- **Flip-Flop Buffering**: The composite value is buffered, so the output remains stable even if the inputs fluctuate during processing.
- **Adapter-based interface**: The inputs and outputs are implemented as standardized 4diac adapters, enabling easy chaining with other adapter-based function blocks.
- **Packages**: The function block is organized in the package `adapter::assembling`.

State overview

The function block does not have an explicit state machine. The internal logic operates as a combination of two components:

- **ASSEMBLE_LWORD_FROM_BOOLS**: Stateless – executes the assembly on every request.
- **E_D_FF_ANY**: Has two states: stored value (Q) and current data input (D). The state changes on every rising edge at the CLK input.

Event-driven behavior:

- **Wait for event**: No calculation is performed; the output remains unchanged.
- **Event Arrived**: Flip-flop assembly + clocking ⟶ output is updated.

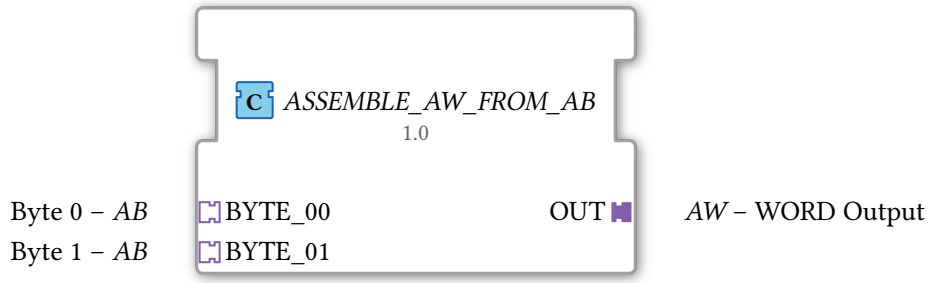
Application Scenarios

- **Parallel Digital Inputs**: Combines 64 digital sensors or switches into a machine-readable LWORD for easy further processing.
- **Bit-Oriented Controls**: In applications where many binary status messages (e.g., error bits, position feedback) need to be bundled.
- **Fieldbus Communication**: An LWORD can be efficiently transmitted via PROFINET, EtherCAT, or similar; this function block converts the individual bits into the compact data format.
- **Adapter-Based Module Libraries**: In modular control architectures based on standardized adapters, this function block can serve as a universal "bit collector."

Comparison with Similar Function Blocks

Function Block	Number of Inputs	Output Type	Special Feature
ASSEMBLE_AL_FROM_AX	64 BOOL (AX)	LWORD (AL)	Adapter-based with flip-flop buffering
`ASSEMBLE_DWORD_FROM_BOOLS`	32 BOOL	DWORD	Classic data input/output, without adapter
`ASSEMBLE_WORD_FROM_BOOLS`	16 BOOL	WORD	As above, for 16-bit word
`DISASSEMBLE_AL_TO_AX`	1 LWORD (AL)	64 AX	Counterpart: Decomposes an LWORD into individual BOOL adapters

The key difference lies in the **adapter interface** and the **buffer buffering** provided by the flip-flop, which ensures robust behavior in event-driven environments.



Conclusion

The **ASSEMBLE_AL_FROM_AX** function block is a powerful tool for creating a compact 64-bit LWORD from 64 distributed Boolean signals. Its adapter-based interface and internal flip-flop buffering make it particularly suitable for clean, event-driven, and modular automation solutions. Full bit coverage without scaling issues makes it a universal solution for applications that need to bundle many digital inputs.

ASSEMBLE_AW_FROM_AB

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASSEMBLE_AW_FROM_AB** is used to combine two unidirectional byte adapters (type `AB`) into a unidirectional word adapter (type `AW`). It combines the data from two byte inputs into a word output, with event logic ensuring that output occurs only when the information is updated.

Interface Structure

The function block has no direct event or data inputs/outputs, but communicates exclusively via adapter interfaces:

Adapter (Plugs – Output)

Name	Type	Direction	Description
OUT	`adapter::types::unidirectional::AW`	Plug	WORD output (16-bit)

Adapter (Sockets – Inputs)

Name	Type	Direction	Description
BYTE_00	`adapter::types::unidirectional::AB`	Socket	Byte 0 (low-order byte)
BYTE_01	`adapter::types::unidirectional::AB`	Socket	Byte 1 (higher-order byte)

Note: Adapters of type `AB` and `AW` are unidirectional. Each adapter contains the signals `E1` (socket/plug event output – internally connected) and `D1` (data signal).

Functionality

The function block (FB) is based internally on two sub-components:

1. **`ASSEMBLE_WORD_FROM_BYTES`** – a predefined assembler that combines two input bytes into a WORD.
2. **`E_D_FF_ANY`** – a D flip-flop that temporarily stores the combined value and passes it on at a clock event.

Process:

- Each incoming event (`E1`) from a BYTE adapter (BYTE_00 or BYTE_01) triggers the assembler (`REQ`).
- The assembler combines the current data from both BYTE inputs into a WORD.

The following applies:
OUT.WORD = (BYTE_01.D1 << 8) | BYTE_00.D1`

- After successful combination, the assembler sends an acknowledgment event (`CNF`).
- This event clocks the D flip-flop (`CLK`), which takes the current WORD value.
- The flip-flop output (`Q`) is continuously passed to the OUT adapter (`D1`).
- The flip-flop's output event (`EO`) activates `OUT.E1`, informing the receiving component about the updated WORD output.

Important feature:

Since both BYTE events lead to the same `REQ` input in the assembler, assembly is re-executed with each event from either input. The output value is therefore always generated from the currently present byte values. The D flip-flop ensures a stable output until the next assembly event arrives.

