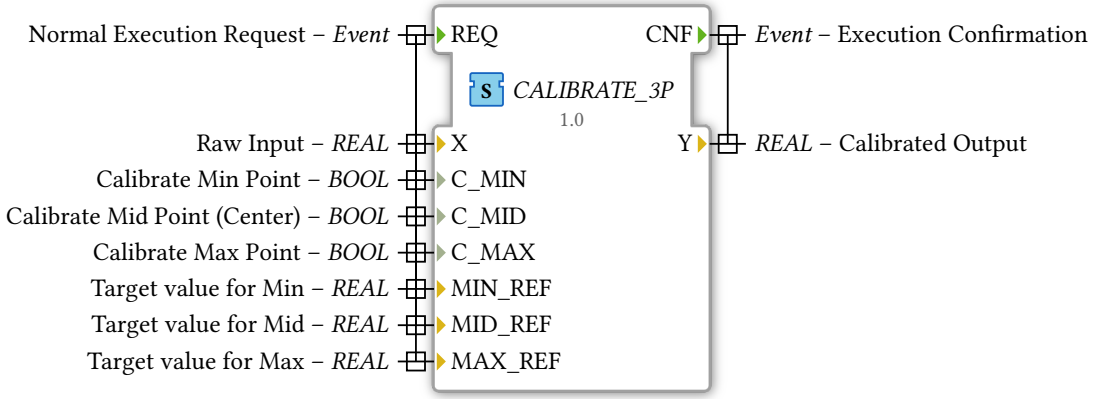
- **Order not enforced**: `CO` must run before `CS`, since `CS` uses the `OFFSET` already determined. As a `SimpleFB` with a single `ECState`, ensuring the correct order is the caller's responsibility.
- **Y after CO only correct when SCALE = 1**: the formula `OFFSET := Y_Offset - X` only yields exactly `Y = Y_Offset` after offset calibration if `SCALE` still has its initial value `1.0`.
- **Triggered via BOOL, not events**: unlike the `E_CALIBRATE*` variants, calibration here runs through the data inputs `CO`/`CS`, re-evaluated on every `REQ` – no dedicated calibration event needed, but also no separate confirmation event per calibration step.

State Overview

`CALIBRATE` is a `SimpleFB` with a single `ECState` (`REQ`): every call immediately runs the `REQ` algorithm and fires `CNF`. There are no state transitions and no real ECC – the "calibration phase" results purely from the value of `CO`/`CS` at call time.

Application Scenarios

- Scaling analog sensors (pressure, temperature, level) with two-point reference calibration
- Systems where the calibration trigger is already available as a Boolean signal (e.g. a button/switch rather than a dedicated event source)
- Simple applications where an accidental wrong order (`CS` before `CO`) poses no risk



⚖️ Comparison with Similar Blocks

Compare with E_CALIBRATE, which performs the same two-point calibration but event-driven (`EICO`/`EICS` instead of `CO`/`CS`). For background on the calibration theory, see Two- and Three-Point Calibration Procedures. For a three-point calibration (e.g. joysticks with a center position) see CALIBRATE_3P.

Conclusion

`CALIBRATE` provides simple, Boolean-triggered two-point calibration for analog signals, and fits applications where the caller ensures the correct order of offset and scale calibration.

CALIBRATE_3P

• – ◦ • – ◦ • – ◦ •

Introduction

`CALIBRATE_3P` is a three-point calibration for raw inputs with a center position, as typically found on joysticks. Instead of a single linear scale like CALIBRATE, it interpolates piecewise linearly between three

stored reference points (Min, Mid, Max), which also compensates for a center position that doesn't sit exactly in the middle of the raw range.

Interface Structure

Event Inputs

- **REQ**: normal execution request, carries `X`, `C_MIN`, `C_MID`, `C_MAX`, `MIN_REF`, `MID_REF`, `MAX_REF`, `X_MIN`, `X_MID`, `X_MAX`. Recomputes `Y` on every call and, where applicable, performs a calibration step.

Event Outputs

- **CNF**: confirms execution, carries `Y`, `X_MIN`, `X_MID`, `X_MAX`.

Data Inputs

- **X** (REAL): raw input value.
- **C_MIN** (BOOL): when `TRUE`, triggers calibration of the minimum point.
- **C_MID** (BOOL): when `TRUE`, triggers calibration of the mid point.
- **C_MAX** (BOOL): when `TRUE`, triggers calibration of the maximum point.
- **MIN_REF** (REAL, initial `0.0`): target output value for the minimum point.
- **MID_REF** (REAL, initial `50.0`): target output value for the mid point.
- **MAX_REF** (REAL, initial `100.0`): target output value for the maximum point.

Data Outputs

- **Y** (REAL): calibrated, interpolated output value, clipped to `MIN_REF..MAX_REF`.

In/Out Variables

- **X_MIN** (REAL, initial `0.0`): stored raw value at the minimum point.
- **X_MID** (REAL, initial `50.0`): stored raw value at the mid point.
- **X_MAX** (REAL, initial `100.0`): stored raw value at the maximum point.

Functionality

On every `REQ`, `CALIBRATE_3P` first checks `C_MIN`, `C_MID` and `C_MAX` (as an `ELSIF` chain, at most one calibration point per call) and, if the corresponding flag is set, stores the current raw value `X` in `X_MIN`/`X_MID`/`X_MAX`.

`Y` is then interpolated piecewise linearly:

- For `X < X_MID`: interpolation between `(X_MIN, MIN_REF)` and `(X_MID, MID_REF)`.
- For `X >= X_MID`: interpolation between `(X_MID, MID_REF)` and `(X_MAX, MAX_REF)`.
- The result is clipped to the range `MIN_REF..MAX_REF`.

The three calibration points can be calibrated in **any order** and repeated individually as often as needed – but at most one is updated per `REQ` call.

Example (joystick with center drift, raw range `0..1000`, desired output range `-100..0..100`):

Step	Action	Result
1	Move joystick to **minimum**, `C_MIN=TRUE`	`X_MIN = 50` (drift from ideal `0`)
2	Move joystick to **center**, `C_MID=TRUE`	`X_MID = 520` (drift from ideal `500`)
3	Move joystick to **maximum**, `C_MAX=TRUE`	`X_MAX = 980` (drift from ideal `1000`)

Result: `Y` is interpolated and clipped between `MIN_REF=-100`, `MID_REF=0` and `MAX_REF=100` – the joystick's actual (drifted) center position now yields exactly `Y=0`.

Technical Details

- **Center-position compensation**: unlike a plain two-point calibration (see CALIBRATE), the center position is captured explicitly – important for joysticks whose mechanical rest position doesn't sit exactly in the middle of the electrical raw range.
- **Output always clipped**: `Y` is clipped to `MIN_REF..MAX_REF` after interpolation, even if `X` lies outside the calibrated raw values.
- **Degenerate calibration points**: if `X_MID` is not above `X_MIN` (or `X_MAX` not above `X_MID`), the affected interpolation returns a constant `MIN_REF` or `MID_REF` instead of dividing by zero.

- **Order not enforced**: as with `CALIBRATE`, being a `SimpleFB` means it's the caller's responsibility to supply sensible calibration values. For an event-driven variant see E_CALIBRATE_3P.

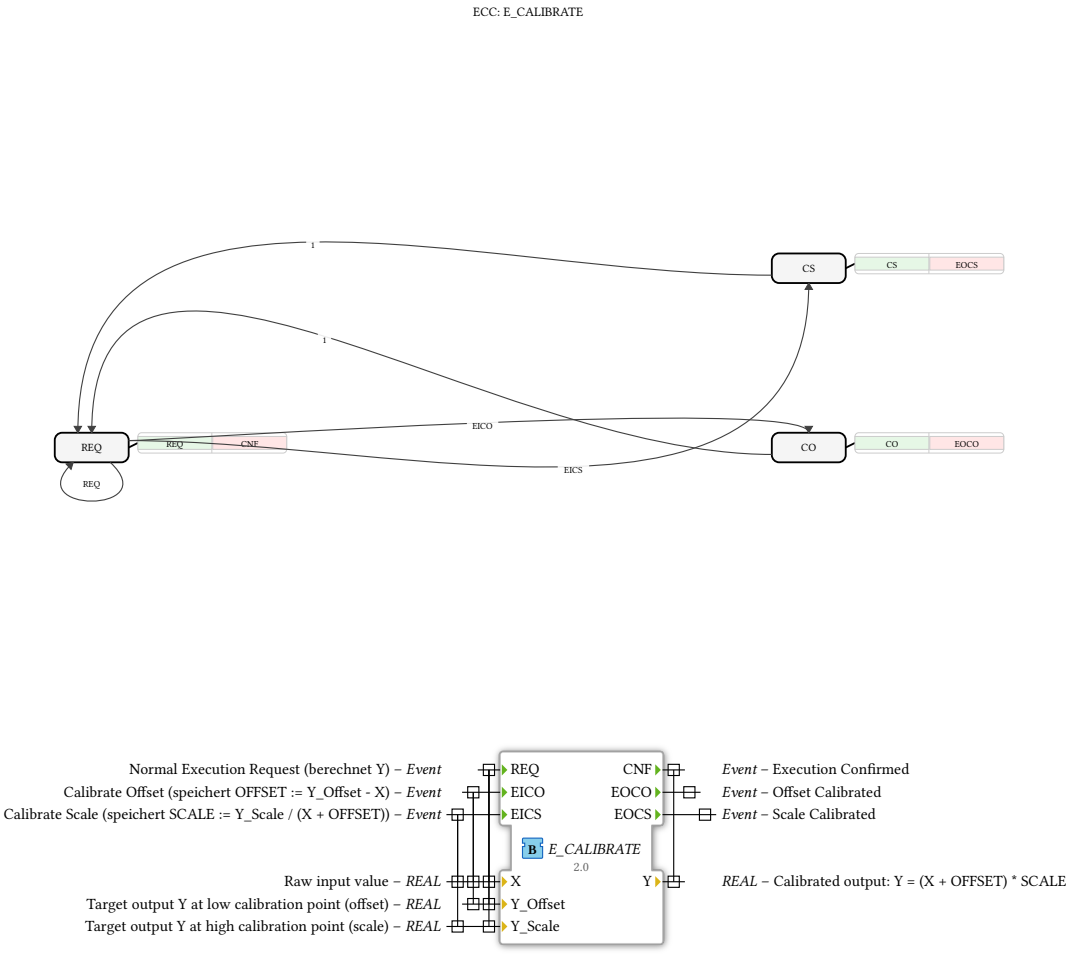
State Overview

`CALIBRATE_3P` is a `SimpleFB` with a single `ECState` (`REQ`): every call immediately runs the `REQ` algorithm and fires `CNF`. There are no state transitions – which calibration point (if any) gets updated is determined purely by `C_MIN`/`C_MID`/`C_MAX` at call time.

Application Scenarios

- Calibrating joysticks and similar controls with a mechanical center position
- Raw inputs with nonlinear or asymmetric behavior around the zero point
- Applications where individual calibration points need to be readjusted independently without affecting the others

⚖️ Comparison with Similar Blocks



For details on the three-point calibration procedure, see Two- and Three-Point Calibration Procedures.

Compare with CALIBRATE, which uses the same Boolean-triggered approach but only offers a linear two-point calibration without a center position, and with E_CALIBRATE_3P, which provides the same three-point logic event-driven (`EI_MIN`/`EI_MID`/`EI_MAX`) with its own confirmation event per point.

Conclusion

`CALIBRATE_3P` fits anywhere a simple two-point calibration falls short because the raw value range isn't symmetric around a (possibly shifted) center point – most notably for joysticks and similar controls.

E_CALIBRATE

• – ○ • – ○ • – ○ •

Introduction

E_CALIBRATE is the event-driven counterpart to CALIBRATE: the two-point calibration (Y = (X + OFFSET) * SCALE) is triggered not by Boolean data values but by its own events EICO/EICS, each with its own confirmation event. For details on the calibration procedure, see Two- and Three-Point Calibration Procedures.

Interface Structure

Event Inputs

- **REQ**: normal execution request – computes Y. Carries X, Y_Offset, Y_Scale, OFFSET, SCALE.
- **EICO**: calibrates the offset (OFFSET := Y_Offset - X). Carries X, Y_Offset.
- **EICS**: calibrates the scale (SCALE := Y_Scale / (X + OFFSET)). Carries X, Y_Scale, OFFSET.

Event Outputs

- **CNF**: confirms REQ, carries Y.
- **EOCO**: confirms offset calibration, carries OFFSET.
- **EOCS**: confirms scale calibration, carries SCALE.

Data Inputs

- **X** (REAL): raw input value.
- **Y_Offset** (REAL): target output value at the low reference point.
- **Y_Scale** (REAL): target output value at the high reference point.

Data Outputs

- **Y** (REAL): calibrated output value.

In/Out Variables

- **OFFSET** (REAL, initial 0.0): stored offset value.
- **SCALE** (REAL, initial 1.0): stored scale factor.

Functionality

E_CALIBRATE has three ECC states, all directly reachable from state REQ:

- **REQ** (start state): on the REQ event, Y := (X + OFFSET) * SCALE is computed and CNF fires; the block stays in REQ.
- **CO**: on EICO, the block transitions to CO, runs OFFSET := Y_Offset - X, fires EOCO and immediately returns to REQ.
- **CS**: on EICS, the block transitions to CS, runs SCALE := Y_Scale / (X + OFFSET) (only if X + OFFSET <> 0), fires EOCS and immediately returns to REQ.

Since both EICO and EICS are reachable from REQ at any time, the ECC does not enforce ordering – EICS can also be fired before EICO, but then yields an inconsistent result since SCALE would be based on an as-yet-uncalibrated OFFSET.

Example (4-20 mA pressure sensor via logiBUS, normalized to 0.0..1.0, desired output range 0.0..500.0):

Step	Action	Result
1	Apply 4 mA (X=0.0), Y_Offset=0.0, fire EICO	OFFSET = 0
2	Apply 20 mA (X=1.0), Y_Scale=500.0, fire EICS	SCALE = 500

Result: Y = (X + 0) * 500 = X * 500 = 0..500.

Technical Details

- **Y after CO only correct when SCALE = 1**: as with CALIBRATE, OFFSET := Y_Offset - X only yields exactly Y = Y_Offset after offset calibration if SCALE is still 1.0.
- **No order enforcement**: EICO and EICS are both directly reachable from REQ – the ECC does not track whether calibration has already happened.
- **REQ stays available at all times**: normal operation (REQ) is possible regardless of calibration status, even between EICO and EICS.

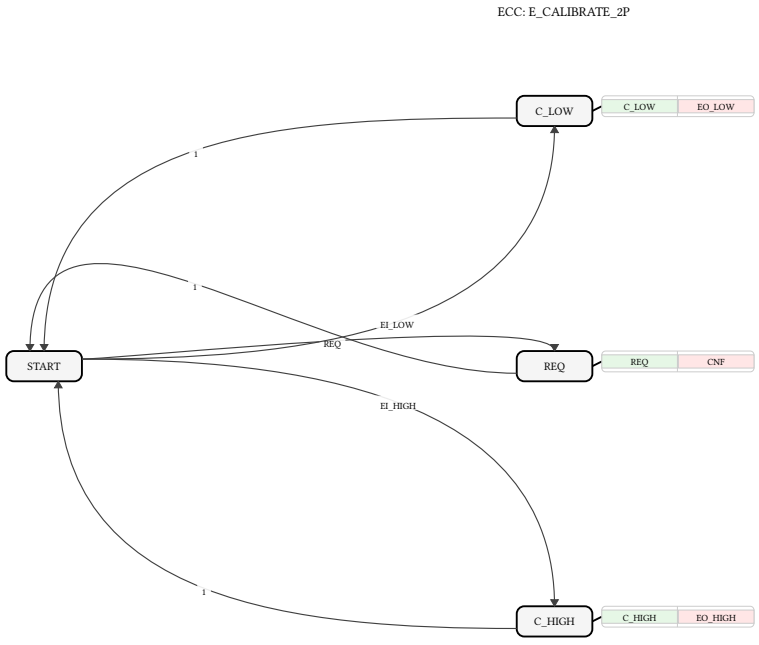
State Overview

```
REQ --EICO--> CO --1--> REQ     (offset calibration)
REQ --EICS--> CS --1--> REQ     (scale calibration)
REQ --REQ---> REQ --1--> REQ    (normal operation)
```

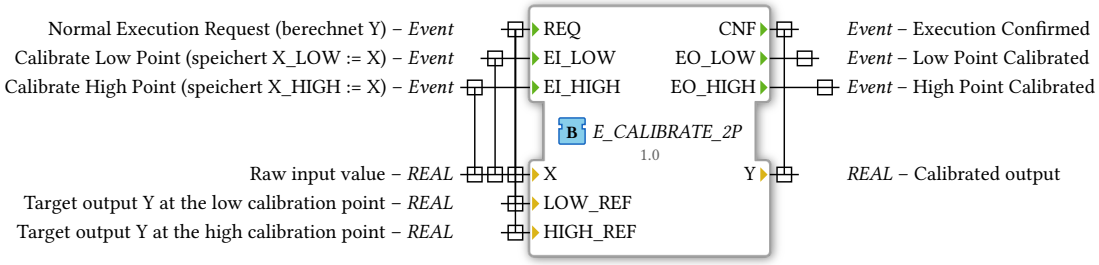
All three states are pass-through states: the block returns to `REQ` immediately after each action.

Application Scenarios

- Two-point calibration of analog sensors in systems that already provide the calibration trigger as an event (e.g. a button-press event rather than a data value)
- Applications where offset and scale calibration each need their own, immediate confirmation (`EOCO`/`EOCS`)
- Systems with occasional offset re-calibration without redetermining the scale



⚖️ Comparison with Similar Blocks



Compare with CALIBRATE, which applies the same formula Boolean-triggered rather than event-driven. For background on the calibration theory, see Two- and Three-Point Calibration Procedures.

Conclusion

`E_CALIBRATE` provides event-driven two-point calibration with its own confirmation event per calibration step, but still leaves the correct order (offset before scale) to the caller.

E_CALIBRATE_2P

• – ○ • – ○ • – ○ •

Introduction

E_CALIBRATE_2P is an event-driven two-point calibration (low/high) with independently stored points. It replaces E_CALIBRATE (E_CALIBRATE_SQ behaviour): the two points are stored completely independently of each other and only combined into a line on reading (REQ). There is therefore no enforced order of EI_LOW/EI_HIGH.

Interface Structure

Event Inputs

- **REQ**: normal execution request, calculates Y. Provides X, LOW_REF, HIGH_REF, X_LOW, X_HIGH.
- **EI_LOW**: calibrates the low point (X_LOW := X). Provides X.
- **EI_HIGH**: calibrates the high point (X_HIGH := X). Provides X.

Event Outputs

- **CNF**: confirms REQ, provides Y.
- **EO_LOW**: low point calibrated, provides X_LOW.
- **EO_HIGH**: high point calibrated, provides X_HIGH.

Data Inputs

- **X** (REAL): raw input value.
- **LOW_REF** (REAL): target output Y at the low calibration point.
- **HIGH_REF** (REAL): target output Y at the high calibration point.

Data Outputs

- **Y** (REAL): calibrated output value.

In/Out Variables (InOut)

- **X_LOW** (REAL, initial value 0.0): stored raw value at the low calibration point.
- **X_HIGH** (REAL, initial value 1.0): stored raw value at the high calibration point.

Adapters

No adapters available.

Functionality

Formula: Y = LOW_REF + (X - X_LOW) * (HIGH_REF - LOW_REF) / (X_HIGH - X_LOW)
The block has a start state START and three action states directly reachable from it:

- **REQ**: calculates Y live by linear interpolation between the two stored points (without clipping, as with E_CALIBRATE_SQ) and fires CNF. If X_HIGH - X_LOW = 0, then Y := LOW_REF.
- **C_LOW**: stores the current raw value in X_LOW and fires EO_LOW.
- **C_HIGH**: stores the current raw value in X_HIGH and fires EO_HIGH.

Every action state returns immediately to START.
Calibration (free order):

1. **Low (EI_LOW)**: apply the low reference, set LOW_REF to the desired output, fire EI_LOW → X_LOW := X
2. **High (EI_HIGH)**: apply the high reference, set HIGH_REF to the desired output, fire EI_HIGH → X_HIGH := X

Either point can be recalibrated on its own at any later time without repeating the other.

Technical Details

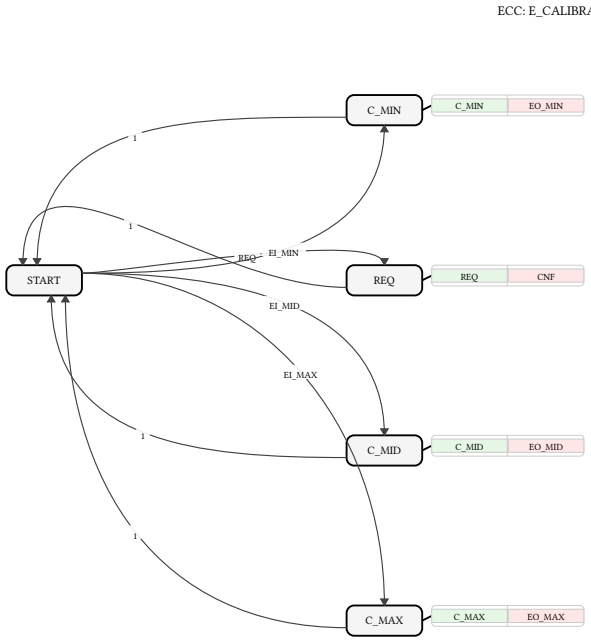
- **Independent points instead of incremental OFFSET/SCALE calculation:** E_CALIBRATE_SQ computes OFFSET/SCALE step by step (EICO sets OFFSET from a live SCALE, EICS computes both from internally remembered values) and is only mathematically valid after at least one EICO. That required an ECC-enforced order to avoid silently wrong offsets. E_CALIBRATE_2P stores X_LOW/X_HIGH like E_CALIBRATE_3P stores its points, with no data dependency between EI_LOW and EI_HIGH.
- No clipping of Y to LOW_REF..HIGH_REF (unlike E_CALIBRATE_3P).
- Degenerate calibration points (X_HIGH = X_LOW) yield LOW_REF instead of a division by zero.

State Overview

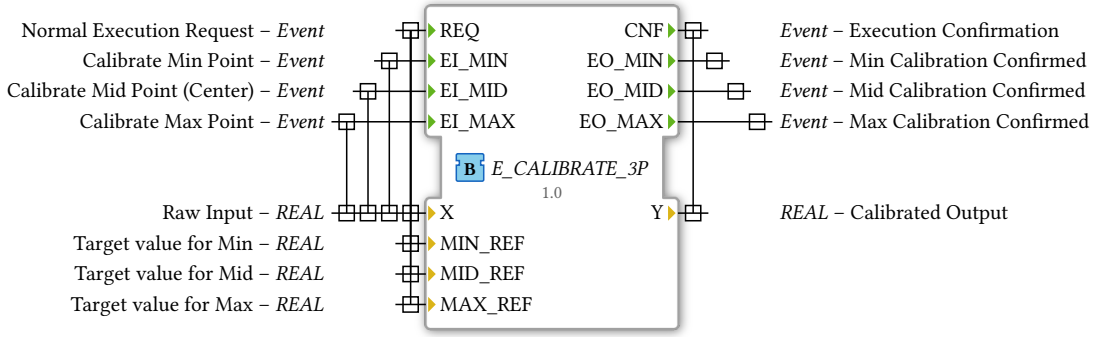
```
START --REQ-----> REQ    --1--> START   (normal operation)
START --EI_LOW--> C_LOW  --1--> START   (calibrate low point)
START --EI_HIGH-> C_HIGH --1--> START   (calibrate high point)
```

Application Scenarios

- Two-point calibration of analog inputs (e.g. sensors) when the calibration trigger is already available as an event
- Readjusting only one point



⚖️ Comparison with Similar Building Blocks



- E_CALIBRATE: variant with `EICO`/`EICS` (`OFFSET`/`SCALE`) in which `EICS` only yields a consistent result after `EICO`
- E_CALIBRATE_3P: three-point variant with piecewise interpolation and clipping

Conclusion

`E_CALIBRATE_2P` provides an event-driven two-point calibration with independently triggerable calibration points and no enforced order.

E_CALIBRATE_3P

• – ○ • – ○ • – ○ •

Introduction

E_CALIBRATE_3P is the event-driven counterpart to CALIBRATE_3P: the three-point calibration with piecewise linear interpolation (Min/Mid/Max) is triggered by its own events EI_MIN/EI_MID/EI_MAX, each with its own confirmation event.

Interface Structure

Event Inputs

- **REQ**: normal execution request – computes Y. Carries X, MIN_REF, MID_REF, MAX_REF, X_MIN, X_MID, X_MAX.
- **EI_MIN**: calibrates the minimum point (X_MIN := X). Carries X.
- **EI_MID**: calibrates the mid point (X_MID := X). Carries X.
- **EI_MAX**: calibrates the maximum point (X_MAX := X). Carries X.

Event Outputs

- **CNF**: confirms REQ, carries Y.
- **EO_MIN**: confirms minimum-point calibration, carries X_MIN.
- **EO_MID**: confirms mid-point calibration, carries X_MID.
- **EO_MAX**: confirms maximum-point calibration, carries X_MAX.

Data Inputs

- **X** (REAL): raw input value.
- **MIN_REF** (REAL, initial 0.0): target output value for the minimum point.
- **MID_REF** (REAL, initial 50.0): target output value for the mid point.
- **MAX_REF** (REAL, initial 100.0): target output value for the maximum point.

Data Outputs

- **Y** (REAL): calibrated, interpolated output value, clipped to MIN_REF..MAX_REF.

In/Out Variables

- **X_MIN** (REAL, initial 0.0): stored raw value at the minimum point.
- **X_MID** (REAL, initial 50.0): stored raw value at the mid point.
- **X_MAX** (REAL, initial 100.0): stored raw value at the maximum point.

Functionality

E_CALIBRATE_3P has a start state START and four action states directly reachable from it:

- **REQ**: interpolates Y piecewise linearly between the stored points (as in CALIBRATE_3P) and fires CNF.
- **C_MIN/C_MID/C_MAX**: store the current raw value X in the corresponding X_MIN/X_MID/X_MAX and fire the matching confirmation event (EO_MIN/EO_MID/EO_MAX).

Each of these four states returns immediately to START, from which all four events are again equally reachable – so the calibration points can be visited in any order and repeated individually as often as needed.

Example (joystick with center drift, raw range 0..1000, desired output range -100..0..100):

Step	Action	Result
1	Move joystick to **minimum**, fire EI_MIN	X_MIN = 50 (drift from ideal 0)
2	Move joystick to **center**, fire EI_MID	X_MID = 520 (drift from ideal 500)
3	Move joystick to **maximum**, fire EI_MAX	X_MAX = 980 (drift from ideal 1000)

Result: Y is interpolated and clipped between MIN_REF=-100, MID_REF=0 and MAX_REF=100.

Technical Details

- **Four equal actions from a shared start state**: there is no dependency between the calibration steps – each point can be re-set independently and in any order.
- **Output always clipped**: Y is clipped to MIN_REF..MAX_REF after interpolation.
- **Degenerate calibration points**: as with CALIBRATE_3P, an interpolation with X_MID <= X_MIN or X_MAX <= X_MID returns a constant MIN_REF or MID_REF instead of dividing by zero.

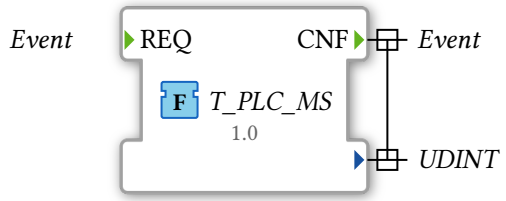
State Overview

```
START --REQ-----> REQ    --1--> START   (normal operation)
START --EI_MIN--> C_MIN  --1--> START   (calibrate minimum)
START --EI_MID--> C_MID  --1--> START   (calibrate mid)
START --EI_MAX--> C_MAX  --1--> START   (calibrate maximum)
```

All four calibration events are independently reachable from `START` – no enforced order.

Application Scenarios

- Three-point calibration of joysticks in systems that already provide the calibration trigger as an event
- Applications where each calibration point needs its own, immediate confirmation (e.g. for UI feedback "point X calibrated")
- Readjusting individual points (e.g. only `EI_MID` after drift) without needing to recalibrate the other two



⚖️ Comparison with Similar Blocks

Compare with CALIBRATE_3P, which applies the same three-point logic Boolean-triggered rather than event-driven, and with E_CALIBRATE, which performs a linear two-point rather than three-point calibration. For details see Two- and Three-Point Calibration Procedures.

Conclusion

`E_CALIBRATE_3P` provides event-driven three-point calibration with independently triggerable, individually confirmed calibration points, and fits especially well for joysticks and similar controls with a center position.

GEN_RMP

this signal generator generates a ramp wave output this signal generator generates a ramp wave output. The ramp wave signal is defined by period time (PT), amplitude (AM), offset (OS) and a specific delay for the output signal (DL). The Output waveform will have its minimum peak at OS and its maximum peak at AM + OS. The delay input can delay a signal up to PT, this can be useful to synchronize different generators and generate interleaving signals. in addition to the analog output Out there is a second boolean output Q with is true for one cycle when the ramp starts.

GEN_SIN

this signal generator generates a sine wave output this signal generator generates a sine wave output. The sine wave signal is defined by period time (PT), amplitude (AM), offset (OS) and a specific delay for the output signal (DL). The Output waveform will have its max peak at AM/2 + OS and its minimum peak at -AM/2 + OS. The delay input can delay a signal up to PT, this can be useful to synchronize different generators and generate interleaving signals. A Cos wave can be generated accordingly. in addition to an analog output Out there is a second boolean output Q with the corresponding binary signal.

CEIL

• – ◦ • – ◦ • – ◦ •

Introduction

The function `CEIL` is a rounding function (ported from `OSCAT_basic`, `CEIL.TcPOU`) that returns the smallest integer greater than or equal to `X`. The result is clamped to the `INT` range.

Interface Structure

Event Inputs

- `REQ`: Starts the calculation. Associated data: `X`

Event Outputs

- `CNF`: Signals the calculation and the output of the result.

Data Inputs

- `X` (`REAL`): Value to be rounded

Data Outputs

- (no name) (`INT`): Rounded-up value, also the return value of the function

Adapters

This function uses no adapters.

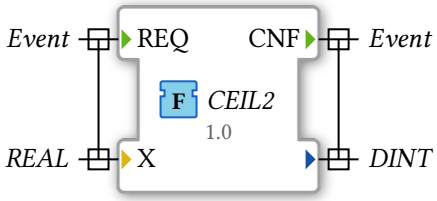
How it works

1. If `X >= 32767.0`, the result is `32767`.
2. If `X <= -32768.0`, the result is `-32768`.
3. Otherwise `X` is converted to an integer with `REAL_TO_INT`. If the result is smaller than `X`, 1 is added.

Examples: `CEIL(3.14) = 4`, `CEIL(-3.14) = -3`.

Technical Details

- Implemented in Structured Text (ST) as a `FUNCTION` without internal state
- Part of the package `OSCAT::Basic::POUs::Mathematical`
- The range check protects against an `INT` overflow (port of 2026-09-17).
- `REAL_TO_INT` is used instead of `TRUNC` (compatibility, revision 1.1 of the OSCAT original).



Application Scenarios

- Rounding up numeric values, e.g. for display or count values

Summary

`CEIL` returns the next greater integer of a `REAL` value as `INT` and clamps the result to the `INT` value range.

CEIL2

• – ◦ • – ◦ • – ◦ •

Introduction

`CEIL2` is a rounding function from the OSCAT Basic library: it returns the smallest integer that is greater than or equal to `X` (rounding up). Compared with `CEIL`, the result is a `DINT`, so the function also works outside the `INT` range. Examples: `CEIL2(3.14) = 4`, `CEIL2(-3.14) = -3`. Ported from `OSCAT_basic CEIL2.TcPOU`.

Interface Structure

Event Inputs

- **REQ**: calculation request (associated with `X`)

Event Outputs

- **CNF**: calculation confirmation (associated with the function result)

Data Inputs

- **X** (REAL): value to be rounded

Data Outputs

- **(function result)** (DINT): smallest integer `>= X`, limited to the `DINT` range

Adapters

No adapters are used.

Functionality

The function is implemented in Structured Text:

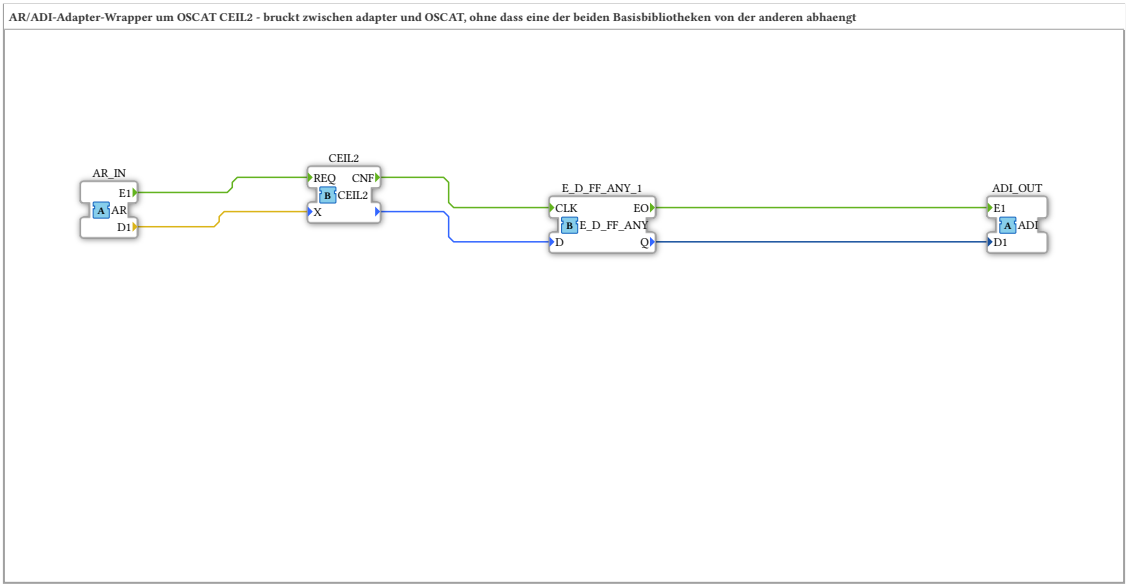
1. If `X >= 2147483647.0`, `2147483647` is returned.
2. If `X <= -2147483648.0`, `-2147483648` is returned.
3. Otherwise `CEIL2 := REAL_TO_DINT(X)` is calculated; if `DINT_TO_REAL(CEIL2) < X`, the result is increased by 1 (`CEIL2 := CEIL2 + 1`).

Technical Details

- The range check protects against `DINT` overflow: values outside the `DINT` range are limited to the boundary values
- Pure function without state; integrated into the event network as a function block with `REQ`/`CNF`
- The output has no name of its own but is the return value of the function

Application Scenarios

- Rounding up a measured or calculated quantity to the next integer, also for large magnitudes



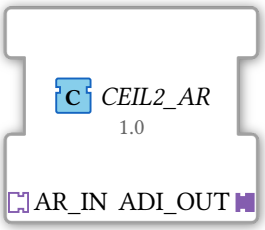
⚖️ Comparison with Similar Blocks

`FLOOR2` is the counterpart for rounding down (largest integer `<= X`).

Conclusion

`CEIL2` rounds a `REAL` value up to the next integer and returns the result as a `DINT` with overflow protection.

CEIL2_AR



• – ○ • – ○ • – ○ •

Introduction

`CEIL2_AR` is an adapter wrapper around `OSCAT::Basic::POUs::Mathematical::CEIL2` (DINT variant of CEIL for values outside the INT range). It connects the `AR` adapter with the OSCAT function `CEIL2` and outputs the result as an `ADI` adapter (smallest integer greater than or equal to X (DINT)). The wrapper bridges the adapter and OSCAT libraries without either base library depending on the other.

Eingangssignal (REAL) – *AR*

ADI – Kleinste ganze Zahl >= X (DINT)

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter `AR_IN`.

Event Outputs

No direct event outputs - events leave via the adapter `ADI_OUT`.

Data Inputs

None.

Data Outputs

None.

Adapters

- **AR_IN** (socket, `adapter::types::unidirectional::AR`): input signal (`REAL`)
- **ADI_OUT** (plug, `adapter::types::unidirectional::ADI`): smallest integer greater than or equal to X (DINT)

Function Blocks (FBs) Used

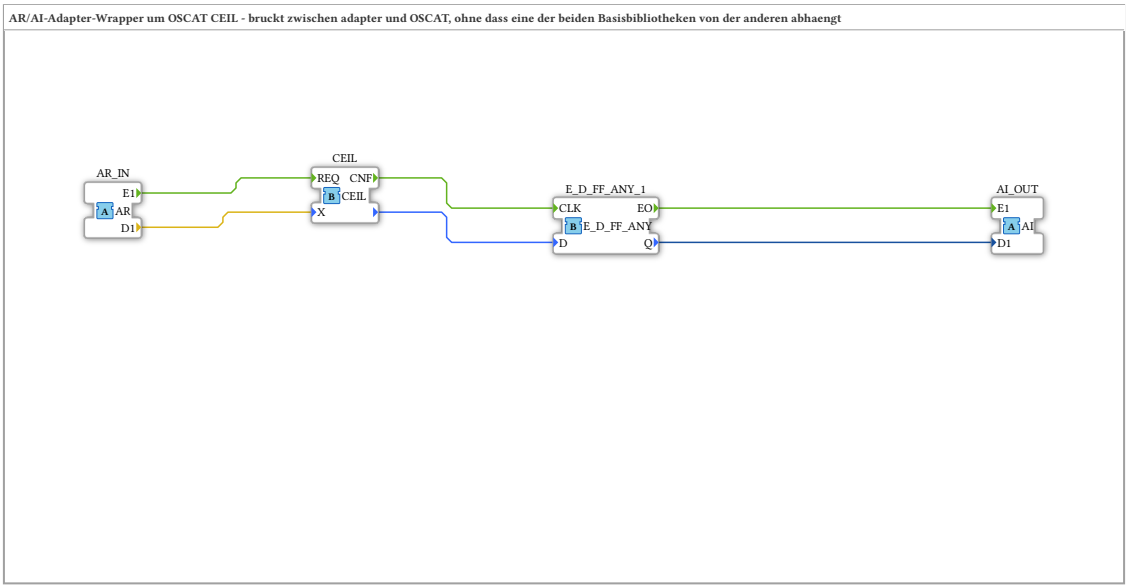
- **`CEIL2`** (`OSCAT::Basic::POUs::Mathematical::CEIL2`): rounding function, see CEIL2
- **`E_D_FF_ANY_1`** (`iec61499::events::E_D_FF_ANY`): change filter

Functionality

- `AR_IN.E1` ⟶ `CEIL2.REQ`; `AR_IN.D1` ⟶ `CEIL2.X`
- `CEIL2.CNF` ⟶ `E_D_FF_ANY_1.CLK`; return value of `CEIL2` ⟶ `E_D_FF_ANY_1.D`
- `E_D_FF_ANY_1.EO` ⟶ `ADI_OUT.E1`; `E_D_FF_ANY_1.Q` ⟶ `ADI_OUT.D1`

Technical Details

- `E_D_FF_ANY_1` (standard library `events-3.0.0`) filters changes: `ADI_OUT.E1` only fires when the result actually changed since the last call. Same pattern as the `FT_DERIV_AR`/`CTRL_PI_AR` wrappers.
- **Why a separate wrapper?** `CEIL2` is a pure OSCAT `Function` without an adapter interface. `adapter` should not depend on `OSCAT` (and vice versa); the bridge therefore lives in the third library project `OSCAT_adapter`, which depends on both.



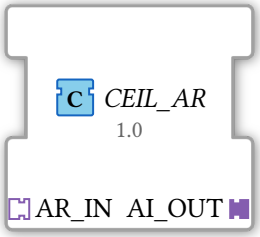
Application Scenarios

- Rounding an `AR` signal in an adapter chain to an integer (`DINT`)

Summary

`CEIL2_AR` rounds an `AR` value with `CEIL2` and outputs the result as an `ADI` adapter only when it changes.

CEIL_AR



• – ○ • – ○ • – ○ •

Introduction

`CEIL_AR` is an adapter wrapper around `OSCAT::Basic::POUs::Mathematical::CEIL`. It connects the `AR` adapter with the OSCAT function `CEIL` and outputs the result as an `AI` adapter (smallest integer greater than or equal to X (INT)). The wrapper bridges the adapter and OSCAT libraries without either base library depending on the other.

Eingangssignal (REAL) – *AR*

AI – Kleinste ganze Zahl >= X (INT)

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter `AR_IN`.

Event Outputs

No direct event outputs - events leave via the adapter `AI_OUT`.

Data Inputs

None.

Data Outputs

None.

Adapters

- **AR_IN** (socket, `adapter::types::unidirectional::AR`): input signal (`REAL`)
- **AI_OUT** (plug, `adapter::types::unidirectional::AI`): smallest integer greater than or equal to X (INT)

Function Blocks (FBs) Used

- **`CEIL`** (`OSCAT::Basic::POUs::Mathematical::CEIL`): rounding function, see CEIL

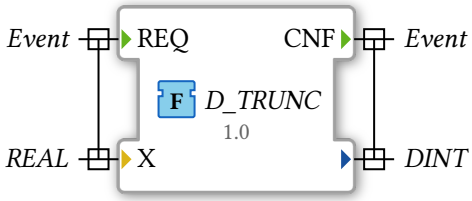
- **E_D_FF_ANY_1** (iec61499::events::E_D_FF_ANY): change filter

Functionality

- AR_IN.E1 ⟶ CEIL.REQ; AR_IN.D1 ⟶ CEIL.X
- CEIL.CNF ⟶ E_D_FF_ANY_1.CLK; return value of CEIL ⟶ E_D_FF_ANY_1.D
- E_D_FF_ANY_1.EO ⟶ AI_OUT.E1; E_D_FF_ANY_1.Q ⟶ AI_OUT.D1

Technical Details

- E_D_FF_ANY_1 (standard library events-3.0.0) filters changes: AI_OUT.E1 only fires when the result actually changed since the last call. Same pattern as the FT_DERIV_AR/CTRL_PI_AR wrappers.
- **Why a separate wrapper?** CEIL is a pure OSCAT Function without an adapter interface. adapter should not depend on OSCAT (and vice versa); the bridge therefore lives in the third library project OSCAT_adapter, which depends on both.



Application Scenarios

- Rounding an AR signal in an adapter chain to an integer (INT)

Summary

CEIL_AR rounds an AR value with CEIL and outputs the result as an AI adapter only when it changes.

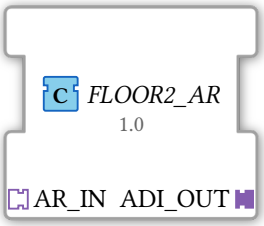
FLOOR2_AR



• – ○ • – ○ • – ○ •

Introduction

`FLOOR2_AR` is an AR/ADI adapter wrapper around the OSCAT function `OSCAT::Basic::POUs::Mathematical::FLOOR2` (largest integer `<= X`, `DINT` variant of `FLOOR` for values outside the `INT` range). It bridges between adapters and OSCAT without either base library depending on the other.