Important feature: Since both BYTE events lead to the same `REQ` input in the assembler, the assembly is re-executed with each event from either input.

Technical Features

- **Pure Adapter Communication:** The function block (FB) has no conventional input/output variables; all data and event transmission occurs via unidirectional adapters.
- **Event Synchronization:** The single-step assembly process avoids race situations, as the flip-flop only updates the output after successful computation.
- **Reusability:** The FB can be embedded in any environment that supports unidirectional `AB`/`AW` adapters.

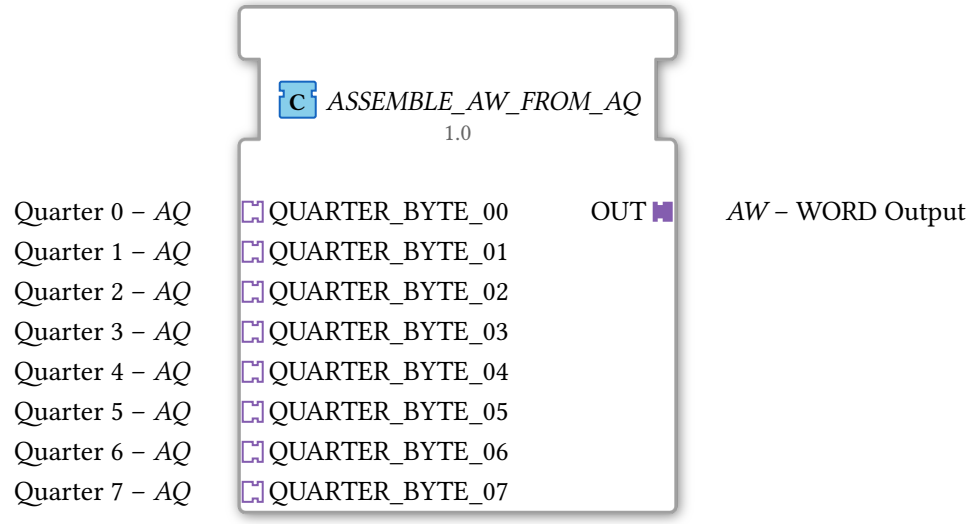
State Overview

The FB does not have an explicit state diagram, as its internal logic operates purely event-driven. Essentially, the following operating states can be distinguished:

- **Ready:** No event is pending; the output holds the last stored WORD value.
- **Assemble:** An incoming event from a BYTE adapter starts the calculation.
- **Output:** After successful assembly, the new WORD value is transferred to the flip-flop, and the output event is triggered.

Application Scenarios

- **Protocol Conversion:** Combining two serial byte streams into a WORD data word for a subsequent processing module.
- **Sensor Fusion:** Combining two 8-bit sensor data (e.g., temperature and humidity) into a 16-bit value.
- **Hardware Control:** Generating a 16-bit output signal from two separate 8-bit register values.



Comparison with Similar Function Blocks

- **`ASSEMBLE_WORD_FROM_BYTES`** – pure assembler without memory. It expects discrete data inputs and outputs the result immediately (provided the event and data are supplied synchronously).
- **`SPLIT_BYTE_FROM_WORD`** – inverse function (WORD -> two BYTEs); symmetrically structured, also uses unidirectional adapters.
- **Custom Function Block with Memory:** This function block integrates the flip-flop, so the output remains stable until new data arrives – unlike function blocks that recalculate with each event but offer no intermediate storage.

Conclusion

The **ASSEMBLE_AW_FROM_AB** function block offers a reliable and elegant way to combine two unidirectional BYTE adapters into a WORD output. The combination of assembly and flip-flop logic creates a stable output that is only updated when data actually changes. Its simple adapter interface makes it flexible for use in modular control architectures according to IEC 61499.

ASSEMBLE_AW_FROM_AQ

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASSEMBLE_AW_FROM_AQ` combines eight individual **AQ (Quarter)** adapters into a single **AW (Word)** adapter. Each quarter represents a 4-bit data packet (half a byte). The block assembles these eight quarter data packets—a total of 32 bits—into a complete word (WORD, 32 bits) and makes it available via a single AW output adapter. Typical applications include the reconstruction of wide data buses from serially or partially arriving fragments.

Interface Structure

The function block has only **adapter interfaces**: There are no direct event or data inputs/outputs at the top level. All communication takes place via the connected adapters.

Event Inputs

- No direct event inputs.
- Events are received via the sockets of the **AQ adapters** (each AQ adapter provides an event output `E1`).

Event Outputs

- No direct event outputs.
- The output event is provided via the **AW adapter** (plug `OUT`) as event `E1`.

Data Inputs

- No direct data inputs.
- The data to be processed is read in via the **AQ adapters** as data input `D1` (4 bytes each).

Data Outputs

- No direct data outputs.
- The compound word (4 bytes) is output via the **AW adapter** as data output `D1`.

Adapter

Name	Type	Direction	Comment
`OUT`	adapter::AW	Plug	Word output (4 bytes)
`QUARTER_BYTE_00`	adapter::AQ	Socket	Quarter 0 (least significant)
`QUARTER_BYTE_01`	adapter::AQ	Socket	Quarter 1
`QUARTER_BYTE_02`	adapter::AQ	Socket	Quarter 2
`QUARTER_BYTE_03`	adapter::AQ	socket	Quarter 3
`QUARTER_BYTE_04`	adapter::AQ	socket	Quarter 4
`QUARTER_BYTE_05`	adapter::AQ	socket	Quarter 5
`QUARTER_BYTE_06`	adapter::AQ	socket	Quarter 6
`QUARTER_BYTE_07`	adapter::AQ	socket	Quarter 7 (highest value)

Functionality

The FB contains two internal function blocks:

1. **`ASSEMBLE_WORD_FROM_QUARTERS`**: A specialized assembler that combines the data from all eight quarter-time inputs (4 bytes each) in the order 00 (LSB) to 07 (MSB) into a 32-bit word.
2. **`E_D_FF_ANY`**: An edge-triggered D flip-flop that buffers the assembled word and outputs it at `Q`.