Eingangssignal (REAL) – *AR*

ADI – Groesste ganze Zahl <= X (DINT)

Interface Structure

Event Inputs

The function block has no direct event inputs.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AR_IN** (socket, `adapter::types::unidirectional::AR`): input signal (REAL)
- **ADI_OUT** (plug, `adapter::types::unidirectional::ADI`): largest integer <= `X` (DINT)

Functionality

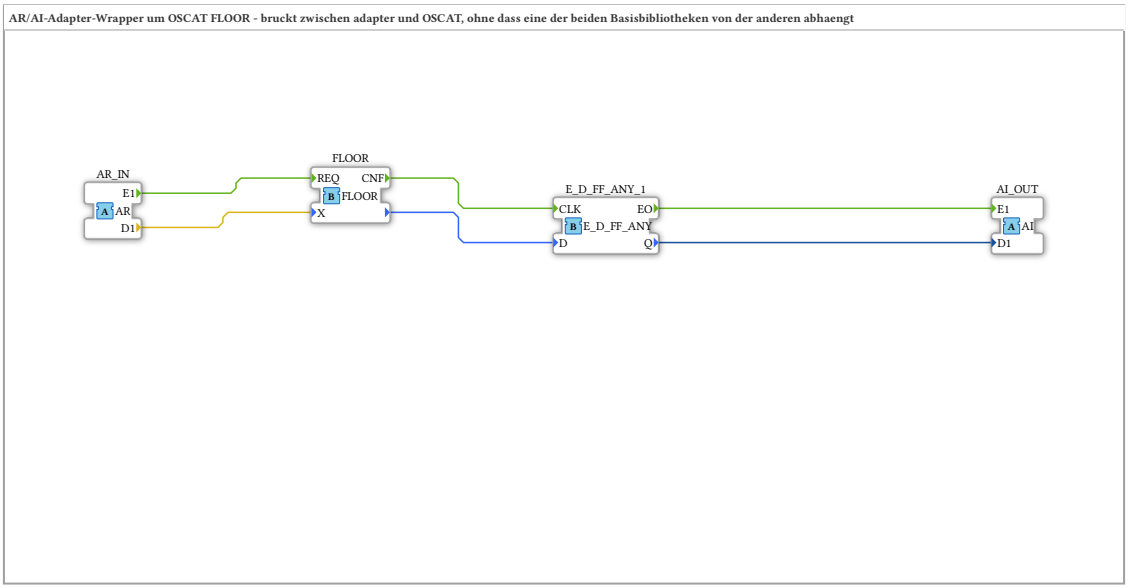
- `AR_IN.E1` ⟶ `FLOOR2.REQ` and `AR_IN.D1` ⟶ `FLOOR2.X`: every new input signal starts the calculation.
- `FLOOR2.CNF` ⟶ `E_D_FF_ANY_1.CLK`; the function result goes to `E_D_FF_ANY_1.D`.
- `E_D_FF_ANY_1` (`iec61499::events::E_D_FF_ANY`) filters changes: `E_D_FF_ANY_1.EO` ⟶ `ADI_OUT.E1` and `E_D_FF_ANY_1.Q` ⟶ `ADI_OUT.D1`, but only if the result has actually changed since the last call.

Technical Details

- Change filter: `ADI_OUT.E1` fires only on an actual value change (same pattern as `CTRL_PI_AR`/ `FT_DERIV_AR`)
- `FLOOR2` is a pure OSCAT function without an adapter interface; `adapter` should not depend on `OSCAT` (and vice versa), so the bridge lives in the third library project `OSCAT_adapter`

Application Scenarios

- Rounding down an adapter-based REAL value to an integer (DINT) in an adapter network



⚖️ Comparison with Similar Blocks

`ROUND_AR` rounds to decimal places (REAL output); `FLOOR2_AR` returns the rounded-down integer as a DINT.

Conclusion

`FLOOR2_AR` provides `FLOOR2` as an adapter block from `AR` to `ADI` and outputs the result only on change.

FLOOR_AR

• – ○ • – ○ • – ○ •

Introduction

`FLOOR_AR` is an adapter wrapper around `OSCAT::Basic::POUs::Mathematical::FLOOR`. It connects the `AR` adapter with the OSCAT function `FLOOR` and outputs the result as an `AI` adapter (largest integer less than

or equal to X (INT)). The wrapper bridges the adapter and OSCAT libraries without either base library depending on the other.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter `AR_IN`.

Event Outputs

No direct event outputs - events leave via the adapter `AI_OUT`.

Data Inputs

None.

Data Outputs

None.

Adapters

- **AR_IN** (socket, `adapter::types::unidirectional::AR`): input signal (`REAL`)
- **AI_OUT** (plug, `adapter::types::unidirectional::AI`): largest integer less than or equal to X (INT)

Function Blocks (FBs) Used

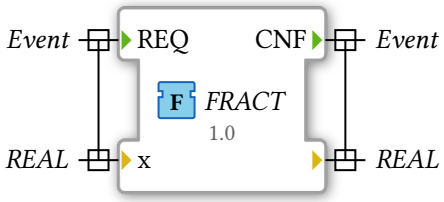
- **`FLOOR`** (`OSCAT::Basic::POUs::Mathematical::FLOOR`): rounding function, see FLOOR
- **`E_D_FF_ANY_1`** (`iec61499::events::E_D_FF_ANY`): change filter

Functionality

- `AR_IN.E1` ⟶ `FLOOR.REQ`; `AR_IN.D1` ⟶ `FLOOR.X`
- `FLOOR.CNF` ⟶ `E_D_FF_ANY_1.CLK`; return value of `FLOOR` ⟶ `E_D_FF_ANY_1.D`
- `E_D_FF_ANY_1.EO` ⟶ `AI_OUT.E1`; `E_D_FF_ANY_1.Q` ⟶ `AI_OUT.D1`

Technical Details

- `E_D_FF_ANY_1` (standard library `events-3.0.0`) filters changes: `AI_OUT.E1` only fires when the result actually changed since the last call. Same pattern as the `FT_DERIV_AR`/`CTRL_PI_AR` wrappers.
- **Why a separate wrapper?** `FLOOR` is a pure OSCAT `Function` without an adapter interface. `adapter` should not depend on `OSCAT` (and vice versa); the bridge therefore lives in the third library project `OSCAT_adapter`, which depends on both.



Application Scenarios

- Rounding an `AR` signal in an adapter chain to an integer (`INT`)

Summary

`FLOOR_AR` rounds an `AR` value with `FLOOR` and outputs the result as an `AI` adapter only when it changes.

RND

• – ◦ • – ◦ • – ◦ •

Introduction

The function `RND` rounds a `REAL` number to `N` **significant** digits (not to digits behind the decimal point). It is ported from `OSCAT_basic`. Unlike `ROUND`, `N` here denotes the total number of significant digits.

Interface Structure

Event Inputs

- **REQ**: starts the calculation. Associated data: `X`, `N`.

Event Outputs

- **CNF**: signals the calculation and the output of the result.

Data Inputs

- **X** (`REAL`): value to round
- **N** (`INT`): number of significant digits

Data Outputs

- **(unnamed)** (`REAL`): rounded value, also the return value of the function

Adapters

This function uses no adapters.

Functionality

1. If `X = 0.0`, the result is `0.0`.
2. Otherwise the factor `M = 10^(LIMIT(1, N, 8) - CEIL(LOG(ABS(X))))` is calculated; the exponent is limited to `-37..8`.
3. If `ABS(X * M) >= 2147483647.0`, `X` is returned unchanged (protection against `DINT` overflow).
4. Otherwise the result is `DINT_TO_REAL(REAL_TO_DINT(X * M)) / M`.

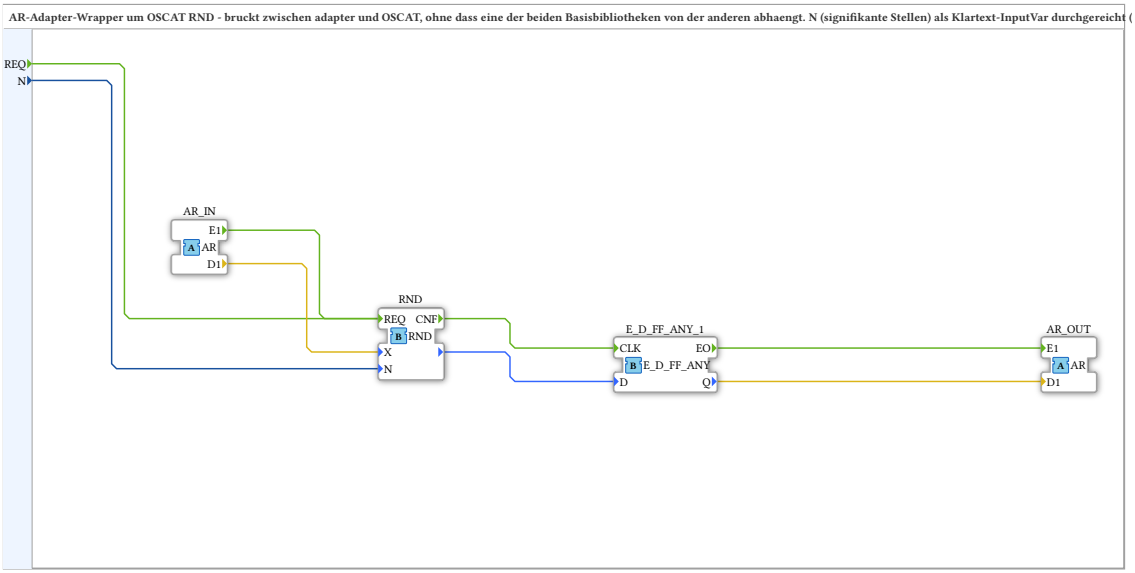
Technical Details

- Implemented in Structured Text (ST) as a `FUNCTION` without internal state, package `OSCAT::Basic::POUs::Mathematical`
- `N` is limited to `1..8`

- Port of 2026-09-17: limiting of `N` (1..8), of the exponent (-37..8) and a range check protect against `DINT` overflow
- Original version 1.1 (4 Apr 2008, hm): type conversion added to avoid warnings under CODESYS 3.0

Application Scenarios

- Rounding measured values to a fixed number of significant digits regardless of magnitude

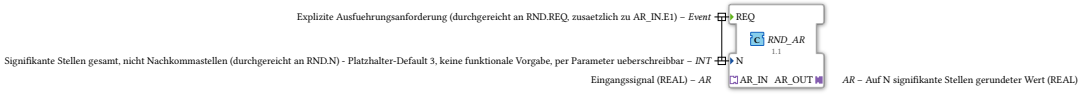


⚖️ Comparison with Similar Building Blocks

- `ROUND` rounds to `N` decimal places, `RND` to `N` significant digits.

Conclusion

`RND` rounds a `REAL` number to `N` significant digits and protects against `DINT` overflow.



RND_AR

• – ○ • – ○ • – ○ •

Introduction

`RND_AR` is an AR adapter wrapper around the OSCAT function `OSCAT::Basic::POUs::Mathematical::RND` (rounds `X` to `N` **significant digits**, not to decimal places). It bridges adapters and OSCAT without either base library depending on the other. `N` is passed through as a plain input variable (default 3).

Interface Structure

Event Inputs

- **REQ**: explicit execution request (passed through to `RND.REQ`, in addition to `AR_IN.E1`)
  - **Associated data**: `N`

Event Outputs

The function block has no direct event outputs.

Data Inputs

- **N** (`INT`): Total significant digits, not decimal places (passed through to `RND.N`); placeholder default 3, no functional requirement, can be overridden via parameter

Data Outputs

The function block has no direct data outputs.

Adapters

- **AR_IN** (socket, `adapter::types::unidirectional::AR`): Input signal (`REAL`)
- **AR_OUT** (plug, `adapter::types::unidirectional::AR`): Value rounded to `N` significant digits (`REAL`)

Function Blocks (FBs) Used

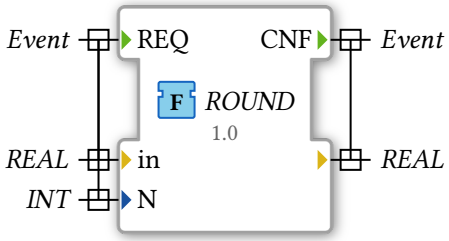
- **`RND`** (`OSCAT::Basic::POUs::Mathematical::RND`): rounding function, see RND
- **`E_D_FF_ANY_1`** (`iec61499::events::E_D_FF_ANY`): change filter

How it works

- `AR_IN.E1` ⟶ `RND.REQ` and `AR_IN.D1` ⟶ `RND.X`; `N` ⟶ `RND.N`.
- `REQ` also leads to `RND.REQ`, in parallel to `AR_IN.E1`.
- `RND.CNF` ⟶ `E_D_FF_ANY_1.CLK`; the function result goes to `E_D_FF_ANY_1.D`.
- `E_D_FF_ANY_1.EO` ⟶ `AR_OUT.E1` and `E_D_FF_ANY_1.Q` ⟶ `AR_OUT.D1`, but only if the rounded result has actually changed since the last call.

Technical Details

- The explicit `REQ` with `With N` was added as a bugfix in version 1.1 (2026-09-20): previously `N` was only passed to `RND` via a data connection and triggered solely via `AR_IN.E1`; since the wrapper had no event input, there was no `With` binding (per IEC 61499, unbound variables are not read reliably). `REQ` allows manual or periodic execution in addition to automatic triggering via `AR_IN.E1`
- Change filter: `AR_OUT.E1` fires only when the rounded value actually changes (same pattern as `CTRL_PI_AR`/`FT_DERIV_AR`, there using `E_D_FF_ANY_3`/`_4` for several values at once)
- `RND` is a pure OSCAT function without an adapter interface; `adapter` should not depend on `OSCAT` (and vice versa), so the bridge lives in the third library project `OSCAT_adapter`
- Difference to `ROUND_AR`: `RND_AR` rounds to significant digits, `ROUND_AR` to decimal places



Application Scenarios

- Rounding an `AR` signal to a fixed number of significant digits in an adapter chain, e.g. for display values

Summary

`RND_AR` rounds an `AR` value to `N` significant digits with `RND` and outputs the result as an `AR` adapter only when it changes.

ROUND

• – ◦ • – ◦ • – ◦ •

Introduction

The function `ROUND` rounds a `REAL` value to `N` digits after the decimal point (0 to 8). It was ported from `OSCAT_basic`.

Interface Structure

Event Inputs

- `REQ`: Starts the calculation. Associated data: `in`, `N`

Event Outputs

- `CNF`: Signals the calculation and the output of the result.

Data Inputs

- `in` (`REAL`): Value to be rounded
- `N` (`INT`): Number of decimal places (limited to 0 to 8)

Data Outputs

- (no name) (`REAL`): Rounded value, also the return value of the function

Adapters

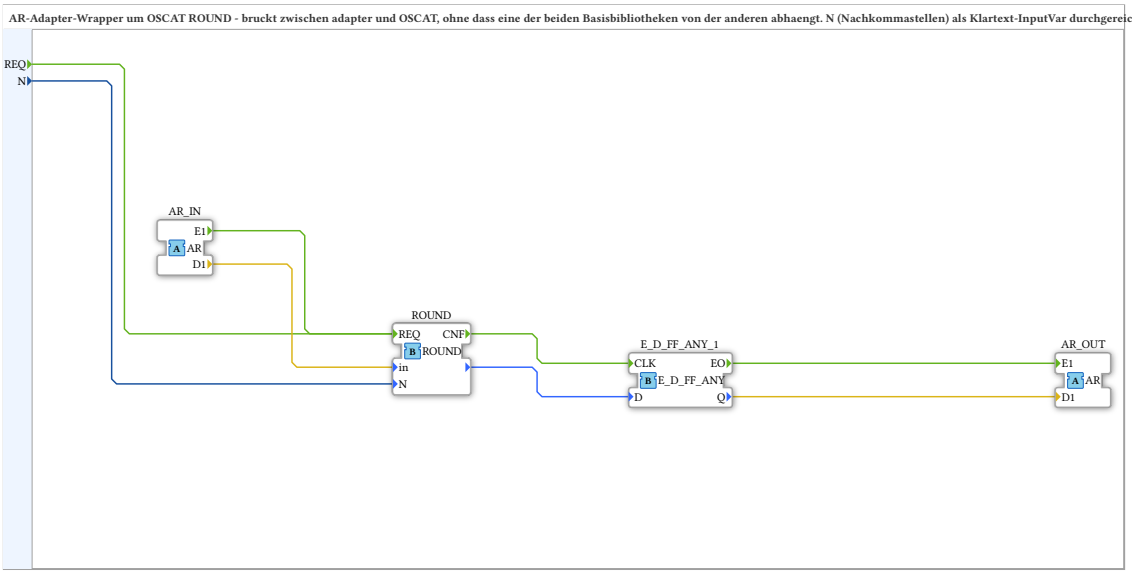
This function uses no adapters.

How it works

1. The factor `X := EXPT(10.0, LIMIT(0, N, 8))` is determined.
2. If `ABS(in * X) >= 2147483647.0` (DINT range), `in` is returned unchanged.
3. Otherwise the result is `DINT_TO_REAL(REAL_TO_DINT(in * X)) / X`.

Technical Details

- Implemented in Structured Text (ST) as a `FUNCTION` with local variable `X`, without internal state
- Part of the package `OSCAT::Basic::POUs::Mathematical`
- `EXPT(10.0, LIMIT(0, N, 8))` replaces the global OSCAT constants `decades`; the range check protects against a `DINT` overflow (port of 2026-09-17).
- `REAL_TO_DINT` instead of `TRUNC` fixes the error with negative numbers (OSCAT revision 1.3).
- `N` is limited to 0 to 8.

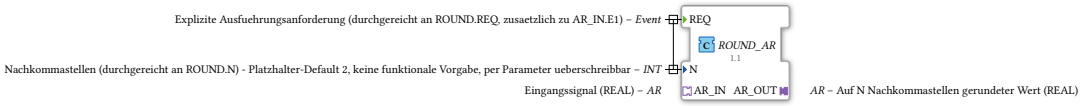


Application Scenarios

- Rounding measured values for display or comparison to a fixed number of decimal places

Summary

`ROUND` rounds a `REAL` value to up to 8 decimal places and returns the input unchanged if the value is too large.



ROUND_AR

• — ○ • — ○ • — ○ •

Introduction

`ROUND_AR` is an AR adapter wrapper around the OSCAT function `OSCAT::Basic::POUs::Mathematical::ROUND` (rounds `in` to `N` decimal places, 0 to 8 digits). It bridges between adapters and OSCAT without either base library depending on the other. `N` is passed through as a plain input variable (default 2).

Interface Structure

Event Inputs

- **REQ**: explicit execution request (passed on to `ROUND.REQ`, in addition to `AR_IN.E1`)
  - **Associated data**: `N`

Event Outputs

The function block has no direct event outputs.

Data Inputs

- **N** (INT): number of decimal places (passed on to `ROUND.N`); placeholder default 2, overridable via parameter

Data Outputs

The function block has no direct data outputs.

Adapters

- **AR_IN** (socket, `adapter::types::unidirectional::AR`): input signal (REAL)
- **AR_OUT** (plug, `adapter::types::unidirectional::AR`): value rounded to `N` decimal places (REAL)

Functionality

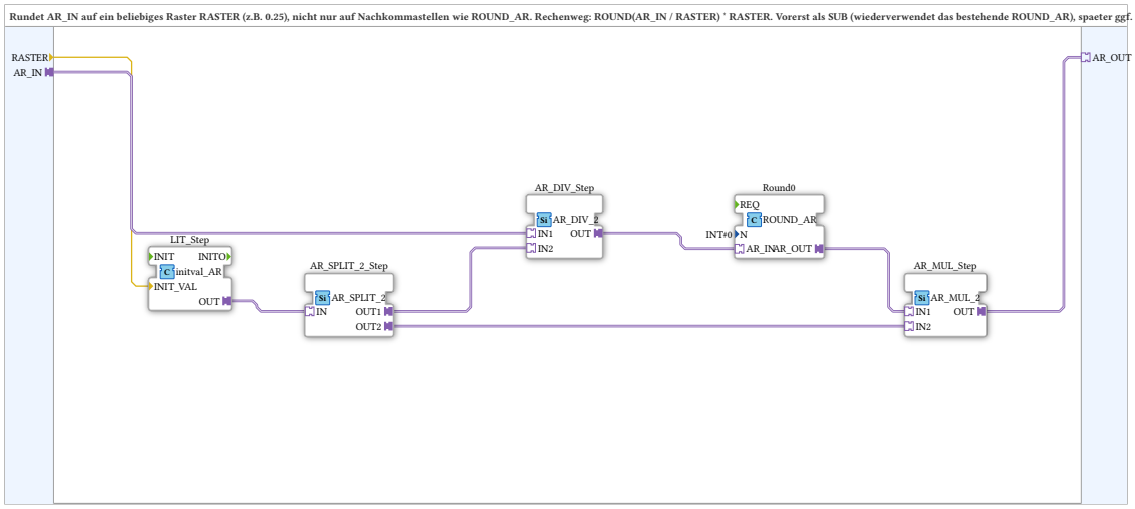
- `AR_IN.E1` ⟶ `ROUND.REQ` and `AR_IN.D1` ⟶ `ROUND.in`; `N` ⟶ `ROUND.N`.
- `REQ` also goes to `ROUND.REQ`, in parallel to `AR_IN.E1`.
- `ROUND.CNF` ⟶ `E_D_FF_ANY_1.CLK`; the function result goes to `E_D_FF_ANY_1.D`.
- `E_D_FF_ANY_1` (`iec61499::events::E_D_FF_ANY`) filters changes: `E_D_FF_ANY_1.EO` ⟶ `AR_OUT.E1` and `E_D_FF_ANY_1.Q` ⟶ `AR_OUT.D1`, but only if the rounded result has actually changed since the last call.

Technical Details

- The explicit `REQ` with `With N` was added because `N` would otherwise only be read via a data connection; per IEC 61499, variables not bound via `With` are not read reliably. `REQ` allows manual or periodic execution in addition to automatic triggering via `AR_IN.E1`
- Change filter: `AR_OUT.E1` fires only when the rounded value actually changes (same pattern as `CTRL_PI_AR`/`FT_DERIV_AR`, there with `E_D_FF_ANY_3`/`_4`)
- `ROUND` is a pure OSCAT function without an adapter interface; the bridge lives in the third library project `OSCAT_adapter`

Application Scenarios

- Rounding displayed or forwarded measured values to a fixed number of decimal places in adapter networks

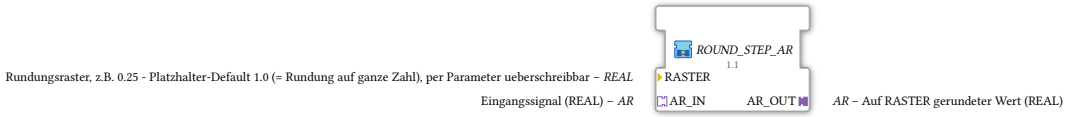


⚖️ Comparison with Similar Blocks

`ROUND_STEP_AR` rounds to an arbitrary grid (e.g. 0.25) instead of only to decimal places and uses `ROUND_AR` internally (`ROUND(AR_IN / RASTER) * RASTER`). `FLOOR2_AR`, in contrast, returns a rounded-down integer as a DINT.

Conclusion

`ROUND_AR` provides `ROUND` as an adapter block from `AR` to `AR`, rounds to `N` decimal places and outputs the result only on change.



ROUND_STEP_AR

• — ○ • — ○ • — ○ •

Introduction

`ROUND_STEP_AR` rounds `AR_IN` to an **arbitrary grid** `RASTER` (e.g. 0.25), not only to decimal places like `ROUND_AR`. Calculation: `ROUND(AR_IN / RASTER) * RASTER`. The block is for now a SubApp that reuses the existing `ROUND_AR`; possibly a separate basic block later.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

- **RASTER** (`REAL`): rounding grid, e.g. `0.25`. Placeholder default `1.0` (= rounding to an integer), can be overridden by parameter.

Data Outputs

None.

Adapters

- **AR_IN** (socket, `adapter::types::unidirectional::AR`): input signal (`REAL`)
- **AR_OUT** (plug, `adapter::types::unidirectional::AR`): value rounded to `RASTER` (`REAL`)

Function Blocks (FBs) Used

- **`LIT_Step`** (`adapter::types::unidirectional::AR::initval::initval_AR`): creates a constant `AR` value from `RASTER`
- **`AR_SPLIT_2_Step`** (`adapter::events::unidirectional::AR_SPLIT_2`): fans `RASTER` out to the division and the multiplication (adapter fan-out is strictly 1:1)
- **`AR_DIV_Step`** (`adapter::iec61131::arithmetic::AR_DIV_2`): `AR_IN / RASTER`
- **`Round0`** (`OSCAT_adapter::Mathematical::ROUND_AR`, `N = 0`): rounds the quotient to an integer
- **`AR_MUL_Step`** (`adapter::iec61131::arithmetic::AR_MUL_2`): multiplies back by `RASTER`

Functionality

- `RASTER` ⟶ `LIT_Step.INIT_VAL`; `LIT_Step.OUT` ⟶ `AR_SPLIT_2_Step.IN`
- `AR_IN` ⟶ `AR_DIV_Step.IN1`; `AR_SPLIT_2_Step.OUT1` ⟶ `AR_DIV_Step.IN2`
- `AR_DIV_Step.OUT` ⟶ `Round0.AR_IN`
- `Round0.AR_OUT` ⟶ `AR_MUL_Step.IN1`; `AR_SPLIT_2_Step.OUT2` ⟶ `AR_MUL_Step.IN2`
- `AR_MUL_Step.OUT` ⟶ `AR_OUT`

Technical Details

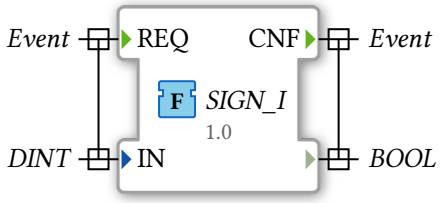
- Rounding to a grid instead of decimal places
- `RASTER` is set by parameter at instantiation
- Example: `RASTER = 0.25` rounds to quarters

Application Scenarios

- Rounding setpoints or display values to step sizes (e.g. 0.25, 0.5, 5)

⚖️ Comparison with Similar Building Blocks

- `ROUND_AR` only rounds to `N` decimal places and is used internally here.



Summary

`ROUND_STEP_AR` rounds an `AR` signal to a freely selectable grid.

2.1.9 Option

2.1.9.1 AOption

Plug (adapter output)

Socket (adapter input)

• – ○ • – ○ • – ○ •

Introduction

The `AOption` adapter (library `Option`) is an option management adapter: it carries an INIT request/confirm handshake with the event input qualifier `QI` (IEC 61499-1). The plug side (requester) can request/activate (`QI=TRUE`) or withdraw/terminate (`QI=FALSE`) an option at the socket side (option group); the socket acknowledges with `INIT_CNF`.

Interface Structure

Event Inputs

Event	Comment
`INIT_CNF`	Initialization confirmed (SOCKET -> PLUG).

Event Outputs

Event	Comment
`INIT_REQ`	Request initialization (PLUG -> SOCKET). Carries the data `QI_OUT`.

Data Inputs

None.

Data Outputs

Variable	Type	Comment
`QI_OUT`	BOOL	Event input qualifier for `INIT_REQ` (IEC 61499-1): `TRUE` = request/activate option (INIT_REQ+), `FALSE` = withdraw/terminate (INIT_REQ-).

(The directions are given from the plug side; they are mirrored on the socket side.)

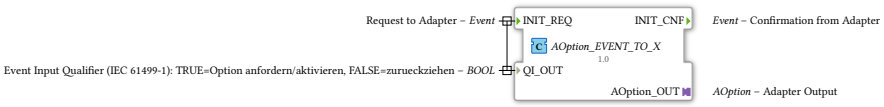
Functionality

The plug sends `INIT_REQ` together with `QI_OUT`. The socket evaluates `QI_OUT` (activate or deactivate the option group) and answers with `INIT_CNF` when done. The adapter itself contains no logic; it only defines the interface. To connect it in your own networks, use the converters `AOption_EVENT_TO_X` (holds the plug) and `AOption_X_TO_EVENT` (holds the socket).

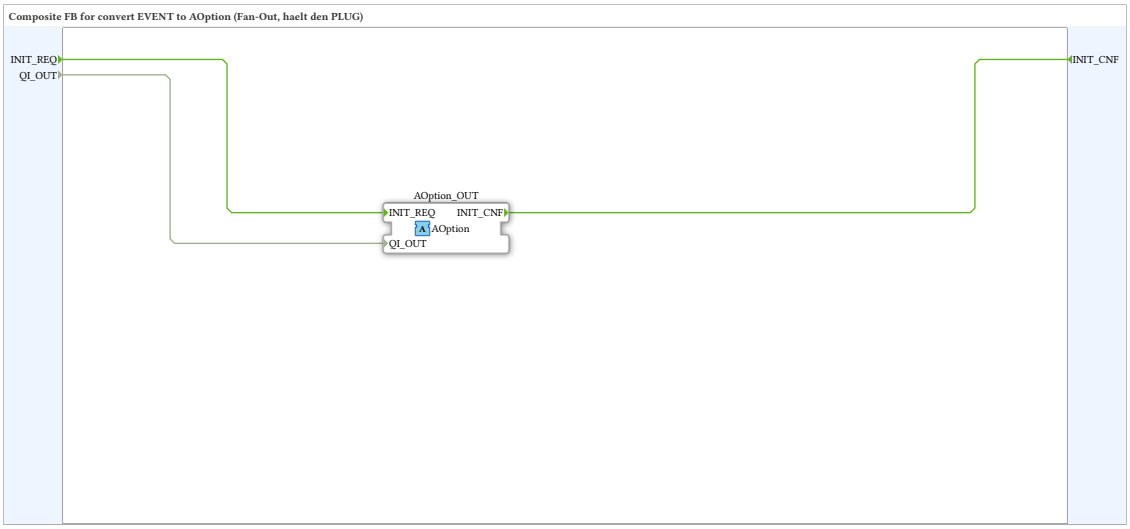
Technical Features

- **Handshake**: every request is acknowledged with `INIT_CNF` (request/confirm).
- **Data binding**: `QI_OUT` is bound to the event `INIT_REQ` via `With`.
- **No state machine**: the adapter is a pure interface type.

Application Scenarios



- Switching optional function groups (e.g. groups containing I/O blocks) on and off via a selection block such as `AOption_AD_DEMUX_2`.



Conclusion

`AOption` provides a lean INIT_REQ/INIT_CNF handshake with `QI` for activating and deactivating optional parts of an application.

2.1.9.2 conversion

AOption_EVENT_TO_X

• – ○ • – ○ • – ○ •

Introduction

`AOption_EVENT_TO_X` is a composite FB that maps events and data onto the option adapter `AOption` (fan-out, holds the PLUG).

Interface Structure

Event Inputs

Event	Type	Comment
`INIT_REQ`	EInit	Request to the adapter. Carries the data `QI_OUT`.

Event Outputs

Event	Type	Comment
`INIT_CNF`	EInit	Confirmation from the adapter.

Data Inputs

Variable	Type	Comment
`QI_OUT`	BOOL	Event input qualifier (IEC 61499-1): `TRUE` = request/activate option, `FALSE` = withdraw.

Data Outputs

None.

Adapters

Adapter	Type	Direction	Comment
`AOption_OUT`	`Option::AOption`	Plug	Adapter output.

Functionality

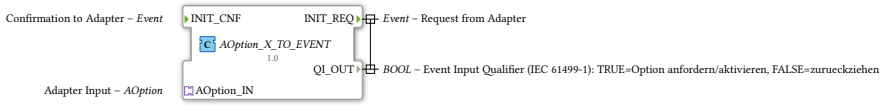
The internal network consists of connections only (no further FBs):

- `INIT_REQ -> AOption_OUT.INIT_REQ`
- `AOption_OUT.INIT_CNF -> INIT_CNF`
- `QI_OUT -> AOption_OUT.QI_OUT`

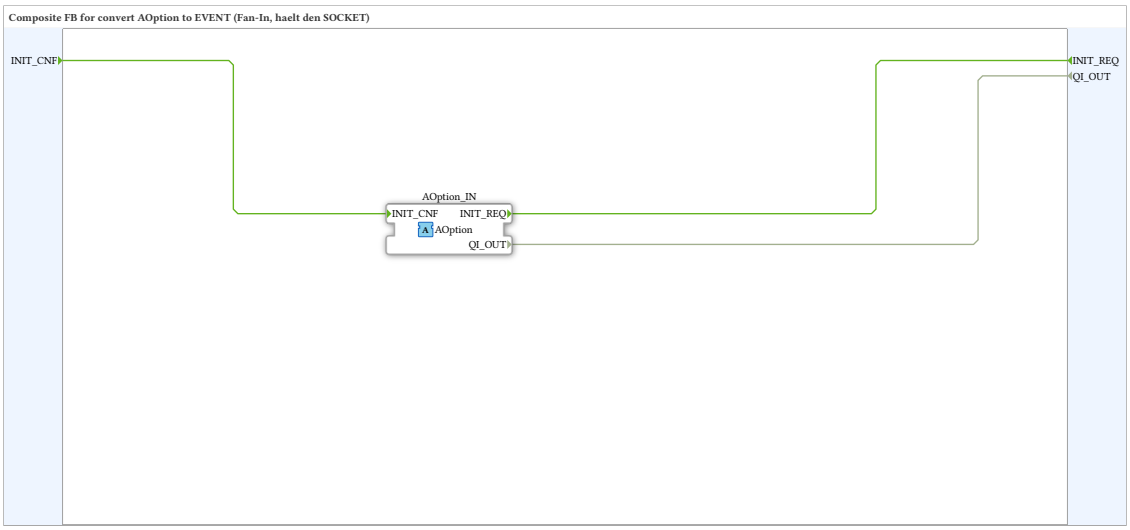
A request is thus passed on unchanged to the adapter, and the socket's confirmation returns as `INIT_CNF`.

Technical Features

- Pure pass-through without logic.
- The counterpart is `AOption_X_TO_EVENT`, which holds the SOCKET.



Application Scenarios



- A requester network sets an option at an option group via this block.

Conclusion

`AOption_EVENT_TO_X` exposes the plug of the `AOption` adapter as an ordinary event/data interface (`INIT_REQ`, `QI_OUT`, `INIT_CNF`).

AOption_X_TO_EVENT

• – ○ • – ○ • – ○ •

Introduction

`AOption_X_TO_EVENT` is a composite FB that converts the option adapter `AOption` into events and data (fan-in, holds the SOCKET). It is used in option groups to receive and acknowledge the request (`INIT_REQ`, `QI_OUT`).

Interface Structure

Event Inputs

Event	Type	Comment
`INIT_CNF`	EInit	Confirmation to the adapter.

Event Outputs

Event	Type	Comment
`INIT_REQ`	EInit	Request from the adapter. Carries the data `QI_OUT`.

Data Inputs

None.

Data Outputs

Variable	Type	Comment
QI_OUT	BOOL	Event input qualifier (IEC 61499-1): TRUE = request/activate option, FALSE = withdraw.

Adapters

Adapter	Type	Direction	Comment
AOption_IN	Option::AOption	Socket	Adapter input.

Functionality

The internal network consists of connections only (no further FBs):

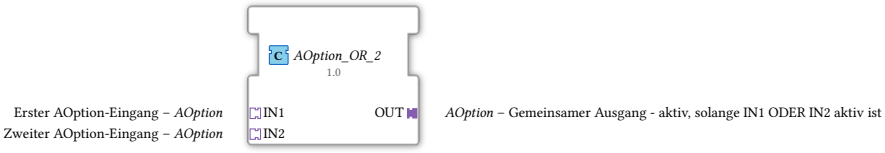
- AOption_IN.INIT_REQ -> INIT_REQ
- INIT_CNF -> AOption_IN.INIT_CNF
- AOption_IN.QI_OUT -> QI_OUT

The plug's request appears as the event INIT_REQ with QI_OUT; once the group is initialized, INIT_CNF is fed into the block and reported back to the plug.

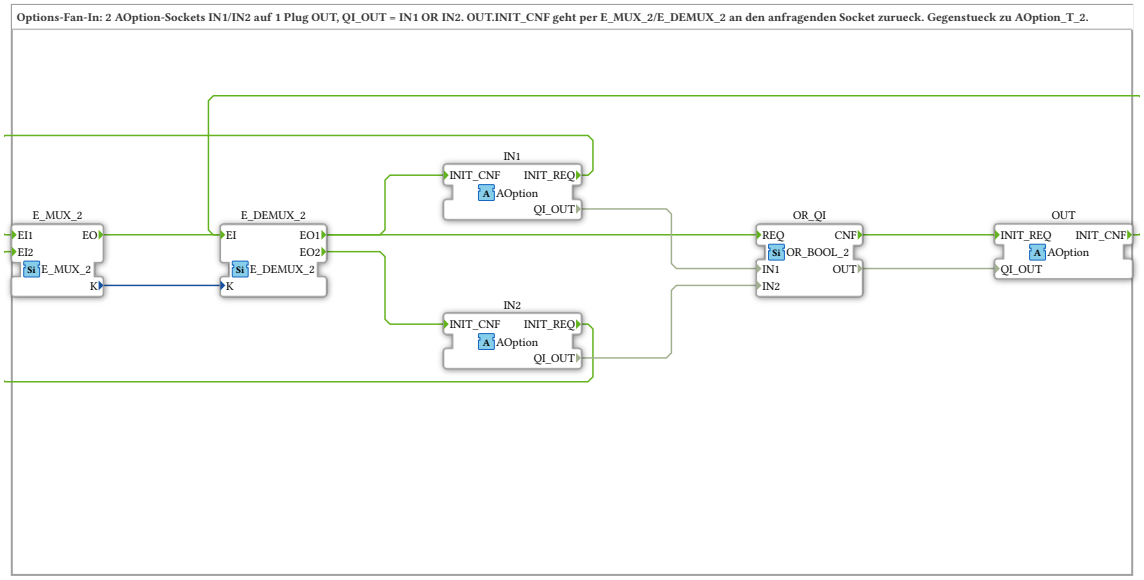
Technical Features

- Pure pass-through without logic.
- The counterpart is AOption_EVENT_TO_X, which holds the PLUG.
- The SubApps OptionalGroup_001 and DummyGroup use it.

Application Scenarios



- Option group: QI_OUT activates/deactivates the group, INIT_CNF acknowledges the activation.



Conclusion

AOption_X_TO_EVENT exposes the socket of the AOption adapter as an ordinary event/data interface (INIT_REQ, QI_OUT, INIT_CNF).

2.1.9.3 Merging

AOption_OR_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AOption_OR_2` is a composite FB that serves as a **fan-in** (OR combination) for the option adapter `AOption`: two option requests at the sockets `IN1` and `IN2` are merged into a single request at the plug `OUT`. `OUT` is active as long as `IN1` **or** `IN2` is active. The block is the counterpart of `AOption_T_2`.

Interface Structure

Event Inputs

None (the events run through the adapters).

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Adapter	Type	Direction	Comment
`IN1`	`Option::AOption`	Socket	First AOption input.
`IN2`	`Option::AOption`	Socket	Second AOption input.
`OUT`	`Option::AOption`	Plug	Common output - active as long as `IN1` OR `IN2` is active.

Functionality

The internal network contains three FBs: `E_MUX_2` (`iec61499::events::E_MUX_2`), `OR_QI` (`iec61131::booleanOperators::OR_BOOL_2`) and `E_DEMUX_2` (`iec61499::events::E_DEMUX_2`).

Events:

- `IN1.INIT_REQ` -> `E_MUX_2.EI1` (`K = 0`) and `IN2.INIT_REQ` -> `E_MUX_2.EI2` (`K = 1`)
- `E_MUX_2.EO` -> `OR_QI.REQ`
- `OR_QI.CNF` -> `OUT.INIT_REQ`
- `OUT.INIT_CNF` -> `E_DEMUX_2.EI`
- `E_DEMUX_2.EO1` -> `IN1.INIT_CNF` and `E_DEMUX_2.EO2` -> `IN2.INIT_CNF`

Data:

- IN1.QI_OUT -> OR_QI.IN1, IN2.QI_OUT -> OR_QI.IN2
- OR_QI.OUT -> OUT.QI_OUT
- E_MUX_2.K -> E_DEMUX_2.K

E_MUX_2 remembers in K which socket the request came from, and only then triggers the OR operation. Its result is passed to OUT as INIT_REQ with QI_OUT. E_DEMUX_2 routes the confirmation OUT.INIT_CNF back, based on K, to exactly the socket that made the request.

Technical Notes

- **Confirmation only after OUT:** an input is confirmed only once the group at OUT has finished. An upstream DEMUX or AOption_T_2 therefore sees the chain as done only when it actually is.
- **Order enforced by wiring:** because OR_QI is triggered via E_MUX_2.EO, K is always set before OUT.INIT_REQ is sent.
- **Only one outstanding request:** K holds exactly one sender. If a second request arrives before OUT.INIT_CNF has returned, the assignment is lost. Behind a DEMUX (break-before-make) this cannot happen; independent sources would need a basic FB with an ECC.
- **A DEMUX output only once:** if the same output must also feed a group of its own, an AOption_T_2 is inserted first.

Application Scenarios

- A shared option group that should be active for several options (K = 2 or K = 3) but not for K = 1 (DummyGroup).

Summary

AOption_OR_2 merges two AOption requests into one (OUT active when IN1 or IN2 is active) and returns the confirmation via E_MUX_2/E_DEMUX_2 to the requesting socket.

AOption_OR_3

• – ○ • – ○ • – ○ •

Introduction

`AOption_OR_3` is a composite FB that serves as a **fan-in** (OR combination) for the option adapter `AOption`: three option requests at the sockets `IN1`, `IN2` and `IN3` are merged into a single request at the plug `OUT`. `OUT` is active as long as `IN1` **or** `IN2` **or** `IN3` is active. Variant of `AOption_OR_2` with 3 inputs.

Interface Structure

Event Inputs

None (the events run through the adapters).

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Adapter	Type	Direction	Comment
`IN1`	`Option::AOption`	Socket	First AOption input.
`IN2`	`Option::AOption`	Socket	Second AOption input.
`IN3`	`Option::AOption`	Socket	Third AOption input.
`OUT`	`Option::AOption`	Plug	Common output - active as long as `IN1` OR `IN2` is active.

Functionality

The internal network contains three FBs: `E_MUX_3` (`iec61499::events::E_MUX_3`), `OR_QI` (`iec61131::booleanOperators::OR_BOOL_3`) and `E_DEMUX_3` (`iec61499::events::E_DEMUX_3`).

Events:

- `IN1.INIT_REQ` -> `E_MUX_3.EI1` (`K = 0`), `IN2.INIT_REQ` -> `E_MUX_3.EI2` (`K = 1`) and `IN3.INIT_REQ` -> `E_MUX_3.EI3` (`K = 2`)

- E_MUX_3.EO -> OR_QI.REQ
- OR_QI.CNF -> OUT.INIT_REQ
- OUT.INIT_CNF -> E_DEMUX_3.EI
- E_DEMUX_3.EO1 -> IN1.INIT_CNF, E_DEMUX_3.EO2 -> IN2.INIT_CNF and E_DEMUX_3.EO3 -> IN3.INIT_CNF

Data:

- IN1.QI_OUT -> OR_QI.IN1, IN2.QI_OUT -> OR_QI.IN2, IN3.QI_OUT -> OR_QI.IN3
- OR_QI.OUT -> OUT.QI_OUT
- E_MUX_3.K -> E_DEMUX_3.K

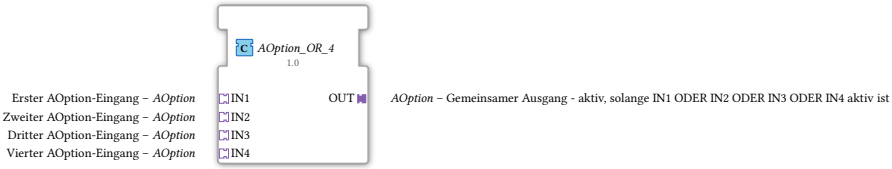
E_MUX_3 remembers in K which socket the request came from, and only then triggers the OR operation. Its result is passed to OUT as INIT_REQ with QI_OUT. E_DEMUX_3 routes the confirmation OUT.INIT_CNF back, based on K, to exactly the socket that made the request.

Technical Notes

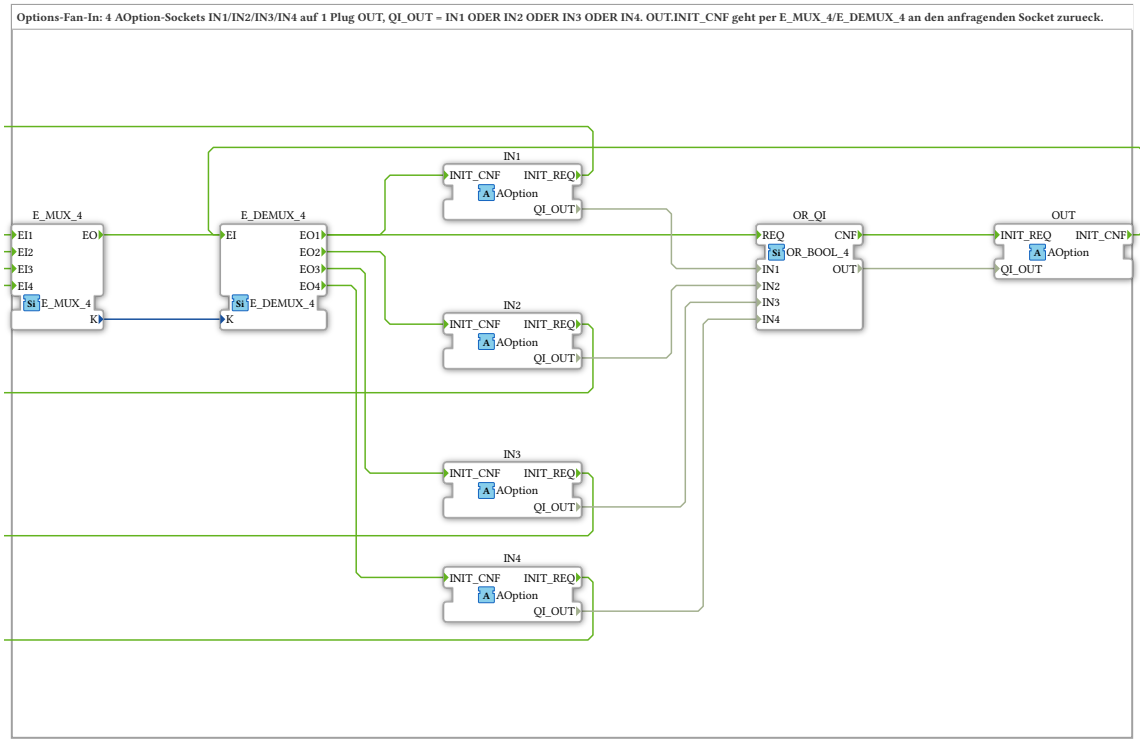
- **Confirmation only after OUT:** an input is confirmed only once the group at OUT has finished. An upstream DEMUX or AOption_T_2 therefore sees the chain as done only when it actually is.
- **Order enforced by wiring:** because OR_QI is triggered via E_MUX_3.EO, K is always set before OUT.INIT_REQ is sent.
- **Only one outstanding request:** K holds exactly one sender. If a second request arrives before OUT.INIT_CNF has returned, the assignment is lost. Behind a DEMUX (break-before-make) this cannot happen; independent sources would need a basic FB with an ECC.
- **A DEMUX output only once:** if the same output must also feed a group of its own, an AOption_T_2 is inserted first.

Application Scenarios

- A shared option group that should be active for several options without cascading AOption_OR_2.



Summary



AOption_OR_3 merges three AOption requests into one (OUT active when IN1, IN2 or IN3 is active) and returns the confirmation via E_MUX_3/E_DEMUX_3 to the requesting socket.

AOption_OR_4

• — ○ • — ○ • — ○ •

Introduction

`AOption_OR_4` is a composite FB that serves as a **fan-in** (OR combination) for the option adapter `AOption`: four option requests at the sockets `IN1`, `IN2`, `IN3` and `IN4` are merged into a single request at the plug `OUT`. `OUT` is active as long as `IN1` **or** `IN2` **or** `IN3` **or** `IN4` is active. Variant of `AOption_OR_2` with 4 inputs.

Interface Structure

Event Inputs

None (the events run through the adapters).

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Adapter	Type	Direction	Comment
`IN1`	`Option::AOption`	Socket	First AOption input.
`IN2`	`Option::AOption`	Socket	Second AOption input.
`IN3`	`Option::AOption`	Socket	Third AOption input.
`IN4`	`Option::AOption`	Socket	Fourth AOption input.
`OUT`	`Option::AOption`	Plug	Common output - active as long as `IN1` OR `IN2` is active.

Functionality

The internal network contains three FBs: `E_MUX_4` (`iec61499::events::E_MUX_4`), `OR_QI` (`iec61131::booleanOperators::OR_BOOL_4`) and `E_DEMUX_4` (`iec61499::events::E_DEMUX_4`).

Events:

- `IN1.INIT_REQ` -> `E_MUX_4.EI1` (`K = 0`), `IN2.INIT_REQ` -> `E_MUX_4.EI2` (`K = 1`), `IN3.INIT_REQ` -> `E_MUX_4.EI3` (`K = 2`) and `IN4.INIT_REQ` -> `E_MUX_4.EI4` (`K = 3`)
- `E_MUX_4.EO` -> `OR_QI.REQ`
- `OR_QI.CNF` -> `OUT.INIT_REQ`
- `OUT.INIT_CNF` -> `E_DEMUX_4.EI`
- `E_DEMUX_4.EO1` -> `IN1.INIT_CNF`, `E_DEMUX_4.EO2` -> `IN2.INIT_CNF`, `E_DEMUX_4.EO3` -> `IN3.INIT_CNF` and `E_DEMUX_4.EO4` -> `IN4.INIT_CNF`

Data:

- `IN1.QI_OUT` -> `OR_QI.IN1`, `IN2.QI_OUT` -> `OR_QI.IN2`, `IN3.QI_OUT` -> `OR_QI.IN3`, `IN4.QI_OUT` -> `OR_QI.IN4`
- `OR_QI.OUT` -> `OUT.QI_OUT`
- `E_MUX_4.K` -> `E_DEMUX_4.K`

`E_MUX_4` remembers in `K` which socket the request came from, and only then triggers the OR operation. Its result is passed to `OUT` as `INIT_REQ` with `QI_OUT`. `E_DEMUX_4` routes the confirmation `OUT.INIT_CNF` back, based on `K`, to exactly the socket that made the request.

Technical Notes

- **Confirmation only after OUT:** an input is confirmed only once the group at `OUT` has finished. An upstream DEMUX or `AOption_T_2` therefore sees the chain as done only when it actually is.
- **Order enforced by wiring:** because `OR_QI` is triggered via `E_MUX_4.EO`, `K` is always set before `OUT.INIT_REQ` is sent.
- **Only one outstanding request:** `K` holds exactly one sender. If a second request arrives before `OUT.INIT_CNF` has returned, the assignment is lost. Behind a DEMUX (break-before-make) this cannot happen; independent sources would need a basic FB with an ECC.
- **A DEMUX output only once:** if the same output must also feed a group of its own, an `AOption_T_2` is inserted first.

Application Scenarios

- A shared option group that should be active for several options without cascading `AOption_OR_2`.

Summary

`AOption_OR_4` merges four `AOption` requests into one (`OUT` active when `IN1`, `IN2`, `IN3` or `IN4` is active) and returns the confirmation via `E_MUX_4`/`E_DEMUX_4` to the requesting socket.

2.1.9.4 selection

AOption_AD_DEMUX_1

• – ○ • – ○ • – ○ •

Introduction

`AOption_AD_DEMUX_1` is a bitmask demultiplexer (native generic FB `GEN_AOption_AD_DEMUX`, no ECC and no algorithm in this type) for `N=1` option outputs of type `Option::AOption`. Via the bidirectional bitmask adapter `K` (`adapter::types::bidirectional::AD2`, DWORD) any number of the 1 outputs can be activated at the same time (multi-select).

Interface Structure

Event Inputs / Outputs

No direct event connections; the events run through the adapters.

Data Inputs / Outputs

No direct data connections; the data runs through the adapters.

Adapters

Adapter	Type	Direction	Comment
`OUT1`	`Option::AOption`	Plug	Option 1, active when bit 0 of `K` is set (value 1).
`K`	`adapter::types::bidirectional::AD2`	Socket	Bitmask (Bit0=OUT1, Bit1=OUT2, ...), bidirectional: `EO1`/`DO1` = new bitmask request in, `EI1`/`DI1` = acknowledgement with the accepted bitmask back.

Functionality

Bit assignment (multi-select):

- `Bit 0` (value 1): `OUT1`

Example: `K = 1` activates `OUT1`, `K = 0` deactivates it. Any number of outputs, or all of them, can be active at the same time.

Switching behaviour: Only bits that change compared to the previous `K` value trigger an `INIT_REQ` at the corresponding output (0->1: `QI=TRUE`, activate; 1->0: `QI=FALSE`, deactivate). Unchanged bits are not triggered again; each output is triggered at most once per incoming `K` value.

Busy gating via the K adapter: While `INIT_CNF` is still awaited from at least one output affected by the last `K` change, every further bitmask request arriving via `K` (plug -> socket, `EO1`/`DO1`) is ignored; it is neither buffered nor caught up later. Once all triggered `INIT_CNF` have arrived, the block reports this backwards via `K` (socket -> plug, `EI1`/`DI1`) with the accepted bitmask (not with the state of the outputs; bits beyond the existing outputs are acknowledged unchanged as well). Only then are new `K` requests accepted again.

Technical Features

- **Multi-select**, in contrast to the single-select of `AOption_AUI_DEMUX_1`.
- **Native generic FB**: the behaviour is implemented in the runtime, not as ECC or algorithm.
- **Acknowledgement**: `K` is only reported back after all `INIT_CNF` have arrived; requests in between are lost.

Application Scenarios

- Switching several optional function groups (e.g. `OptionalGroup_001`) on and off simultaneously via a bitmask.

Conclusion

`AOption_AD_DEMUX_1` switches arbitrary combinations of 1 options via the bitmask `K` and reports the accepted bitmask only after all activations have completed.

AOption_AD_DEMUX_2

• – ○ • – ○ • – ○ •

Introduction

`AOption_AD_DEMUX_2` is a bitmask demultiplexer (native generic FB `GEN_AOption_AD_DEMUX`, no ECC and no algorithm in this type) for `N=2` option outputs of type `Option::AOption`. Via the bidirectional

bitmask adapter K (adapter::types::bidirectional::AD2, DWORD) any number of the 2 outputs can be activated at the same time (multi-select).

Interface Structure

Event Inputs / Outputs

No direct event connections; the events run through the adapters.

Data Inputs / Outputs

No direct data connections; the data runs through the adapters.

Adapters

Adapter	Type	Direction	Comment
OUT1	Option::AOption	Plug	Option 1, active when bit 0 of K is set (value 1).
OUT2	Option::AOption	Plug	Option 2, active when bit 1 of K is set (value 2).
K	adapter::types::bidirectional::AD2	Socket	Bitmask (Bit0=OUT1, Bit1=OUT2, ...), bidirectional: EO1/DO1 = new bitmask request in, EI1/DI1 = acknowledgement with the accepted bitmask back.

Functionality

Bit assignment (multi-select):

- Bit 0 (value 1): OUT1
- Bit 1 (value 2): OUT2

Example: K = 3 (bit 0 and bit 1 set) activates OUT1 and OUT2; all other outputs stay off. Any number of outputs, or all of them, can be active at the same time.

Switching behaviour: Only bits that change compared to the previous K value trigger an INIT_REQ at the corresponding output (0->1: QI=TRUE, activate; 1->0: QI=FALSE, deactivate). Unchanged bits are not triggered again; each output is triggered at most once per incoming K value.

Busy gating via the K adapter: While INIT_CNF is still awaited from at least one output affected by the last K change, every further bitmask request arriving via K (plug -> socket, EO1/DO1) is ignored; it is neither buffered nor caught up later. Once all triggered INIT_CNF have arrived, the block reports this backwards via K (socket -> plug, EI1/DI1) with the accepted bitmask (not with the state of the outputs; bits beyond the existing outputs are acknowledged unchanged as well). Only then are new K requests accepted again.

Technical Features

- **Multi-select**, in contrast to the single-select of AOption_AUI_DEMUX_2.
- **Native generic FB**: the behaviour is implemented in the runtime, not as ECC or algorithm.
- **Acknowledgement**: K is only reported back after all INIT_CNF have arrived; requests in between are lost.

Application Scenarios

- Switching several optional function groups (e.g. OptionalGroup_001) on and off simultaneously via a bitmask.

Conclusion

AOption_AD_DEMUX_2 switches arbitrary combinations of 2 options via the bitmask K and reports the accepted bitmask only after all activations have completed.

AOption_AD_DEMUX_3

• — ○ • — ○ • — ○ •

Introduction

`AOption_AD_DEMUX_3` is a bitmask demultiplexer (native generic FB `GEN_AOption_AD_DEMUX`, no ECC and no algorithm in this type) for `N=3` option outputs of type `Option::AOption`. Via the bidirectional bitmask adapter `K` (`adapter::types::bidirectional::AD2`, DWORD) any number of the 3 outputs can be activated at the same time (multi-select).

Interface Structure

Event Inputs / Outputs

No direct event connections; the events run through the adapters.

Data Inputs / Outputs

No direct data connections; the data runs through the adapters.

Adapters

Adapter	Type	Direction	Comment
`OUT1`	`Option::AOption`	Plug	Option 1, active when bit 0 of `K` is set (value 1).
`OUT2`	`Option::AOption`	Plug	Option 2, active when bit 1 of `K` is set (value 2).
`OUT3`	`Option::AOption`	Plug	Option 3, active when bit 2 of `K` is set (value 4).
`K`	`adapter::types::bidirectional::AD2`	Socket	Bitmask (Bit0=OUT1, Bit1=OUT2, ...), bidirectional: `EO1/DO1` = new bitmask request in, `EI1/DI1` = acknowledgement with the accepted bitmask back.

Functionality

Bit assignment (multi-select):

- `Bit 0` (value 1): `OUT1`
- `Bit 1` (value 2): `OUT2`
- `Bit 2` (value 4): `OUT3`

Example: `K = 3` (bit 0 and bit 1 set) activates `OUT1` and `OUT2`; all other outputs stay off. Any number of outputs, or all of them, can be active at the same time.

Switching behaviour: Only bits that change compared to the previous `K` value trigger an `INIT_REQ` at the corresponding output (0->1: `QI=TRUE`, activate; 1->0: `QI=FALSE`, deactivate). Unchanged bits are not triggered again; each output is triggered at most once per incoming `K` value.

Busy gating via the K adapter: While `INIT_CNF` is still awaited from at least one output affected by the last `K` change, every further bitmask request arriving via `K` (plug -> socket, `EO1/DO1`) is ignored; it is neither buffered nor caught up later. Once all triggered `INIT_CNF` have arrived, the block reports this backwards via `K` (socket -> plug, `EI1/DI1`) with the accepted bitmask (not with the state of the outputs; bits beyond the existing outputs are acknowledged unchanged as well). Only then are new `K` requests accepted again.

Technical Features

- **Multi-select**, in contrast to the single-select of `AOption_AUI_DEMUX_3`.
- **Native generic FB**: the behaviour is implemented in the runtime, not as ECC or algorithm.

- **Acknowledgement**: `K` is only reported back after all `INIT_CNF` have arrived; requests in between are lost.

Application Scenarios

- Switching several optional function groups (e.g. `OptionalGroup_001`) on and off simultaneously via a bitmask.

Conclusion

`AOption_AD_DEMUX_3` switches arbitrary combinations of 3 options via the bitmask `K` and reports the accepted bitmask only after all activations have completed.

AOption_AD_DEMUX_4

• – ○ • – ○ • – ○ •

Introduction

`AOption_AD_DEMUX_4` is a bitmask demultiplexer (native generic FB `GEN_AOption_AD_DEMUX`, no ECC and no algorithm in this type) for `N=4` option outputs of type `Option::AOption`. Via the bidirectional bitmask adapter `K` (`adapter::types::bidirectional::AD2`, DWORD) any number of the 4 outputs can be activated at the same time (multi-select).

Interface Structure

Event Inputs / Outputs

No direct event connections; the events run through the adapters.

Data Inputs / Outputs

No direct data connections; the data runs through the adapters.

Adapters

Adapter	Type	Direction	Comment
`OUT1`	`Option::AOption`	Plug	Option 1, active when bit 0 of `K` is set (value 1).
`OUT2`	`Option::AOption`	Plug	Option 2, active when bit 1 of `K` is set (value 2).
`OUT3`	`Option::AOption`	Plug	Option 3, active when bit 2 of `K` is set (value 4).
`OUT4`	`Option::AOption`	Plug	Option 4, active when bit 3 of `K` is set (value 8).
`K`	`adapter::types::bidirectional::AD2`	Socket	Bitmask (Bit0=OUT1, Bit1=OUT2, ...), bidirectional: `EO1/DO1` = new bitmask request in, `EI1/DI1` = acknowledgement with the accepted bitmask back.

Functionality

Bit assignment (multi-select):

- `Bit 0` (value 1): `OUT1`
- `Bit 1` (value 2): `OUT2`
- `Bit 2` (value 4): `OUT3`
- `Bit 3` (value 8): `OUT4`

Example: `K = 3` (bit 0 and bit 1 set) activates `OUT1` and `OUT2`; all other outputs stay off. Any number of outputs, or all of them, can be active at the same time.

Switching behaviour: Only bits that change compared to the previous `K` value trigger an `INIT_REQ` at the corresponding output (0->1: `QI=TRUE`, activate; 1->0: `QI=FALSE`, deactivate). Unchanged bits are not triggered again; each output is triggered at most once per incoming `K` value.

Busy gating via the K adapter: While `INIT_CNF` is still awaited from at least one output affected by the last `K` change, every further bitmask request arriving via `K` (plug -> socket, `EO1`/`DO1`) is ignored; it is neither buffered nor caught up later. Once all triggered `INIT_CNF` have arrived, the block reports this backwards via `K` (socket -> plug, `EI1`/`DI1`) with the accepted bitmask (not with the state of the outputs; bits beyond the existing outputs are acknowledged unchanged as well). Only then are new `K` requests accepted again.

Technical Features

- **Multi-select**, in contrast to the single-select of `AOption_AUI_DEMUX_4`.
- **Native generic FB**: the behaviour is implemented in the runtime, not as ECC or algorithm.
- **Acknowledgement**: `K` is only reported back after all `INIT_CNF` have arrived; requests in between are lost.

Application Scenarios

- Switching several optional function groups (e.g. `OptionalGroup_001`) on and off simultaneously via a bitmask.

Conclusion

`AOption_AD_DEMUX_4` switches arbitrary combinations of 4 options via the bitmask `K` and reports the accepted bitmask only after all activations have completed.

AOption_AD_DEMUX_5

• – ○ • – ○ • – ○ •

Introduction

`AOption_AD_DEMUX_5` is a bitmask demultiplexer (native generic FB `GEN_AOption_AD_DEMUX`, no ECC and no algorithm in this type) for `N=5` option outputs of type `Option::AOption`. Via the bidirectional bitmask adapter `K` (`adapter::types::bidirectional::AD2`, DWORD) any number of the 5 outputs can be activated at the same time (multi-select).

Interface Structure

Event Inputs / Outputs

No direct event connections; the events run through the adapters.

Data Inputs / Outputs

No direct data connections; the data runs through the adapters.

Adapters

Adapter	Type	Direction	Comment
`OUT1`	`Option::AOption`	Plug	Option 1, active when bit 0 of `K` is set (value 1).
`OUT2`	`Option::AOption`	Plug	Option 2, active when bit 1 of `K` is set (value 2).
`OUT3`	`Option::AOption`	Plug	Option 3, active when bit 2 of `K` is set (value 4).

OUT4	Option::AOption	Plug	Option 4, active when bit 3 of K is set (value 8).
OUT5	Option::AOption	Plug	Option 5, active when bit 4 of K is set (value 16).
K	adapter::types::bidirectional::AD2	Socket	Bitmask (Bit0=OUT1, Bit1=OUT2, ...), bidirectional: EO1/DO1 = new bitmask request in, EI1/DI1 = acknowledgement with the accepted bitmask back.

Functionality

Bit assignment (multi-select):

- Bit 0 (value 1): OUT1
- Bit 1 (value 2): OUT2
- Bit 2 (value 4): OUT3
- Bit 3 (value 8): OUT4
- Bit 4 (value 16): OUT5

Example: K = 3 (bit 0 and bit 1 set) activates OUT1 and OUT2; all other outputs stay off. Any number of outputs, or all of them, can be active at the same time.

Switching behaviour: Only bits that change compared to the previous K value trigger an INIT_REQ at the corresponding output (0->1: QI=TRUE, activate; 1->0: QI=FALSE, deactivate). Unchanged bits are not triggered again; each output is triggered at most once per incoming K value.

Busy gating via the K adapter: While INIT_CNF is still awaited from at least one output affected by the last K change, every further bitmask request arriving via K (plug -> socket, EO1/DO1) is ignored; it is neither buffered nor caught up later. Once all triggered INIT_CNF have arrived, the block reports this backwards via K (socket -> plug, EI1/DI1) with the accepted bitmask (not with the state of the outputs; bits beyond the existing outputs are acknowledged unchanged as well). Only then are new K requests accepted again.

Technical Features

- **Multi-select**, in contrast to the single-select of AOption_AUI_DEMUX_5.
- **Native generic FB**: the behaviour is implemented in the runtime, not as ECC or algorithm.
- **Acknowledgement**: K is only reported back after all INIT_CNF have arrived; requests in between are lost.

Application Scenarios

- Switching several optional function groups (e.g. OptionalGroup_001) on and off simultaneously via a bitmask.

Conclusion

AOption_AD_DEMUX_5 switches arbitrary combinations of 5 options via the bitmask K and reports the accepted bitmask only after all activations have completed.

AOption_AD_DEMUX_6

• – ○ • – ○ • – ○ •

Introduction

AOption_AD_DEMUX_6 is a bitmask demultiplexer (native generic FB GEN_AOption_AD_DEMUX, no ECC and no algorithm in this type) for N=6 option outputs of type Option::AOption. Via the bidirectional bitmask adapter K (adapter::types::bidirectional::AD2, DWORD) any number of the 6 outputs can be activated at the same time (multi-select).

Interface Structure

Event Inputs / Outputs

No direct event connections; the events run through the adapters.

Data Inputs / Outputs

No direct data connections; the data runs through the adapters.

Adapters

Adapter	Type	Direction	Comment
OUT1	Option::AOption	Plug	Option 1, active when bit 0 of K is set (value 1).
OUT2	Option::AOption	Plug	Option 2, active when bit 1 of K is set (value 2).
OUT3	Option::AOption	Plug	Option 3, active when bit 2 of K is set (value 4).
OUT4	Option::AOption	Plug	Option 4, active when bit 3 of K is set (value 8).
OUT5	Option::AOption	Plug	Option 5, active when bit 4 of K is set (value 16).
OUT6	Option::AOption	Plug	Option 6, active when bit 5 of K is set (value 32).
K	adapter::types::bidirectional::AD2	Socket	Bitmask (Bit0=OUT1, Bit1=OUT2, ...), bidirectional: EO1/DO1 = new bitmask request in, EI1/DI1 = acknowledgement with the accepted bitmask back.

Functionality

Bit assignment (multi-select):

- Bit 0 (value 1): OUT1
- Bit 1 (value 2): OUT2
- Bit 2 (value 4): OUT3
- Bit 3 (value 8): OUT4
- Bit 4 (value 16): OUT5
- Bit 5 (value 32): OUT6

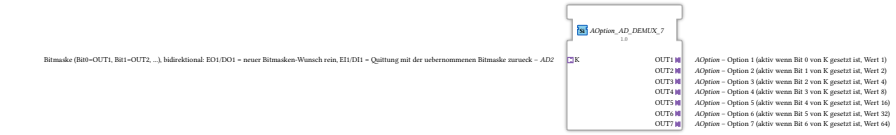
Example: K = 3 (bit 0 and bit 1 set) activates OUT1 and OUT2; all other outputs stay off. Any number of outputs, or all of them, can be active at the same time.

Switching behaviour: Only bits that change compared to the previous K value trigger an INIT_REQ at the corresponding output (0->1: QI=TRUE, activate; 1->0: QI=FALSE, deactivate). Unchanged bits are not triggered again; each output is triggered at most once per incoming K value.

Busy gating via the K adapter: While INIT_CNF is still awaited from at least one output affected by the last K change, every further bitmask request arriving via K (plug -> socket, EO1/DO1) is ignored; it is neither buffered nor caught up later. Once all triggered INIT_CNF have arrived, the block reports this backwards via K (socket -> plug, EI1/DI1) with the accepted bitmask (not with the state of the outputs; bits beyond the existing outputs are acknowledged unchanged as well). Only then are new K requests accepted again.

Technical Features

- **Multi-select**, in contrast to the single-select of AOption_AUI_DEMUX_6.
- **Native generic FB**: the behaviour is implemented in the runtime, not as ECC or algorithm.
- **Acknowledgement**: K is only reported back after all INIT_CNF have arrived; requests in between are lost.



Application Scenarios

- Switching several optional function groups (e.g. `OptionalGroup_001`) on and off simultaneously via a bitmask.

Conclusion

`AOption_AD_DEMUX_6` switches arbitrary combinations of 6 options via the bitmask `K` and reports the accepted bitmask only after all activations have completed.

AOption_AD_DEMUX_7

• – ○ • – ○ • – ○ •

Introduction

The function block AOption_AD_DEMUX_7 is a demultiplexer (native generic FB, no ECC and no algorithm in this type) for 7 option outputs of type `Option::AOption`. Selection is done by a **bit mask** on the bidirectional adapter `K` (`adapter::types::bidirectional::AD2`, DWORD). This is the multi-select variant: any number of outputs can be active at the same time.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **K** (Socket, `adapter::types::bidirectional::AD2`): bit mask (bit 0 = OUT1, bit 1 = OUT2, ...). Bidirectional: `EO1/DO1` = new bit mask request comes in, `EI1/DI1` = acknowledgement with the accepted bit mask goes back
- **OUT1** (Plug, `Option::AOption`): option 1, active when bit 0 of K is set (value 1)
- **OUT2** (Plug, `Option::AOption`): option 2, active when bit 1 of K is set (value 2)
- **OUT3** (Plug, `Option::AOption`): option 3, active when bit 2 of K is set (value 4)
- **OUT4** (Plug, `Option::AOption`): option 4, active when bit 3 of K is set (value 8)
- **OUT5** (Plug, `Option::AOption`): option 5, active when bit 4 of K is set (value 16)
- **OUT6** (Plug, `Option::AOption`): option 6, active when bit 5 of K is set (value 32)
- **OUT7** (Plug, `Option::AOption`): option 7, active when bit 6 of K is set (value 64)

Each output `OUTx` uses the adapter `Option::AOption`: the event `INIT_REQ` (together with `QI_OUT`) runs in the plug → socket direction, the confirmation `INIT_CNF` in the opposite direction.

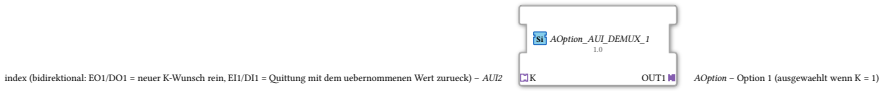
Functionality

Bit assignment (multi-select):

- Bit 0 (value 1) — `OUT1`
- Bit 1 (value 2) — `OUT2`
- Bit 2 (value 4) — `OUT3`
- Bit 3 (value 8) — `OUT4`
- Bit 4 (value 16) — `OUT5`
- Bit 5 (value 32) — `OUT6`

- Bit 6 (value 64) — `OUT7`

Example: `K = 3` (bit 0 and bit 1 set) activates `OUT1` and `OUT2`, all other outputs are off. Any number of outputs, or all of them, can be active simultaneously.



Switching behavior: Only bits that change compared to the previous `K` value trigger an `INIT_REQ` on the corresponding output (0⟶1: `QI=TRUE`, activate; 1⟶0: `QI=FALSE`, deactivate). Unchanged bits are not triggered again — each output is triggered at most once per incoming `K` value.

Busy gating via the bidirectional K adapter: As long as `INIT_CNF` is still awaited from at least one output affected by the last K change, every further bit mask request arriving via `K` (plug ⟶ socket direction, `EO1`/`DO1`) is ignored — it is neither buffered nor replayed. Once all triggered `INIT_CNF` have arrived, the block reports this back via `K` (socket ⟶ plug direction, `EI1`/`DI1`) with the accepted bit mask (not with the state of the outputs: bits beyond the available outputs are acknowledged unchanged as well). Only then are new K requests accepted again.

⚖️ Comparison with Similar Blocks

AOption_AUI_DEMUX_7 is the single-select variant with an index (`AUI2`) instead of a bit mask: at most one output is active there.

AOption_AUI_DEMUX_1

• – ○ • – ○ • – ○ •

Introduction

The function block AOption_AUI_DEMUX_1 is a demultiplexer (native generic FB, no ECC and no algorithm in this type) for 1 option output of type `Option::AOption`. Selection is done by an **index** on the bidirectional adapter `K` (`adapter::types::bidirectional::AUI2`, UINT). This is the single-select variant: at most one output is active at a time.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **K** (Socket, `adapter::types::bidirectional::AUI2`): index. Bidirectional: `EO1`/`DO1` = new K request comes in, `EI1`/`DI1` = acknowledgement with the accepted value goes back
- **OUT1** (Plug, `Option::AOption`): option 1, selected when K = 1

Each output `OUTx` uses the adapter `Option::AOption`: the event `INIT_REQ` (together with `QI_OUT`) runs in the plug ⟶ socket direction, the confirmation `INIT_CNF` in the opposite direction.

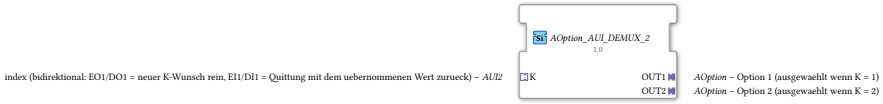
Functionality

Index assignment:

- `K = 0` — all outputs OFF
- `K = 1` — `OUT1` ON, all others OFF
- any other value (> 1) — all outputs OFF

Switching behavior (break-before-make): If K changes from one active output to another, the previously active output is deactivated first (INIT_REQ with QI=FALSE). Only once INIT_CNF has arrived from that output is the newly selected output activated (INIT_REQ with QI=TRUE). Thus never more than one option is active at the same time. Each output is triggered at most once per incoming K value; unaffected outputs are left untouched.

Busy gating via the bidirectional K adapter: While a switchover is in progress (waiting for INIT_CNF from the previous and/or new output), every further index request arriving via K (plug → socket direction, EO1/DO1) is ignored — it is neither buffered nor replayed. When finished, the block reports this back via K (socket → plug direction, EI1/DI1) with the accepted K value (not with the state of the outputs: an invalid value is acknowledged unchanged as well). Only then are new index requests accepted again. What counts is always the state after completion of the last change actually processed.



⚖️ Comparison with Similar Blocks

AOption_AD_DEMUX_1 is the multi-select variant with a bit mask (AD2): several outputs can be active at the same time there.

AOption_AUI_DEMUX_2

• — ○ • — ○ • — ○ •

Introduction

The function block AOption_AUI_DEMUX_2 is a demultiplexer (native generic FB, no ECC and no algorithm in this type) for 2 option outputs of type Option::AOption. Selection is done by an **index** on the bidirectional adapter K (adapter::types::bidirectional::AUI2, UINT). This is the single-select variant: at most one output is active at a time.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **K** (Socket, adapter::types::bidirectional::AUI2): index. Bidirectional: EO1/DO1 = new K request comes in, EI1/DI1 = acknowledgement with the accepted value goes back
- **OUT1** (Plug, Option::AOption): option 1, selected when K = 1
- **OUT2** (Plug, Option::AOption): option 2, selected when K = 2

Each output OUTx uses the adapter Option::AOption: the event INIT_REQ (together with QI_OUT) runs in the plug → socket direction, the confirmation INIT_CNF in the opposite direction.

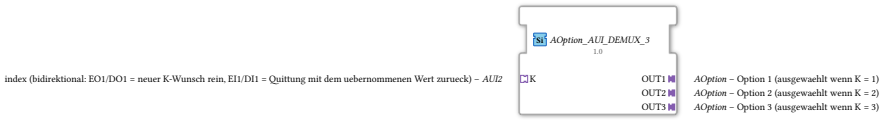
Functionality

Index assignment:

- `K = 0` — all outputs OFF
- `K = 1` — `OUT1` ON, all others OFF
- `K = 2` — `OUT2` ON, all others OFF
- any other value (> 2) — all outputs OFF

Switching behavior (break-before-make): If `K` changes from one active output to another, the previously active output is deactivated first (`INIT_REQ` with `QI=FALSE`). Only once `INIT_CNF` has arrived from that output is the newly selected output activated (`INIT_REQ` with `QI=TRUE`). Thus never more than one option is active at the same time. Each output is triggered at most once per incoming `K` value; unaffected outputs are left untouched.

Busy gating via the bidirectional K adapter: While a switchover is in progress (waiting for `INIT_CNF` from the previous and/or new output), every further index request arriving via `K` (plug → socket direction, `EO1`/`DO1`) is ignored — it is neither buffered nor replayed. When finished, the block reports this back via `K` (socket → plug direction, `EI1`/`DI1`) with the accepted K value (not with the state of the outputs: an invalid value is acknowledged unchanged as well). Only then are new index requests accepted again. What counts is always the state after completion of the last change actually processed.



⚖️ Comparison with Similar Blocks

AOption_AD_DEMUX_2 is the multi-select variant with a bit mask (`AD2`): several outputs can be active at the same time there.

AOption_AUI_DEMUX_3

• — ○ • — ○ • — ○ •

Introduction

The function block AOption_AUI_DEMUX_3 is a demultiplexer (native generic FB, no ECC and no algorithm in this type) for 3 option outputs of type `Option::AOption`. Selection is done by an **index** on the bidirectional adapter `K` (`adapter::types::bidirectional::AUI2`, UINT). This is the single-select variant: at most one output is active at a time.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **K** (Socket, `adapter::types::bidirectional::AUI2`): index. Bidirectional: `EO1`/`DO1` = new K request comes in, `EI1`/`DI1` = acknowledgement with the accepted value goes back
- **OUT1** (Plug, `Option::AOption`): option 1, selected when K = 1
- **OUT2** (Plug, `Option::AOption`): option 2, selected when K = 2
- **OUT3** (Plug, `Option::AOption`): option 3, selected when K = 3

Each output OUTx uses the adapter Option::AOption: the event INIT_REQ (together with QI_OUT) runs in the plug ⟶ socket direction, the confirmation INIT_CNF in the opposite direction.

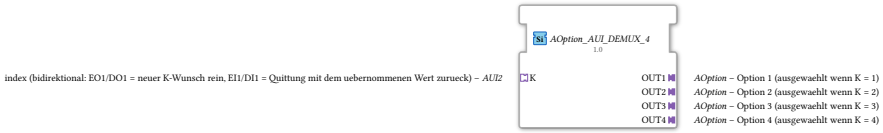
Functionality

Index assignment:

- K = 0 — all outputs OFF
- K = 1 — OUT1 ON, all others OFF
- K = 2 — OUT2 ON, all others OFF
- K = 3 — OUT3 ON, all others OFF
- any other value (> 3) — all outputs OFF

Switching behavior (break-before-make): If K changes from one active output to another, the previously active output is deactivated first (INIT_REQ with QI=FALSE). Only once INIT_CNF has arrived from that output is the newly selected output activated (INIT_REQ with QI=TRUE). Thus never more than one option is active at the same time. Each output is triggered at most once per incoming K value; unaffected outputs are left untouched.

Busy gating via the bidirectional K adapter: While a switchover is in progress (waiting for INIT_CNF from the previous and/or new output), every further index request arriving via K (plug ⟶ socket direction, EO1/DO1) is ignored — it is neither buffered nor replayed. When finished, the block reports this back via K (socket ⟶ plug direction, EI1/DI1) with the accepted K value (not with the state of the outputs: an invalid value is acknowledged unchanged as well). Only then are new index requests accepted again. What counts is always the state after completion of the last change actually processed.



⚖️ Comparison with Similar Blocks

AOption_AD_DEMUX_3 is the multi-select variant with a bit mask (AD2): several outputs can be active at the same time there.

- `K = 6` — `OUT6` ON, all others OFF
- any other value (> 6) — all outputs OFF

Switching behavior (break-before-make): If `K` changes from one active output to another, the previously active output is deactivated first (`INIT_REQ` with `QI=FALSE`). Only once `INIT_CNF` has arrived from that output is the newly selected output activated (`INIT_REQ` with `QI=TRUE`). Thus never more than one option is active at the same time. Each output is triggered at most once per incoming `K` value; unaffected outputs are left untouched.

Busy gating via the bidirectional K adapter: While a switchover is in progress (waiting for `INIT_CNF` from the previous and/or new output), every further index request arriving via `K` (plug → socket direction, `EO1`/`DO1`) is ignored — it is neither buffered nor replayed. When finished, the block reports this back via `K` (socket → plug direction, `EI1`/`DI1`) with the accepted K value (not with the state of the outputs: an invalid value is acknowledged unchanged as well). Only then are new index requests accepted again. What counts is always the state after completion of the last change actually processed.

⚖️ Comparison with Similar Blocks
AOption_AD_DEMUX_6 is the multi-select variant with a bit mask (`AD2`): several outputs can be active at the same time there.

AOption_AUI_DEMUX_7

• — ◦ • — ◦ • — ◦ •

Introduction

The function block AOption_AUI_DEMUX_7 is a demultiplexer (native generic FB, no ECC and no algorithm in this type) for 7 option outputs of type `Option::AOption`. Selection is done by an **index** on the bidirectional adapter `K` (`adapter::types::bidirectional::AUI2`, UINT). This is the single-select variant: at most one output is active at a time.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **K** (Socket, `adapter::types::bidirectional::AUI2`): index. Bidirectional: `EO1/DO1` = new K request comes in, `EI1/DI1` = acknowledgement with the accepted value goes back
- **OUT1** (Plug, `Option::AOption`): option 1, selected when K = 1
- **OUT2** (Plug, `Option::AOption`): option 2, selected when K = 2
- **OUT3** (Plug, `Option::AOption`): option 3, selected when K = 3
- **OUT4** (Plug, `Option::AOption`): option 4, selected when K = 4
- **OUT5** (Plug, `Option::AOption`): option 5, selected when K = 5
- **OUT6** (Plug, `Option::AOption`): option 6, selected when K = 6
- **OUT7** (Plug, `Option::AOption`): option 7, selected when K = 7

Each output `OUTx` uses the adapter `Option::AOption`: the event `INIT_REQ` (together with `QI_OUT`) runs in the plug ⟶ socket direction, the confirmation `INIT_CNF` in the opposite direction.

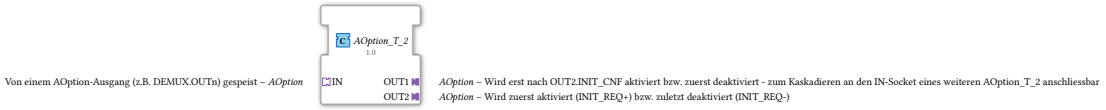
Functionality

Index assignment:

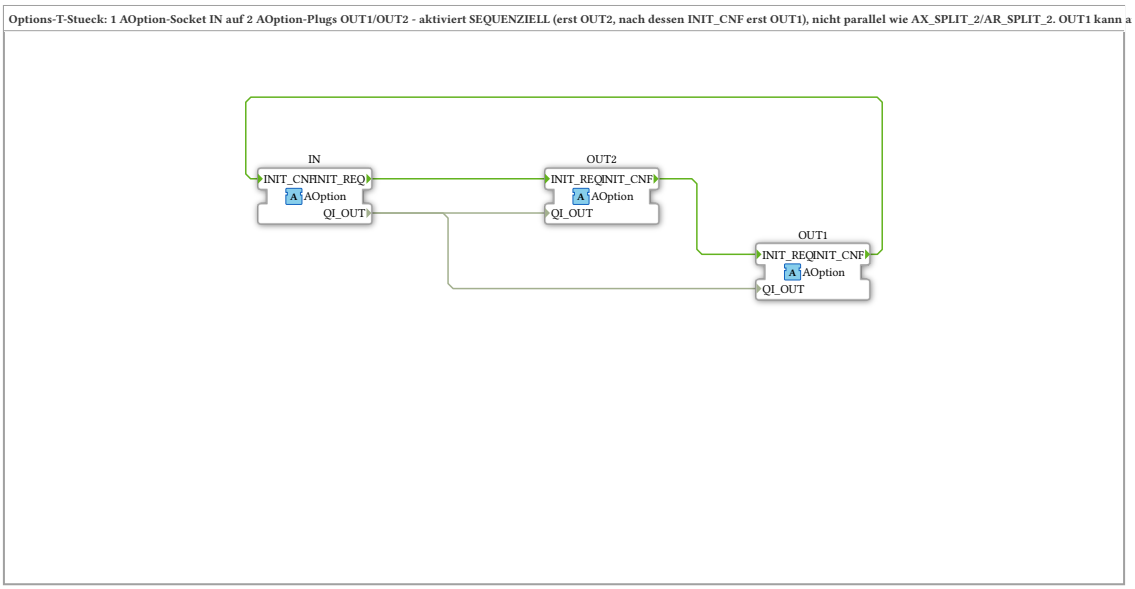
- `K = 0` — all outputs OFF
- `K = 1` — `OUT1` ON, all others OFF
- `K = 2` — `OUT2` ON, all others OFF
- `K = 3` — `OUT3` ON, all others OFF
- `K = 4` — `OUT4` ON, all others OFF
- `K = 5` — `OUT5` ON, all others OFF
- `K = 6` — `OUT6` ON, all others OFF
- `K = 7` — `OUT7` ON, all others OFF
- any other value (> 7) — all outputs OFF

Switching behavior (break-before-make): If `K` changes from one active output to another, the previously active output is deactivated first (`INIT_REQ` with `QI=FALSE`). Only once `INIT_CNF` has arrived from that output is the newly selected output activated (`INIT_REQ` with `QI=TRUE`). Thus never more than one

option is active at the same time. Each output is triggered at most once per incoming `K` value; unaffected outputs are left untouched.



Busy gating via the bidirectional K adapter: While a switchover is in progress (waiting for `INIT_CNF` from the previous and/or new output), every further index request arriving via `K` (plug ⟶ socket direction, `EO1`/`DO1`) is ignored — it is neither buffered nor replayed. When finished, the block reports this back via `K` (socket ⟶ plug direction, `EI1`/`DI1`) with the accepted K value (not with the state of the outputs: an invalid value is acknowledged unchanged as well). Only then are new index requests accepted again. What counts is always the state after completion of the last change actually processed.