Process:

- As soon as a connected AQ adapter sends an event at its output `E1`, this event is forwarded to the `REQ` input of the assembler. All eight AQ adapters are connected to the same `REQ`, so each incoming event (regardless of the sender) triggers a new processing step.
- The assembler processes the current data from all eight quarters and places the result at the data output.
- After the calculation is complete, the assembler sends an acknowledgment event (`CNF`), which triggers the clock input (`CLK`) of the D flip-flop.

- The flip-flop receives the calculated value and passes it stably to `Q`. The OUT adapter then makes both the event `E1` and the data value `D1` available on the output side.
- After the calculation is complete, the assembler sends an acknowledgment event (`CNF`), which triggers the clock input (`CLK`) of the D flip-flop. This structure ensures that the output word is only updated after a complete calculation has been performed—regardless of which quarter was updated last.

Technical Features

- **Flip-Flop Intermediate Storage**: The use of a D flip-flop prevents glitches or incomplete data transmission if multiple quarters are updated in rapid succession. The output only changes when the assembler has calculated a new, valid value.
- **Adapter-Based Interface**: All inputs and outputs are handled via adapters, making the function block particularly suitable for modular, typed data flow architectures in 4diac.
- **Synchronous Processing**: Processing is triggered by each incoming event of a quarter, but only generates an output event when the calculation is complete.
- **Adapter-Based Interface**:

Status Overview

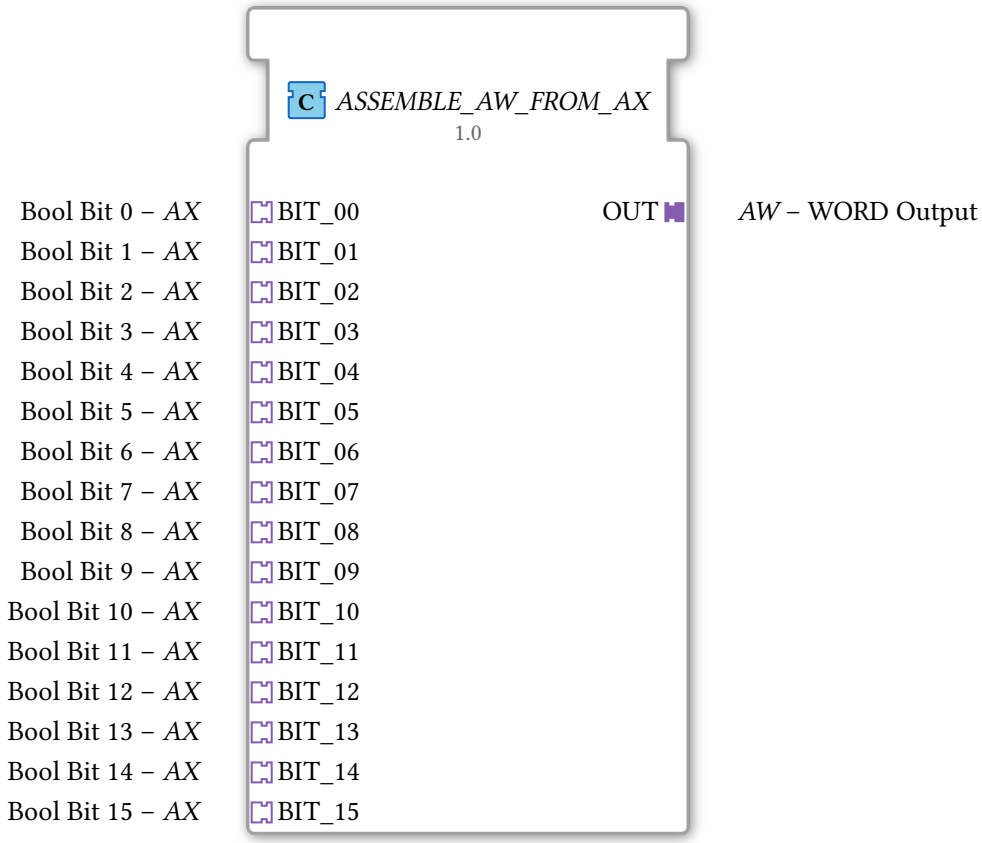
The function block (FB) does not have its own execution control chart (ECC) – the internal logic is implemented entirely by the included function blocks `ASSEMBLE_WORD_FROM_QUARTERS` and `E_D_FF_ANY`. The function block therefore behaves like a combinational circuit with an edge-triggered memory stage.

Application Scenarios

- **Reconstruction of Wide Data Paths**: In automation technology, data is often transmitted in small packets ("nibbles"), e.g., across multiple parallel I/O modules. The FB reassembles these into a complete 32-bit value.
- **Serial-Parallel Conversion**: If a sensor or actuator delivers its data in 4-bit quads (e.g., via asynchronous interfaces), the FB can buffer the incoming fragments and combine them into a consistent total value.
- **Data Consolidation**: In hierarchical control systems where multiple sub-modules each provide a quarter value, this function block (FB) can centrally consolidate the values.

Comparison with Similar Function Blocks

- **`ASSEMBLE_BYTE_FROM_NIBBLES`**: Combines two half-bytes into one byte (8 bits). This FB operates at the next higher level with 8 quarters (32 bits).
- **Simple Data Converters**: Converters like `WORD_TO_BYTE` or `BYTE_TO_NIBBLE` usually operate without intermediate storage and event handling. `ASSEMBLE_AW_FROM_AQ` offers event-driven, stable forwarding with optional storage.