⚖ Comparison with Similar Blocks

AOption_AD_DEMUX_7 is the multi-select variant with a bit mask (`AD2`): several outputs can be active at the same time there.

2.1.9.5 splitting

AOption_T_2

• — ○ • — ○ • — ○ •

Introduction

`AOption_T_2` is a composite FB that serves as a sequential **T-piece** for the option adapter `AOption`: it receives a single option request via the socket `IN` and activates two downstream option consumers (plugs `OUT2` and `OUT1`) **one after the other**, not in parallel. `OUT2` is addressed first, and only after its `INIT_CNF` does `OUT1` follow. `IN` is confirmed only once both outputs have confirmed.

Interface Structure

Event Inputs

None (the events travel via the adapters).

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Adapter	Type	Direction	Comment
IN	Option::AOption	Socket	Fed by an AOption output (e.g. DEMUX.OUTn).
OUT2	Option::AOption	Plug	Activated first (INIT_REQ with QI_OUT=TRUE) or deactivated last (QI_OUT=FALSE).
OUT1	Option::AOption	Plug	Activated only after OUT2.INIT_CNF, or deactivated first; can be connected to the socket IN of another AOption_T_2 for cascading.

Functionality

The internal network consists of connections only (no further FBs, no algorithms, no ECC):
Events:

- IN.INIT_REQ -> OUT2.INIT_REQ
- OUT2.INIT_CNF -> OUT1.INIT_REQ
- OUT1.INIT_CNF -> IN.INIT_CNF

Data:

- IN.QI_OUT -> OUT2.QI_OUT
- IN.QI_OUT -> OUT1.QI_OUT

A request at IN therefore triggers the chain IN.INIT_REQ -> OUT2 -> (waits for OUT2.INIT_CNF) -> OUT1 -> (waits for OUT1.INIT_CNF) -> IN.INIT_CNF. Deactivation uses the same wiring in the same order; QI_OUT then carries FALSE instead of TRUE. The event chain itself does not distinguish between activation and deactivation.

Technical Features

- **Sequential instead of parallel:** The *_SPLIT_2 blocks (e.g. AX_SPLIT_2, AR_SPLIT_2) forward an event or value in parallel to several outputs. AOption_T_2 deliberately serializes the activation so that a group that depends on a previously activated group only starts once that group is actually done.
- **Cascadable:** OUT1 can be connected to the IN socket of another AOption_T_2, so any number of groups can be started strictly one after another without each option group having to provide its own forwarding plug (cf. the daisy-chain style in OptionalGroup_001a).
- **Composite instead of ECC basic FB:** No state logic of its own is needed; the plain chaining of the events already enforces the order.

Application Scenarios

- One option request (e.g. from an AOption demultiplexer) is to activate two option groups in sequence, where the second may only start after the first has finished.
- Several cascaded AOption_T_2 for longer chains of option groups.

Summary

AOption_T_2 distributes an AOption request sequentially to two outputs (OUT2, then OUT1) without logic of its own and confirms IN only after both confirmations.

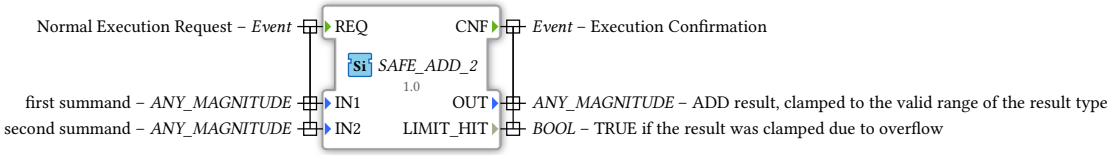
2.1.10 SafeArithmetic

Saturating (clamping) arithmetic function blocks, developed under the EPL-2.0 license by HR Agrartechnik GmbH. Motivated by a real hardware finding (`Uebung_011b3`): plain IEC 61131-3 arithmetic silently wraps around on overflow/underflow for integer types, and produces `INF`/`NaN` for REAL/LREAL — both dangerous for real measurement values. Every block in this library instead clamps the result into the valid range and reports the limit condition via a `LIMIT_HIT` output.



- Arithmetic Functions

2.1.10.1 Arithmetic Functions

Here you will find the SafeArithmetic library's saturating (clamping) arithmetic function blocks — drop-in, safety-oriented replacements for the standard library's plain arithmetic blocks that report an overflow/underflow/division-by-zero via `LIMIT_HIT` instead of silently wrapping around (integers) or producing `INF`/`NaN` (REAL/LREAL).

SAFE_ADD_2

• – ◦ • – ◦ • – ◦ •

Introduction

SAFE_ADD_2 is part of the **SafeArithmetic** library (`SafeArithmetic::arithmetic`, EPL-2.0, HR Agrartechnik GmbH). It is a generic, 2-input addition function block that behaves like the standard library's `ADD_2`, but never lets an overflow pass silently: on overflow the result is **clamped** (saturated) into the valid range of the result type, and `LIMIT_HIT` reports that clamping happened.

This library exists because plain IEC 61131-3 arithmetic function blocks (like `ADD_2` itself, for integer types) compute the standard's specified two's-complement wraparound on overflow — correct per the standard, but dangerous for real measurement values. `Uebung_011b3` demonstrates this on real hardware: plain `F_SUB` computes `UDINT#1 - UDINT#12 = UDINT#4294967285`, a silent underflow wraparound.

Interface Structure

Event Inputs

- `REQ`: Normal Execution Request

Event Outputs

- `CNF`: Execution Confirmation

Data Inputs

- `IN1` (ANY_MAGNITUDE): first summand
- `IN2` (ANY_MAGNITUDE): second summand

Data Outputs

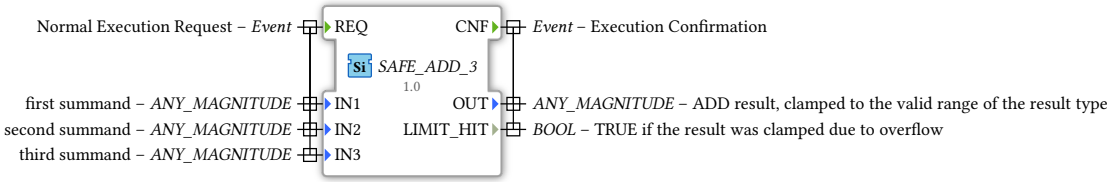
- `OUT` (ANY_MAGNITUDE): ADD result, clamped to the valid range of the result type
- `LIMIT_HIT` (BOOL): TRUE if the result was clamped due to overflow

Functionality

1. **Calculation Request**: `REQ` event with values for IN1, IN2.
2. **Calculation**: computes `IN1 + IN2` left-to-right, one pairwise step at a time. Each step checks for overflow; if a step overflows, its result is clamped into the result type's valid range and `LIMIT_HIT` is set (sticky — once set by any step, it stays set for the rest of the fold).
3. **Result Output**: `CNF` event with the calculated `OUT` and `LIMIT_HIT`.

Overflow / Saturation Behavior

- **Signed integer** types: on overflow, clamps to `numeric_limits::max()` or `::min()`, direction determined by the operand signs of the step that overflowed.
- **Unsigned integer** types: on overflow, clamps to `numeric_limits::max()`.
- **REAL/LREAL**: a non-finite intermediate or final result is always caught, regardless of whether the *inputs* to that step were already non-finite — `+INF`/`-INF` clamp to `numeric_limits::max()`/`::lowest()`, and `NaN` (e.g. from a prior step going non-finite and combining in a way that produces `NaN`) becomes a deterministic `0`. `LIMIT_HIT` is set in every case.
- **Incompatible types** (e.g. mixing a magnitude type with an unrelated type where no `ADD` is defined): the offending step is skipped (logged as an error), `OUT` keeps whatever value the fold had accumulated so far, and `LIMIT_HIT` is **not** set for this case — it is a type error, not a numeric limit event.



Related Function Blocks

- ADD_2 — the plain, non-saturating standard-library equivalent (silent wraparound/`INF` on overflow instead of clamping and reporting).
- Uebung_011b3 — the hardware finding that motivated this library.

Conclusion

SAFE_ADD_2 gives you the same 2-input addition as `ADD_2`, but with an explicit, type-range-aware limit signal instead of a silent wraparound (integers) or a silently-corrupted result (floats) — at the cost of the arity-≥3/signed chaining caveat documented above, which is a deliberate design trade-off, not an oversight.

SAFE_ADD_3

• – ◦ • – ◦ • – ◦ •

Introduction

SAFE_ADD_3 is part of the **SafeArithmetic** library (`SafeArithmetic::arithmetic`, EPL-2.0, HR Agrartechnik GmbH). It is a generic, 3-input addition function block that behaves like the standard library's `ADD_3`, but never lets an overflow pass silently: on overflow the result is **clamped** (saturated) into the valid range of the result type, and `LIMIT_HIT` reports that clamping happened.

This library exists because plain IEC 61131-3 arithmetic function blocks (like `ADD_3` itself, for integer types) compute the standard's specified two's-complement wraparound on overflow — correct per the standard, but dangerous for real measurement values. `Uebung_011b3` demonstrates this on real hardware: plain `F_SUB` computes `UDINT#1 - UDINT#12 = UDINT#4294967285`, a silent underflow wraparound.

Interface Structure

Event Inputs

- `REQ`: Normal Execution Request

Event Outputs

- `CNF`: Execution Confirmation

Data Inputs

- IN1 (ANY_MAGNITUDE): first summand
- IN2 (ANY_MAGNITUDE): second summand
- IN3 (ANY_MAGNITUDE): third summand

Data Outputs

- OUT (ANY_MAGNITUDE): ADD result, clamped to the valid range of the result type
- LIMIT_HIT (BOOL): TRUE if the result was clamped due to overflow

Functionality

1. **Calculation Request**: REQ event with values for IN1, IN2, IN3.
2. **Calculation**: computes IN1 + IN2 + IN3 left-to-right, one pairwise step at a time. Each step checks for overflow; if a step overflows, its result is clamped into the result type's valid range and LIMIT_HIT is set (sticky — once set by any step, it stays set for the rest of the fold).
3. **Result Output**: CNF event with the calculated OUT and LIMIT_HIT.

Overflow / Saturation Behavior

- **Signed integer** types: on overflow, clamps to numeric_limits::max() or ::min(), direction determined by the operand signs of the step that overflowed.
- **Unsigned integer** types: on overflow, clamps to numeric_limits::max().
- **REAL/LREAL**: a non-finite intermediate or final result is always caught, regardless of whether the *inputs* to that step were already non-finite — +INF/-INF clamp to numeric_limits::max()/::lowest(), and NaN (e.g. from a prior step going non-finite and combining in a way that produces NaN) becomes a deterministic 0. LIMIT_HIT is set in every case.
- **Incompatible types** (e.g. mixing a magnitude type with an unrelated type where no ADD is defined): the offending step is skipped (logged as an error), OUT keeps whatever value the fold had accumulated so far, and LIMIT_HIT is **not** set for this case — it is a type error, not a numeric limit event.

Known Limitation for Chained (Arity ≥ 3) addition With SIGNED Types

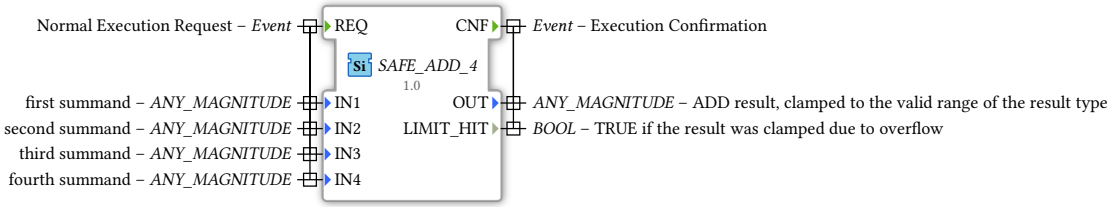
SAFE_ADD_3 evaluates as a strict left-to-right pairwise fold: ((IN1 + IN2) + IN3) + ..., clamping after every step. For **signed** integer types (and REAL/LREAL, which have no unsigned notion) this means a transient intermediate overflow that a later input would otherwise cancel back into range gets permanently baked into OUT, together with a LIMIT_HIT that no longer reflects the true total.

Example (INT, IN1=20000, IN2=20000, IN3=−30000): the true result is 10000, well within INT's range, but the fold clamps after the second step and never recovers.

This is **not** a bug being silently patched — it is documented, intentional behavior: the fold evaluates as a real chain of fixed-width operations, exactly like the plain (non-safe) ADD_3 does, and reports a genuine intermediate limit condition rather than silently reordering the computation.

Unsigned chains of any arity are unaffected and always report a true overflow: for addition, a later non-negative term can never bring an already-overflowed running total back in range (the total only grows).

SAFE_ADD_2 (single pairwise operation, no chaining) always reports a true, correct overflow regardless of signedness — the ambiguity only exists for arity ≥ 3.



Related Function Blocks

- ADD_3 — the plain, non-saturating standard-library equivalent (silent wraparound/INF on overflow instead of clamping and reporting).
- Uebung_011b3 — the hardware finding that motivated this library.

Conclusion

SAFE_ADD_3 gives you the same 3-input addition as ADD_3, but with an explicit, type-range-aware limit signal instead of a silent wraparound (integers) or a silently-corrupted result (floats) — at the cost of the arity-≥-3/signed chaining caveat documented above, which is a deliberate design trade-off, not an oversight.

SAFE_ADD_4

• – ◦ • – ◦ • – ◦ •

Introduction

SAFE_ADD_4 is part of the **SafeArithmetic** library (`SafeArithmetic::arithmetic`, EPL-2.0, HR Agrartechnik GmbH). It is a generic, 4-input addition function block that behaves like the standard library's `ADD_4`, but never lets an overflow pass silently: on overflow the result is **clamped** (saturated) into the valid range of the result type, and `LIMIT_HIT` reports that clamping happened.

This library exists because plain IEC 61131-3 arithmetic function blocks (like `ADD_4` itself, for integer types) compute the standard's specified two's-complement wraparound on overflow — correct per the standard, but dangerous for real measurement values. `Uebung_011b3` demonstrates this on real hardware: plain `F_SUB` computes `UDINT#1 - UDINT#12 = UDINT#4294967285`, a silent underflow wraparound.

Interface Structure

Event Inputs

- `REQ`: Normal Execution Request

Event Outputs

- `CNF`: Execution Confirmation

Data Inputs

- `IN1` (ANY_MAGNITUDE): first summand
- `IN2` (ANY_MAGNITUDE): second summand
- `IN3` (ANY_MAGNITUDE): third summand
- `IN4` (ANY_MAGNITUDE): fourth summand

Data Outputs

- `OUT` (ANY_MAGNITUDE): ADD result, clamped to the valid range of the result type
- `LIMIT_HIT` (BOOL): TRUE if the result was clamped due to overflow

Functionality

1. **Calculation Request**: `REQ` event with values for IN1, IN2, IN3, IN4.
2. **Calculation**: computes `IN1 + IN2 + IN3 + IN4` left-to-right, one pairwise step at a time. Each step checks for overflow; if a step overflows, its result is clamped into the result type's valid range and `LIMIT_HIT` is set (sticky — once set by any step, it stays set for the rest of the fold).
3. **Result Output**: `CNF` event with the calculated `OUT` and `LIMIT_HIT`.

Overflow / Saturation Behavior

- **Signed integer** types: on overflow, clamps to `numeric_limits::max()` or `::min()`, direction determined by the operand signs of the step that overflowed.
- **Unsigned integer** types: on overflow, clamps to `numeric_limits::max()`.
- **REAL/LREAL**: a non-finite intermediate or final result is always caught, regardless of whether the *inputs* to that step were already non-finite — `+INF`/`-INF` clamp to `numeric_limits::max()`/`::lowest()`, and `NaN` (e.g. from a prior step going non-finite and combining in a way that produces `NaN`) becomes a deterministic `0`. `LIMIT_HIT` is set in every case.
- **Incompatible types** (e.g. mixing a magnitude type with an unrelated type where no `ADD` is defined): the offending step is skipped (logged as an error), `OUT` keeps whatever value the fold had accumulated so far, and `LIMIT_HIT` is **not** set for this case — it is a type error, not a numeric limit event.

Known Limitation for Chained (Arity ≥ 3) addition With SIGNED Types

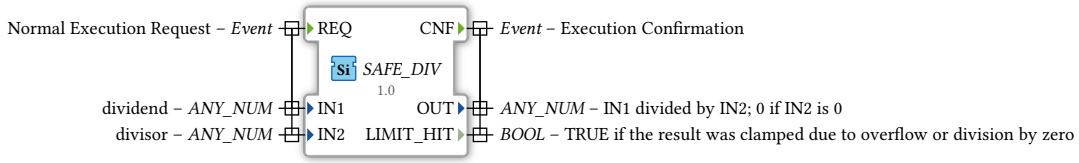
`SAFE_ADD_4` evaluates as a strict left-to-right pairwise fold: `((IN1 + IN2) + IN3) + ...`, clamping after every step. For **signed** integer types (and REAL/LREAL, which have no unsigned notion) this means a transient intermediate overflow that a later input would otherwise cancel back into range gets permanently baked into `OUT`, together with a `LIMIT_HIT` that no longer reflects the true total.

Example (INT, IN1=20000, IN2=20000, IN3=−30000, IN4=0): the true result is `10000`, well within INT's range, but the fold clamps after the second step and never recovers.

This is **not** a bug being silently patched — it is documented, intentional behavior: the fold evaluates as a real chain of fixed-width operations, exactly like the plain (non-safe) `ADD_4` does, and reports a genuine intermediate limit condition rather than silently reordering the computation.

Unsigned chains of any arity are unaffected and always report a true overflow: for addition, a later non-negative term can never bring an already-overflowed running total back in range (the total only grows).

`SAFE_ADD_2` (single pairwise operation, no chaining) always reports a true, correct overflow regardless of signedness — the ambiguity only exists for arity ≥ 3.



Related Function Blocks

- ADD_4 — the plain, non-saturating standard-library equivalent (silent wraparound/`INF` on overflow instead of clamping and reporting).
- Uebung_011b3 — the hardware finding that motivated this library.

Conclusion

SAFE_ADD_4 gives you the same 4-input addition as `ADD_4`, but with an explicit, type-range-aware limit signal instead of a silent wraparound (integers) or a silently-corrupted result (floats) — at the cost of the arity-≥-3/signed chaining caveat documented above, which is a deliberate design trade-off, not an oversight.

SAFE_DIV

• – ◦ • – ◦ • – ◦ •

Introduction

SAFE_DIV is part of the **SafeArithmetic** library (`SafeArithmetic::arithmetic`, EPL-2.0, HR Agrartechnik GmbH). It is a fixed 2-input division function block that behaves like the standard library's `F_DIV`, but never traps, produces `INF`/`NaN`, or lets an overflow pass silently: division by zero and overflow are treated as **clamp** conditions, and `LIMIT_HIT` reports that clamping happened.

Like `SAFE_SUB`, `SAFE_DIV` is **not** generic-arity: division is neither associative nor commutative, so a "chained" division has no well-defined meaning the way extensible ADD/MUL do.

Interface Structure

Event Inputs

- `REQ`: Normal Execution Request

Event Outputs

- `CNF`: Execution Confirmation

Data Inputs

- `IN1` (ANY_NUM): dividend
- `IN2` (ANY_NUM): divisor

Data Outputs

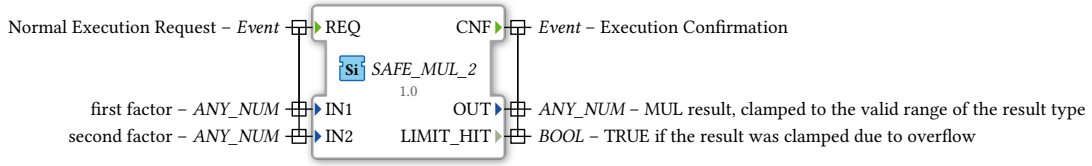
- `OUT` (ANY_NUM): IN1 divided by IN2; 0 if IN2 is 0
- `LIMIT_HIT` (BOOL): TRUE if the result was clamped due to overflow or division by zero

Functionality

1. **Calculation Request**: `REQ` event with values for IN1 and IN2.
2. **Division**: computes `IN1 / IN2`.
3. **Result Output**: `CNF` event with the calculated `OUT` and `LIMIT_HIT`.

Overflow / Division-by-Zero Behavior

- **Any integer** type, `IN2 == 0`: clamps to `0` with `LIMIT_HIT = TRUE`, instead of trapping (integer division by zero is undefined behavior in plain C++ and would crash `F_DIV`).
- **Signed integer** types: the one remaining case that can overflow, `INT_MIN / -1`, clamps to `numeric_limits::max()`.
- **REAL/LREAL**, `IN2 == 0.0`: clamps to `0` with `LIMIT_HIT = TRUE`, instead of producing IEEE-754 `+INF`/`-INF`/`NaN` (`0.0 / 0.0`).
- **REAL/LREAL**, `IN2 != 0.0`: a non-finite intermediate or final result is always caught, regardless of whether the *inputs* were already non-finite — `+INF`/`-INF` clamp to `numeric_limits::max()`/`::lowest()`, and `NaN` becomes a deterministic `0`. `LIMIT_HIT` is set in every case.
- **Incompatible types** (e.g. mixing a numeric type with an unrelated type where no division is defined): the result is undefined by this operation (logged as an error), `OUT` is left unchanged, and `LIMIT_HIT` is **not** set for this case — it is a type error, not a numeric limit event.



Related Function Blocks

- F_DIV — the plain, non-saturating standard-library equivalent (undefined behavior on integer division by zero, `INF`/`NaN` on float division by/of zero, instead of clamping and reporting).
- Uebung_011b7 — a division-by-zero demo with `SAFE_DIV`, `LIMIT_HIT` wired to a second output so the clamping is visible on hardware.

Conclusion

SAFE_DIV gives you the same division as `F_DIV`, but with an explicit, type-range-aware limit signal instead of undefined behavior (integer division by zero) or a silently-corrupted result (float overflow/`NaN`).

SAFE_MUL_2

• – ◦ • – ◦ • – ◦ •

Introduction

SAFE_MUL_2 is part of the **SafeArithmetic** library (`SafeArithmetic::arithmetic`, EPL-2.0, HR Agrartechnik GmbH). It is a generic, 2-input multiplication function block that behaves like the standard library's `F_MUL`, but never lets an overflow pass silently: on overflow the result is **clamped** (saturated) into the valid range of the result type, and `LIMIT_HIT` reports that clamping happened.

This library exists because plain IEC 61131-3 arithmetic function blocks (like `F_MUL` itself, for integer types) compute the standard's specified two's-complement wraparound on overflow — correct per the standard, but dangerous for real measurement values. `Uebung_011b3` demonstrates this on real hardware: plain `F_SUB` computes `UDINT#1 - UDINT#12 = UDINT#4294967285`, a silent underflow wraparound.

Interface Structure

Event Inputs

- `REQ`: Normal Execution Request

Event Outputs

- `CNF`: Execution Confirmation

Data Inputs

- `IN1` (ANY_NUM): first factor

- IN2 (ANY_NUM): second factor

Data Outputs

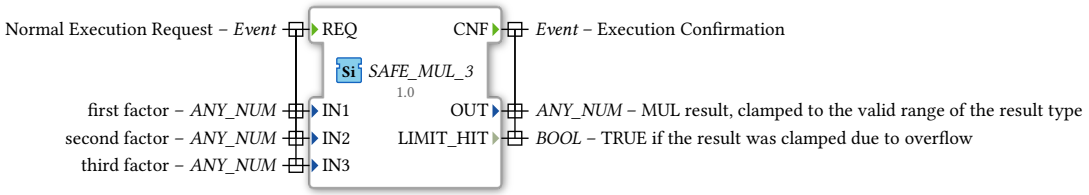
- OUT (ANY_NUM): MUL result, clamped to the valid range of the result type
- LIMIT_HIT (BOOL): TRUE if the result was clamped due to overflow

Functionality

1. **Calculation Request**: REQ event with values for IN1, IN2.
2. **Calculation**: computes IN1 * IN2 left-to-right, one pairwise step at a time. Each step checks for overflow; if a step overflows, its result is clamped into the result type's valid range and LIMIT_HIT is set (sticky — once set by any step, it stays set for the rest of the fold).
3. **Result Output**: CNF event with the calculated OUT and LIMIT_HIT.

Overflow / Saturation Behavior

- **Signed integer** types: on overflow, clamps to numeric_limits::max() or ::min(), direction determined by the operand signs of the step that overflowed.
- **Unsigned integer** types: on overflow, clamps to numeric_limits::max().
- **REAL/LREAL**: a non-finite intermediate or final result is always caught, regardless of whether the *inputs* to that step were already non-finite — +INF/-INF clamp to numeric_limits::max()/::lowest(), and NaN (e.g. from a prior step going non-finite and combining in a way that produces NaN) becomes a deterministic 0. LIMIT_HIT is set in every case.
- **Incompatible types** (e.g. mixing a magnitude type with an unrelated type where no MUL is defined): the offending step is skipped (logged as an error), OUT keeps whatever value the fold had accumulated so far, and LIMIT_HIT is **not** set for this case — it is a type error, not a numeric limit event.



Related Function Blocks

- F_MUL — the plain, non-saturating standard-library equivalent (silent wraparound/INF on overflow instead of clamping and reporting).
- Uebung_011b3 — the hardware finding that motivated this library.

Conclusion

SAFE_MUL_2 gives you the same 2-input multiplication as F_MUL, but with an explicit, type-range-aware limit signal instead of a silent wraparound (integers) or a silently-corrupted result (floats) — at the cost of the arity-≥-3/signed chaining caveat documented above, which is a deliberate design trade-off, not an oversight.

SAFE_MUL_3

• – ◦ • – ◦ • – ◦ •

Introduction

SAFE_MUL_3 is part of the **SafeArithmetic** library (SafeArithmetic::arithmetic, EPL-2.0, HR Agrartechnik GmbH). It is a generic, 3-input multiplication function block that extends the standard library's fixed 2-input F_MUL pattern to 3 inputs (the standard library has no generic multi-input MUL_n yet, unlike ADD_2/3/4), and never lets an overflow pass silently: on overflow the result is **clamped** (saturated) into the valid range of the result type, and LIMIT_HIT reports that clamping happened.

This library exists because plain IEC 61131-3 arithmetic function blocks (like F_MUL itself, for integer types) compute the standard's specified two's-complement wraparound on overflow — correct per the standard, but dangerous for real measurement values. Uebung_011b3 demonstrates this on real hardware: plain F_SUB computes UDINT#1 - UDINT#12 = UDINT#4294967285, a silent underflow wraparound.

Interface Structure

Event Inputs

- `REQ`: Normal Execution Request

Event Outputs

- `CNF`: Execution Confirmation

Data Inputs

- `IN1` (ANY_NUM): first factor
- `IN2` (ANY_NUM): second factor
- `IN3` (ANY_NUM): third factor

Data Outputs

- `OUT` (ANY_NUM): MUL result, clamped to the valid range of the result type
- `LIMIT_HIT` (BOOL): TRUE if the result was clamped due to overflow

Functionality

1. **Calculation Request**: `REQ` event with values for IN1, IN2, IN3.
2. **Calculation**: computes `IN1 * IN2 * IN3` left-to-right, one pairwise step at a time. Each step checks for overflow; if a step overflows, its result is clamped into the result type's valid range and `LIMIT_HIT` is set (sticky — once set by any step, it stays set for the rest of the fold).
3. **Result Output**: `CNF` event with the calculated `OUT` and `LIMIT_HIT`.

Overflow / Saturation Behavior

- **Signed integer** types: on overflow, clamps to `numeric_limits::max()` or `::min()`, direction determined by the operand signs of the step that overflowed.
- **Unsigned integer** types: on overflow, clamps to `numeric_limits::max()`.
- **REAL/LREAL**: a non-finite intermediate or final result is always caught, regardless of whether the *inputs* to that step were already non-finite — `+INF`/`-INF` clamp to `numeric_limits::max()`/`::lowest()`, and `NaN` (e.g. from a prior step going non-finite and combining in a way that produces `NaN`) becomes a deterministic `0`. `LIMIT_HIT` is set in every case.
- **Incompatible types** (e.g. mixing a magnitude type with an unrelated type where no `MUL` is defined): the offending step is skipped (logged as an error), `OUT` keeps whatever value the fold had accumulated so far, and `LIMIT_HIT` is **not** set for this case — it is a type error, not a numeric limit event.

Known Limitation for Chained (Arity ≥ 3) multiplication With SIGNED Types

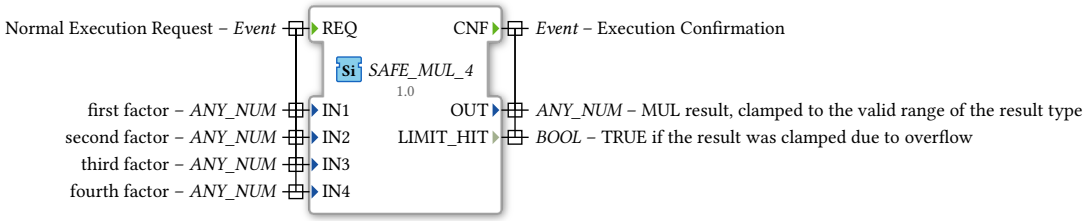
`SAFE_MUL_3` evaluates as a strict left-to-right pairwise fold: `((IN1 * IN2) * IN3) * ...`, clamping after every step. For **signed** integer types (and REAL/LREAL, which have no unsigned notion) this means a transient intermediate overflow that a later input would otherwise cancel back into range gets permanently baked into `OUT`, together with a `LIMIT_HIT` that no longer reflects the true total.

Example (INT, IN1=40000, IN2=40000, IN3=0): the true result is `0`, well within INT's range, but the fold clamps after the second step and never recovers.

This is **not** a bug being silently patched — it is documented, intentional behavior: the fold evaluates as a real chain of fixed-width operations, exactly like the plain (non-safe) `F_MUL` does, and reports a genuine intermediate limit condition rather than silently reordering the computation.

Unsigned chains of any arity are unaffected and always report a true overflow: a later factor is either 0 (collapses the result cleanly to 0 regardless of any prior clamping) or ≥ 1 (keeps the product non-decreasing), so an unsigned chain's intermediate clamp can never diverge from the true total.

`SAFE_MUL_2` (single pairwise operation, no chaining) always reports a true, correct overflow regardless of signedness — the ambiguity only exists for arity ≥ 3.



Related Function Blocks

- F_MUL — the fixed 2-input, non-saturating standard-library block this pattern extends (silent wrap-around/`INF` on overflow instead of clamping and reporting; no 3-input standard equivalent exists).
- Uebung_011b3 — the hardware finding that motivated this library.

Conclusion

SAFE_MUL_3 extends F_MUL's multiplication to 3 inputs, with an explicit, type-range-aware limit signal instead of a silent wraparound (integers) or a silently-corrupted result (floats) — at the cost of the arity-≥-3/signed chaining caveat documented above, which is a deliberate design trade-off, not an oversight.

SAFE_MUL_4

• – ◦ • – ◦ • – ◦ •

Introduction

SAFE_MUL_4 is part of the **SafeArithmetic** library (`SafeArithmetic::arithmetic`, EPL-2.0, HR Agrartechnik GmbH). It is a generic, 4-input multiplication function block that extends the standard library's fixed 2-input `F_MUL` pattern to 4 inputs (the standard library has no generic multi-input `MUL_n` yet, unlike `ADD_2/3/4`), and never lets an overflow pass silently: on overflow the result is **clamped** (saturated) into the valid range of the result type, and `LIMIT_HIT` reports that clamping happened.

This library exists because plain IEC 61131-3 arithmetic function blocks (like `F_MUL` itself, for integer types) compute the standard's specified two's-complement wraparound on overflow — correct per the standard, but dangerous for real measurement values. `Uebung_011b3` demonstrates this on real hardware: plain `F_SUB` computes `UDINT#1 - UDINT#12 = UDINT#4294967285`, a silent underflow wraparound.

Interface Structure

Event Inputs

- `REQ`: Normal Execution Request

Event Outputs

- `CNF`: Execution Confirmation

Data Inputs

- `IN1` (ANY_NUM): first factor
- `IN2` (ANY_NUM): second factor
- `IN3` (ANY_NUM): third factor
- `IN4` (ANY_NUM): fourth factor

Data Outputs

- `OUT` (ANY_NUM): MUL result, clamped to the valid range of the result type
- `LIMIT_HIT` (BOOL): TRUE if the result was clamped due to overflow

Functionality

1. **Calculation Request**: `REQ` event with values for IN1, IN2, IN3, IN4.
2. **Calculation**: computes `IN1 * IN2 * IN3 * IN4` left-to-right, one pairwise step at a time. Each step checks for overflow; if a step overflows, its result is clamped into the result type's valid range and `LIMIT_HIT` is set (sticky — once set by any step, it stays set for the rest of the fold).
3. **Result Output**: `CNF` event with the calculated `OUT` and `LIMIT_HIT`.

Overflow / Saturation Behavior

- **Signed integer** types: on overflow, clamps to `numeric_limits::max()` or `::min()`, direction determined by the operand signs of the step that overflowed.
- **Unsigned integer** types: on overflow, clamps to `numeric_limits::max()`.
- **REAL/LREAL**: a non-finite intermediate or final result is always caught, regardless of whether the *inputs* to that step were already non-finite — `+INF`/`-INF` clamp to `numeric_limits::max()`/`::lowest()`,

and NaN (e.g. from a prior step going non-finite and combining in a way that produces NaN) becomes a deterministic 0. LIMIT_HIT is set in every case.
- **Incompatible types** (e.g. mixing a magnitude type with an unrelated type where no MUL is defined): the offending step is skipped (logged as an error), OUT keeps whatever value the fold had accumulated so far, and LIMIT_HIT is **not** set for this case — it is a type error, not a numeric limit event.

Known Limitation for Chained (Arity ≥ 3) multiplication With SIGNED Types

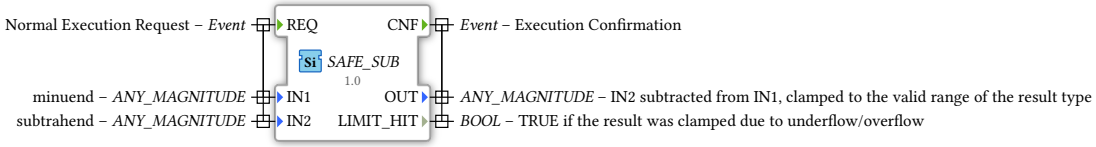
SAFE_MUL_4 evaluates as a strict left-to-right pairwise fold: ((IN1 * IN2) * IN3) * ..., clamping after every step. For **signed** integer types (and REAL/LREAL, which have no unsigned notion) this means a transient intermediate overflow that a later input would otherwise cancel back into range gets permanently baked into OUT, together with a LIMIT_HIT that no longer reflects the true total.

Example (INT, IN1=40000, IN2=40000, IN3=0, IN4=1): the true result is 0, well within INT's range, but the fold clamps after the second step and never recovers.

This is **not** a bug being silently patched — it is documented, intentional behavior: the fold evaluates as a real chain of fixed-width operations, exactly like the plain (non-safe) F_MUL does, and reports a genuine intermediate limit condition rather than silently reordering the computation.

Unsigned chains of any arity are unaffected and always report a true overflow: a later factor is either 0 (collapses the result cleanly to 0 regardless of any prior clamping) or ≥ 1 (keeps the product non-decreasing), so an unsigned chain's intermediate clamp can never diverge from the true total.

SAFE_MUL_2 (single pairwise operation, no chaining) always reports a true, correct overflow regardless of signedness — the ambiguity only exists for arity ≥ 3.



Related Function Blocks

- F_MUL — the fixed 2-input, non-saturating standard-library block this pattern extends (silent wrap-around/INF on overflow instead of clamping and reporting; no 4-input standard equivalent exists).
- Uebung_011b3 — the hardware finding that motivated this library.

Conclusion

SAFE_MUL_4 extends F_MUL's multiplication to 4 inputs, with an explicit, type-range-aware limit signal instead of a silent wraparound (integers) or a silently-corrupted result (floats) — at the cost of the arity-≥-3/signed chaining caveat documented above, which is a deliberate design trade-off, not an oversight.

SAFE_SUB

• – ◦ • – ◦ • – ◦ •

Introduction

SAFE_SUB is part of the **SafeArithmetic** library (SafeArithmetic::arithmetic, EPL-2.0, HR Agrartechnik GmbH). It is a fixed 2-input subtraction function block that behaves like the standard library's F_SUB, but never lets an underflow/overflow pass silently: on a limit violation the result is **clamped** (saturated) into the valid range of the result type, and LIMIT_HIT reports that clamping happened.

This is the block that motivated the whole library: Uebung_011b3 demonstrates on real ESP32-P4 hardware that plain F_SUB computes UDINT#1 - UDINT#12 = UDINT#4294967285 — exactly the IEC 61131-3-specified two's-complement wraparound for unsigned types, but dangerous for real measurement values (setpoint differences, remaining-distance calculations). SAFE_SUB computes the same subtraction instead as UDINT#0 with LIMIT_HIT = TRUE.

Unlike SAFE_ADD_2/3/4/SAFE_MUL_2/3/4, SAFE_SUB is **not** generic-arity: subtraction is neither associative nor commutative, so an N-ary "extensible" SAFE_SUB_n would not have a well-defined meaning the way extensible ADD/MUL do.

Interface Structure

Event Inputs

- `REQ`: Normal Execution Request

Event Outputs

- `CNF`: Execution Confirmation

Data Inputs

- `IN1` (ANY_MAGNITUDE): minuend
- `IN2` (ANY_MAGNITUDE): subtrahend

Data Outputs

- `OUT` (ANY_MAGNITUDE): IN2 subtracted from IN1, clamped to the valid range of the result type
- `LIMIT_HIT` (BOOL): TRUE if the result was clamped due to underflow/overflow

Functionality

1. **Calculation Request**: `REQ` event with values for IN1 and IN2.
2. **Subtraction**: computes `IN1 - IN2`.
3. **Result Output**: `CNF` event with the calculated `OUT` and `LIMIT_HIT`.

Overflow / Underflow Behavior

- **Signed integer** types: on overflow/underflow, clamps to `numeric_limits::min()` or `::max()`, direction determined by the sign of `IN2`.
- **Unsigned integer** types: subtraction can only ever underflow (go below 0), so it always clamps to `0` — this is exactly the `Uebung_011b3` case: `UDINT#1 - UDINT#12` clamps to `UDINT#0` with `LIMIT_HIT = TRUE` instead of wrapping to `UDINT#4294967285`.
- **REAL/LREAL**: a non-finite intermediate or final result is always caught, regardless of whether the *inputs* were already non-finite — `+INF`/`-INF` clamp to `numeric_limits::max()`/`::lowest()`, and `NaN` (e.g. `INF - INF`) becomes a deterministic `0`. `LIMIT_HIT` is set in every case.
- **Incompatible types** (e.g. mixing a magnitude type with an unrelated type where no subtraction is defined): the result is undefined by this operation (logged as an error), `OUT` is left unchanged, and `LIMIT_HIT` is **not** set for this case — it is a type error, not a numeric limit event.

Related Function Blocks

- F_SUB — the plain, non-saturating standard-library equivalent (silent wraparound/`INF` on overflow instead of clamping and reporting).
- Uebung_011b3 — the hardware finding that motivated this library.
- Uebung_011b5 — the same `1 - 12` scenario re-run with `SAFE_SUB`, with `LIMIT_HIT` wired to a second output so the clamping is visible on hardware.

Conclusion

SAFE_SUB gives you the same subtraction as `F_SUB`, but with an explicit, type-range-aware limit signal instead of a silent wraparound (integers) or a silently-corrupted result (floats) — directly closing the gap `Uebung_011b3` found in the standard library.

AR_CALIBRATE

ECC: AR_CALIBRATE

• – ○ • – ○ • – ○ •

Introduction

The function block `AR_CALIBRATE` is used for offset and scale calibration of an analog input signal provided via an adapter. It enables two-stage calibration: First, the offset is determined by comparison with a reference value during active calibration (`CO`), and then the scale is determined using a second reference (`CS`). The calibrated output signal is calculated continuously.

Interface Structure

Event Inputs

Name	Type	With	Description
`SET`	`EInit`	`Y_Offset`, `Y_Scale`	Sets the reference values for offset and scale calibration

CO	Event		Atomic trigger for offset calibration (reads current raw value from X)
CS	Event		Atomic trigger for scale calibration (reads current raw value from X)

Event Outputs

This function block does not have its own event outputs. However, events are sent via the connected adapters (e.g., Y.E1, OFFSET.EO1, SCALE.EO1).

Data Inputs

Name	Type	Description
Y_Offset	REAL	Reference value for offset calibration
Y_Scale	REAL	Reference value for scale calibration

Data Outputs

The FB has no direct data outputs. The calculated values are provided via the adapters Y, OFFSET, and SCALE.

Adapters

Plugs (providing interfaces):

Adapter	Type	Description
Y	adapter::types::unidirectional::AR	Calibrated output (data + event)
OFFSET	adapter::types::bidirectional::AR2	Returns the calculated offset value (bidirectional)
SCALE	adapter::types::bidirectional::AR2	Returns the calculated scale factor (bidirectional)

Sockets (user interfaces):

Adapter	Type	Description
X	adapter::types::unidirectional::AR	Analog input value (unidirectional)

Functionality

The function block operates with three basic algorithms, which are executed in the states REQ, CO, and CS:

- **REQ** (Normal Operation):
  `Y.D1 := (X.D1 + OFFSET.DI1) * SCALE.DI1`
  The output value is calculated from the input, the current offset, and the scale factor.
- **CO** (Offset Calibration):
  `OFFSET.DO1 := Y_Offset - X.D1`
  The offset is determined as the difference between the reference value Y_Offset and the current input value.
- **CS** (Scale Calibration):
  `SCALE.DO1 := Y_Scale / (X.D1 + OFFSET.DI1)`
  The scale factor is calculated by dividing the reference value Y_Scale by the input value corrected by the offset.

Calibration Procedure:

1. In state REQ, the function block (FB) is transitioned to state CO by receiving event CO. There, the offset is calculated and output via adapter OFFSET. The FB then immediately returns to state REQ.
2. Scale calibration is performed analogously via event CS and state CS.
3. The event SET updates the reference values Y_Offset and Y_Scale without exiting the calibration state.
4. Repeated measurements (via X.E1) update the output Y with the current calibration parameters.

The transitions between the states are defined as follows:

- REQ ⟶ REQ: at X.E1, SET, OFFSET.EI1, or SCALE.EI1
- REQ ⟶ CO: when event CO is received
- REQ ⟶ CS: when event CS is received
- CO ⟶ REQ: always (condition 1)
- CS ⟶ REQ: always (condition 1)

Technical Features

- **Atomic Event Triggering**: Calibration commands CO and CS are defined as direct event inputs, eliminating intermediate AX adapters and data-guard checks.
- **Bidirectional Calibration Adapters**: The adapters OFFSET and SCALE are bidirectional (AR2), allowing them to be written by the calibration FB and read by external modules.
- **Two-Stage Calibration**: Offset and scaling are calibrated sequentially. The scaling factor already uses the determined offset to ensure correct linear correction.
- **No Own Event Output**: The function block does not generate its own events but triggers them via the adapter events (e.g., Y.E1 after each calculation).