Conclusion

The function block `ASSEMBLE_AW_FROM_AQ` provides a robust and flexible solution for generating a consistent 32-bit word from eight independent quarter data points (4 bits each). Thanks to its adapter-based interfaces and integrated D flip-flop, it is particularly well-suited for real-time applications where data packets arrive asynchronously and must be reliably combined into a single value.

ASSEMBLE_AW_FROM_AX

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASSEMBLE_AW_FROM_AX` combines 16 Boolean signals, provided by separate AX adapters, into a 16-bit word (WORD) and outputs it via an AW adapter. It enables the conversion of a discrete group of digital signals into a uniform data word value for further processing.

Interface Structure

Event Inputs

No direct event inputs. Events are received via the 16 AX adapters (sockets): Each AX adapter triggers an event (`E1`) upon a data change, which initiates processing.

Event Outputs

No direct event outputs. The compound word is output via the AW adapter (Plug). The output adapter releases the data value as soon as it receives an event (`E1`) from the internal flip-flop.

Data Inputs

No direct data inputs. The 16 individual values (BOOL) are read in via the AX adapters (data output `D1`).

Data Outputs

No direct data outputs. The resulting 16-bit word (WORD) is output via the AW adapter (data input `D1`).

Adapters

Type	Name	Description
Socket (Input)	`BIT_00`	AX Adapter, Bool Bit 0
Socket (Input)	`BIT_01`	AX Adapter, Bool Bit 1

Socket (Input)	BIT_02	AX Adapter, Bool Bit 2
Socket (Input)	BIT_03	AX Adapter, Bool Bit 3
Socket (Input)	BIT_04	AX Adapter, Bool Bit 4
Socket (Input)	BIT_05	AX Adapter, Bool Bit 5
Socket (Input)	BIT_06	AX Adapter, Bool Bit 6
Socket (Input)	BIT_07	AX Adapter, Bool Bit 7
Socket (Input)	BIT_08	AX Adapter, Bool Bit 8
Socket (Input)	BIT_09	AX Adapter, Bool Bit 9
Socket (Input)	BIT_10	AX Adapter, Bool Bit 10
Socket (Input)	BIT_11	AX Adapter, Bool Bit 11
Socket (Input)	BIT_12	AX Adapter, Bool Bit 12
Socket (Input)	BIT_13	AX Adapter, Bool Bit 13
Socket (Input)	BIT_14	AX Adapter, Bool Bit 14
Socket (Input)	BIT_15	AX Adapter, Bool Bit 15
Plug (Output)	OUT	AW Adapter, WORD Output

Functionality

1. **Input Signal Acquisition**: Each of the 16 AX adapters (BIT_00 to BIT_15) provides a Boolean value via its data channel (D1). As soon as the value of one of these adapters changes, it sends an event via its output E1.
2. **Combination**: The events from all 16 adapters are fed to the input REQ of an internal module ASSEMBLE_WORD_FROM_BOOLS. This module reads the current Boolean values from all 16 channels and combines them into a 16-bit word (WORD).
3. **Synchronization**: The completed word is passed to an edge-triggered D flip-flop (E_D_FF_ANY). The flip-flop receives the value at its D input as soon as it receives a clock signal (from the output CNF of the merge block).
4. **Output**: After successful transfer, the flip-flop outputs a clock signal at its output EO and places the stored word at its Q output. This event triggers the AW adapter OUT, which makes the WORD available on its data channel (D1).

Technical Features

- **Use of a flip-flop**: Output occurs only after a complete merge cycle. This prevents inconsistent or fluctuating data – the output remains stable until a new event occurs.
- **No state machine**: The function block is purely event-driven and has no inherent state; its behavior is determined by the internal function blocks ASSEMBLE_WORD_FROM_BOOLS and E_D_FF_ANY.
- **Adapter interface**: Both the inputs and the output are implemented as adapters. This allows for flexible reuse and encapsulation of the signal types.

State overview

The function block does not contain an explicit state machine. The internal D flip-flop E_D_FF_ANY has two states (Q = 0 or Q = 1) that store the current data value. The flip-flop's output is updated only on a rising edge at the clock input.

Application Scenarios

- **Bundling of Discrete Signals**: In automation technology, 16 individual digital sensors or switches (e.g., limit switches, pushbuttons) are often required. This function block combines these into a single word, which can be used via a fieldbus or as an input for a higher-level controller.
- **Data Preparation for Communication**: Before transmission via a network adapter (e.g., PROFINET, EtherCAT), multiple binary signals must be packed into a single data word.

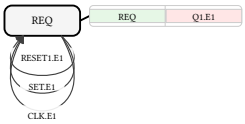
- **Signal Register**: The component can be used as a simple 16-bit register that buffers the current state of all inputs and updates them only when changes occur.

Comparison with Similar Components

- **Classic Boolean-to-WORD Components**: Standard components often combine Boolean inputs directly into an integer type, but without an adapter interface. `ASSEMBLE_AW_FROM_AX` uses an adapter, which enables clearly separated signal and event transmission and simplifies reuse in modular architectures.
- **Adapter-Based Alternatives**: Similar components exist for other word sizes (e.g., BYTE, DWORD) or with additional filtering capabilities. This component focuses on the essentials and uses a flip-flop output for clean synchronization.

Conclusion

The `ASSEMBLE_AW_FROM_AX` function block offers a clean, synchronized way to combine 16 Boolean signals (via AX adapter) into a 16-bit word (via AW adapter). The combination of the merging block and the edge-triggered flip-flop ensures stable output and is particularly suitable for use in time-critical or signal processing environments.



2.1.11.5 Numeric Index (adapter)

Here you will find all exercises from the `adapter` workspace, listed in ascending order. ...

AX_FB_RS_T_FF

ECC: AX_FB_RS_T_FF

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AX_FB_RS_T_FF** implements a reset-dominant bistable latch with an additional toggle function. The block communicates via standardized adapter interfaces and enables flexible integration with other components.

Interface Structure

The block has no direct event or data inputs/outputs at the FB level. All communication takes place via **adapters**, which in turn provide their own event and data channels.

Event Inputs

The following adapter events trigger processing:

- **SET.E1** – Event to set the output
- **RESET1.E1** – Event to reset the output (priority)
- **CLK.E1** – Event for the clock signal, which triggers a toggle on its rising edge

Event Outputs

- **Q1.E1** – Event sent after each execution of the algorithm (regardless of the result)

Data Inputs

The following data values are received via the adapters:

- **SET.D1** (BOOL) – Set input: `TRUE` ⟶ sets Q1 to `TRUE`
- **RESET1.D1** (BOOL) – Reset input: `TRUE` ⟶ sets Q1 to `FALSE` (has priority over SET)
- **CLK.D1** (BOOL) – Clock input: Edge transition from `FALSE` to `TRUE` triggers toggle

Data Outputs

- **Q1.D1** (BOOL) – Output value of the flip-flop

Adapter

Adapter	Type	Role	Comment
`SET`	adapter::types::unidirectional::AX	Input	Set
`RESET1`	adapter::types::unidirectional::AX	Input	Reset
`CLK`	adapter::types::unidirectional::AX	Input	Clock
`Q1`	adapter::types::unidirectional::AX	Output	Output

All adapters are of type `AX` (unidirectional) and each provides one event channel (`.E1`) and one data channel (`.D1`).

| `Q1` | | |] ...

Functionality

The module operates according to the following deterministic algorithm, which is executed upon each incoming event (SET, RESET1, or CLK):

1. **Priority: Reset Dominates**

If `RESET1.D1 = TRUE` is present, `Q1.D1` is set to `FALSE`.

1. **Otherwise: Set Takes Precedence**

If only `SET.D1 = TRUE` (and `RESET1.D1 = FALSE`) is present, `Q1.D1` is set to `TRUE`.

1. **Otherwise: Toggle on rising edge**

If neither RESET1 nor SET is present, the program checks whether `CLK.D1 = TRUE` was present in the previous cycle and `FALSE` in the previous cycle (rising edge). In this case, the output `Q1` is inverted (`NOT Q1.D1`).

1. **Edge Detection**

The internal variable `EDGE` stores the last value of `CLK.D1`. It is updated after each iteration (`EDGE := CLK.D1`). This detects the rising edge as soon as `CLK.D1` transitions from `FALSE` to `TRUE`.

After the algorithm executes, the event `Q1.E1` is always sent.

Technical Features

- **Adapter-Based Communication**: The device uses adapters exclusively for input and output, facilitating loose coupling and reusability in different contexts.
- **Reset Dominance**: The reset input takes precedence over the set input. This corresponds to the typical behavior of an RS flip-flop with reset priority.
- **Edge-Triggered Toggle**: The toggle occurs only on a rising edge of the clock signal, not on a static high level. Internal edge detection prevents multiple switching operations during a sustained `TRUE` event at the clock.
- **Single-State ECC**: The function block has only one state (`REQ`). All transitions return to this state, enabling continuous processing of each incoming event without additional state logic.

State Overview

The function block is implemented as a **Basic FB** with the following ECC:

State	Action	Output
`REQ`	Execute algorithm `REQ`	`Q1.E1` (after algorithm)

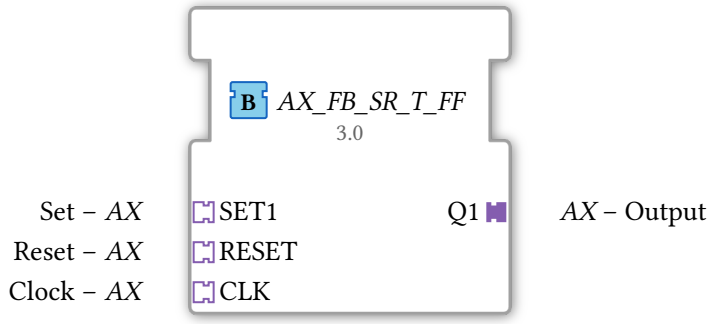
Transitions:

- From `REQ` to `REQ` at **RESET1.E1**
- From `REQ` to `REQ` at **SET.E1**
- From `REQ` to `REQ` at **CLK.E1**

There are no other states. The algorithm is always executed in the same context.

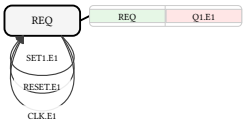
Application Scenarios

- **Safety Controllers**: Reset-dominant behavior is useful when a fault state (reset) must have the highest priority, e.g., in emergency stop circuits.
- **Toggle Function with Clock**: Switching between two states on each clock pulse, e.g., for a flashing light or pulse counter.
- **Hybrid Circuits**: Combines set/reset and toggle functionality in a single component, saving space and logic.



Comparison with Similar Components

- **RS Flip-Flop (Reset-Dominant)**: Behaves like a conventional RS flip-flop with reset priority, but does not offer toggle functionality.
- **T Flip-Flop**: Can only toggle; it does not have separate set/reset inputs.
- **JK Flip-Flop**: Offers set, reset, and toggle functionality, but with different priority logic (no explicit reset dominance).
- **AX_FB_RS_T_FF** combines reset dominance and edge-triggered toggle functionality in a single component, utilizing adapters for platform-independent connectivity.