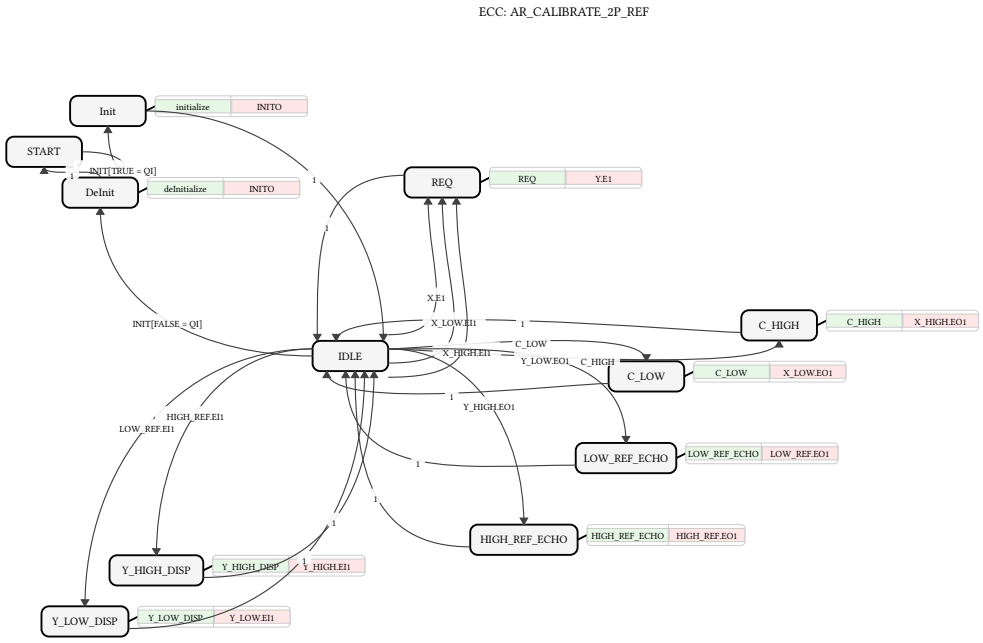
State Overview

State	Description	Action
REQ	Normal Operation – Calculation of the Calibrated Output	Executes algorithm REQ, sends event to Y.E1
CO	Offset Calibration	Executes algorithm CO, sends event to OFFSET.EO1
CS	Scale Calibration	Executes algorithm CS, sends event to SCALE.EO1

Application Scenarios

- **Industrial Measurement Processing**: Calibration of pressure sensors, temperature sensors, or other analog transmitters where offset and gain need readjustment.
- **Measurement Chain Calibration**: After connecting a sensor, the entire chain can be linearized by establishing a zero point (offset) and a second reference point (scale).
- **Automated Recalibration**: Triggering event inputs CO and CS can compensate for sensor drift during operation.

Comparison with Similar Blocks

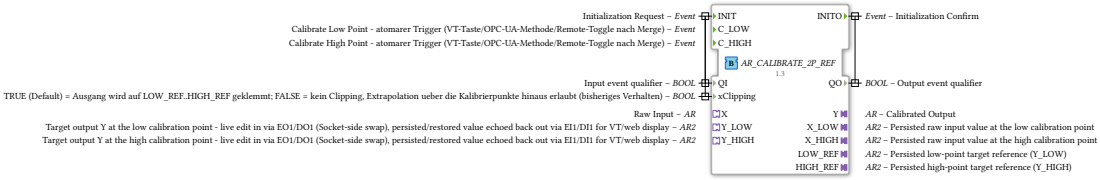


Details on calibration methods can be found under Two-point and Three-point Calibration Methods.

Simple scaling blocks (e.g., SCALE) offer fixed multiplication and addition without automatic calibration. In contrast, AR_CALIBRATE integrates the complete calibration logic—including reference values and event-driven activation—making it suitable for dynamic environments where parameters must be adjusted during operation.

Conclusion

The AR_CALIBRATE function block provides a robust solution for offset and scale calibration of analog signals. Thanks to its atomic event inputs and clear state machine, it integrates seamlessly into automation solutions and enables accurate, repeatable measurement corrections.



AR_CALIBRATE_2P_REF

• — ○ • — ○ • — ○ •

Introduction

`AR_CALIBRATE_2P_REF` is an adapter-based 2-point calibration (Low/High). Both points are stored independently of each other, so there is no ordering dependency as with `AR_CALIBRATE_SQ_REF`. The reference targets (`Y_LOW`/`Y_HIGH`) are live `AR2` sockets and are persisted via two additional `AR2` plugs (`LOW_REF`/`HIGH_REF`). Interpolation happens live on every `X.E1`.

Interface Structure

Event Inputs

- `INIT`: Initialization or deinitialization. Associated data: `QI`, `xClipping`.
- `C_LOW`: Atomic trigger to calibrate the low point (VT button, OPC UA method or remote toggle after merge).
- `C_HIGH`: Atomic trigger to calibrate the high point.

Event Outputs

- `INITO`: Initialization confirmation. Associated data: `QO`.

Data Inputs

Name	Data type	Default	Comment
`QI`	`BOOL`		Input qualifier (TRUE = enable, FALSE = disable).
`xClipping`	`BOOL`	`TRUE`	TRUE: output is clamped to `LOW_REF..HIGH_REF`; FALSE: no clipping, extrapolation beyond the calibration points allowed.

Data Outputs

- `QO` (`BOOL`): Output qualifier.

Adapters

Direction	Name	Adapter type	Comment
Plug (output)	`Y`	`adapter::types::unidirectional::AR`	Calibrated output.
Plug (output)	`X_LOW`	`adapter::types::bidirectional::AP2`	Persisted raw value at the low calibration point.
Plug (output)	`X_HIGH`	`adapter::types::bidirectional::AP2`	Persisted raw value at the high calibration point.
Plug (output)	`LOW_REF`	`adapter::types::bidirectional::AP2`	Persisted low-point target (Y_LOW).
Plug (output)	`HIGH_REF`	`adapter::types::bidirectional::AP2`	Persisted high-point target (Y_HIGH).
Socket (input)	`X`	`adapter::types::unidirectional::AR`	Raw input.
Socket (input)	`Y_LOW`	`adapter::types::bidirectional::AP2`	Target output at the low point: live edit in via `EO1`/`DO1`, the persisted/restored value is echoed back out via `EI1`/`DI1` for VT/web display.
Socket (input)	`Y_HIGH`	`adapter::types::bidirectional::AP2`	Same as `Y_LOW`, for the high point.

Functionality

The block is a basic FB. In state `IDLE` it reacts to the following events:

Event	State	Action
`X.EI1`, `X_LOW.EI1`, `X_HIGH.EI1`	`REQ`	Computes the calibrated value and emits `Y.EI1`.
`C_LOW`	`C_LOW`	`X_LOW.DO1 := X.D1`, emits `X_LOW.EO1`.
`C_HIGH`	`C_HIGH`	`X_HIGH.DO1 := X.D1`, emits `X_HIGH.EO1`.
`Y_LOW.EO1`	`LOW_REF_ECHO`	`LOW_REF.DO1 := Y_LOW.DO1`, emits `LOW_REF.EO1` (persist).
`Y_HIGH.EO1`	`HIGH_REF_ECHO`	`HIGH_REF.DO1 := Y_HIGH.DO1`, emits `HIGH_REF.EO1`.
`LOW_REF.EI1`	`Y_LOW_DISP`	`Y_LOW.DI1 := LOW_REF.DI1`, emits `Y_LOW.EI1` (display after boot and after every change).
`HIGH_REF.EI1`	`Y_HIGH_DISP`	`Y_HIGH.DI1 := HIGH_REF.DI1`, emits `Y_HIGH.EI1`.

All action states return to `IDLE` immediately. Initialization runs `START` → `Init` (`INIT` with `QI = TRUE`, `QO := QI`, `INITO`) → `IDLE`; `INIT` with `QI = FALSE` leads from `IDLE` via `DeInit` (`QO := FALSE`, `INITO`) back to `START`.

Calculation in state `REQ`:

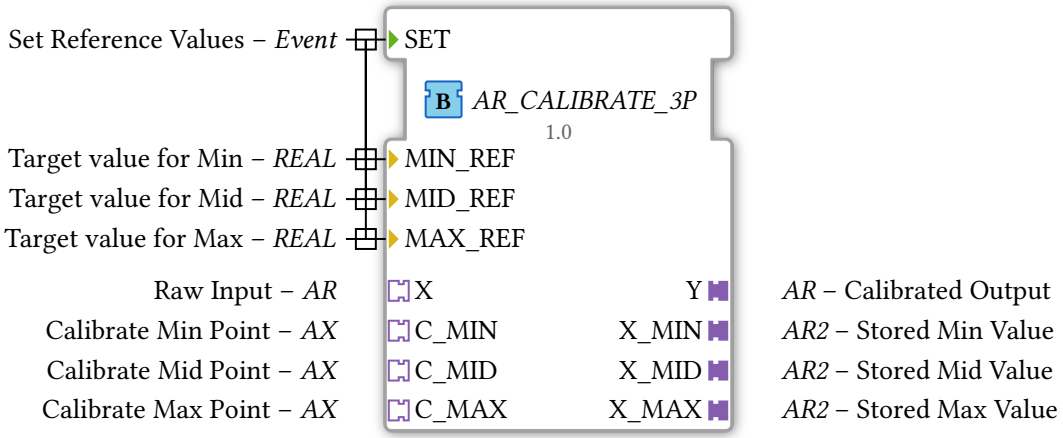
1. `QO := QI`. The calculation is only performed when `QI = TRUE`.
2. Internal latched flags: `xLowCal` / `xHighCal` become TRUE as soon as `X_LOW.DI1` / `X_HIGH.DI1` differs from the default `0.0`.
3. If both points are calibrated: `Y.D1 = LOW_REF + (X - X_LOW) * (HIGH_REF - LOW_REF) / (X_HIGH - X_LOW)`; if `X_HIGH = X_LOW`, `LOW_REF` is output.
4. If only low is calibrated, `LOW_REF` is output; if only high is calibrated, `HIGH_REF`; if nothing is calibrated, `LOW_REF`.
5. Clipping to `[LOW_REF, HIGH_REF]` only if `xClipping` is TRUE and both points are calibrated.

Technical Details

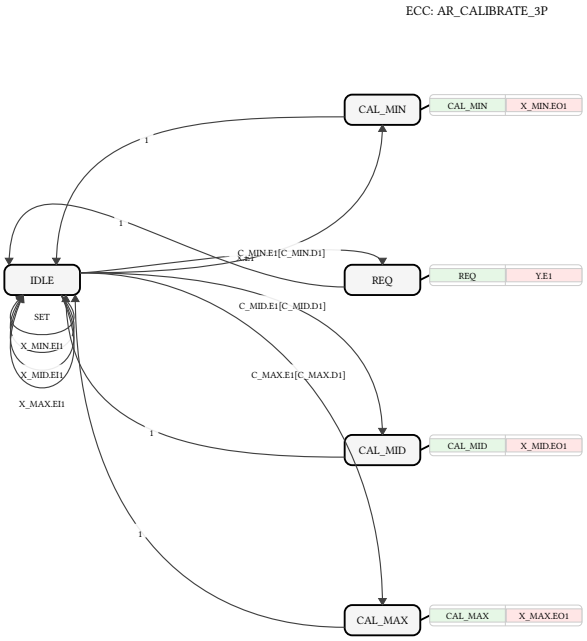
- **No ordering dependency:** `C_LOW` and `C_HIGH` store their raw value independently; each point can be re-calibrated individually at any time.
- **Partial calibration:** As long as only one point is calibrated, the block does not interpolate against the other point still at `0.0` but outputs the known REF value.
- **Persistence:** `X_LOW`, `X_HIGH`, `LOW_REF` and `HIGH_REF` are bidirectional `AR2` plugs; permanent storage is done by a downstream block (e.g. `INI_AR2/NVS_AR2`). Values read back at boot reappear at `Y_LOW/Y_HIGH` via `LOW_REF.EI1/HIGH_REF.EI1`.
- **Atomic triggers:** `C_LOW/C_HIGH` are plain event inputs, not an `AX` adapter with an edge guard.

Application Scenarios

- Calibrating an analog sensor at two reference points (e.g. zero and end value) with the target values entered on the VT.
- Re-trimming a drifted zero point later without re-calibrating the high point.



Summary



`AR_CALIBRATE_2P_REF` calibrates an `AR` signal using two independently stored raw values and two live-editable, persistable reference targets, and outputs the linearly interpolated (optionally clamped) result via `Y`.

AR_CALIBRATE_3P

• – ○ • – ○ • – ○ •

Introduction

The **AR_CALIBRATE_3P** function block enables 3-point calibration of an analog input signal using adapters. It is specifically designed for joysticks that exhibit center drift and corrects this drift by linearizing between three reference points: minimum, mean, and maximum. The calibration points are saved and can be reset as needed.

Interface Structure

Event Inputs

Name	Type	With	Comment
`SET`	`Event`	`MIN_REF`, `MID_REF`, `MAX_REF`	Sets the reference values for the calibration curve. Does not trigger a calculation, but only sets the target output values.
`C_MIN`	`Event`		Atomic trigger for calibrating the minimum point (reads current raw value from `X`).
`C_MID`	`Event`		Atomic trigger for calibrating the midpoint (reads current raw value from `X`).
`C_MAX`	`Event`		Atomic trigger for calibrating the maximum point (reads current raw value from `X`).

Event Outputs

No explicit event outputs are available. Output is exclusively via the **Y** adapter.

Data Inputs

Name	Data Type	Default Value	Comment
`MIN_REF`	`REAL`	`0.0`	Target value for the smallest input value (Min).

MID_REF	REAL	50.0	Target value for the midpoint (Mid).
MAX_REF	REAL	100.0	Target value for the largest input value (Max).

Data Outputs

No direct data outputs – all outputs are provided via **plugs** (output adapters).

Adapters

Direction	Name	Adapter Type	Comment
Plug (Output)	Y	adapter::types::unidirectional::AC	Calibrated output value (analog value plus event).
Plug (Output)	X_MIN	adapter::types::bidirectional::AR2	Stored minimum value (from the raw value).
Plug (Output)	X_MID	adapter::types::bidirectional::AR2	Stored midpoint value (from the raw value).
Plug (Output)	X_MAX	adapter::types::bidirectional::AR2	Stored maximum value (from the raw value).
Socket (Input)	X	adapter::types::unidirectional::AR	Raw value from the sensor (analog value plus event).

Functionality

The calibration is based on piecewise linear interpolation between three stored raw values (X_MIN, X_MID, X_MAX) and the corresponding reference values (MIN_REF, MID_REF, MAX_REF).

1. **Calibration of the Points:**
   An event at one of the calibration inputs (C_MIN, C_MID, C_MAX) saves the currently applied raw value (X.D1) to the corresponding stored value (X_MIN.DO1, X_MID.DO1, X_MAX.DO1).
2. **Calculation of the Calibrated Value:**
   As soon as an event arrives from the raw value adapter (X.E1), the function block becomes active and executes the **REQ** algorithm. The raw value X.D1 is then linearly mapped:
   - If the raw value is below the stored midpoint X_MID.DI1, the lower branch of the characteristic curve is used:
     `Y.D1 = MIN_REF + (X.D1 – X_MIN.DI1) * (MID_REF – MIN_REF) / (X_MID.DI1 – X_MIN.DI1)`
     If the intervals are invalid (division by zero or negative range), MIN_REF is used.
   - If the raw value is above or equal to X_MID.DI1, the upper branch is calculated:
     `Y.D1 = MID_REF + (X.D1 – X_MID.DI1) * (MAX_REF – MID_REF) / (X_MAX.DI1 – X_MID.DI1)`
     Here too, invalid intervals result in MID_REF being output.
3. **Clipping:**
   The calculated output value is clipped to the interval [MIN_REF, MAX_REF] to ensure physically meaningful results.
4. **Output:**
   The calibrated value is output via the adapter Y (event Y.E1 and data Y.D1).

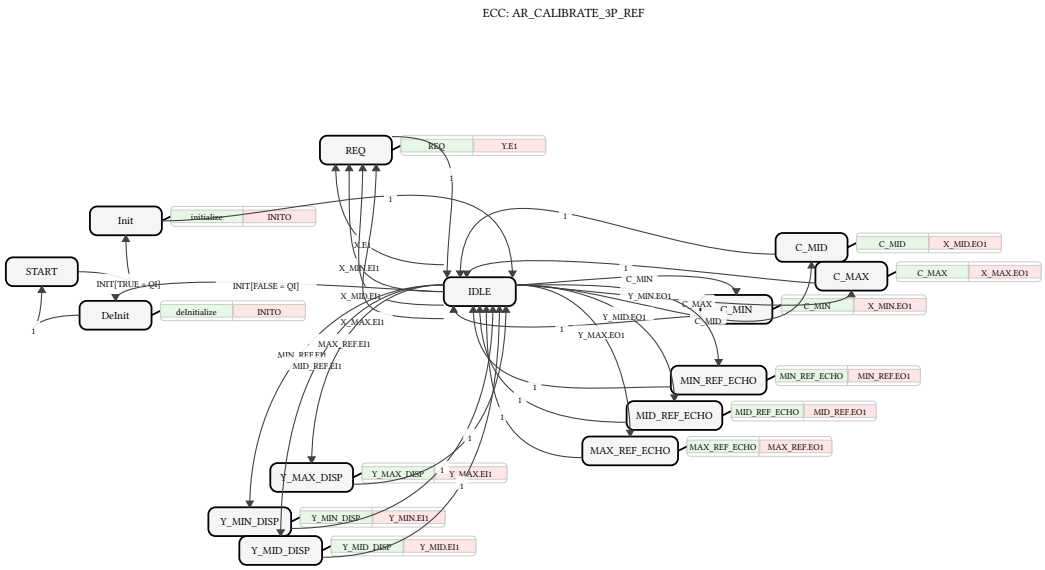
Technical Features

- **Bidirectional Adapters for Calibration Points:** The stored raw values (X_MIN, X_MID, X_MAX) are bidirectional adapters of type AR2. They can be both written to (during calibration) and read from (during calculation). This makes the calibration points available for subsequent calculations (non-volatile retention across reinitialization or power loss requires an external storage block such as INI/NVS).
- **Atomic Event Triggering:** Calibration of the three points is triggered directly by specific event inputs (C_MIN, C_MID, C_MAX), eliminating intermediate AX adapters and data guards.
- **Protection Against Invalid Intervals:** The algorithms check whether the ranges of the stored raw values are positive. If not (e.g., if the system is not yet calibrated), safe default values are output.

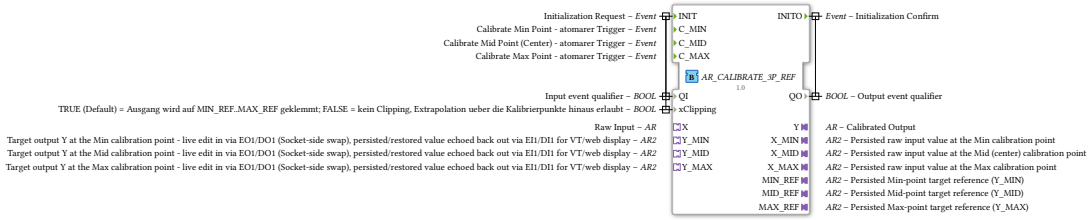
- **No Self-Calibration:** The function block does not store a history – the system must explicitly set the calibration points by triggering the calibration events.

State Overview

State	Description
IDLE	Waiting state. Transitions: For `SET` ⟶ IDLE; for `X_MIN.EI1`, `X_MID.EI1`, `X_MAX.EI1` ⟶ IDLE; for `C_MIN` ⟶ CAL_MIN; for `C_MID` ⟶ CAL_MID; for `C_MAX` ⟶ CAL_MAX; for `X.E1` ⟶ REQ.
REQ	Calculates the calibrated output value. Returns to IDLE immediately after execution.
CAL_MIN	Stores the current raw value as minimum (`X_MIN.DO1 := X.D1`). Returns to IDLE automatically.
CAL_MID	Stores the current raw value as midpoint (`X_MID.DO1 := X.D1`). Returns to IDLE automatically.
CAL_MAX	Stores the current raw value as maximum (`X_MAX.DO1 := X.D1`). Returns to IDLE automatically.



Transition Conditions:



- `X.E1` ⟶ Start of calculation
- `C_MIN` ⟶ Calibration of the minimum point
- `C_MID` ⟶ Calibration of the midpoint
- `C_MAX` ⟶ Calibration of the maximum point
- `SET`, `X_MIN.EI1`, `X_MID.EI1`, `X_MAX.EI1` ⟶ No state change (remains in IDLE)

Application Scenarios

- **Joystick Calibration:** A joystick with an analog output (e.g., 0–10 V) exhibits component-related deviations at center and end positions. The operator moves the joystick to the three positions (Min, Mid, Max) and triggers the calibration events via pushbuttons. `Y` then delivers a linearized value normalized to target limits.
- **Analog Potentiometer:** A sliding potentiometer affected by wear can be corrected via 3-point calibration.

AR_CALIBRATE_3P_REF

• – ○ • – ○ • – ○ •

Introduction

`AR_CALIBRATE_3P_REF` is an adapter-based three-point calibration for joysticks and sensors with a centre position (Min, Mid, Max), in free order like AR_CALIBRATE_3P. The reference targets (`Y_MIN`/`Y_MID`/`Y_MAX`) are **live `AR2` sockets** and are persisted via three additional `AR2` plugs (`MIN_REF`/`MID_REF`/`MAX_REF`). The same live-echo pattern as in `AR_CALIBRATE_SQ_REF` and AR_CALIBRATE_2P_REF applies.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialisation request. Associated with `QI`, `xClipping`.
- **C_MIN**: calibrate the min point, atomic trigger.
- **C_MID**: calibrate the mid point (centre), atomic trigger.
- **C_MAX**: calibrate the max point, atomic trigger.

Event Outputs

- **INITO** (`EInit`): initialisation confirm. Associated with `QO`.

Data Inputs

- **QI** (`BOOL`): event input qualifier
- **xClipping** (`BOOL`, default `TRUE`): `TRUE` = output is clamped to `MIN_REF..MAX_REF`; `FALSE` = no clipping, extrapolation beyond the calibration points allowed

Data Outputs

- **QO** (`BOOL`): event output qualifier

Adapters

Plugs:

- **Y** (`adapter::types::unidirectional::AR`): calibrated output
- **X_MIN**, **X_MID**, **X_MAX** (`adapter::types::bidirectional::AR2`): persisted raw input value at the min/mid/max calibration point
- **MIN_REF**, **MID_REF**, **MAX_REF** (`adapter::types::bidirectional::AR2`): persisted target reference (`Y_MIN`/`Y_MID`/`Y_MAX`)

Sockets:

- **X** (`adapter::types::unidirectional::AR`): raw input
- **Y_MIN**, **Y_MID**, **Y_MAX** (`adapter::types::bidirectional::AR2`): target output `Y` at the min/mid/max point. Live edit in via `EO1`/`DO1` (socket-side swap); the persisted/restored value is echoed back out via `EI1`/`DI1` for VT/web display.

Functionality

The block starts in state `START`; `INIT` with `QI = TRUE` leads via `Init` to `IDLE` (`QO := QI`), `INIT` with `QI = FALSE` leads via `DeInit` back to `START` (`QO := FALSE`). From `IDLE` the following action states are reachable, each returning immediately to `IDLE`:

- **REQ** (on `X.E1` or an event `X_MIN.EI1`/`X_MID.EI1`/`X_MAX.EI1`): calculates `Y` and fires `Y.E1`
- **C_MIN**/**C_MID**/**C_MAX**: store the raw input `X.D1` in `X_MIN.DO1`/`X_MID.DO1`/`X_MAX.DO1` and fire `X_MIN.EO1`/`X_MID.EO1`/`X_MAX.EO1`
- **MIN_REF_ECHO**/**MID_REF_ECHO**/**MAX_REF_ECHO** (on `Y_MIN.EO1`/`Y_MID.EO1`/`Y_MAX.EO1`): transfer the live reference `Y_xxx.DO1` to `xxx_REF.DO1` (persistence)

- **Y_MIN_DISP/Y_MID_DISP/Y_MAX_DISP** (on MIN_REF.EI1/MID_REF.EI1/MAX_REF.EI1): echo the persisted/restored reference back to Y_xxx.DI1 (after boot and after every change)

Formula: piecewise linear interpolation between (X_MIN, MIN_REF), (X_MID, MID_REF) and (X_MAX, MAX_REF), clipped to MIN_REF..MAX_REF unless xClipping = FALSE.

Partial calibration (before all three points are set): each point is tracked internally (xMinCal/xMidCal/xMaxCal, latched TRUE once its raw value differs from the INI default 0.0; stays correctly set across restarts because the boot restore returns the persisted value). Until all three are calibrated, REQ falls back cleanly instead of pivoting on a still-uncalibrated X_MID.DI1 (which would sit at 0.0 and make the MIN branch permanently unreachable):

- Only one point calibrated: Y = that point's own REF value (no interpolation possible)
- Two points calibrated: two-point line between exactly those two, the third is ignored
- All three calibrated: full piecewise interpolation
- None calibrated: Y := MID_REF

Clipping only takes place if xClipping is set and both MIN and MAX are calibrated; otherwise the still-uncalibrated bound at its INI default 0.0 would corrupt the partial-calibration fallback. MID is irrelevant for this.

Calibration (three-point, free order):

1. **Min (C_MIN)**: move to minimum, set Y_MIN, trigger C_MIN ⟶ X_MIN := X
2. **Mid (C_MID)**: move to centre, set Y_MID, trigger C_MID ⟶ X_MID := X
3. **Max (C_MAX)**: move to maximum, set Y_MAX, trigger C_MAX ⟶ X_MAX := X

Technical Details

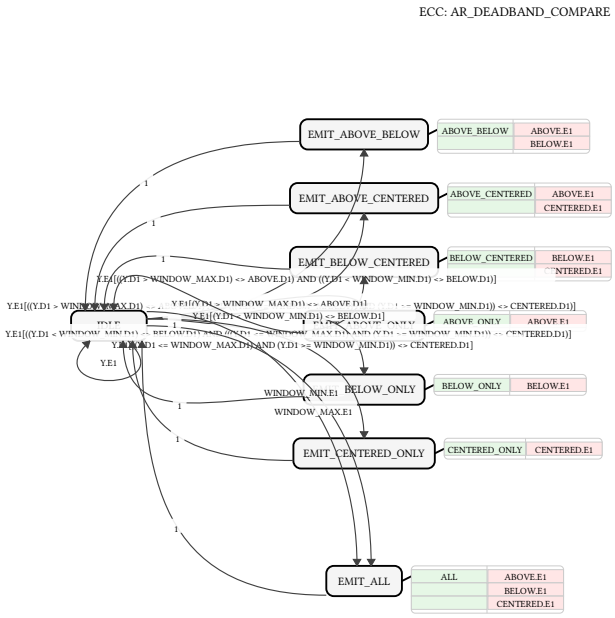
- **Free order** as with AR_CALIBRATE_3P: each point is stored independently and can be recalibrated on its own (e.g. only re-trimming the centre), with no data dependency between the calibration actions.
- **References as live sockets:** Y_MIN/Y_MID/Y_MAX are bidirectional AR2 sockets fed from an external VT/web reader, mirrored outward via the AR2 plugs MIN_REF/MID_REF/MAX_REF for persistence (INI_AR2/NVS_AR2) and echoed back via MIN_REF.EI1/MID_REF.EI1/MAX_REF.EI1, so that a value restored after boot appears on screen without the operator re-entering it.
- Degenerate points (X_MID <= X_MIN or X_MAX <= X_MID) yield the respective REF value instead of a division by zero.

State Overview

```
START --INIT[QI]--> Init --1--> IDLE
IDLE --INIT[!QI]--> DeInit --1--> START
IDLE --X.E1 / X_xxx.EI1--> REQ --1--> IDLE
IDLE --C_MIN / C_MID / C_MAX--> C_xxx --1--> IDLE
IDLE --Y_xxx.EO1--> xxx_REF_ECHO --1--> IDLE
IDLE --xxx_REF.EI1--> Y_xxx_DISP --1--> IDLE
```

Application Scenarios

- Steering angle sensor: Min = full lock left, Mid = straight ahead, Max = full lock right. MIN_REF/MID_REF/MAX_REF hold the desired calibrated angle values (e.g. −30.0 / 0.0 / 30.0 degrees), X_MIN/X_MID/X_MAX the raw sensor values actually measured.
- Joysticks with a centre position and persisted reference values editable on the VT

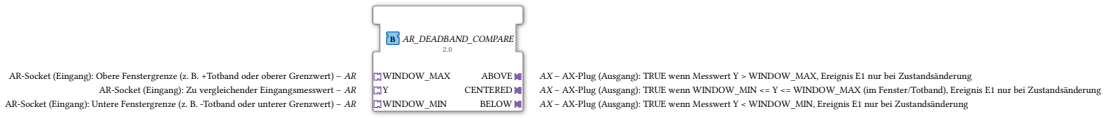


⚖️ Comparison with Similar Building Blocks

- AR_CALIBRATE_3P: three-point calibration without *_REF sockets
- AR_CALIBRATE_2P_REF: two-point variant with the same live references

Conclusion

AR_CALIBRATE_3P_REF calibrates three points in free order, keeps raw values and references persisted via AR2 adapters and falls back cleanly on partial calibration.



AR_DEADBAND_COMPARE

• — ○ • — ○ • — ○ •

Introduction

`AR_DEADBAND_COMPARE` compares a `REAL` measured value `Y` (via an `AR` socket) against a window `[WINDOW_MIN, WINDOW_MAX]` and reports the result via three `AX` plugs: `ABOVE` (`Y > WINDOW_MAX`), `BELOW` (`Y < WINDOW_MIN`) and `CENTERED` (in between). For a symmetric deadband around zero, set `WINDOW_MIN = -deadband` and `WINDOW_MAX = +deadband` (e.g. steering angle centering); the block can equally be used for arbitrary windows (e.g. colour limits).

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets (`Y.E1`, `WINDOW_MIN.E1`, `WINDOW_MAX.E1`).

Event Outputs

No direct event outputs - events are sent via the adapter plugs (`ABOVE.E1`, `BELOW.E1`, `CENTERED.E1`).

Data Inputs

No direct data inputs (values arrive via the sockets, data port `D1`).

Data Outputs

No direct data outputs (values are output via the plugs, data port `D1`).

Adapters

Sockets (inputs):

Adapter	Type	Description
`Y`	`adapter::types::unidirectional::AR`	Input measured value to be compared

WINDOW_MIN	adapter::types::unidirectional::AR	Lower window limit (e.g. -deadband or lower threshold)
WINDOW_MAX	adapter::types::unidirectional::AR	Upper window limit (e.g. +deadband or upper threshold)

Plugs (outputs):

Adapter	Type	Description
ABOVE	adapter::types::unidirectional::AX	TRUE if Y > WINDOW_MAX; event E1 only on state change
CENTERED	adapter::types::unidirectional::AX	TRUE if WINDOW_MIN <= Y <= WINDOW_MAX (inside window/deadband); event E1 only on state change
BELOW	adapter::types::unidirectional::AX	TRUE if Y < WINDOW_MIN; event E1 only on state change

How it works

The block is a basic FB with an idle state IDLE and seven emit states, each of which returns to IDLE immediately (condition 1) after its action.

- **Y change (Y.E1)**: The transitions compare the newly computed value of ABOVE, BELOW and CENTERED with the value currently stored in the respective plug (<>). Only the outputs whose boolean value actually changes are recomputed and send their E1:
  - EMIT_ABOVE_BELOW: ABOVE and BELOW change
  - EMIT_ABOVE_CENTERED: ABOVE and CENTERED change
  - EMIT_BELOW_CENTERED: BELOW and CENTERED change
  - EMIT_ABOVE_ONLY, EMIT_BELOW_ONLY, EMIT_CENTERED_ONLY: only the respective output changes
  - If none of the values changes, Y.E1 leads directly IDLE ⟶ IDLE with no output event.
- **Window limit change (WINDOW_MIN.E1 or WINDOW_MAX.E1)**: State EMIT_ALL recomputes all three outputs and sends ABOVE.E1, BELOW.E1 and CENTERED.E1 (in practice usually only once at start-up).

Calculations (ST algorithms):

```
ABOVE.D1    := Y.D1 > WINDOW_MAX.D1;
BELOW.D1    := Y.D1 < WINDOW_MIN.D1;
CENTERED.D1 := (Y.D1 <= WINDOW_MAX.D1) AND (Y.D1 >= WINDOW_MIN.D1);
```

Technical Details

- **Event efficiency**: On a Y change, each plug fires only if its own value actually changes (not all three on every update)
- **Window limits**: On a change of WINDOW_MIN/WINDOW_MAX, all three outputs are always set again for simplicity
- **Limit values**: The limits themselves belong to CENTERED (<=/>=); ABOVE and BELOW are strict (>/<)
- A fixed value for a limit can be supplied via adapter::types::unidirectional::AR::initval::initval_AR
- Version history: 1.0 (initial, axle steering centre automation), 1.1 (DEADBAND as AR socket), 2.0 (generalised to an arbitrary window WINDOW_MIN/WINDOW_MAX)

State Overview

State	Description	Action
IDLE	Waits for events on Y.E1, WINDOW_MIN.E1 or WINDOW_MAX.E1	-
EMIT_ABOVE_BELOW	Update ABOVE and BELOW	ABOVE.E1, BELOW.E1
EMIT_ABOVE_CENTERED	Update ABOVE and CENTERED	ABOVE.E1, CENTERED.E1

EMIT_BELOW_CENTERED	Update BELOW and CENTERED	`BELOW.E1`, `CENTERED.E1`
EMIT_ABOVE_ONLY	Update ABOVE only	`ABOVE.E1`
EMIT_BELOW_ONLY	Update BELOW only	`BELOW.E1`
EMIT_CENTERED_ONLY	Update CENTERED only	`CENTERED.E1`
EMIT_ALL	Update all three (window limits changed)	`ABOVE.E1`, `BELOW.E1`, `CENTERED.E1`

Application Scenarios

- **Steering angle centering**: Checking whether a steering sensor lies within the deadband around 0° (`WINDOW_MIN = -deadband`, `WINDOW_MAX = +deadband`)
- **Window/hysteresis monitoring**: Evaluating limit or colour ranges (e.g. green/red in visualisations)

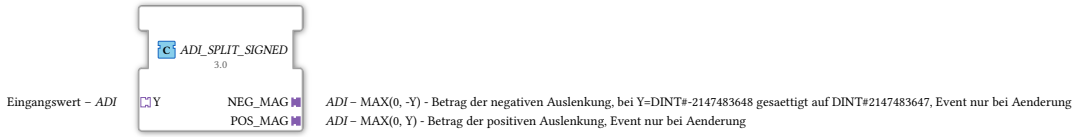
Summary

`AR_DEADBAND_COMPARE` provides the three states above, below and inside a window for an `AR` measured value as `AX` signals and generates events only on an actual state change.

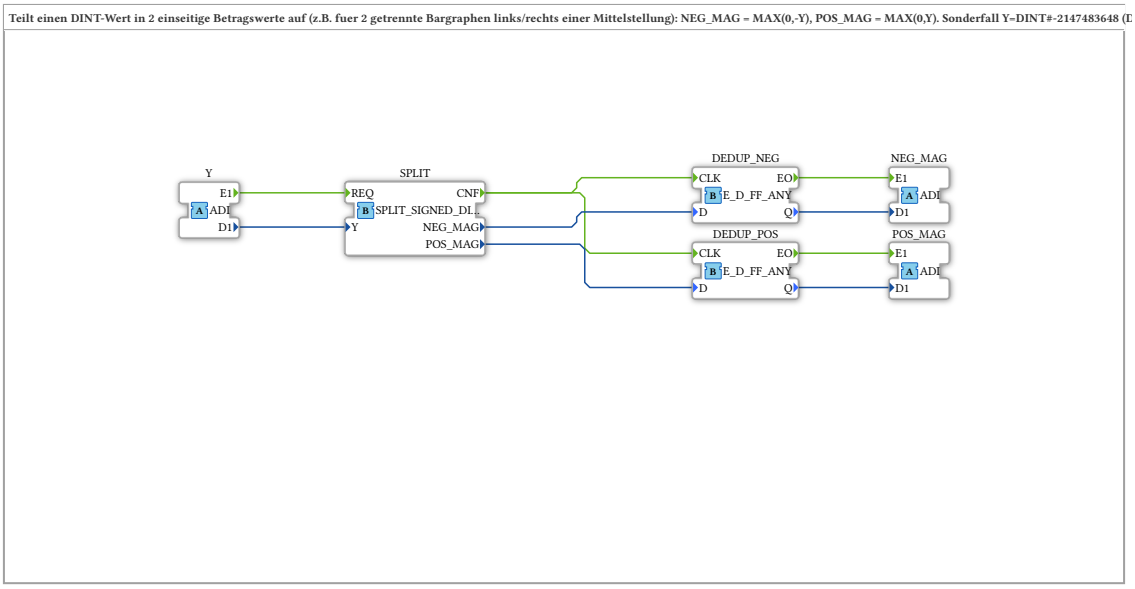
Splitting

Signed Splitting Function Blocks

This library contains function blocks for splitting signed signals (`SINT`, `INT`, `DINT`, `LINT`, `REAL`, `LREAL`) into two positive magnitude components (`NEG_MAG` and `POS_MAG`).



Basic FBs (Pure Calculation)



- SPLIT_SIGNED_SINT – Splitting for `SINT`
- SPLIT_SIGNED_INT – Splitting for `INT`
- SPLIT_SIGNED_DINT – Splitting for `DINT`
- SPLIT_SIGNED_LINT – Splitting for `LINT`
- SPLIT_SIGNED_REAL – Splitting for `REAL`
- SPLIT_SIGNED_LREAL – Splitting for `LREAL`

Adapter Wrapper Composite FBs (With D-Flip-Flop Event Filtering)

- AS_SPLIT_SIGNED – Adapter wrapper for `SINT` (`AS`)
- AI_SPLIT_SIGNED – Adapter wrapper for `INT` (`AI`)
- ADI_SPLIT_SIGNED – Adapter wrapper for `DINT` (`ADI`)
- ALI_SPLIT_SIGNED – Adapter wrapper for `LINT` (`ALI`)
- AR_SPLIT_SIGNED – Adapter wrapper for `REAL` (`AR`)
- ALR_SPLIT_SIGNED – Adapter wrapper for `LREAL` (`ALR`)

ADI_SPLIT_SIGNED

• — ○ • — ○ • — ○ •

Introduction

The **ADI_SPLIT_SIGNED** function block is an adapter wrapper (Composite FB) that splits a signed `DINT` measurement value into two single-sided magnitude components using unidirectional adapters (`adapter::types::unidirectional::ADI`):

- `NEG_MAG`: Magnitude of negative deflection (`MAX(0, -Y)`)
- `POS_MAG`: Magnitude of positive deflection (`MAX(0, Y)`)

The block encapsulates calculation FB **SPLIT_SIGNED_DINT** and two **E_D_FF_ANY** D-Flip-Flop blocks to emit the initial event on the first `CLK` and thereafter emit events on plugs `NEG_MAG` and `POS_MAG` **only when the new input value differs from the stored output state** (`D <> Q`).

Interface Structure

Adapter Sockets (Input)

Name	Type	Comment
`Y`	`adapter::types::unidirectional::ADI`	Signed input value (ADI adapter socket)

Adapter Plugs (Output)

Name	Type	Comment
`NEG_MAG`	`adapter::types::unidirectional::ADI`	Negative magnitude (`MAX(0, -Y)`), initial event on 1st call, thereafter on change only
`POS_MAG`	`adapter::types::unidirectional::ADI`	Positive magnitude (`MAX(0, Y)`), initial event on 1st call, thereafter on change only

Functionality

Internally, the composite network consists of three components:

1. **SPLIT (SPLIT_SIGNED_DINT)**: Computes `NEG_MAG` and `POS_MAG` from `Y.D1` upon every `Y.E1` event.
2. **DEDUP_NEG (E_D_FF_ANY)**: An event-driven D-Flip-Flop that emits the initial output event upon the first `CLK` event, and thereafter forwards `CLK` to `EO` and updates `Q := D` only when the new data value `D` differs from the current output state `Q` (`D <> Q`).
3. **DEDUP_POS (E_D_FF_ANY)**: A second D-Flip-Flop of the same type that similarly emits the initial output event on the first call and subsequently emits event `POS_MAG.E1` only when the positive magnitude value changes.

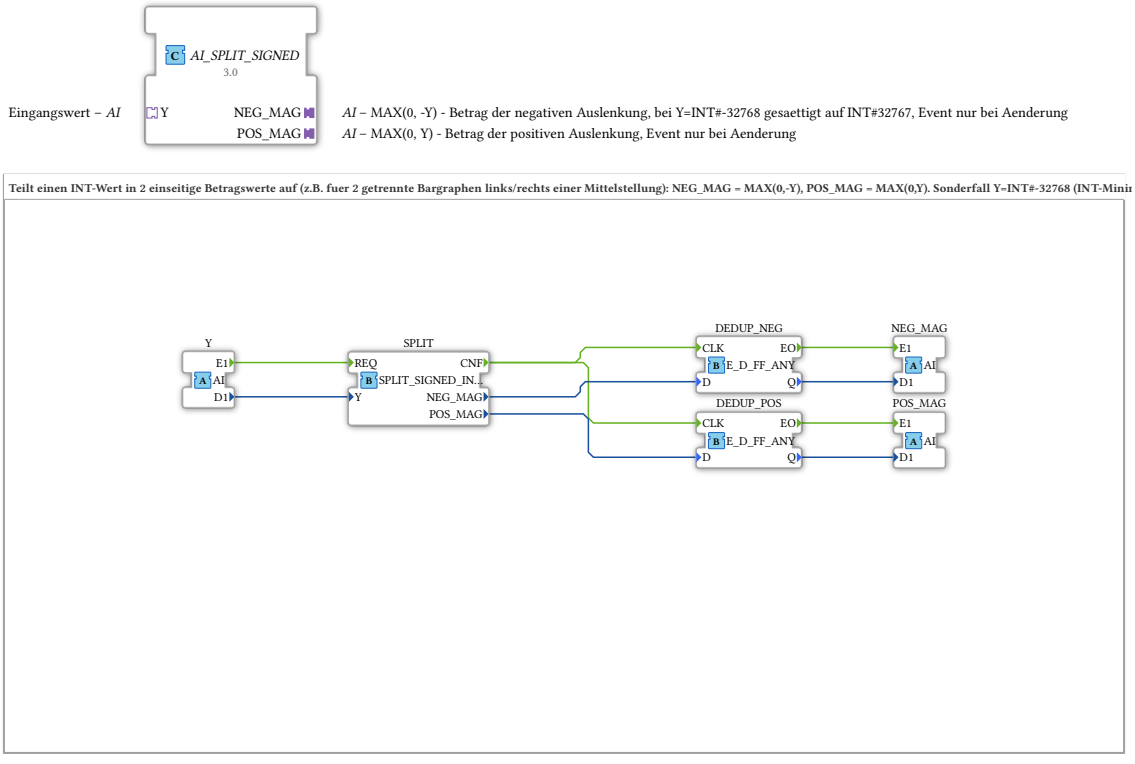
```
Y (ADI Adapter Socket)
 ├──> SPLIT (SPLIT_SIGNED_DINT)
       ├──> NEG_MAG ──> DEDUP_NEG (E_D_FF_ANY D-Flip-Flop) ──> NEG_MAG (ADI Adapter
Plug)
       └──> POS_MAG ──> DEDUP_POS (E_D_FF_ANY D-Flip-Flop) ──> POS_MAG (ADI Adapter
Plug)
```

Technical Features

- **Adapter-Driven Architecture:** Fully compatible with unidirectional adapter family `adapter::types::unidirectional::ADI`.
- **D-Flip-Flop Event Filtering:** The `E_D_FF_ANY` blocks guarantee by definition that the initial output event is emitted on the first `CLK`, and subsequent output events `EO` are generated only when the new input `D` differs from the stored output `Q`.
- **Overflow Safety:** Inherits saturation logic from `SPLIT_SIGNED_DINT` for two's complement integer limits.

Application Scenarios

- Connecting bipolar sensors (e.g. steering angle sensor, tilt sensor, joystick) to dual VT bargraph displays.
- Adapter-driven actuation of hydraulic cylinders (extend/retract).



Comparison with Similar Blocks

- **ADI_SPLIT_SIGNED**: Composite FB with adapter interfaces and D-Flip-Flop event filtering.
- **SPLIT_SIGNED_DINT**: Underlying Basic FB for pure signal computation without adapters.

Conclusion

ADI_SPLIT_SIGNED delivers an elegant, adapter-driven, and event-efficient solution for signed signal splitting in IEC 61499 applications.

AI_SPLIT_SIGNED

Introduction

The **AI_SPLIT_SIGNED** function block is an adapter wrapper (Composite FB) that splits a signed `INT` measurement value into two single-sided magnitude components using unidirectional adapters (`adapter::types::unidirectional::AI`):

- `NEG_MAG`: Magnitude of negative deflection (`MAX(0, -Y)`)
- `POS_MAG`: Magnitude of positive deflection (`MAX(0, Y)`)

The block encapsulates calculation FB **SPLIT_SIGNED_INT** and two **E_D_FF_ANY** D-Flip-Flop blocks to emit the initial event on the first `CLK` and thereafter emit events on plugs `NEG_MAG` and `POS_MAG` **only when the new input value differs from the stored output state** (`D <> Q`).

Interface Structure

Adapter Sockets (Input)

Name	Type	Comment
`Y`	`adapter::types::unidirectional::AI`	Signed input value (AI adapter socket)

Adapter Plugs (Output)

Name	Type	Comment
`NEG_MAG`	`adapter::types::unidirectional::AI`	Negative magnitude (`MAX(0, -Y)`), initial event on 1st call, thereafter on change only
`POS_MAG`	`adapter::types::unidirectional::AI`	Positive magnitude (`MAX(0, Y)`), initial event on 1st call, thereafter on change only

Functionality

Internally, the composite network consists of three components:

1. **SPLIT (SPLIT_SIGNED_INT)**: Computes `NEG_MAG` and `POS_MAG` from `Y.D1` upon every `Y.E1` event.
2. **DEDUP_NEG (E_D_FF_ANY)**: An event-driven D-Flip-Flop that emits the initial output event upon the first `CLK` event, and thereafter forwards `CLK` to `EO` and updates `Q := D` only when the new data value `D` differs from the current output state `Q` (`D <> Q`).
3. **DEDUP_POS (E_D_FF_ANY)**: A second D-Flip-Flop of the same type that similarly emits the initial output event on the first call and subsequently emits event `POS_MAG.E1` only when the positive magnitude value changes.

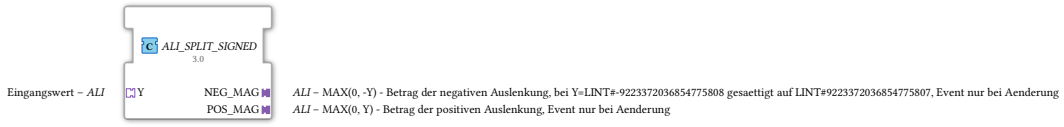
```
Y (AI Adapter Socket)
 ├──> SPLIT (SPLIT_SIGNED_INT)
       ├──> NEG_MAG ──> DEDUP_NEG (E_D_FF_ANY D-Flip-Flop) ──> NEG_MAG (AI Adapter Plug)
       └──> POS_MAG ──> DEDUP_POS (E_D_FF_ANY D-Flip-Flop) ──> POS_MAG (AI Adapter Plug)
```

Technical Features

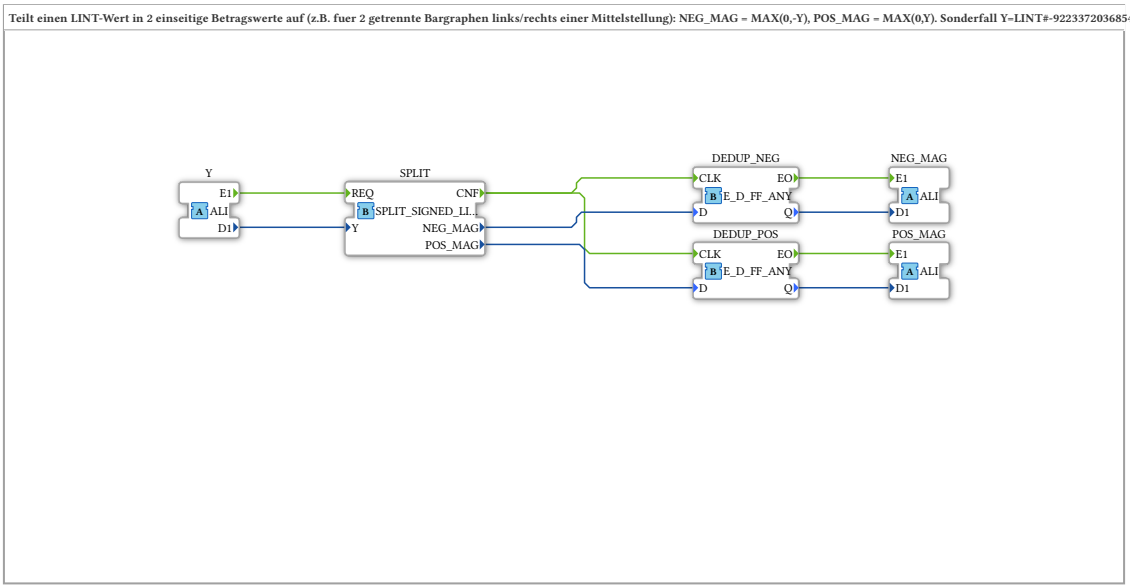
- **Adapter-Driven Architecture:** Fully compatible with unidirectional adapter family `adapter::types::unidirectional::AI`.
- **D-Flip-Flop Event Filtering:** The `E_D_FF_ANY` blocks guarantee by definition that the initial output event is emitted on the first `CLK`, and subsequent output events `EO` are generated only when the new input `D` differs from the stored output `Q`.
- **Overflow Safety:** Inherits saturation logic from `SPLIT_SIGNED_INT` for two's complement integer limits.

Application Scenarios

- Connecting bipolar sensors (e.g. steering angle sensor, tilt sensor, joystick) to dual VT bargraph displays.
- Adapter-driven actuation of hydraulic cylinders (extend/retract).



Comparison with Similar Blocks



- **AI_SPLIT_SIGNED**: Composite FB with adapter interfaces and D-Flip-Flop event filtering.
- **SPLIT_SIGNED_INT**: Underlying Basic FB for pure signal computation without adapters.

Conclusion

AI_SPLIT_SIGNED delivers an elegant, adapter-driven, and event-efficient solution for signed signal splitting in IEC 61499 applications.

ALI_SPLIT_SIGNED

• – ○ • – ○ • – ○ •

Introduction

The **ALI_SPLIT_SIGNED** function block is an adapter wrapper (Composite FB) that splits a signed `LINT` measurement value into two single-sided magnitude components using unidirectional adapters (`adapter::types::unidirectional::ALI`):

- `NEG_MAG`: Magnitude of negative deflection (`MAX(0, -Y)`)
- `POS_MAG`: Magnitude of positive deflection (`MAX(0, Y)`)

The block encapsulates calculation FB **SPLIT_SIGNED_LINT** and two **E_D_FF_ANY** D-Flip-Flop blocks to emit the initial event on the first `CLK` and thereafter emit events on plugs `NEG_MAG` and `POS_MAG` **only when the new input value differs from the stored output state** (`D <> Q`).

Interface Structure

Adapter Sockets (Input)

Name	Type	Comment
`Y`	`adapter::types::unidirectional::ALI`	Signed input value (ALI adapter socket)

Adapter Plugs (Output)

Name	Type	Comment
`NEG_MAG`	`adapter::types::unidirectional::ALI`	Negative magnitude (`MAX(0, -Y)`), initial event on 1st call, thereafter on change only
`POS_MAG`	`adapter::types::unidirectional::ALI`	Positive magnitude (`MAX(0, Y)`), initial event on 1st call, thereafter on change only

Functionality

Internally, the composite network consists of three components:

1. **SPLIT (SPLIT_SIGNED_LINT)**: Computes `NEG_MAG` and `POS_MAG` from `Y.D1` upon every `Y.E1` event.
2. **DEDUP_NEG (E_D_FF_ANY)**: An event-driven D-Flip-Flop that emits the initial output event upon the first `CLK` event, and thereafter forwards `CLK` to `EO` and updates `Q := D` only when the new data value `D` differs from the current output state `Q` (`D <> Q`).
3. **DEDUP_POS (E_D_FF_ANY)**: A second D-Flip-Flop of the same type that similarly emits the initial output event on the first call and subsequently emits event `POS_MAG.E1` only when the positive magnitude value changes.

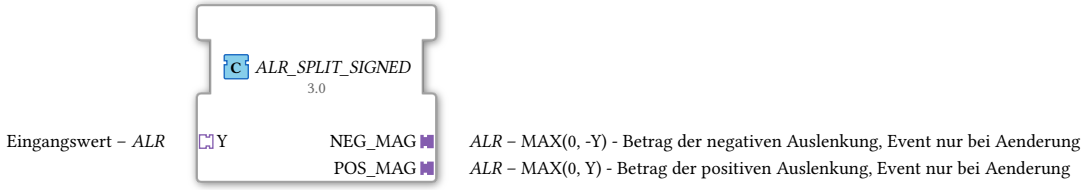
```
Y (ALI Adapter Socket)
 ├──> SPLIT (SPLIT_SIGNED_LINT)
       ├──> NEG_MAG ──> DEDUP_NEG (E_D_FF_ANY D-Flip-Flop) ──> NEG_MAG (ALI Adapter
Plug)
       └──> POS_MAG ──> DEDUP_POS (E_D_FF_ANY D-Flip-Flop) ──> POS_MAG (ALI Adapter
Plug)
```

Technical Features

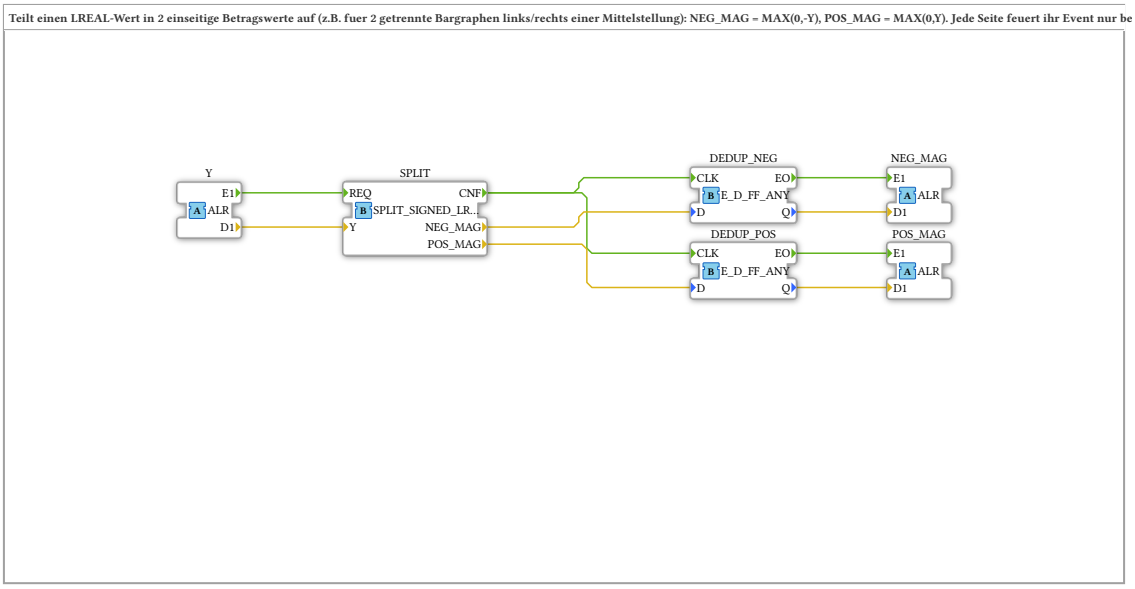
- **Adapter-Driven Architecture:** Fully compatible with unidirectional adapter family `adapter::types::unidirectional::ALI`.
- **D-Flip-Flop Event Filtering:** The `E_D_FF_ANY` blocks guarantee by definition that the initial output event is emitted on the first `CLK`, and subsequent output events `EO` are generated only when the new input `D` differs from the stored output `Q`.
- **Overflow Safety:** Inherits saturation logic from `SPLIT_SIGNED_LINT` for two's complement integer limits.

Application Scenarios

- Connecting bipolar sensors (e.g. steering angle sensor, tilt sensor, joystick) to dual VT bargraph displays.
- Adapter-driven actuation of hydraulic cylinders (extend/retract).



Comparison with Similar Blocks



- **ALI_SPLIT_SIGNED**: Composite FB with adapter interfaces and D-Flip-Flop event filtering.
- **SPLIT_SIGNED_LINT**: Underlying Basic FB for pure signal computation without adapters.

Conclusion

ALI_SPLIT_SIGNED delivers an elegant, adapter-driven, and event-efficient solution for signed signal splitting in IEC 61499 applications.

ALR_SPLIT_SIGNED

• — ○ • — ○ • — ○ •

Introduction

The **ALR_SPLIT_SIGNED** function block is an adapter wrapper (Composite FB) that splits a signed `LREAL` measurement value into two single-sided magnitude components using unidirectional adapters (`adapter::types::unidirectional::ALR`):

- `NEG_MAG`: Magnitude of negative deflection (`MAX(0, -Y)`)
- `POS_MAG`: Magnitude of positive deflection (`MAX(0, Y)`)

The block encapsulates calculation FB **SPLIT_SIGNED_LREAL** and two **E_D_FF_ANY** D-Flip-Flop blocks to emit the initial event on the first `CLK` and thereafter emit events on plugs `NEG_MAG` and `POS_MAG` **only when the new input value differs from the stored output state** (`D <> Q`).

Interface Structure

Adapter Sockets (Input)

Name	Type	Comment
`Y`	`adapter::types::unidirectional::ALR`	Signed input value (ALR adapter socket)

Adapter Plugs (Output)

Name	Type	Comment
`NEG_MAG`	`adapter::types::unidirectional::ALR`	Negative magnitude (`MAX(0, -Y)`), initial event on 1st call, thereafter on change only
`POS_MAG`	`adapter::types::unidirectional::ALR`	Positive magnitude (`MAX(0, Y)`), initial event on 1st call, thereafter on change only

Functionality

Internally, the composite network consists of three components:

1. **SPLIT (SPLIT_SIGNED_LREAL)**: Computes `NEG_MAG` and `POS_MAG` from `Y.D1` upon every `Y.E1` event.
2. **DEDUP_NEG (E_D_FF_ANY)**: An event-driven D-Flip-Flop that emits the initial output event upon the first `CLK` event, and thereafter forwards `CLK` to `EO` and updates `Q := D` only when the new data value `D` differs from the current output state `Q` (`D <> Q`).
3. **DEDUP_POS (E_D_FF_ANY)**: A second D-Flip-Flop of the same type that similarly emits the initial output event on the first call and subsequently emits event `POS_MAG.E1` only when the positive magnitude value changes.

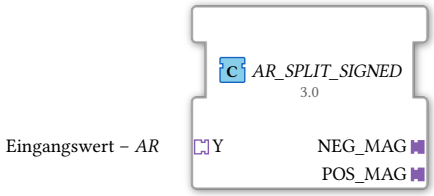
```
Y (ALR Adapter Socket)
 ├──> SPLIT (SPLIT_SIGNED_LREAL)
       ├──> NEG_MAG ──> DEDUP_NEG (E_D_FF_ANY D-Flip-Flop) ──> NEG_MAG (ALR Adapter
Plug)
       └──> POS_MAG ──> DEDUP_POS (E_D_FF_ANY D-Flip-Flop) ──> POS_MAG (ALR Adapter
Plug)
```

Technical Features

- **Adapter-Driven Architecture:** Fully compatible with unidirectional adapter family `adapter::types::unidirectional::ALR`.
- **D-Flip-Flop Event Filtering:** The `E_D_FF_ANY` blocks guarantee by definition that the initial output event is emitted on the first `CLK`, and subsequent output events `EO` are generated only when the new input `D` differs from the stored output `Q`.
- **Overflow Safety:** Inherits saturation logic from `SPLIT_SIGNED_LREAL` for two's complement integer limits.

Application Scenarios

- Connecting bipolar sensors (e.g. steering angle sensor, tilt sensor, joystick) to dual VT bargraph displays.
- Adapter-driven actuation of hydraulic cylinders (extend/retract).

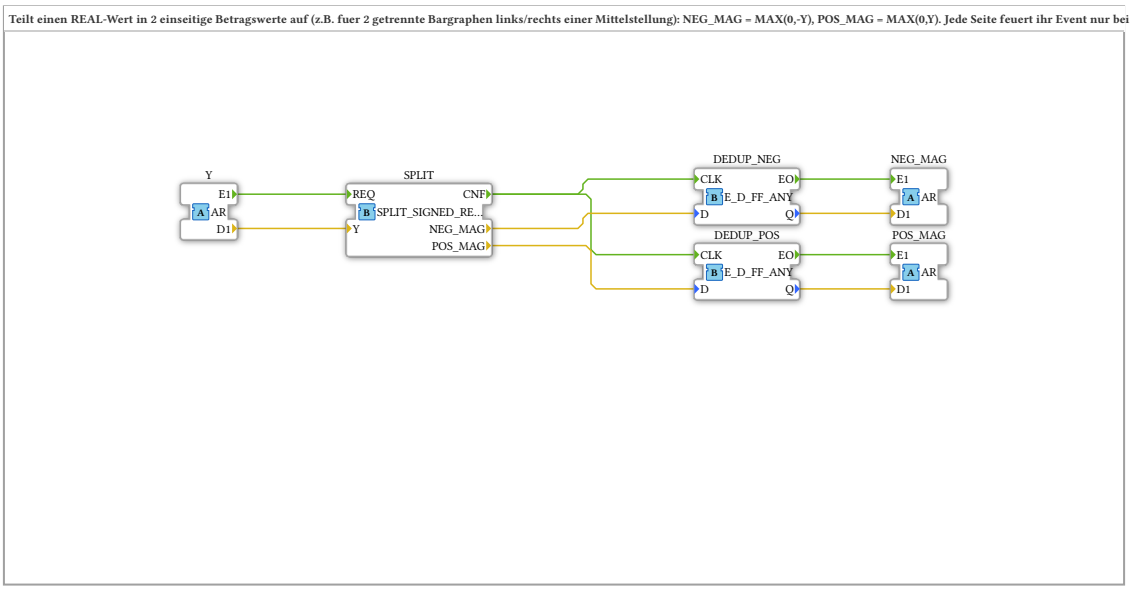


Comparison with Similar Blocks

- **ALR_SPLIT_SIGNED**: Composite FB with adapter interfaces and D-Flip-Flop event filtering.
- **SPLIT_SIGNED_LREAL**: Underlying Basic FB for pure signal computation without adapters.

Conclusion

ALR_SPLIT_SIGNED delivers an elegant, adapter-driven, and event-efficient solution for signed signal splitting in IEC 61499 applications.



AR_SPLIT_SIGNED

Eingangswert – *AR*

AR – MAX(0, -Y) - Betrag der negativen Auslenkung, Event nur bei Aenderung

AR – MAX(0, Y) - Betrag der positiven Auslenkung, Event nur bei Aenderung

• – ○ • – ○ • – ○ •

Introduction

The **AR_SPLIT_SIGNED** function block is an adapter wrapper (Composite FB) that splits a signed `REAL` measurement value into two single-sided magnitude components using unidirectional adapters (`adapter::types::unidirectional::AR`):

- `NEG_MAG`: Magnitude of negative deflection (`MAX(0, -Y)`)
- `POS_MAG`: Magnitude of positive deflection (`MAX(0, Y)`)

The block encapsulates calculation FB **SPLIT_SIGNED_REAL** and two **E_D_FF_ANY** D-Flip-Flop blocks to emit the initial event on the first `CLK` and thereafter emit events on plugs `NEG_MAG` and `POS_MAG` **only when the new input value differs from the stored output state** (`D <> Q`).

Interface Structure

Adapter Sockets (Input)

Name	Type	Comment
`Y`	`adapter::types::unidirectional::AR`	Signed input value (AR adapter socket)

Adapter Plugs (Output)

Name	Type	Comment
`NEG_MAG`	`adapter::types::unidirectional::AR`	Negative magnitude (`MAX(0, -Y)`), initial event on 1st call, thereafter on change only
`POS_MAG`	`adapter::types::unidirectional::AR`	Positive magnitude (`MAX(0, Y)`), initial event on 1st call, thereafter on change only

Functionality

Internally, the composite network consists of three components:

1. **SPLIT (SPLIT_SIGNED_REAL)**: Computes `NEG_MAG` and `POS_MAG` from `Y.D1` upon every `Y.E1` event.
2. **DEDUP_NEG (E_D_FF_ANY)**: An event-driven D-Flip-Flop that emits the initial output event upon the first `CLK` event, and thereafter forwards `CLK` to `EO` and updates `Q := D` only when the new data value `D` differs from the current output state `Q` (`D <> Q`).
3. **DEDUP_POS (E_D_FF_ANY)**: A second D-Flip-Flop of the same type that similarly emits the initial output event on the first call and subsequently emits event `POS_MAG.E1` only when the positive magnitude value changes.

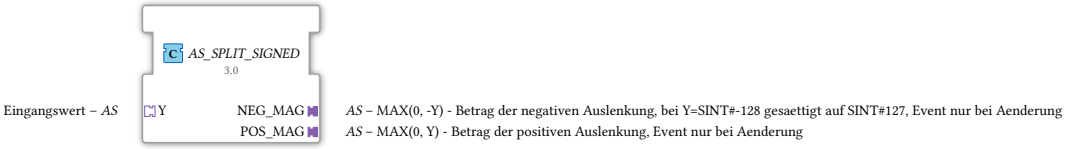
```
Y (AR Adapter Socket)
 ├──> SPLIT (SPLIT_SIGNED_REAL)
       ├──> NEG_MAG ──> DEDUP_NEG (E_D_FF_ANY D-Flip-Flop) ──> NEG_MAG (AR Adapter Plug)
       └──> POS_MAG ──> DEDUP_POS (E_D_FF_ANY D-Flip-Flop) ──> POS_MAG (AR Adapter Plug)
```

Technical Features

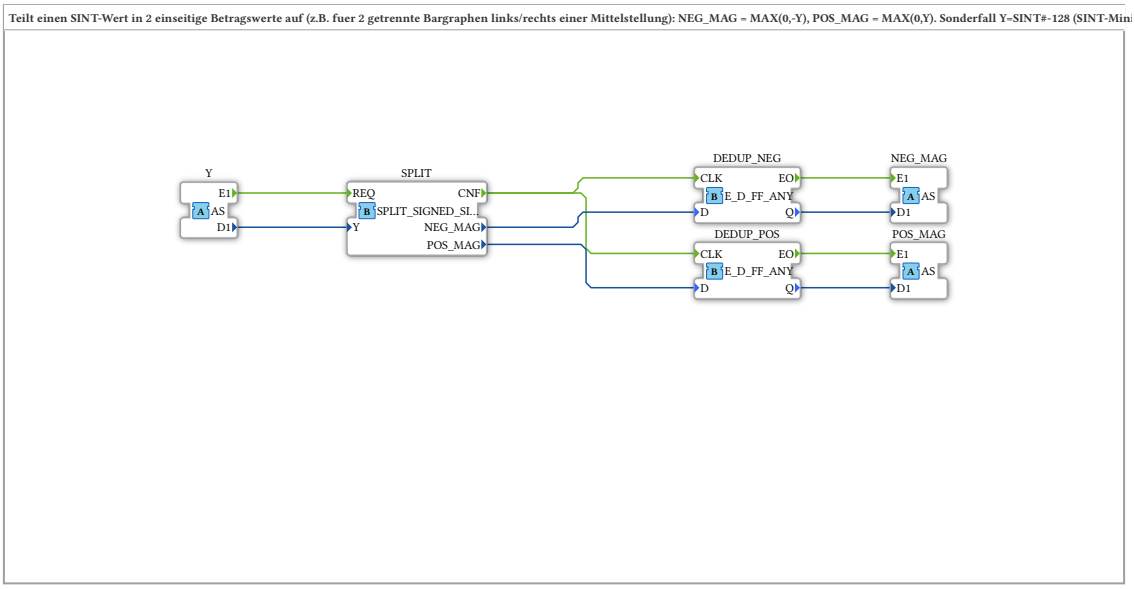
- **Adapter-Driven Architecture:** Fully compatible with unidirectional adapter family `adapter::types::unidirectional::AR`.
- **D-Flip-Flop Event Filtering:** The `E_D_FF_ANY` blocks guarantee by definition that the initial output event is emitted on the first `CLK`, and subsequent output events `EO` are generated only when the new input `D` differs from the stored output `Q`.
- **Overflow Safety:** Inherits saturation logic from `SPLIT_SIGNED_REAL` for two's complement integer limits.

Application Scenarios

- Connecting bipolar sensors (e.g. steering angle sensor, tilt sensor, joystick) to dual VT bargraph displays.
- Adapter-driven actuation of hydraulic cylinders (extend/retract).



Comparison with Similar Blocks



- **AR_SPLIT_SIGNED**: Composite FB with adapter interfaces and D-Flip-Flop event filtering.
- **SPLIT_SIGNED_REAL**: Underlying Basic FB for pure signal computation without adapters.

Conclusion

AR_SPLIT_SIGNED delivers an elegant, adapter-driven, and event-efficient solution for signed signal splitting in IEC 61499 applications.

AS_SPLIT_SIGNED

• – ○ • – ○ • – ○ •

Introduction

The **AS_SPLIT_SIGNED** function block is an adapter wrapper (Composite FB) that splits a signed `SINT` measurement value into two single-sided magnitude components using unidirectional adapters (`adapter::types::unidirectional::AS`):

- `NEG_MAG`: Magnitude of negative deflection (`MAX(0, -Y)`)
- `POS_MAG`: Magnitude of positive deflection (`MAX(0, Y)`)

The block encapsulates calculation FB **SPLIT_SIGNED_SINT** and two **E_D_FF_ANY** D-Flip-Flop blocks to emit the initial event on the first `CLK` and thereafter emit events on plugs `NEG_MAG` and `POS_MAG` **only when the new input value differs from the stored output state** (`D <> Q`).

Interface Structure

Adapter Sockets (Input)

Name	Type	Comment
`Y`	`adapter::types::unidirectional::AS`	Signed input value (AS adapter socket)

Adapter Plugs (Output)

Name	Type	Comment
`NEG_MAG`	`adapter::types::unidirectional::AS`	Negative magnitude (`MAX(0, -Y)`), initial event on 1st call, thereafter on change only
`POS_MAG`	`adapter::types::unidirectional::AS`	Positive magnitude (`MAX(0, Y)`), initial event on 1st call, thereafter on change only

Functionality

Internally, the composite network consists of three components:

1. **SPLIT (SPLIT_SIGNED_SINT)**: Computes `NEG_MAG` and `POS_MAG` from `Y.D1` upon every `Y.E1` event.
2. **DEDUP_NEG (E_D_FF_ANY)**: An event-driven D-Flip-Flop that emits the initial output event upon the first `CLK` event, and thereafter forwards `CLK` to `EO` and updates `Q := D` only when the new data value `D` differs from the current output state `Q` (`D <> Q`).
3. **DEDUP_POS (E_D_FF_ANY)**: A second D-Flip-Flop of the same type that similarly emits the initial output event on the first call and subsequently emits event `POS_MAG.E1` only when the positive magnitude value changes.

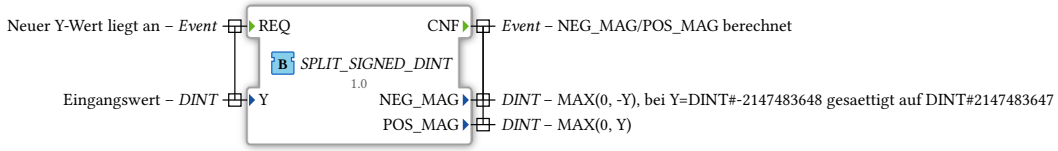
```
Y (AS Adapter Socket)
 ├──> SPLIT (SPLIT_SIGNED_SINT)
       ├──> NEG_MAG ──> DEDUP_NEG (E_D_FF_ANY D-Flip-Flop) ──> NEG_MAG (AS Adapter Plug)
       └──> POS_MAG ──> DEDUP_POS (E_D_FF_ANY D-Flip-Flop) ──> POS_MAG (AS Adapter Plug)
```

Technical Features

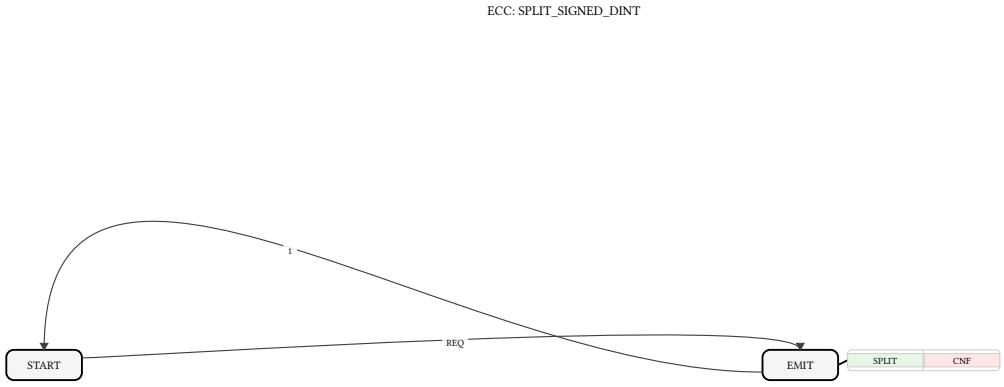
- **Adapter-Driven Architecture:** Fully compatible with unidirectional adapter family `adapter::types::unidirectional::AS`.
- **D-Flip-Flop Event Filtering:** The `E_D_FF_ANY` blocks guarantee by definition that the initial output event is emitted on the first `CLK`, and subsequent output events `EO` are generated only when the new input `D` differs from the stored output `Q`.
- **Overflow Safety:** Inherits saturation logic from `SPLIT_SIGNED_SINT` for two's complement integer limits.

Application Scenarios

- Connecting bipolar sensors (e.g. steering angle sensor, tilt sensor, joystick) to dual VT bargraph displays.
- Adapter-driven actuation of hydraulic cylinders (extend/retract).



Comparison with Similar Blocks



- **AS_SPLIT_SIGNED**: Composite FB with adapter interfaces and D-Flip-Flop event filtering.
- **SPLIT_SIGNED_SINT**: Underlying Basic FB for pure signal computation without adapters.

Conclusion

AS_SPLIT_SIGNED delivers an elegant, adapter-driven, and event-efficient solution for signed signal splitting in IEC 61499 applications.

SPLIT_SIGNED_DINT

• – ○ • – ○ • – ○ •

Introduction

The **SPLIT_SIGNED_DINT** function block splits a signed `DINT` input value `Y` into two single-sided magnitude components:

- `NEG_MAG = MAX(0, -Y)` (magnitude of negative deflection)
- `POS_MAG = MAX(0, Y)` (magnitude of positive deflection)

It serves as the core calculation block for directional indicators (e.g. separate bargraphs for left/right deflection from center position) or dual directional actuators (e.g. raise/lower or forward/reverse).

Interface Structure

Event Inputs

Name	Type	Comment
`REQ`	`Event`	Request calculation (with `Y`)

Event Outputs

Name	Type	Comment
`CNF`	`Event`	Calculation confirmation (with `NEG_MAG`, `POS_MAG`)

Data Inputs

Name	Type	Comment
`Y`	`DINT`	Signed input value

Data Outputs

Name	Type	Comment
`NEG_MAG`	`DINT`	`MAX(0, -Y)` – Magnitude of negative deflection

POS_MAG	DINT	MAX(0, Y) – Magnitude of positive deflection

Functionality

Upon receiving event REQ, the block executes the following splitting logic:

```
IF Y = DINT#-2147483648 THEN
    NEG_MAG := DINT#2147483647;
ELSE
    NEG_MAG := MAX(DINT#0, -Y);
END_IF;
POS_MAG := MAX(DINT#0, Y);
```

The block emits confirmation event CNF on every REQ. Event filtering for unchanged values is handled at the adapter wrapper level (**ADI_SPLIT_SIGNED**) using **E_D_FF_ANY** D-Flip-Flop instances.

Overflow Handling & Saturation

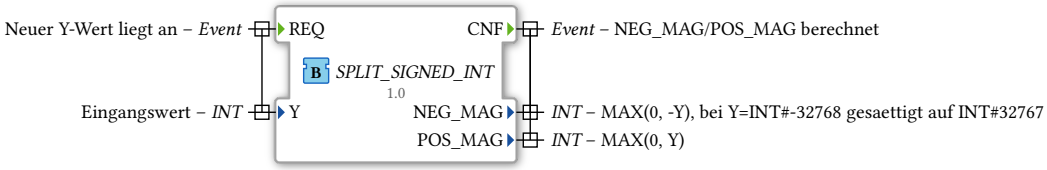
For two's complement integer types, the magnitude of the negative minimum (-2147483648) is 1 greater than the representable positive maximum (2147483647). Mathematical negation of DINT#-2147483648 without special handling would result in integer overflow and incorrect sign reversal.

SPLIT_SIGNED_DINT explicitly handles this edge case:

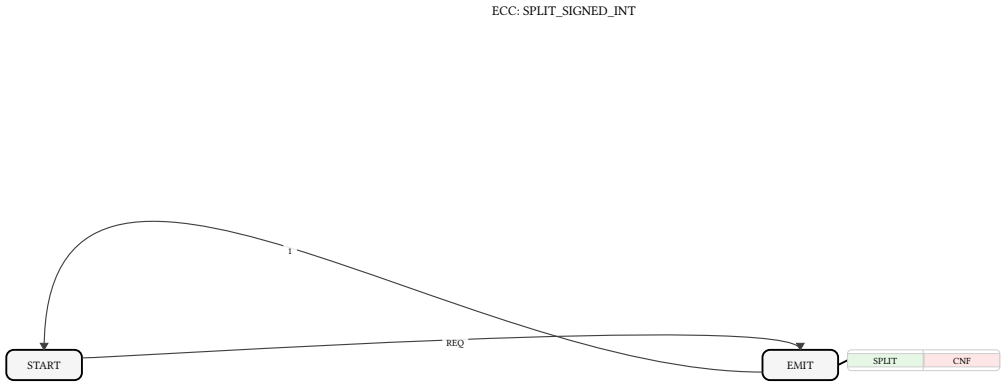
- When Y = DINT#-2147483648, NEG_MAG saturates to the maximum representable positive value DINT#2147483647.
- Control engineering advantage: Saturation at range limit instead of overflow or sign flip.

Application Scenarios

- Splitting bipolar signals for separate visual components (e.g. left/right bargraphs).
- Driving two unidirectional actuators (e.g. raise vs. lower valves) from a single bipolar setpoint.
- Pre-processing in control loops with direction-dependent deadbands or curves.



Comparison with Similar Blocks



- **SPLIT_SIGNED_DINT**: Pure value/event calculation block for DINT (Basic FB).
- **ADI_SPLIT_SIGNED**: Composite FB wrapper featuring adapter interfaces (adapter::types::unidirectional::ADI) and automatic per-side D-Flip-Flop event filtering (E_D_FF_ANY).

Conclusion

SPLIT_SIGNED_DINT provides robust, overflow-safe splitting of DINT values into positive magnitude components.

SPLIT_SIGNED_INT

• – ○ • – ○ • – ○ •

Introduction

The **SPLIT_SIGNED_INT** function block splits a signed `INT` input value `Y` into two single-sided magnitude components:

- `NEG_MAG = MAX(0, -Y)` (magnitude of negative deflection)
- `POS_MAG = MAX(0, Y)` (magnitude of positive deflection)

It serves as the core calculation block for directional indicators (e.g. separate bargraphs for left/right deflection from center position) or dual directional actuators (e.g. raise/lower or forward/reverse).

Interface Structure

Event Inputs

Name	Type	Comment
`REQ`	`Event`	Request calculation (with `Y`)

Event Outputs

Name	Type	Comment
`CNF`	`Event`	Calculation confirmation (with `NEG_MAG`, `POS_MAG`)

Data Inputs

Name	Type	Comment
`Y`	`INT`	Signed input value

Data Outputs

Name	Type	Comment
`NEG_MAG`	`INT`	`MAX(0, -Y)` – Magnitude of negative deflection

POS_MAG	INT	MAX(0, Y) – Magnitude of positive deflection

Functionality

Upon receiving event REQ, the block executes the following splitting logic:

```
IF Y = INT#-32768 THEN
    NEG_MAG := INT#32767;
ELSE
    NEG_MAG := MAX(INT#0, -Y);
END_IF;
POS_MAG := MAX(INT#0, Y);
```

The block emits confirmation event CNF on every REQ. Event filtering for unchanged values is handled at the adapter wrapper level (**AI_SPLIT_SIGNED**) using **E_D_FF_ANY** D-Flip-Flop instances.

Overflow Handling & Saturation

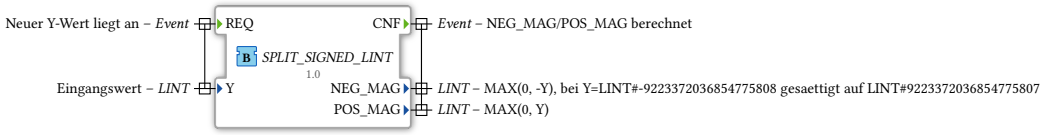
For two's complement integer types, the magnitude of the negative minimum (-32768) is 1 greater than the representable positive maximum (32767). Mathematical negation of INT#-32768 without special handling would result in integer overflow and incorrect sign reversal.

SPLIT_SIGNED_INT explicitly handles this edge case:

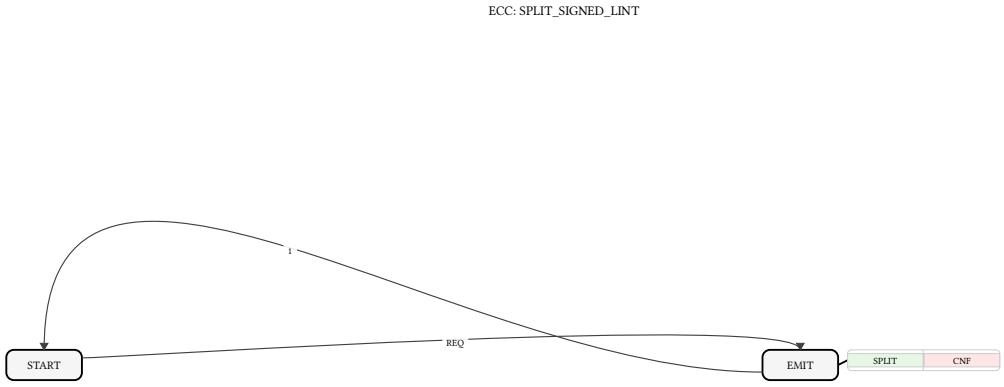
- When Y = INT#-32768, NEG_MAG saturates to the maximum representable positive value INT#32767.
- Control engineering advantage: Saturation at range limit instead of overflow or sign flip.

Application Scenarios

- Splitting bipolar signals for separate visual components (e.g. left/right bargraphs).
- Driving two unidirectional actuators (e.g. raise vs. lower valves) from a single bipolar setpoint.
- Pre-processing in control loops with direction-dependent deadbands or curves.



Comparison with Similar Blocks



- **SPLIT_SIGNED_INT**: Pure value/event calculation block for INT (Basic FB).
- **AI_SPLIT_SIGNED**: Composite FB wrapper featuring adapter interfaces (adapter::types::unidirectional::AI) and automatic per-side D-Flip-Flop event filtering (E_D_FF_ANY).

Conclusion

SPLIT_SIGNED_INT provides robust, overflow-safe splitting of INT values into positive magnitude components.

SPLIT_SIGNED_LINT

• – ○ • – ○ • – ○ •

Introduction

The **SPLIT_SIGNED_LINT** function block splits a signed `LINT` input value `Y` into two single-sided magnitude components:

- `NEG_MAG = MAX(0, -Y)` (magnitude of negative deflection)
- `POS_MAG = MAX(0, Y)` (magnitude of positive deflection)

It serves as the core calculation block for directional indicators (e.g. separate bargraphs for left/right deflection from center position) or dual directional actuators (e.g. raise/lower or forward/reverse).

Interface Structure

Event Inputs

Name	Type	Comment
`REQ`	`Event`	Request calculation (with `Y`)

Event Outputs

Name	Type	Comment
`CNF`	`Event`	Calculation confirmation (with `NEG_MAG`, `POS_MAG`)

Data Inputs

Name	Type	Comment
`Y`	`LINT`	Signed input value

Data Outputs

Name	Type	Comment
`NEG_MAG`	`LINT`	`MAX(0, -Y)` – Magnitude of negative deflection

POS_MAG	LINT	MAX(0, Y) – Magnitude of positive deflection

Functionality

Upon receiving event REQ, the block executes the following splitting logic:

```
IF Y = LINT#-9223372036854775808 THEN
    NEG_MAG := LINT#9223372036854775807;
ELSE
    NEG_MAG := MAX(LINT#0, -Y);
END_IF;
POS_MAG := MAX(LINT#0, Y);
```

The block emits confirmation event CNF on every REQ. Event filtering for unchanged values is handled at the adapter wrapper level (**ALI_SPLIT_SIGNED**) using **E_D_FF_ANY** D-Flip-Flop instances.

Overflow Handling & Saturation

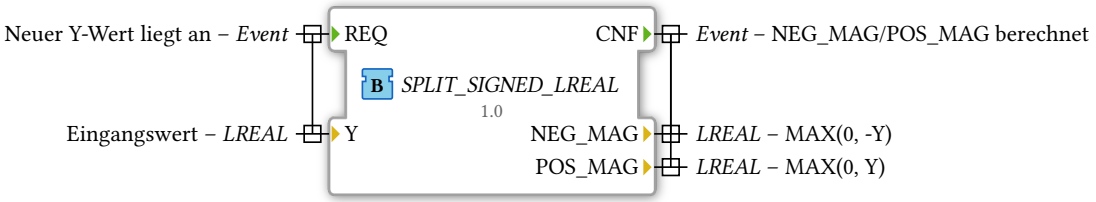
For two's complement integer types, the magnitude of the negative minimum (-9223372036854775808) is 1 greater than the representable positive maximum (9223372036854775807). Mathematical negation of LINT#-9223372036854775808 without special handling would result in integer overflow and incorrect sign reversal.