Conclusion

The **AX_FB_RS_T_FF** is a versatile, adapter-based function block for bistable circuits with reset-dominant logic and an integrated toggle function. It can be easily integrated into modular automation systems using adapters. Edge detection and clear input priority make it robust and reliable for typical control tasks.

AX_FB_SR_T_FF

ECC: AX_FB_SR_T_FF

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_FB_SR_T_FF** implements a bistable, set-dominant latch (SR flip-flop) combined with a toggle function. All communication takes place via adapter interfaces that bundle both event and data signals.

Interface Structure

The block has no direct event or data inputs/outputs, but only adapters. These adapters each provide one event (`E1`) and one data value (`D1`) of type `BOOL`.

Event Inputs

No direct event inputs. The following adapters provide the trigger mechanism via their event `E1`:

- **SET1** – Set event
- **RESET** – Reset event
- **CLK** – Clock event (for toggle)

Event Outputs

No direct event outputs. The adapter **Q1** provides confirmation of the output change via its event `E1`.

Data Inputs

The three input adapters each provide a data value `D1` (BOOL):

- **SET1.D1** – Set signal (active when TRUE)
- **RESET.D1** – Reset signal (active when TRUE)
- **CLK.D1** – Clock signal (rising edge triggers toggle)

Data Outputs

The output adapter **Q1** outputs the current state of the latch as a BOOL value via **Q1.D1**.

Adapters

Adapter	Type	Direction	Description
`SET1`	`adapter::types::unidirectional::AX`	Socket (Input)	Set Input
`RESET`	`adapter::types::unidirectional::AX`	Socket (Input)	Reset Input
`CLK`	`adapter::types::unidirectional::AX`	Socket (Input)	Clock Input for Toggle
`Q1`	`adapter::types::unidirectional::AX`	Plug (Output)	Latch Output

Functionality

The function block operates according to the following priority-controlled algorithm:

1. **Set Dominance**: If `SET1.D1 = TRUE` is active, the output `Q1.D1` is set to `TRUE`.
2. **Reset**: Otherwise, if `RESET.D1 = TRUE` is active, `Q1.D1` is set to `FALSE`.
3. **Toggle**: If neither the set nor the reset operation is active, and a **rising edge** (transition from FALSE to TRUE) is detected at the clock input `CLK.D1`, the current output value is toggled (`Q1.D1 := NOT Q1.D1`).

The edge detection is performed by the internal variable `EDGE`: It stores the previous value of `CLK.D1`. The algorithm checks whether `CLK.D1 = TRUE` and `EDGE = FALSE` are active. After the calculation, `EDGE` is set to the current `CLK.D1`.

Technical Features

- **Pure Adapter Interface**: The module does not use traditional event/data ports, but rather encapsulates the signals in adapters. This allows for flexible reuse and encapsulation of interfaces.
- **Set Dominant Behavior**: Simultaneous setting and resetting always results in the output being set.
- **Toggle with Upward Edge**: The toggle function reacts only to rising edges of the clock signal, not to static levels.
- **Single ECC State**: The ECC consists only of the state `REQ`. Each incoming event (`SET1.E1`, `RESET.E1`, or `CLK.E1`) immediately triggers the re-execution of the algorithm.

State Overview

The function block has only one state:

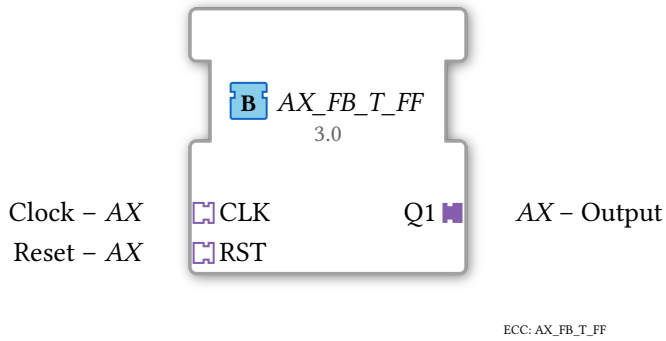
- **REQ** – Waits for incoming events. The algorithm `REQ` is executed upon each event. All transitions return to `REQ`.

Internally, the variable `EDGE` is used for edge detection; it is part of the internal state but is not visible as an ECC state.

Application Scenarios

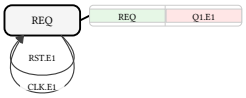
- **Priority Control**: When a set pulse should always take precedence over a reset pulse, e.g., in safety circuits.
- **Combined Set/Reset and Toggle Function**: For applications where an output can be set/reset by external signals and also toggled by a push button (e.g., manual operation with priority).
- **Adapter-Based Systems**: In a modular environment where interfaces are standardized via adapters (e.g., AX adapter system).

Comparison with Similar Function Blocks



- **SR Flip-Flop (Set-Dominant)** – pure set/reset function without toggle. This function block extends this by adding the toggle capability.

- **T Flip-Flop** – toggle only (no set/reset). AX_FB_SR_T_FF offers additional set and reset priority.
- **Reset-Dominant SR Flip-Flops** – resets in case of conflicts. This function block behaves in the opposite way.



Conclusion

The **AX_FB_SR_T_FF** combines a set-dominant SR latch with an edge-triggered toggle function in a compact module. Its exclusive use of adapters makes it ideal for modular, adapter-based automation solutions. Clear prioritization and edge detection provide predictable and robust switching behavior.

AX_FB_T_FF

ECC: AX_FB_T_FF

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AX_FB_T_FF** implements a clock-edge-triggered toggle flip-flop (T-FF). It toggles its output state on each active clock edge and can be reset asynchronously.

Inputs and outputs are exclusively via adapters of type `AX`, which transmit both an event and a Boolean data value.

Interface Structure

The function block has no direct event or data interfaces.

All communication takes place via **adapters** (plugs and sockets).

Event Inputs

None (events are received via adapters `CLK` and `RST`).

Event Outputs

None (Events are sent via adapter `Q1`).

Data Inputs

None (Data is received via adapters `CLK` and `RST`).

Data Outputs

None (Data is sent via adapter `Q1`).

Adapter

Direction	Name	Type	Description
Socket (Input)	`CLK`	`adapter::types::unidirectional::AX`	Clock signal – with each incoming event (E1), the Boolean value (D1) is evaluated as the clock level.
Socket (Input)	`RST`	`adapter::types::unidirectional::AX`	Reset – with an incoming event (E1), the output is set to FALSE, independent of the clock (asynchronous reset).
Plug (Output)	`Q1`	`adapter::types::unidirectional::AX`	Output – with each clock change or reset, an event (E1) is triggered and the current Boolean value (D1) is sent.

The adapters of type `unidirectional::AX` contain internally:

- An event (E1)
- A data (D1) of type `BOOL`

Functionality

The device operates as a **toggle flip-flop with positive edge detection**.
It has an internal memory `EDGE` that stores the last clock level.
Algorithm (in REQ state):

1. When a reset event arrives at `RST.E1`:

- Output `Q1.D1` is set to `FALSE`.
- Output event `Q1.E1` is triggered.

1. Otherwise, if a clock event arrives at `CLK.E1`:

- Check if the current clock level is `CLK.D1 = TRUE` and the previous level is `EDGE = FALSE` (i.e., a rising edge).
- If so: `Q1.D1` is inverted (`NOT Q1.D1`).
- Regardless of the edge, `EDGE := CLK.D1` is set (level marker).
- Output event `Q1.E1` is triggered.

1. If the output remains unchanged when `RST.E1` or `CLK.E1` does not arrive, no event is sent.

Technical Features

- **Adapter-based interface**: The module uses adapters exclusively, which facilitates modular coupling with other modules of the same type.
- **Edge detection**: The internal variable `EDGE` implements simple positive edge detection. A key change from 0⟶1 triggers the toggling; a constant high level triggers only once.
- **Asynchronous reset**: The reset takes precedence over the clock edge – it immediately resets the output, even if a clock event is simultaneously occurring.
- **Only one ECC state**: The entire process takes place in the state `REQ`. Both transitions (`CLK.E1` and `RST.E1`) return to this state.

State Overview

The ECC consists of a single state, `REQ`.

Each incoming event pulse (via `CLK.E1` or `RST.E1`) triggers the execution of the algorithm `REQ` and an immediate output event on `Q1.E1`.

Current State	Incoming Event	Next State	Executed Action
REQ	`RST.E1`	REQ	RESET: Q1.D1 = FALSE
REQ	`CLK.E1`	REQ	Toggle on rising edge and update EDGE

No other states or dwell times.

Application Scenarios

- **Clock-Controlled State Transition**: Switching an output on each rising edge of a clock signal (e.g., for frequency dividers or counters).
- **Key Debouncing**: Combined with a debouncing component, the flip-flop can generate a stable state transition with each key press.
- **Signal Switching**: Switching a signal on and off using repeated pulses.
- **Control in Automation Systems**: E.g., switching between two operating modes.

Comparison with Similar Components

- **Standard T-FF (e.g., `F_TRIG`/`R_TRIG`)**: These components only detect edges but do not toggle the output. `AX_FB_T_FF` combines edge detection and toggle functionality.
- **SR Flip-Flop (Set/Reset)**: Unlike the SR flip-flop, the T flip-flop has only one reset input and toggles on every clock cycle instead of being controlled by separate set and reset signals.
- **Adapter-Based Variants**: Other T flip-flops in 4diac often use direct inputs/outputs. This component allows loose coupling via adapters, which increases reusability.

Conclusion

The `AX_FB_T_FF` is a compact and flexible function block that implements a toggle flip-flop with positive edge detection and asynchronous reset.

Its pure adapter interface makes it particularly well-suited for modular, adapter-based designs where data and event transmission occur over a single channel.

Its simple logic and minimal state machine make it reliable and easy to understand.

AB_AND_2

• – ◦ • – ◦ • – ◦ •

Introduction

AB_AND_2 is a generic function block for the bitwise AND operation across 2 input values of type `BYTE` (8-bit bit pattern (byte)). Unlike the Boolean operation on single truth values (as in the `AX_AND` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs
No event inputs available

Event Outputs
No event outputs available

Data Inputs
No direct data inputs available

Data Outputs
No direct data outputs available

Adapters
Input Adapters:

- **IN1**: AND input 1 (Type: adapter::types::unidirectional::AB)
- **IN2**: AND input 2 (Type: adapter::types::unidirectional::AB)

Output Adapter:

- **OUT**: AND result (Type: adapter::types::unidirectional::AB)

Functionality
As soon as an event arrives at one of the 2 input adapters (`IN1` … `IN2`), the block combines the bit patterns of all 2 inputs bitwise using **AND** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits set (identity element of the AND operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features
- **Generic function block**: The FB is defined as a generic type (`GEN_AB_AND`) and covers all arities (2 to 4 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_AND` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AB` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