SPLIT_SIGNED_LINT explicitly handles this edge case:

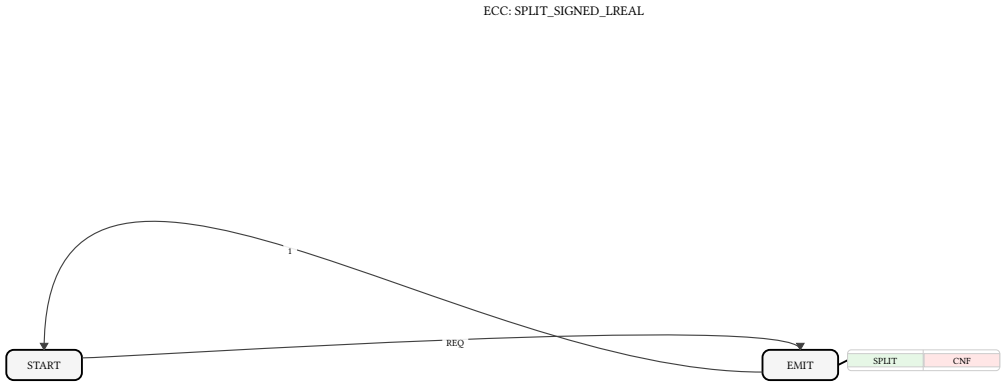
- When Y = LINT#-9223372036854775808, NEG_MAG saturates to the maximum representable positive value LINT#9223372036854775807.
- Control engineering advantage: Saturation at range limit instead of overflow or sign flip.

Application Scenarios

- Splitting bipolar signals for separate visual components (e.g. left/right bargraphs).
- Driving two unidirectional actuators (e.g. raise vs. lower valves) from a single bipolar setpoint.
- Pre-processing in control loops with direction-dependent deadbands or curves.



Comparison with Similar Blocks



- **SPLIT_SIGNED_LINT**: Pure value/event calculation block for LINT (Basic FB).
- **ALI_SPLIT_SIGNED**: Composite FB wrapper featuring adapter interfaces (adapter::types::unidirectional::ALI) and automatic per-side D-Flip-Flop event filtering (E_D_FF_ANY).

Conclusion

SPLIT_SIGNED_LINT provides robust, overflow-safe splitting of LINT values into positive magnitude components.

SPLIT_SIGNED_LREAL

• – ○ • – ○ • – ○ •

Introduction

The **SPLIT_SIGNED_LREAL** function block splits a signed `LREAL` input value `Y` into two single-sided magnitude components:

- `NEG_MAG = MAX(0, -Y)` (magnitude of negative deflection)
- `POS_MAG = MAX(0, Y)` (magnitude of positive deflection)

It serves as the core calculation block for directional indicators (e.g. separate bargraphs for left/right deflection from center position) or dual directional actuators (e.g. raise/lower or forward/reverse).

Interface Structure

Event Inputs

Name	Type	Comment
`REQ`	`Event`	Request calculation (with `Y`)

Event Outputs

Name	Type	Comment
`CNF`	`Event`	Calculation confirmation (with `NEG_MAG`, `POS_MAG`)

Data Inputs

Name	Type	Comment
`Y`	`LREAL`	Signed input value

Data Outputs

Name	Type	Comment
`NEG_MAG`	`LREAL`	`MAX(0, -Y)` – Magnitude of negative deflection

POS_MAG	LREAL	MAX(0, Y) – Magnitude of positive deflection

Functionality

Upon receiving event REQ, the block executes the following splitting logic:

```
NEG_MAG := MAX(LREAL#0.0, -Y);
POS_MAG := MAX(LREAL#0.0, Y);
```

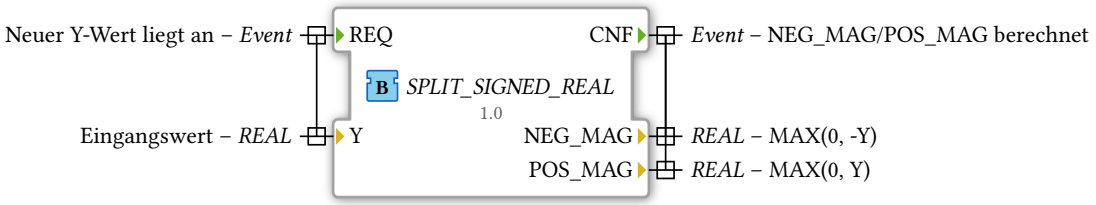
The block emits confirmation event CNF on every REQ. Event filtering for unchanged values is handled at the adapter wrapper level (**ALR_SPLIT_SIGNED**) using **E_D_FF_ANY** D-Flip-Flop instances.

Floating-Point Behavior

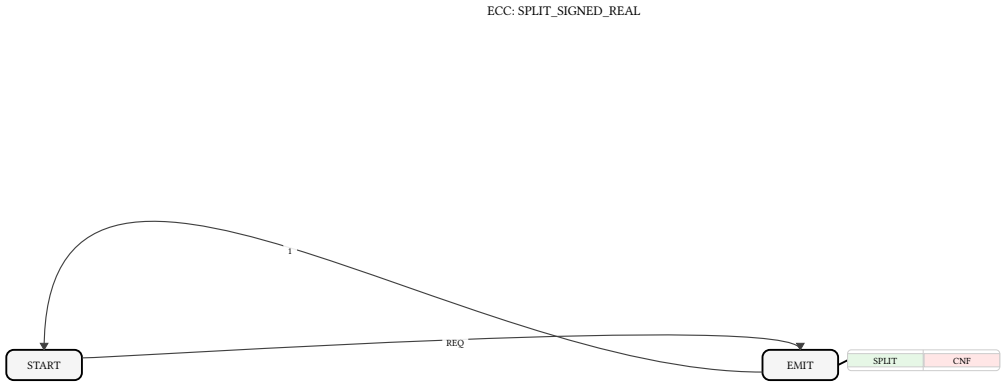
Since LREAL is a floating-point type, the two's complement integer asymmetry issue does not apply. Negation -Y is representable across the full range without overflow.

Application Scenarios

- Splitting bipolar signals for separate visual components (e.g. left/right bargraphs).
- Driving two unidirectional actuators (e.g. raise vs. lower valves) from a single bipolar setpoint.
- Pre-processing in control loops with direction-dependent deadbands or curves.



Comparison with Similar Blocks



- **SPLIT_SIGNED_LREAL**: Pure value/event calculation block for LREAL (Basic FB).
- **ALR_SPLIT_SIGNED**: Composite FB wrapper featuring adapter interfaces (adapter::types::unidirectional::ALR) and automatic per-side D-Flip-Flop event filtering (E_D_FF_ANY).

Conclusion

SPLIT_SIGNED_LREAL provides robust, overflow-safe splitting of LREAL values into positive magnitude components.

SPLIT_SIGNED_REAL

• – ○ • – ○ • – ○ •

Introduction

The **SPLIT_SIGNED_REAL** function block splits a signed `REAL` input value `Y` into two single-sided magnitude components:

- `NEG_MAG = MAX(0, -Y)` (magnitude of negative deflection)
- `POS_MAG = MAX(0, Y)` (magnitude of positive deflection)

It serves as the core calculation block for directional indicators (e.g. separate bargraphs for left/right deflection from center position) or dual directional actuators (e.g. raise/lower or forward/reverse).

Interface Structure

Event Inputs

Name	Type	Comment
`REQ`	`Event`	Request calculation (with `Y`)

Event Outputs

Name	Type	Comment
`CNF`	`Event`	Calculation confirmation (with `NEG_MAG`, `POS_MAG`)

Data Inputs

Name	Type	Comment
`Y`	`REAL`	Signed input value

Data Outputs

Name	Type	Comment
`NEG_MAG`	`REAL`	`MAX(0, -Y)` – Magnitude of negative deflection

POS_MAG	REAL	MAX(0, Y) – Magnitude of positive deflection

Functionality

Upon receiving event REQ, the block executes the following splitting logic:

```
NEG_MAG := MAX(REAL#0.0, -Y);
POS_MAG := MAX(REAL#0.0, Y);
```

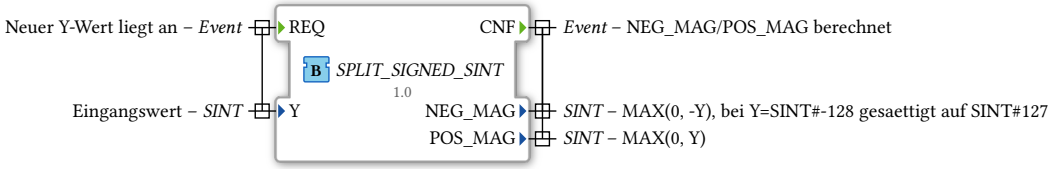
The block emits confirmation event CNF on every REQ. Event filtering for unchanged values is handled at the adapter wrapper level (**AR_SPLIT_SIGNED**) using **E_D_FF_ANY** D-Flip-Flop instances.

Floating-Point Behavior

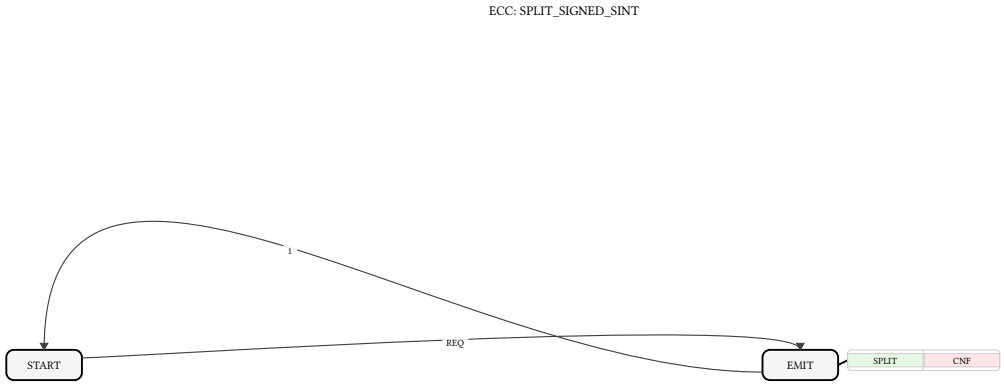
Since REAL is a floating-point type, the two's complement integer asymmetry issue does not apply. Negation -Y is representable across the full range without overflow.

Application Scenarios

- Splitting bipolar signals for separate visual components (e.g. left/right bargraphs).
- Driving two unidirectional actuators (e.g. raise vs. lower valves) from a single bipolar setpoint.
- Pre-processing in control loops with direction-dependent deadbands or curves.



Comparison with Similar Blocks



- **SPLIT_SIGNED_REAL**: Pure value/event calculation block for REAL (Basic FB).
- **AR_SPLIT_SIGNED**: Composite FB wrapper featuring adapter interfaces (adapter::types::unidirectional::AR) and automatic per-side D-Flip-Flop event filtering (E_D_FF_ANY).

Conclusion

SPLIT_SIGNED_REAL provides robust, overflow-safe splitting of REAL values into positive magnitude components.

SPLIT_SIGNED_SINT

• – ○ • – ○ • – ○ •

Introduction

The **SPLIT_SIGNED_SINT** function block splits a signed `SINT` input value `Y` into two single-sided magnitude components:

- `NEG_MAG = MAX(0, -Y)` (magnitude of negative deflection)
- `POS_MAG = MAX(0, Y)` (magnitude of positive deflection)

It serves as the core calculation block for directional indicators (e.g. separate bargraphs for left/right deflection from center position) or dual directional actuators (e.g. raise/lower or forward/reverse).

Interface Structure

Event Inputs

Name	Type	Comment
`REQ`	`Event`	Request calculation (with `Y`)

Event Outputs

Name	Type	Comment
`CNF`	`Event`	Calculation confirmation (with `NEG_MAG`, `POS_MAG`)

Data Inputs

Name	Type	Comment
`Y`	`SINT`	Signed input value

Data Outputs

Name	Type	Comment
`NEG_MAG`	`SINT`	`MAX(0, -Y)` – Magnitude of negative deflection

POS_MAG	SINT	MAX(0, Y) – Magnitude of positive deflection

Functionality

Upon receiving event REQ, the block executes the following splitting logic:

```
IF Y = SINT#-128 THEN
    NEG_MAG := SINT#127;
ELSE
    NEG_MAG := MAX(SINT#0, -Y);
END_IF;
POS_MAG := MAX(SINT#0, Y);
```

The block emits confirmation event CNF on every REQ. Event filtering for unchanged values is handled at the adapter wrapper level (**AS_SPLIT_SIGNED**) using **E_D_FF_ANY** D-Flip-Flop instances.

Overflow Handling & Saturation

For two's complement integer types, the magnitude of the negative minimum (-128) is 1 greater than the representable positive maximum (127). Mathematical negation of SINT#-128 without special handling would result in integer overflow and incorrect sign reversal.

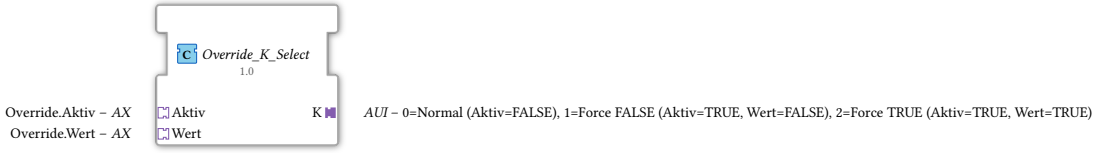
SPLIT_SIGNED_SINT explicitly handles this edge case:

- When Y = SINT#-128, NEG_MAG saturates to the maximum representable positive value SINT#127.
- Control engineering advantage: Saturation at range limit instead of overflow or sign flip.

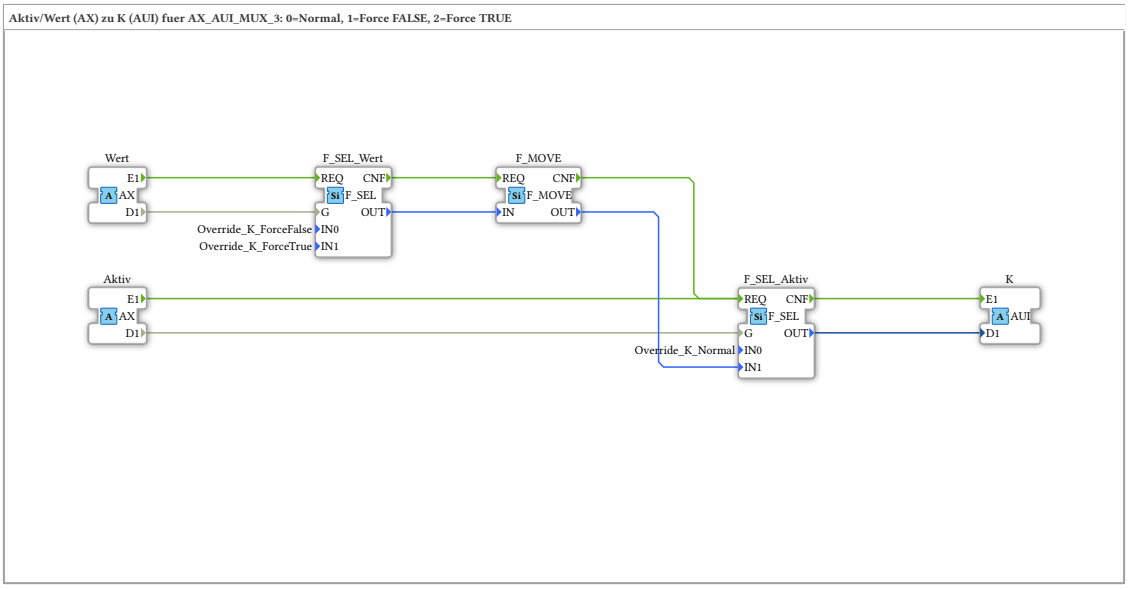
Application Scenarios

- Splitting bipolar signals for separate visual components (e.g. left/right bargraphs).
- Driving two unidirectional actuators (e.g. raise vs. lower valves) from a single bipolar setpoint.
- Pre-processing in control loops with direction-dependent deadbands or curves.

Comparison with Similar Blocks



- **SPLIT_SIGNED_SINT**: Pure value/event calculation block for SINT (Basic FB).
- **AS_SPLIT_SIGNED**: Composite FB wrapper featuring adapter interfaces (adapter::types::unidirectional::AS) and automatic per-side D-Flip-Flop event filtering (E_D_FF_ANY).



Conclusion

SPLIT_SIGNED_SINT provides robust, overflow-safe splitting of SINT values into positive magnitude components.

2.1.11.3 OverrideK

Override_K_Select

• — ○ • — ○ • — ○ •

Introduction

The `Override_K_Select` function block converts a pair of boolean override signals (`Aktiv`/`Wert`, each as an AX adapter) into a single `UINT` selector `K` (as an AUI adapter), as expected by an `AX_AUI_MUX_3`. It encapsulates the recurring project pattern "a sensor value can be forced to either `FALSE` or `TRUE` via an RW override" (see `Sensor.Leermelder.Override.*` in `docs/datenpunkte.md` of the Getreideannahme application) in a single, reusable block, instead of re-wiring the conversion at every call site.

Interface Structure

Event Inputs

None of its own. Events flow exclusively through the `Aktiv`/`Wert` adapter sockets.

Event Outputs

None of its own. The result is emitted through the `K` adapter plug.

Data Inputs

None of its own. All data is carried through the adapter sockets.

Data Outputs

None of its own. The result is emitted through the `K` adapter plug.

Adapters

Direction	Name	Type	Description
Socket (input)	`Aktiv`	`adapter::types::unidirectional::AX`	`Override.Aktiv`
Socket (input)	`Wert`	`adapter::types::unidirectional::AX`	`Override.Wert`
Plug (output)	`K`	`adapter::types::unidirectional::AUI`	0=Normal (`Aktiv`=FALSE), 1=Force FALSE (`Aktiv`=TRUE, `Wert`=FALSE), 2=Force TRUE (`Aktiv`=TRUE, `Wert`=TRUE)

Functionality

Internally the block uses two chained, generic `F_SEL` blocks (the standard IEC 61131-3 selector `OUT := G ? IN1 : IN0`) instead of custom ST logic:

1. **F_SEL_Wert**: `G := Wert.D1`. Returns `Override_K_ForceFalse` (1) when `Wert = FALSE`, otherwise `Override_K_ForceTrue` (2). Triggered by `Wert.E1`.
2. **F_MOVE** (attribute `DataType="UINT"`): captures `F_SEL_Wert.OUT`, triggered by `F_SEL_Wert.CNF`. Acts as a type anchor for `F_SEL`'s generic `ANY` result (see Technical Details) and then re-triggers `F_SEL_Aktiv`.
3. **F_SEL_Aktiv**: `G := Aktiv.D1`. Returns `Override_K_Normal` (0) when `Aktiv = FALSE`, otherwise the value most recently held by `F_MOVE` (1 or 2). Triggered both directly by `Aktiv.E1` and indirectly via `F_MOVE.CNF`, so a change in `Wert` alone still produces a fresh `K` even when `Aktiv` itself hasn't changed.
4. `F_SEL_Aktiv.OUT`/`F_SEL_Aktiv.CNF` are wired directly onto the data output variable `K.D1` and the event `K.E1` of the block's own plug — no separate `_TO_AUI` conversion FB in between (see Technical Details).

Technical Details

- **Writing directly onto its own plug pins.** Instead of routing through a `UINT_TO_AUI`-style conversion FB, the block connects `F_SEL_Aktiv.OUT`/`.CNF` directly to `K.D1`/`K.E1` — the event/data variables the `AUI` adapter type itself declares on the plug side. The same technique is used by const_AX_TRUE and const_AX_FALSE for their own `OUT` plug.
- **`F_MOVE` as a type anchor for `F_SEL`'s generic `ANY` result.** `F_SEL.OUT` is generic (`ANY`); without a downstream `F_MOVE` carrying a fixed `DataType` attribute, the value can't be cleanly passed to the second `F_SEL` call as a `UINT`.
- **The K values are named constants, not literals.** `Override_K_Normal`/`Override_K_ForceFalse`/`Override_K_ForceTrue` come from the global constants package Override_K (`adapter::OverrideK::const`), not as bare `UINT#0`/`UINT#1`/ `UINT#2` literals directly in the `F_SEL` parameters.
- **No `REQ`/`CNF` of its own.** The block reacts exclusively to the sockets' own events (`Aktiv.E1`, `Wert.E1`) — there is no external trigger input.

State Overview

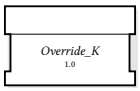
The block has no state machine of its own (a composite FB without an ECC); its behavior is purely combinational, recomputed on every change to `Aktiv` or `Wert`.

Aktiv	Wert	K
FALSE	—	0 (Normal)
TRUE	FALSE	1 (Force FALSE)
TRUE	TRUE	2 (Force TRUE)

Application Scenarios

- **Sensor override via RW OPC-UA nodes**: feed an `Aktiv`/`Wert` pair subscribed via `AX_SUBSCRIBE_1` (e.g. `Sensor.Leermelder.Override.Aktiv`/`.Wert`) directly into the `K` input of an `AX_AUI_MUX_3`, whose three inputs supply the normal value, `FALSE`, and `TRUE`.
- **Diagnostic/test pages**: any boolean sensor that a web UI needs to force to a fixed value for testing can reuse the same `Aktiv`/`Wert`/`K` pattern.

⚖️ Comparison with Similar Blocks



- **AX_AUI_MUX_3**: the actual multiplexer that `Override_K_Select` drives with its `K` output. `Override_K_Select` only computes the selector; it does not select a value itself.
- **const_AX_TRUE** / **const_AX_FALSE**: supply the fixed `IN2`/`IN3` values (Force FALSE/TRUE) that the selector computed by `Override_K_Select` picks out on the `AX_AUI_MUX_3`.
- **Override_K**: the global constants package with the three named K values this block uses internally.

Conclusion

`Override_K_Select` bundles the conversion of an Aktiv/Wert override pair into a MUX selector in a single, reusable block, built entirely from standard blocks (`F_SEL`, `F_MOVE`) with no custom ST algorithms of its own. Combined with `AX_AUI_MUX_3` and the `const_AX_TRUE`/`const_AX_FALSE` constants, this forms the complete, reusable pattern for a boolean sensor value that can be forced via OPC-UA.

const

Override_K

• – ◦ • – ◦ • – ◦ •

Introduction

The global constants package `Override_K` supplies the three named `UINT` values that Override_K_Select uses to populate its `K` output for `AX_AUI_MUX_3`. Instead of wiring `UINT#0`/`UINT#1`/`UINT#2` as literals into the `F_SEL` parameters, the block references these three constants by their descriptive name. The package is defined in the `adapter::OverrideK::const` namespace.

Interface Structure

Being a global-constants package, it has no event- or data-flow-based interface in the conventional function-block sense.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The constants are replaced by their fixed defined values at compile time:

- `Override_K_Normal`: `UINT#0` — the K value for "no override" (`AX_AUI_MUX_3.IN1`, the normal value).
- `Override_K_ForceFalse`: `UINT#1` — the K value for "override forced to FALSE" (`AX_AUI_MUX_3.IN2`).
- `Override_K_ForceTrue`: `UINT#2` — the K value for "override forced to TRUE" (`AX_AUI_MUX_3.IN3`).

Technical Details

- **Directly coupled to `AX_AUI_MUX_3`'s input order.** The numeric values 0/1/2 correspond exactly to `AX_AUI_MUX_3`'s input numbering (`IN1`/`IN2`/`IN3`) — any change to that order in Override_K_Select would need to be kept in sync here.
- **Used only by `Override_K_Select`.** Unlike, say, `OPC_UA_Endpoints`, this package is tightly coupled to a single block rather than several independent call sites.

State Overview

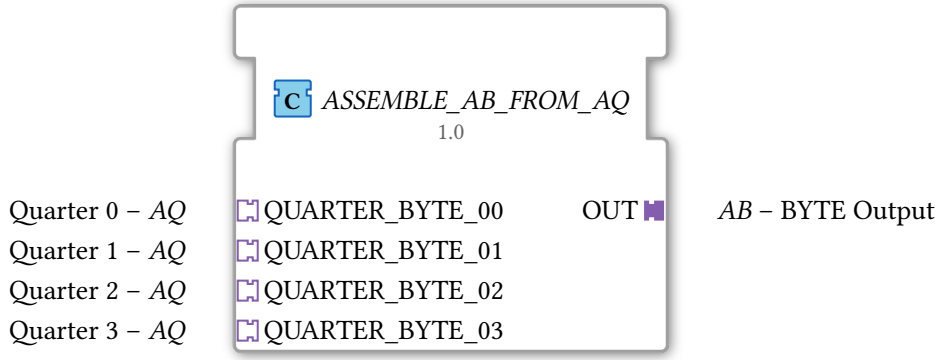
Being static, constant values, there is no state machine.

Application Scenarios

- Referenced in the `IN0`/`IN1` `Parameter` values of the two `F_SEL` blocks in Override_K_Select.
- Comparison values for a consumer that wants to evaluate an `AX_AUI_MUX_3`'s raw `K` value rather than just its muxed output.

⚖️ Comparison with Similar Blocks

- **IDs** (ISOBUS UT library): follows the same GCF pattern (named constants instead of literals), but covers ISOBUS object IDs rather than a MUX selector.



Conclusion

`Override_K` is a small, tightly-coupled constants package that names the three K values used by `Override_K_Select`, making them more readable and maintainable than scattered `UINT#0/1/2` literals.

2.1.11.4 Numeric Index (adapter)

Here you will find all exercises from the `adapter` workspace, listed in ascending order. ...

ASSEMBLE_AB_FROM_AQ

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASSEMBLE_AB_FROM_AQ** combines four **AQ** quarter adapters (quarter bytes) into a single **AB** byte adapter. It encapsulates the logic for assembling a complete byte from four incoming 4-bit values and providing it via a standardized adapter interface. The block is specifically designed for use in distributed automation systems according to IEC 61499.

Interface Structure

Event Inputs

The block does not have dedicated top-level event inputs.

All incoming events are transmitted via the **adapter sockets**. Each application adapter of type `AQ` has an event output `E1`, which is internally connected to the REQ input of the assembly module.

Event Outputs

- **OUT.E1**: Event output of the byte adapter. It becomes active as soon as a new byte has been fully assembled and clocked via the internal flip-flop.

Data Inputs

Data is read in via the **adapter sockets** in the form of 4-bit values (nibbles):

- **QUARTER_BYTE_00.D1**: Nibble for the least significant bits (bits 0-3)
- **QUARTER_BYTE_01.D1**: Nibble for bits 4-7
- **QUARTER_BYTE_02.D1**: Nibble for bits 8-11
- **QUARTER_BYTE_03.D1**: Nibble for bits 12-15

(Note: The actual bit order may vary depending on the implementation of the internal `ASSEMBLE_BYTE_FROM_QUARTERS` module; usually, the bits are combined in ascending order.)

Data Outputs

- **OUT.D1**: Output of the byte adapter. Returns the fully assembled byte (8 bits) as an integer value.

Adapter

Type	Direction	Name	Description
`adapter::types::unidirectional::AQ`	Socket (Input)	`QUARTER_BYTE_00` .. `QUARTER_BYTE_03`	Four quarter adapters, each providing a nibble and an event.
`adapter::types::unidirectional::PAB`	Plug (Output)	`OUT`	Byte adapter providing the assembled byte and an event.

Functionality

The function block operates entirely event-driven. As soon as one of the four connected AQ adapters sends an event on its `E1` output, this event is forwarded to the internal component `ASSEMBLE_BYTE_FROM_QUARTERS` (event `REQ`). Simultaneously, the current nibble values from all four AQ adapter inputs are transferred to the assembly component via data connections.

The assembly component internally combines the four nibbles into an 8-bit value. After successful processing, it sends an acknowledgment event `CNF` to the edge-triggered D flip-flop (`E_D_FF_ANY`). The flip-flop takes the data value (from the assembly output) on a rising edge and passes it to the data output `OUT.D1`. Simultaneously, the output event `OUT.E1` is generated.

Thus, the output is always clock-synchronized: Only when a complete byte has been calculated is it passed through. Multiple events on different quarter inputs lead to repeated calculations, with all four current nibble values being reprocessed each time.

Technical Features

- **Internal Cascading**: The function block uses two internal blocks – `ASSEMBLE_BYTE_FROM_QUARTERS` for bit combination and `E_D_FF_ANY` for edge-triggered output.
- **Event Synchronization**: Every incoming event triggers the assembly; it is not necessary for all four adapters to deliver an event simultaneously – the block operates with the currently available data.
- **Adapter Interface**: Input and output are exclusively via unidirectional adapters, which simplifies reuse in application networks.
- **No state storage in the function block itself**: The function block is a pure network component that completely delegates logic.

State Overview

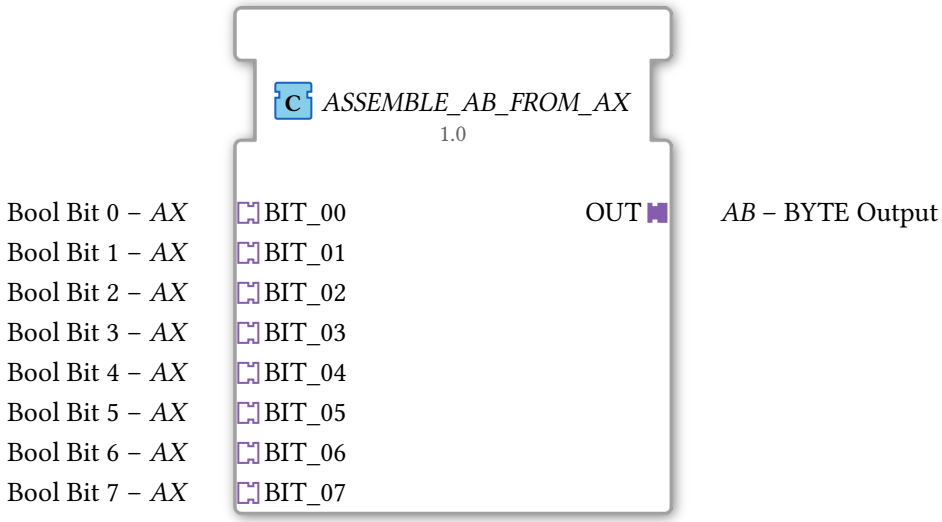
The function block does not have its own state machine. The internal logic is determined by the states of `ASSEMBLE_BYTE_FROM_QUARTERS` and `E_D_FF_ANY`:

1. **Waiting for input event**: After initialization or processing, the function block waits for an event from one of the AQ adapters.
2. **Assembly**: At `REQ`, the nibbles are assembled; the D flip-flop waits for the `CNF` event.
3. **Output**: After the flip-flop is clocked, the result is sent to the OUT adapter. The function block then returns to the wait state.

Application Scenarios

- **Bus Data Merging**: When four separate 4-bit lines (e.g., from sensors or data sources) need to be combined into a single byte.
- **Adapter-Based Data Integration**: In systems based on IEC 61499 adapter architecture, this function block can serve as a generic “byte assembler” at the network layer.
- **Protocol Conversion**: From a quarter-byte protocol to a full-byte protocol, e.g., in serial communication.
- **Test and Simulation Environments**: For easily connecting test adapters.

Comparison with Similar Function Blocks



- **ASSEMBLE_BYTE_FROM_QUARTERS** (direct): This function block operates without adapters – it expects four separate data and event inputs. This function block encapsulates this interface in adapters, which increases modularity.
- **ARRAY_TO_BYTE** or similar function blocks: Often implemented using arrays; here specifically for exactly four nibbles and with adapter support.

- **Custom Adapter-Based Assembler**: If needed, `ASSEMBLE_AB_FROM_AQ` can be easily modified for other data widths by adjusting the internal function blocks.

Conclusion

The **ASSEMBLE_AB_FROM_AQ** function block offers an elegant, adapter-based solution for merging four quarter-byte data streams into a full byte. Thanks to the internal cascading of assembly logic and edge-triggered output, the behavior is deterministic and integrates well into event-driven systems. It is particularly suitable for modular automation projects based on IEC 61499 adapter architecture that require a clean separation of data and event flows.

ASSEMBLE_AB_FROM_AX

• – ◦ • – ◦ • – ◦ •

Introduction

The **ASSEMBLE_AB_FROM_AX** function block combines eight Boolean signals, provided via AX adapters (unidirectional, Bool), into a single byte and outputs it via an AB adapter (unidirectional, BYTE). It encapsulates the logic for byte generation and provides a modular, adapter-based interface for processing 8 bits.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are output exclusively via the adapter plug.

Data Inputs

None. All data is transmitted via the adapter sockets.

Data Outputs

None. All data is output via the adapter plug.

Adapter

Direction	Name	Type	Description
Socket (Input)	`BIT_00`	`adapter::types::unidirectional::AX`	Boolean value for bit 0 (least significant bit)
	`BIT_01`	`adapter::types::unidirectional::AX`	Boolean value for bit 1

	BIT_02	adapter::types::unidirectional::AX	Boolean value for bit 2
	BIT_03	adapter::types::unidirectional::AX	Boolean value for bit 3
	BIT_04	adapter::types::unidirectional::AX	Boolean value for bit 4
	BIT_05	adapter::types::unidirectional::AX	Boolean value for bit 5
	BIT_06	adapter::types::unidirectional::AX	Boolean value for bit 6
	BIT_07	adapter::types::unidirectional::AX	Boolean value for bit 7 (most significant bit)
Plug (output)	OUT	adapter::types::unidirectional::AB	Composite byte (BYTE)

Each AX adapter provides the Boolean value via its data input `D1` and the corresponding event via its event input `E1`. The AB adapter provides the byte via its data output `D1` and the acknowledgment event via its event output `E1`.

Functionality

The function block is implemented as a composite module and consists internally of:

1. **ASSEMBLE_BYTE_FROM_BOOLS** – Receives the eight Boolean values (from `BIT_00` to `BIT_07`) and assembles them into a byte.
2. **E_D_FF_ANY** – A D flip-flop that buffers the calculated byte value and only releases it on a rising edge at the clock input.

Procedure:

- As soon as an event arrives at **one** of the AX adapters (e.g., `BIT_00`), it is forwarded to the `REQ` input of the internal module **ASSEMBLE_BYTE_FROM_BOOLS**.
- The internal component calculates the byte from the current Boolean values of all eight adapters and places it at its data output.
- After the calculation is complete, `ASSEMBLE_BYTE_FROM_BOOLS` sends a `CNF` event, which triggers the clock input (`CLK`) of the D flip-flop **E_D_FF_ANY**.
- The flip-flop receives the current byte value and outputs it at its output `Q`.
- Simultaneously, the flip-flop's event `EO` is passed to the AB adapter's event output `OUT.E1`.

This ensures that the output byte is only updated when an input bit changes, and that the output is stable and synchronized.

Technical Features

- **Adapter-Based Interface** – The component uses only adapters (`AX`/`AB`) instead of individual event and data ports. This allows for easy encapsulation and reuse in modular designs.
- **Internal D Flip-Flop** – The flip-flop prevents intermediate states and only releases the completed byte after the calculation is finished. It also acts as a buffer if multiple input events arrive in quick succession.
- **Efficient Event Control** – Every event at one of the eight AX sockets triggers a recalculation. Unnecessary updates are avoided because the output only occurs after a clock cycle.

State Overview

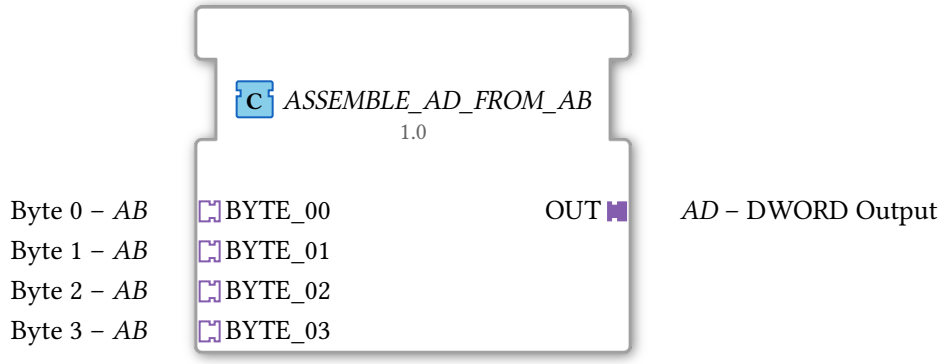
The functional block does not have its own state machine; It is structured as a pure network consisting of two sub-modules. Its behavior is entirely determined by the internal logic of **ASSEMBLE_BYTE_FROM_BOOLS** and **E_D_FF_ANY**.

Application Scenarios

- **Combining 8 digital sensors** – e.g., limit switches, light barriers, or binary inputs of a PLC, whose states are to be transmitted as bytes.
- **Bit-parallel data transmission** – Conversion of an 8-bit parallel signal into a serial byte for another module (e.g., via adapter coupling).
- **Modular automation functions** – Integration into hierarchies where multiple `ASSEMBLE_AB_FROM_AX` blocks are used to assemble larger data words (e.g., WORD, DWORD).

Comparison with similar modules

Module	Description	Difference
`ASSEMBLE_BYTE_FROM_BOOLS`	Internal block that generates a byte from 8 Boolean inputs (without adapters)	`ASSEMBLE_AB_FROM_AX` encapsulates this block and uses adapters for connectivity.
`eclipse4diac::utils::assembling::ASSEMBLE_BYTE_FROM_BOOLS`	Same function, but with direct event/data ports	`ASSEMBLE_AB_FROM_AX` provides an adapter-based interface and adds a D flip-flop for synchronization.
Custom-built byte assembler	Can be implemented as desired, e.g., using the ST algorithm	Adapters `AX`/`AB` are predefined standard types in 4diac that promote reusability and interchangeability.



Conclusion

The function block **ASSEMBLE_AB_FROM_AX** is a practical, adapter-based tool for converting eight Boolean signals into one byte. Thanks to the integration of a D flip-flop, it operates reliably and avoids inconsistent intermediate states. Its modular design facilitates reuse in larger project structures, making it a useful component in automation technology with 4diac.

ASSEMBLE_AD_FROM_AB

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASSEMBLE_AD_FROM_AB** is used to combine four individual byte values, received via unidirectional **AB** adapters (bytes), into a 32-bit **DWORD** value and output it via a unidirectional **AD** adapter. The bytes are combined in the order BYTE_00 (least significant byte) to BYTE_03 (most significant byte). The function block uses an internal combiner and an edge-triggered flip-flop to update the output only after the combination is complete.

Interface Structure

Event Inputs

The function block does not have direct event inputs. Events are received via the connected **Socket Adapters** (BYTE_00 ... BYTE_03).

Event Outputs

There is no direct event output. The output event is provided via the **Plug Adapter** (OUT).

Data Inputs

There are no direct data inputs. All data is received via the **Socket Adapters** (BYTE_00 ... BYTE_03).

Data Outputs

There is no direct data output. The merged DWORD value is output via the **Plug Adapter** (OUT).

Adapters

Name	Type	Direction	Description
BYTE_00	`adapter::types::unidirectional::AB`	Socket	Byte 0 (least significant byte)
BYTE_01	`adapter::types::unidirectional::AB`	Socket	Byte 1
BYTE_02	`adapter::types::unidirectional::AB`	Socket	Byte 2
BYTE_03	`adapter::types::unidirectional::AB`	Socket	Byte 3 (most significant byte)
OUT	`adapter::types::unidirectional::AD`	Plug	32-bit DWORD output

Functionality

The component operates entirely within a sub-application network:

1. An event at one of the four socket adapters (BYTE_00 ... BYTE_03) triggers the **REQ** input of the internal `ASSEMBLE_DWORD_FROM_BYTES` component via the respective `E1` line.
2. This component reads the current values at its data inputs (`BYTE_00` ... `BYTE_03`), combines them into a 32-bit value, and signals this with **CNF**.
3. The **CNF** event triggers the **CLK** input of the internal `E_D_FF_ANY` flip-flop. The flip-flop receives the data value (the merged DWORD) present at its **D** input.
4. The flip-flop's **Q** output is permanently connected to the **D1** data output of the plug adapter **OUT**.
5. Simultaneously, the flip-flop output signal triggers the **E1** event of the plug adapter, informing the receiving side of the new value.

This ensures that the output is only updated when an event has arrived at at least one socket adapter and the merge is complete. The last merged value is retained until a new process is completed.

Technical Features

- **Event Synchronization**: All four socket events are placed on a common `REQ` of the merge block. This triggers processing anew with each incoming byte event – it is not necessary to update all four bytes simultaneously.
- **Caching**: The built-in `E_D_FF_ANY` prevents output during the merging phase. Only when the result is stable is it passed on to the plug.
- **Adapter-based**: The component has no direct inputs/outputs, but communicates exclusively via standardized unidirectional adapters (`AB` and `AD`). This allows for flexible integration into existing adapter interfaces.

State Overview

The component itself does not have an explicit state machine. Its behavior is determined by the internal components:

- **Waiting for Event**: No new event is present at the sockets. The output value is static.
- **Summation & Update**: An event occurs → merging is triggered → flip-flop takes on the new value → output is updated.
- **Wait for Next Event**: After a successful update, the state is retained until the next socket event.

Application Scenarios

- **Data Stream Merging**: Merging four byte-oriented sensor or communication data into a single 32-bit value (e.g., for a fieldbus interface).
- **Protocol Wrapper**: Combining individual bytes from different sources into a complete data word, which is then passed to higher-level logic via an AD adapter.
- **Test and Simulation Environments**: Used as a converter between existing byte adapter components and DWORD adapter components.

Comparison with Similar Function Blocks

- **Direct Data Type Converter** (e.g., `BYTE_TO_DWORD`): These often work with simple data inputs/outputs without an event log. The `ASSEMBLE_AD_FROM_AB`, on the other hand, integrates event control and is tailored to the adapter interface.
- **Manual Chaining of Adapters**: Instead of four separate `AB` adapters and a manually configured network, this function block offers a pre-built and tested solution that requires less wiring effort.

Conclusion

The **ASSEMBLE_AD_FROM_AB** is a specialized, adapter-based function block for merging four byte values into a DWORD. Through the internal use of a merger and a flip-flop, reliable, event-driven updates of the output value are achieved. It is ideally suited for systems that rely on standardized unidirectional adapters and require clean, flicker-free data transmission.

ASSEMBLE_AD_FROM_AQ

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASSEMBLE_AD_FROM_AQ` is used to combine sixteen separate `AQ` adapters (quarters) into a single `AD` output adapter (DWORD). The term “quarter” indicates that each `AQ` adapter represents part of a 32-bit word—specifically, one byte (8 bits). The block combines these 16 bytes into a complete DWORD and makes it available via a `AD` plug. It is particularly suitable for applications where data arrives in smaller units and only needs to be combined into a larger data type at the receiving end.

Interface Structure

The function block has no independent event or data inputs/outputs. All input and output is handled exclusively via adapters.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Sockets (Inputs)	QUARTER_BYTE_00, ..., QUARTER_BYTE_15	`adapter::types::unidirectional::AQ`	16 identical adapters, each providing an 8-bit data value (quarter/byte) and a corresponding event (`E1`).
Plug (Output)	OUT	`adapter::types::unidirectional::AQ`	Output adapter providing the DWORD (`D1`) composed of the 16 quarter values and an event (`E1`).

Functionality

The function block operates entirely event-driven:

1. As soon as one of the 16 `QUARTER_BYTE` sockets receives an event (`E1`), it is forwarded to the internal function block `ASSEMBLE_DWORD_FROM_QUARTERS` (type `eclipse4diac::utils::assembling::ASSEMBLE_DWORD_FROM_QUARTERS`).
2. The internal function block combines the current data of all 16 quarter values into a 32-bit DWORD (bits 0…7 = Quarter 0, bits 8…15 = Quarter 1, … bits 120…127 = Quarter 15).
3. The result is passed to an edge-triggered D flip-flop (`E_D_FF_ANY`).
4. On the next rising edge of its clock input (`CLK`), the flip-flop outputs the assembled DWORD to the `OUT` adapter and generates an event (`E0`), which in turn triggers the output event `E1` of the `OUT` adapter.

The use of the flip-flop ensures that the output is only updated when the data is fully assembled and stable – even if multiple quarter-wave events arrive virtually simultaneously.

Technical Features

- **No dedicated inputs/outputs:** The component communicates exclusively via adapters, enabling clean encapsulation and reusability in different project contexts.
- **Synchronous Update:** The D flip-flop prevents data inconsistencies if multiple quarters change their values almost simultaneously. The output only changes after all inputs have been evaluated.
- **Autonomous Triggering:** Every quarter event (regardless of the socket) triggers a recalculation. The component always operates with the currently available values of all 16 quarter data.
- **Internal Indirection:** The actual assembly is performed by a specialized sub-component (`ASSEMBLE_DWORD_FROM_QUARTERS`), which keeps the design modular and maintainable.

State Overview

The function block itself does not have its own state machine. It behaves like combinational logic with downstream synchronization. However, the internal flip-flop `E_D_FF_ANY` has an internal state (the stored DWORD value). This state is only changed when an event arrives at `CLK`.

In the idle state (no event at a quarter socket), the output value of the `OUT` adapter remains unchanged.

Application Scenarios

- **Distributed Measurement System:** Multiple sensors each deliver one byte; these are combined in a central processing unit to form a complete DWORD.
- **Data Packet Reconstruction:** Fragmented communication frames (e.g., 16-byte payloads) are reassembled.
- **Mediator Structures:** As part of an adapter chain for converting data widths in IEC 61499 applications.

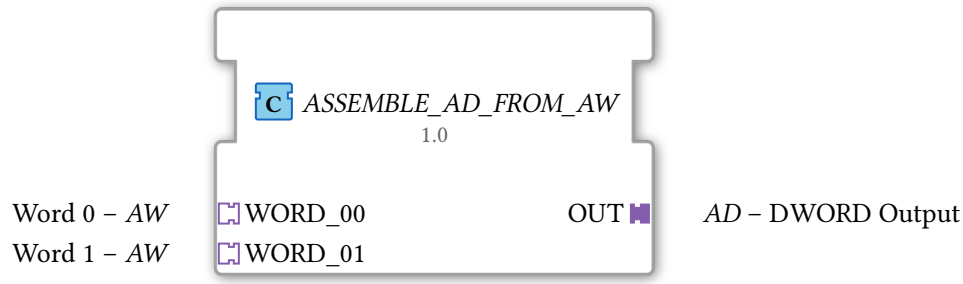
- **Control Word Synthesis:** Multiple 8-bit control channels are combined into a 32-bit command word.

Comparison with Similar Components

Component	Number of Inputs	Output	Synchronization	Properties
`ASSEMBLE_AD_FROM_AQ`	16 (AQ adapter)	1 (AD adapter)	Yes (flip-flop)	For event-driven byte collection.
`ASSEMBLE_DWORD_FROM_QUARTERS` (internal)	16 data inputs (no adapters)	1 DWORD output	No	Pure data assembly without event synchronization.
Simple `MERGE` component (fictional)	2 ... n data inputs	1 Data Output	Often no	Data concatenation only, no adapter structure.

This component is characterized by the encapsulation of the adapter interfaces and integrated synchronization, making it particularly suitable for heterogeneous, event-driven environments.

Conclusion



ASSEMBLE_AD_FROM_AQ` is a specialized adapter component for concatenating 16-byte-wide quarter data into a DWORD. Its purely adapter-based interface makes it flexible in its application, while internal synchronization via a flip-flop ensures data consistency during asynchronous events. It is ideally suited for use in modular IEC 61499 applications where data arrives in smaller units and must be assembled into a complete word at the receiving end.

ASSEMBLE_AD_FROM_AW

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASSEMBLE_AD_FROM_AW** combines two word values (WORD) from a single unidirectional AW adapter into a double word (DWORD), which is output via a unidirectional AD adapter. The block encapsulates the logical combination of two 16-bit inputs into a 32-bit output and stores the result using an edge-triggered D flip-flop.

Interface Structure

Event Inputs

The function block has no directly visible event inputs. Event control is handled indirectly via the incoming adapters **WORD_00** and **WORD_01**: Each of these adapters provides a signal via its implicit event output (`E1`) that triggers the internal processing sequence.

Event Outputs

There are no direct event outputs here either. The output adapter **OUT** provides the output event via its implicit event input (`E1`), which is triggered after processing is complete and the data value has been transferred.

Data Inputs

Data is read in via the two socket adapters:

Adapter	Type	Description
`WORD_00`	`adapter::types::unidirectional::AW`	First 16-bit word (lower-order part of the double word)
WORD_01`	`adapter::types::unidirectional::AW`	Second 16-bit word (higher-order part of the double word)

Each of these adapters provides a data output (`D1`) containing the actual WORD value.

Data Outputs

The output is via a plug adapter:

Adapter	Type	Description
OUT`	`adapter::types::unidirectional::AD`	Composite 32-bit Double Word (DWORD)

The adapter `OUT` has one data input (`D1`) that is internally connected to the stored result.

Adapters

The function block provides two incoming adapters (sockets) and one outgoing adapter (plug), all of which are unidirectional:

- **WORD_00**, **WORD_01**: Each returns a WORD and an associated event.
- **OUT**: Receives a DWORD and passes it on with an event.

Functionality

1. As soon as one of the two input events (`WORD_00.E1` or `WORD_01.E1`) arrives, the internal function block `ASSEMBLE_DWORD_FROM_WORDS` is activated via its event input `REQ`.
2. This internal block assembles the 32-bit double word from the two incoming 16-bit values (`WORD_00.D1` and `WORD_01.D1`). `WORD_00` is interpreted as the lower-order word and `WORD_01` as the higher-order word.
3. After the calculation is complete, `ASSEMBLE_DWORD_FROM_WORDS` signals the clock signal for an edge-triggered D flip-flop (`E_D_FF_ANY`) with the event `CNF`.
4. The flip-flop receives the calculated DWORD value at its data input `D` and outputs it at its output `Q`.
5. The stored value is transmitted via the data connection to the adapter `OUT.D1`. Simultaneously, the adapter's event input `OUT.E1` is activated via the flip-flop's output event (`EO`).

... This ensures that the output value is only updated when there are actual changes or valid new inputs and remains stable until the next event.

Technical Features

- The module uses an internal function block (`ASSEMBLE_DWORD_FROM_WORDS`) for word combination and an edge-triggered D flip-flop (`E_D_FF_ANY`) for output storage.
- Event processing is asynchronous: Each incoming event at either of the two AW adapters triggers a new calculation and subsequent output. The state of the input events is not stored – the flip-flop always uses the last calculated DWORD.
- Word composition is performed at the hardware level: WORD_00 = low-order 16-bit word (bits 0-15), WORD_01 = high-order 16-bit word (bits 16-31).

State Overview

The function block itself does not have an explicit state machine. However, its internal process can be characterized by the states of the D flip-flop:

State	Description

Waiting for Event	The flip-flop holds the last calculated value; no new input event is pending.
Calculation Active	An event from WORD_00 or WORD_01 triggers the merge, and the flip-flop is clocked.
Output Active	After the clock cycle, the new value is passed to `OUT`, and the output event is sent.

The state transitions occur strictly according to the event chain.

Application Scenarios

- **Data Format Conversion**: Combining two 16-bit sensor values (e.g., from two separate analog input modules) into a 32-bit data word for a higher-level controller.
- **Adapter Integration**: Integrating AW-based components (e.g., word adapters from bus systems) into systems that expect an AD adapter (DWORD).
- **Interface Adaptation**: Simplifying wiring when two logically related 16-bit channels need to be combined into a double word.

Comparison with Similar Function Blocks

- **ASSEMBLE_DWORD_FROM_WORDS** (internal FB): Offers the same data merging, but without adapter interfaces and without output storage. `ASSEMBLE_AD_FROM_AW` extends this functionality with adapter encapsulation and a D flip-flop.
- **SPLIT_AD_TO_AW**: Performs the reverse operation (splitting a DWORD into two words) and provides the values via an AW adapter.
- **MUX_WORDS_TO_DWORD**: An alternative function block for word combination that typically operates without an adapter or edge-triggered storage.

Conclusion

ASSEMBLE_AD_FROM_AW` is a specialized function block for cleanly encapsulating word-to-double-word conversion in an adapter-based environment. The combination of a pure arithmetic unit and edge-triggered storage ensures stable output values despite changing input events. This function block is particularly suitable for modular automation solutions that rely on unidirectional adapter interfaces.

ASSEMBLE_AD_FROM_AX

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASSEMBLE_AD_FROM_AX** is used to combine up to 32 Boolean signals, provided via AX adapters (type: `adapter::types::unidirectional::AX`), into a 32-bit double word (DWORD) and output it via an AD adapter (type: `adapter::types::unidirectional::AD`). This enables the compact transmission of multiple discrete binary signals over a single data connection.

Interface Structure

The function block has only **adapter interfaces** (sockets and plugs). There are no direct event or data inputs/outputs at the top level.

Event Inputs

No explicit event inputs. Events are received implicitly via the AX adapters:

- Each of the 32 AX adapters (`BIT_00 … BIT_31`) provides an event output (`E1`) that is activated when the value of the associated BOOL signal changes.

Event Outputs

No explicit event outputs. The AD output adapter (`OUT`) triggers an event (`E1`) as soon as the composite DWORD assumes a new value.

Data Inputs

No explicit data inputs. The Boolean input values are obtained via the data ports (`D1`) of the AX adapters:

- `BIT_00.D1` ... `BIT_31.D1`: each a **BOOL** (bit 0 ... bit 31 of the resulting DWORD).

Data Outputs

No explicit data outputs. The composite DWORD is output via the data port (`D1`) of the AD adapter:

- `OUT.D1`: **DWORD** (the 32-bit word composed from the 32 BOOL inputs).

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AX`	`BIT_00` ... `BIT_31`	Socket (Input)	32 Boolean individual signals, each with its own event (data change)
`adapter::types::unidirectional::AD`	`OUT`	Plug (Output)	Output of the compound double word with update event

Functionality

1. **Event Receipt**: As soon as one of the 32 AX adapters reports a change in its Boolean value (event `E1`), the event is forwarded to the internal block `ASSEMBLE_DWORD_FROM_BOOLS.REQ`.
2. **Data Assembly**: The internal block `ASSEMBLE_DWORD_FROM_BOOLS` combines all 32 Boolean values (from `BIT_00.D1` to `BIT_31.D1`) into a single DWORD. Bit 0 corresponds to `BIT_00`, bit 1 to `BIT_01`, and so on.
3. **Storage and Output**: The resulting DWORD is passed to the next internal block, `E_D_FF_ANY`. This edge-triggered flip-flop stores the value and outputs it at its output `Q`. Simultaneously, it generates an event (`E0`) that is signaled externally via the AD adapter (`OUT.E1`) indicating that a new DWORD value is present.
4. **Buffering**: The flip-flop ensures that the output value is only updated when actual changes occur and does not output the same value multiple times in succession for each individual bit event.

Technical Features

- **Adapter-based Interface**: The function block uses only adapters (AX, AD) and no direct input/output pins. This allows for flexible coupling with other adapters in a service-oriented architecture.
- **Event Synchronization**: The integrated `E_D_FF_ANY` (arbitrary-edge E-D flip-flop) acts as a debouncing and synchronization stage. It prevents multiple output events from being generated when several bits are changed simultaneously – the output is updated only once per change cycle.
- **Bit Order**: Bit 0 (LSB) corresponds to adapter `BIT_00`, and bit 31 (MSB) corresponds to adapter `BIT_31`. A consistent assignment must be observed when wiring.
- **Type Hash**: The function block contains an attribute `eclipse4diac::core::TypeHash`, which is used to validate the block definition.

State Overview

The function block itself does not have an explicit state machine. The internal function block `E_D_FF_ANY` implements a simple memory state:

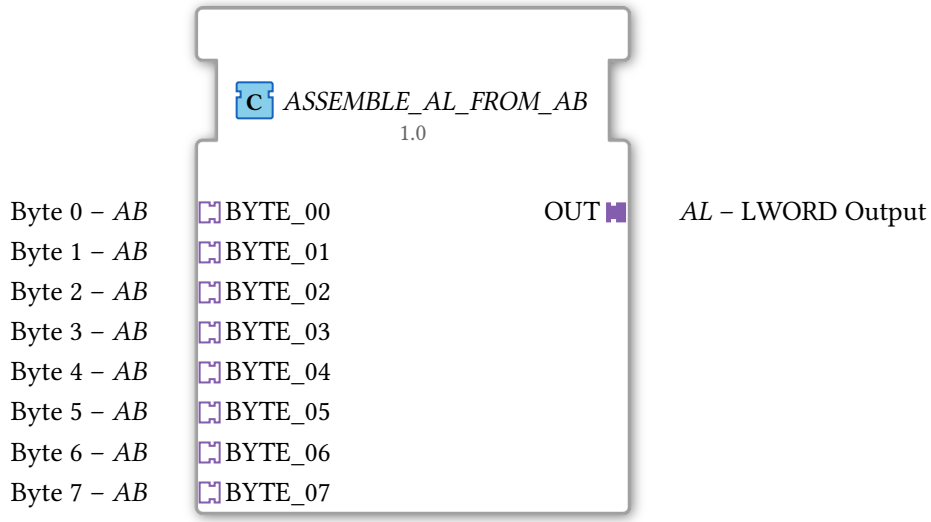
- **State 0**: Flip-flop output `Q` contains the last loaded DWORD value.
- **State Transition**: Upon an event at `ASSEMBLE_DWORD_FROM_BOOLS.CNF`, the new DWORD value is transferred to the flip-flop, and the output is updated.

Application Scenarios

- **Digital Input Summarization**: In a controller, 32 discrete sensors (e.g., limit switches, light barriers) are read via AX adapters. The function block summarizes their states in a DWORD, which can be transmitted as a compact data word via a fieldbus or other interface.
- **Parallel-to-Serial Conversion**: Preparation of parallel binary data for serial transmission, where the DWORD is sent as a single telegram.
- **Status Query**: A central function block (FB) regularly queries the output adapter and receives the current overall status of all 32 binary digits at once.

Comparison with Similar Function Blocks

- **ASSEMBLE_DWORD_FROM_BOOLS**: This function block has direct BOOL inputs and a DWORD output, but no adapter interface. `ASSEMBLE_AD_FROM_AX` encapsulates this logic in an adapter-based component and adds flip-flop memory.
- **AD_TO_AX_SPLITTER**: The reverse process—splitting a DWORD into individual BOOL signals—is enabled by a corresponding splitter function block.
- **Direct Bit Manipulation**: In some environments, the bits could also be assembled using logical operations. However, the FB described here offers a standardized, reusable, and event-driven solution.



Conclusion

The `ASSEMBLE_AD_FROM_AX` is a useful building block for efficiently bundling a large number of binary signals into a single data word. The use of adapters allows for loose coupling and facilitates integration into service-oriented automation architectures. Integrated flip-flop synchronization prevents unnecessary output events and ensures a stable, up-to-date overall value. Its clear structure makes it particularly suitable for applications where many discrete signals need to be centrally acquired and processed.

ASSEMBLE_AL_FROM_AB

• – ◦ • – ◦ • – ◦ •

Introduction

The function block ASSEMBLE_AL_FROM_AB combines eight individual byte pieces of information from adapters of type AB (unidirectional) into a single, contiguous 64-bit data word (LWORD). The result is output via an output adapter of type AL. This function block serves as a central repository for byte-oriented data and enables modular and clear data structuring.

Interface Structure

Event Inputs

None. Event control is handled exclusively via the connected adapters.

Event Outputs

None. The output event is provided via the adapter OUT.

Data Inputs

None. Data inputs are supplied via the byte adapters.

Data Outputs

None. The composite LWORD is output via the adapter OUT.

Adapters

Sockets (Input Adapters)

Name	Data Type	Description
BYTE_00	adapter::types::unidirectional::AB	Byte 0 (least significant byte)
BYTE_01	adapter::types::unidirectional::AB	Byte 1
BYTE_02	adapter::types::unidirectional::AB	Byte 2
BYTE_03`	adapter::types::unidirectional::AB	Byte 3
BYTE_04`	adapter::types::unidirectional::AB	Byte 4
BYTE_05`	adapter::types::unidirectional::AB	Byte 5
BYTE_06`	adapter::types::unidirectional::AB	Byte 6
BYTE_07`	adapter::types::unidirectional::AD	Byte 7 (most significant byte)

Each byte adapter provides one event (E1) and one data byte (D1).

Plugs (Output Adapters)

Name	Data Type	Description
OUT	adapter::types::unidirectional::AL	Output: composite LWORD; event output via E1, data value via D1

Functionality

The function block is implemented as a composite FB and contains two internal function blocks: ASSEMBLE_LWORD_FROM_BYTES and E_D_FF_ANY.

1. **Data Collection**: As soon as one of the eight byte adapters (BYTE_00 ... BYTE_07) delivers an event at its output E1, this event is forwarded to the input REQ of ASSEMBLE_LWORD_FROM_BYTES. Simultaneously, the corresponding byte values from each adapter are routed to the appropriate data inputs of the assembler block (BYTE_00 ... BYTE_07).
2. **Conversion**: The internal component ASSEMBLE_LWORD_FROM_BYTES combines the eight bytes in the order BYTE_00 to BYTE_07 into a 64-bit word (LWORD). BYTE_00 is the least significant byte, and BYTE_07 is the most significant. After completion of the operation, an acknowledgment event (CNF) is issued, and the constructed LWORD is made available at its data output.
3. **Buffering and Output**: The event CNF triggers the edge-triggered flip-flop E_D_FF_ANY. This flip-flop takes the current LWORD value and stores it temporarily. On each rising edge at the clock input (CLK),

the value at the data output `Q` is updated. The output `Q` is connected to the data output `D1` of the adapter plug `OUT`. The stored event `E0` of the flip-flop is provided as the output event `E1` of the adapter plug `OUT`.

Thus, with each update of one of the eight byte inputs, the entire LWORD is recalculated and output via the output adapter.

Technical Features

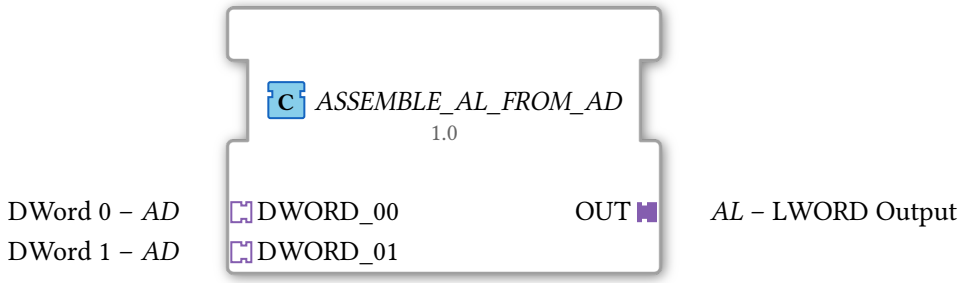
- **Adapter-based interfaces**: The component uses adapters exclusively for input and output. This enables flexible and loose coupling with other components that use the same adapter type.
- **Composite Architecture**: The internal structure is built from proven standard components (`ASSEMBLE_LWORD_FROM_BYTES` and `E_D_FF_ANY`). This hides complexity and increases maintainability.
- **Flip-Flop Buffering**: The `E_D_FF_ANY` buffers the assembled value and only releases it after assembly is complete. This prevents inconsistent output during individual byte updates and ensures that a complete data value is always available.
- **Event Synchronization**: All byte adapter signals are routed to a common `REQ` input. This ensures that any change to any byte is processed immediately. However, the merging of all bytes always occurs based on the currently available values.

State Overview

Since this is a composite function block (FB), it does not have its own state machine. The internal `E_D_FF_ANY` has an internal state: the stored LWORD value. This value only changes on rising edges at the clock input, i.e., after each successful assembly. The state is retained until another assembly is triggered.

Application Scenarios

- **Data Aggregation in Sensor Networks**: Several byte-oriented sensors (e.g., temperature, pressure, humidity) are connected via separate adapters. The function block combines them into a 64-bit data telegram, which is forwarded to a central controller.
- **Protocol Conversion**: A byte stream received via multiple adapters (e.g., a serial interface with 8 payload bytes) is converted into a single LWORD, which is easier to handle for further processing.
- **Modular I/O Expansion**: In a modular automation solution, eight digital/analog byte inputs (e.g., via I/O modules) can be combined into a single 64-bit variable.



Comparison with Similar Components

- **`ARRAY_TO_LWORD` Components**: These components typically use arrays as inputs and have a different interface (no adapters). The `ASSEMBLE_AL_FROM_AB` offers an adapter-based, event-driven alternative that fits better into modular, typed adapter structures.
- **Multiplexer (MUX)**: A multiplexer selects one of several inputs, while this component combines all inputs simultaneously into a larger data word.
- **Direct Bit Concatenation**: Without this component, byte concatenation would have to be performed manually using bitwise shifting and OR operations. The `ASSEMBLE_AL_FROM_AB` encapsulates this logic and reduces development and testing effort.

Conclusion

The `ASSEMBLE_AL_FROM_AB`This is a specialized function block for the modular and event-driven aggregation of eight-byte data sets into a single LWORD. Its exclusive use of adapters makes it ideal for use in adapter-based architectures and promotes a clear separation of data sources and sinks. Integrated buffering via the flip-flop and triggering by each incoming event ensure that a consistent, complete data value is always output. This component significantly simplifies data aggregation and contributes to maintainable and reusable control logic.

ASSEMBLE_AL_FROM_AD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASSEMBLE_AL_FROM_AD** is used to combine two 32-bit values provided via AD adapters (DWORD) into a 64-bit LWORD and output this LWORD via an AL adapter. It encapsulates the combination logic and provides a buffered, event-driven interface for 64-bit data.

Interface Structure

Event Inputs

- **DWORD_00.E1** – Event from the first AD adapter that triggers the combination.
- **DWORD_01.E1** – Event from the second AD adapter that also triggers the combination.

Event Outputs

- **OUT.E1** – Event at the AL adapter indicating that a new LWORD value is present at the output.

Data Inputs

- **DWORD_00.D1** – First 32-bit DWORD (lower-order part).
- **DWORD_01.D1** – Second 32-bit DWORD (higher-order part).

Data Outputs

- **OUT.D1** – Composite 64-bit LWORD.

Adapters

- **DWORD_00** (Socket, type `adapter::types::unidirectional::AD`) – Input adapter for the first DWORD.
- **DWORD_01** (Socket, type `adapter::types::unidirectional::AD`) – Input adapter for the second DWORD.
- **OUT** (Plug, type `adapter::types::unidirectional::AL`) – Output adapter for the resulting LWORD.

Functionality

The FB operates internally as an FB network consisting of two sub-blocks:

1. **ASSEMBLE_LWORD_FROM_DWORDS** – Combines the two DWORD inputs `DWORD_00` and `DWORD_01` into one LWORD. The function block is triggered by the event `REQ`, which can be sent by **both** AD adapters (via `DWORD_00.E1` and `DWORD_01.E1`). After the combination is complete, the event `CNF` is output.
2. **E_D_FF_ANY** – Any D flip-flop that buffers the combined LWORD. The `CNF` event clocks the flip-flop (`CLK`), with the combined value present at the data input `D`. The stored value appears at output `Q` and is passed on via `OUT.D1`. Simultaneously, the flip-flop output event `EO` is triggered as `OUT.E1`.

Thus, the LWORD is only updated when one of the two AD adapters sends an event – the flip-flop prevents multiple or unwanted outputs when the inputs remain unchanged.

Technical Features

- **Event-driven processing** – The combination is only triggered by incoming events from the AD adapters, thus avoiding unnecessary processing load.

- **Buffered output** – The D flip-flop ensures that a calculated LWORD remains stable at the output until the next update.
- **Independence of inputs** – Each of the two DWORD adapters can send an event at any time; The combination is then performed using the currently available values.
- **No dedicated event inputs at the top level** – The function block reacts exclusively via the adapter interfaces.

State Overview

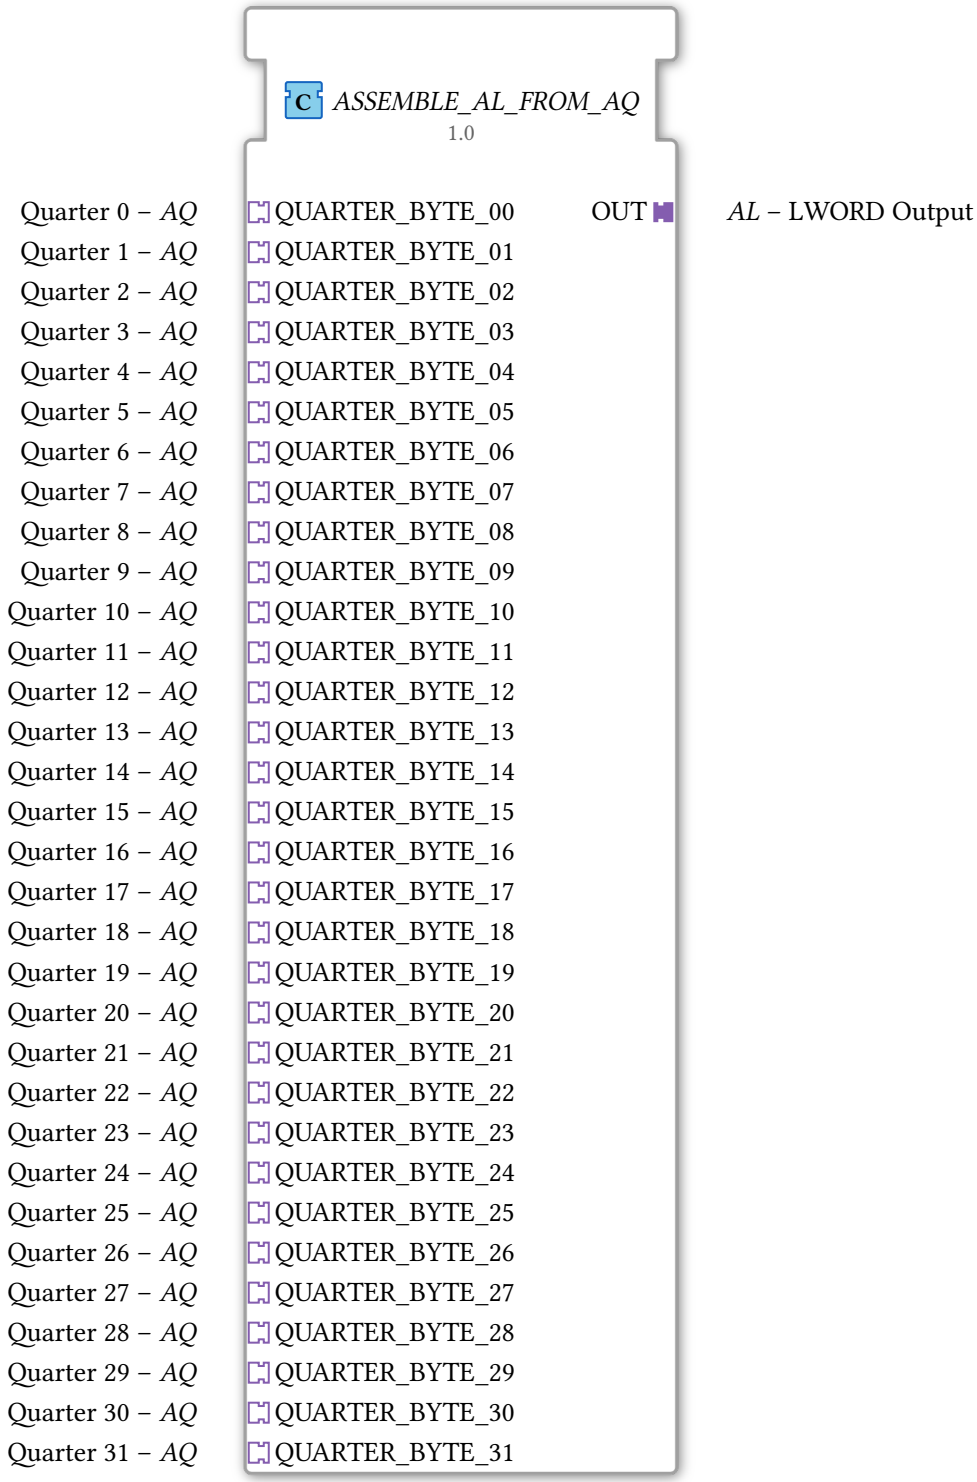
The function block does not use an explicit ECC, but rather an internal function block network. The functional sequence is:

1. **Waiting** for an event from `DWORD_00.E1` or `DWORD_01.E1`.
2. **Combining** – ASSEMBLE_LWORD_FROM_DWORDS processes the current DWORD values and creates the LWORD.
3. **Buffering** – The flip-flop takes the LWORD and outputs it via `OUT.D1`.
4. **Signaling** – The event `OUT.E1` is triggered.
5. Return to wait state.

A simultaneous request from both inputs results in only one processing step, as both events trigger the same `REQ` function of the combination block.

Application Scenarios

- **64-bit Data Processing** – When a system operates with 32-bit interfaces and large values (e.g., high-resolution timestamps, counter readings, physical measurements) need to be combined into a single LWORD.
- **Protocol Conversion** – In fieldbuses or controllers that deliver data in separate DWORD segments and require 64-bit processing.
- **Secure Data Combination** – The buffered output prevents intermediate values from occurring with asynchronously arriving DWORDs.



Comparison with Similar Function Blocks

- **ASSEMBLE_DWORD_FROM_WORDS** – Combines two WORDs into one DWORD; analogous principle, but for different word widths.
- **ASSEMBLE_LWORD_FROM_DWORDS** – The internal function block that performs the pure combination without buffering; ASSEMBLE_AL_FROM_AD adds event-driven buffering and the adapter interface.
- **Direct Use of a Type Converter** – Would be possible, but without event synchronization; the present function block offers a clean, industrialized solution with adapters.

Conclusion

The **ASSEMBLE_AL_FROM_AD** function block is a specialized but useful building block for combining two DWORDs into one LWORD. It combines event-driven processing with stable output buffering and is ideal for control systems that exchange 64-bit data via standardized adapters. The use of adapters allows for easy integration into existing model structures.

ASSEMBLE_AL_FROM_AQ

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASSEMBLE_AL_FROM_AQ` is used to combine 32 unidirectional AQ adapters (“quarters”) into a single AL adapter (LWORD). It is implemented as a pure composition block without its own event or data ports at the top level and uses internal sub-function blocks to combine the incoming quarter data into a 64-bit word and stabilize it on the output side.

Interface Structure

Event Inputs

The block has **no** its own event inputs at its top level.
Event control is handled exclusively via the integrated AQ adapters (sockets) and the internal wiring.

Event Outputs

There are **no** event output ports.
The output signal is transmitted externally via the AL plug adapter (E1) in an event-driven manner.

Data Inputs

There are **no** directly accessible data inputs.
Data is fed into the module via the 32 AQ adapters (sockets).

Data Outputs

There are **no** directly accessible data outputs.
The composite LWORD is output via the AL plug adapter (D1).

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AQ`	`QUARTER_BYTE_00` ... `QUARTER_BYTE_31`	Socket (Input)	32 identical adapters, each providing a 2-bit value (“quarter”). Each socket has an event output (E1) and a data output (D1).
`adapter::types::unidirectional::AL`	`OUT`	Plug (Output)	Output adapter that passes a 64-bit LWORD (D1) and an associated event (E1).

Functionality

1. **Data Acquisition** – Each of the 32 `QUARTER_BYTE_xx` sockets provides its data value (D1) upon receiving an incoming event (E1).
2. **Assembly** – The event is forwarded to the internal sub-function block `ASSEMBLE_LWORD_FROM_QUARTERS` (all 32 events are connected to the same `REQ` input). Simultaneously, all 32 quarter data values are routed to the corresponding inputs of this sub-block.
3. **Internal Processing** – `ASSEMBLE_LWORD_FROM_QUARTERS` combines the 32 2-bit quarters into a 64-bit LWORD. Its output signal is then routed through an edge-triggered D flip-flop (`E_D_FF_ANY`).
4. **Output Stabilization** – The flip-flop is clocked by the completion event (`CNF`) of `ASSEMBLE_LWORD_FROM_QUARTERS`. It holds the combined value until a new assembly cycle is complete. The flip-flop’s output feeds the data port `OUT.D1` of the AL plug adapter, and the corresponding event `OUT.E1` is triggered after the clock signal.

Technical Features

- **Pure Adapter Composition** – The component has no conventional input/output ports at the top level, but uses only adapters. This enables modular encapsulation and easy reuse in different contexts.
- **Internal Data Aggregation** – The 32 quarter values (2 bits each) are combined into a 64-bit LWORD. This fully utilizes the LWORD capacity.
- **Edge-Triggered Output Synchronization** – The D flip-flop prevents flickering or incomplete data words at the output by only passing the value after the aggregation is complete and on a rising clock edge.
- **No Internal State Logic** – The component does not contain an ECC (Execution Control Chart); the logic is entirely derived from the interconnection of the sub-blocks.

State Overview

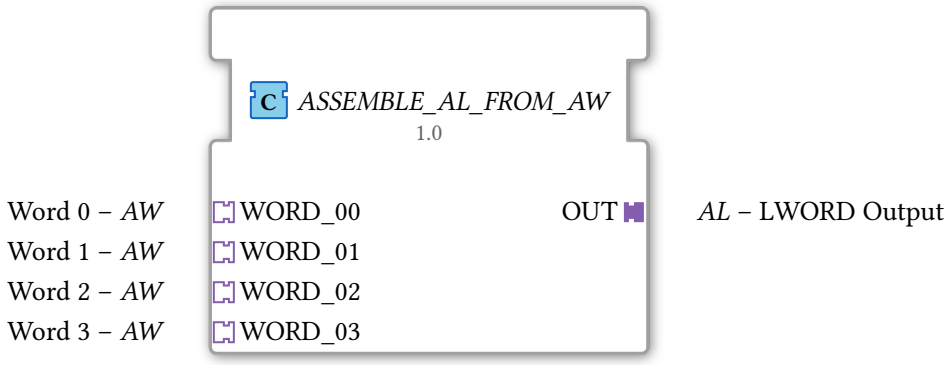
The component does not have its own state machine.

The state logic is implemented by the internal blocks ASSEMBLE_LWORD_FROM_QUARTERS (data-driven) and E_D_FF_ANY (event-driven).

Application Scenarios

- **Combining Bit Subwords** – In industrial control engineering, data from multiple sensors or subsystems (e.g., 32 switching states, each encoding 2 bits) often needs to be combined into a single, coherent data word.
- **Querying Parallel Data Sources** – If 32 independent modules each deliver a 2-bit signal via adapters, ASSEMBLE_AL_FROM_AQ can combine these into a 64-bit word in one step and provide it in an event-driven manner.
- **Platform-Independent Adapter Interfaces** – Thanks to its pure adapter usage, this component is suitable for use in heterogeneous systems where data types are abstracted by the adapter definitions.

Comparison with Similar Components



Component	Operating Principle	Number of Inputs	Output Type	Special Feature
ASSEMBLE_AL_FROM_AQ	Adapter-Based Composition	32 × 2-Bit (AQ)	1 × LWORD (AL)	Edge-Triggered Output, Pure Composition
ASSEMBLE_LWORD_FROM_QUARTERS (internal)	Data-Oriented Composition	32 × 2-Bit (direct)	LWORD (Data)	No adapters, no flip-flop
Classic multiplexer (e.g., MUX)	Input selection via control line	n inputs, 1 selection	Simple data type	Requires dedicated address signals

Compared to a multiplexer, ASSEMBLE_AL_FROM_AQ offers the advantage that *all* quarter values are combined in parallel and without selection logic to form a complete word. The additional flip-flop ensures clean, event-driven output.

Conclusion

The ASSEMBLE_AL_FROM_AQ function block provides an elegant and modular solution for combining 32 2-bit quarter data values into a 64-bit LWORD using adapters. The strict separation of data and event paths, as well as the internal use of an edge-triggered flip-flop, ensures reliable and deterministic output signal generation. Due to its purely compositional structure, it is particularly suitable for use in IEC 61499 systems that rely on adapter-based interfaces.

ASSEMBLE_AL_FROM_AW

• – ◦ • – ◦ • – ◦ •

Introduction

The function block ASSEMBLE_AL_FROM_AW combines the data from four **AW (WORD)** adapter interfaces into one **AL (LWORD)** output value. It is used to combine multiple 16-bit words into a 64-bit word and output it via a clocked signal.

Interface Structure

Event Inputs

None – event control is handled exclusively via the connected adapters (see section Adapters).

Event Outputs

None – event output is provided via the OUT adapter (`OUT.E1`).

Data Inputs

No direct data inputs – the data to be processed is obtained via the four AW sockets.

Data Outputs

No direct data outputs – the result is output via the OUT adapter.

Adapters

Name	Type	Comment
Sockets		
`WORD_00`	`adapter::types::unidirectional::AW`	Word 0 (least significant 16-bit word)
`WORD_01`	`adapter::types::unidirectional::AW`	Word 1
`WORD_02`	`adapter::types::unidirectional::AW`	Word 2
`WORD_03`	`adapter::types::unidirectional::AW`	Word 3 (highest-order 16-bit word)
Plugs		
`OUT`	`adapter::types::unidirectional::AL`	LWORD output (64-bit)

Functionality

The module utilizes an internal network of two function blocks:

1. **`ASSEMBLE_LWORD_FROM_WORDS`** – performs the logical combination of the four 16-bit words (`WORD_00` to `WORD_03`) into a 64-bit LWORD.
2. **`E_D_FF_ANY`** – a clock-edge-triggered D flip-flop that only transmits the combined value to the output adapter `OUT` when a rising edge is present at the clock input.

The events from the four input adapters (`WORD_00.E1` … `WORD_03.E1`) are all connected to the `REQ` event input of `ASSEMBLE_LWORD_FROM_WORDS`. As soon as an event arrives at one of the input adapters, the combination is recalculated. Upon completion (`CNF`), `E_D_FF_ANY` is clocked, which then adopts the calculated value into its internal state and outputs it via `OUT.D1`. The event at the output adapter (`OUT.E1`) signals the availability of the new value.

As soon as an event arrives at one of the input adapters, the combination is recalculated.

Technical Features

- **Clock Edge Triggered Output** – The use of the `E_D_FF_ANY` prevents unwanted intermediate values and ensures that only fully composed LWORDs are output.
- **Arbitrary Order of Input Events** – Since all four sockets are combined into the same `REQ` input, each incoming event triggers a recalculation. The function block therefore reacts to each partial word, but only updates the output after the complete composition.
- **Adapter-Based Interface** – The use of unidirectional adapters (AW and AL) enables loose coupling and reuse in different contexts.

State Overview

The function block does not have its own ECC (Execution Control Chart), but consists of a combinational circuit with a downstream flip-flop. The internal state logic is fully implemented by the two sub-modules `ASSEMBLE_LWORD_FROM_WORDS` and `E_D_FF_ANY`.

Application Scenarios

- **Industrial Data Acquisition** – Combining four 16-bit sensor values (e.g., temperature, pressure, flow rate, level) into a single 64-bit data packet.
- **Communication Interfaces** – Processing separately arriving 16-bit data blocks for a 64-bit interface (e.g., Modbus register ⟶ OPC UA).
- **Bit-Parallel Processing** – Combining four microcontroller registers into a single large register for advanced logic applications.

Comparison with Similar Modules

Module	Description
`ASSEMBLE_AL_FROM_BYTES`	Combines multiple 8-bit values into an LWORD
`ASSEMBLE_AL_FROM_DWORDS`	Combines two 32-bit double words into a 64-bit word
`ASSEMBLE_AL_FROM_AW` (this one)	Combines four 16-bit words into an LWORD

All these building blocks follow the same principle but differ in the word width of the input data and the number of sockets required.

Conclusion

ASSEMBLE_AL_FROM_AW` is a specialized function block for concatenating four 16-bit words into a single 64-bit word. Clocked output via a D flip-flop ensures consistent data transmission. Thanks to its adapter-based interface, it integrates seamlessly into modular 4diac projects and simplifies word-to-long-word conversions.

Introduction

The function block **ASSEMBLE_AL_FROM_AX** is used to combine up to 64 Boolean signals from **AX adapters** (type: `adapter::types::unidirectional::AX`) into a single **LWORD** value and output it via an **AL adapter** (type: `adapter::types::unidirectional::AL`). The block encapsulates the logic for bit combination and provides the result stably as soon as one of the input bits returns an event.

Interface Structure

Event Inputs

The function block does not have traditional event inputs (EVENT). Event control is handled indirectly via the **AX adapters (sockets)**. Each socket `BIT_00` ... `BIT_63` can receive a triggering event (E1).

Name	Type	Description
`BIT_00` ... `BIT_63`	AX adapter	Event from an external Boolean source that triggers the assembly of the LWORD

Event Outputs

No traditional event outputs. The output of the assembled LWORD is event-driven via the **AL adapter (plug)** `OUT`.

| Name | Type | Description | | |—|—|—————| | `OUT` | AL Adapter | Provides the composite LWORD when the internal flip-flop is clocked |

Data Inputs

Each AX adapter carries a Boolean data value (D1). These are used as input bits for the LWORD.

Name	Type	Description
`BIT_00.D1` ... `BIT_63.D1`	BOOL (via adapter)	Boolean signal for bits 0 ... 63

Data Outputs

The combined result is output as a 64-bit word via the AL adapter.

Name	Type	Description
`OUT.D1`	LWORD (via adapter)	Combined LWORD from the 64 Boolean inputs

Adapter

Type	Direction	Name	Description
`adapter::types::unidirectional::AX`	Socket (input)	`BIT_00` ... `BIT_63`	Boolean Input Adapter
`adapter::types::unidirectional::AL`	Plug (Output)	`OUT`	LWORD Output Adapter

Functionality

1. **Event Reception**: As soon as an event arrives at one of the 64 AX adapters (sockets) (at its E1), an internal REQ event is sent to the function block `ASSEMBLE_LWORD_FROM_BOOLS`.
2. **Bit Assembly**: The internal function block `ASSEMBLE_LWORD_FROM_BOOLS` receives the 64 Boolean values from the data ports `BIT_00.D1` ... `BIT_63.D1` and assembles them into an LWORD value. Each input is assigned a corresponding bit (0 for BIT_00, 1 for BIT_01, ... 63 for BIT_63).
3. **Central Storage (Flip-Flop)**: The assembled LWORD is passed to the data input of an **E_D_FF_ANY** (flip-flop). The result event (CNF) of `ASSEMBLE_LWORD_FROM_BOOLS` clocks the flip-flop. This sets the current LWORD value at the flip-flop's output Q.
4. **Output**: The stored value is made available as an LWORD via the AL plug `OUT`. Simultaneously, an event is generated at the flip-flop's output (EO), which triggers the connected AL adapter input (E1).

The logic operates **event-driven**: The output is only updated when any input bit changes (via the event). This saves processing power and ensures a stable output.

Technical Features

- **Full Bit Mapping**: All 64 bits of an LWORD are derived from individual Boolean adapters. Exactly 64 sockets are required – no gaps.
- **Event Synchronization**: An event from *any* bit adapter triggers a complete recalculation of the LWORD. It is not necessary to update all inputs simultaneously.