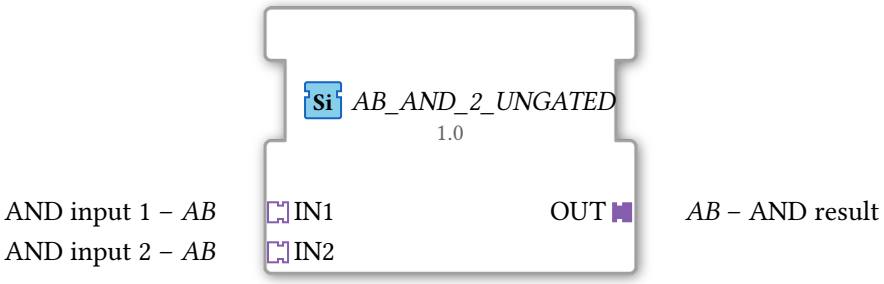
State Overview
Since this is a combinational logic block, AB_AND_2 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared AND operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks
Unlike `AX_AND_2`, which combines individual Boolean truth values, `AB_AND_2` operates on the full bit pattern of a `BYTE` value. Compared to the standard block AND_2, `AB_AND_2` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AB_AND_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AB_AND_2 offers a reliable, generic implementation of the bitwise AND function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AB_AND_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AB_AND_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AB_AND_2_UNGATED is a generic function block for the bitwise AND operation across 2 input values of type `BYTE` (8-bit bit pattern (byte)). Unlike the Boolean operation on single truth values (as in the `AX_AND` blocks), every bit of the data word is combined independently here.

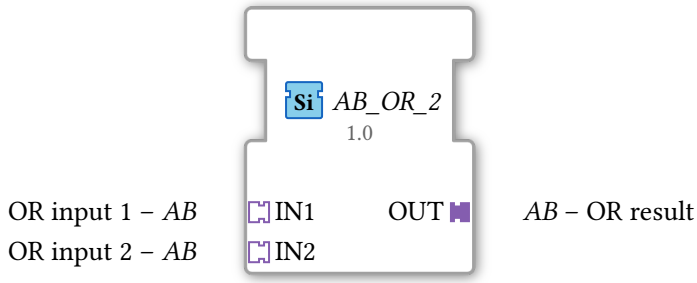
- **`AB_OR_10`**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AB_OR_10_UNGATED offers a reliable, generic implementation of the bitwise OR function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AB_OR_2

• – ◦ • – ◦ • – ◦ •

Introduction

AB_OR_2 is a generic function block for the bitwise OR operation across 2 input values of type `BYTE` (8-bit bit pattern (byte)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AB)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AB)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AB)

Functionality

As soon as an event arrives at one of the 2 input adapters (`IN1` … `IN2`), the block combines the bit patterns of all 2 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AB_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AB` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AB_OR_2 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

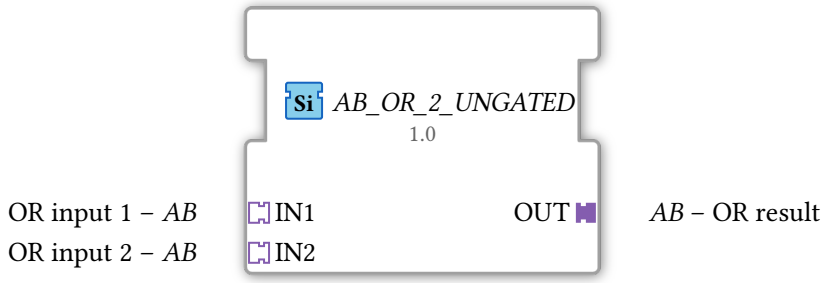
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_2`, which combines individual Boolean truth values, `AB_OR_2` operates on the full bit pattern of a `BYTE` value. Compared to the standard block OR_2, `AB_OR_2` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AB_OR_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AB_OR_2 offers a reliable, generic implementation of the bitwise OR function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AB_OR_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AB_OR_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AB_OR_2_UNGATED is a generic function block for the bitwise OR operation across 2 input values of type `BYTE` (8-bit bit pattern (byte)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

- **IN6**: OR input 6 (Type: adapter::types::unidirectional::AB)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AB)

Functionality

As soon as an event arrives at one of the 6 input adapters (`IN1` … `IN6`), the block combines the bit patterns of all 6 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AB_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AB` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AB_OR_6 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

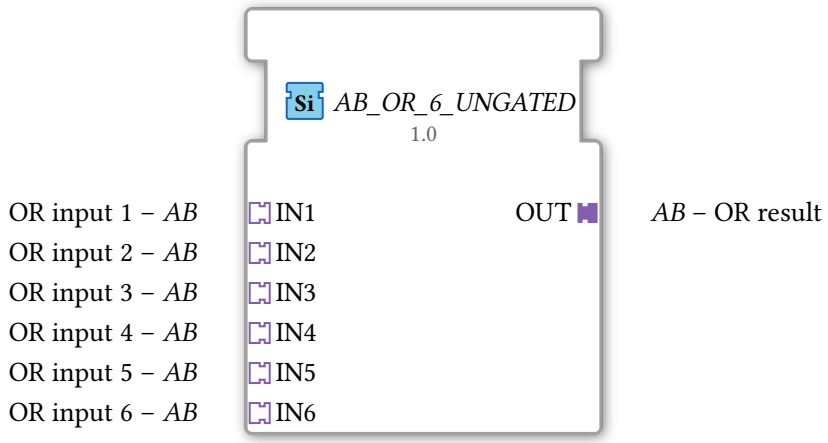
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_6`, which combines individual Boolean truth values, `AB_OR_6` operates on the full bit pattern of a `BYTE` value. Compared to the standard block OR_2, `AB_OR_6` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AB_OR_6_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AB_OR_6 offers a reliable, generic implementation of the bitwise OR function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AB_OR_6_UNGATED

> **i UNGATED variant:** This block is the ungated version of AB_OR_6. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AB_OR_6_UNGATED is a generic function block for the bitwise OR operation across 6 input values of type `BYTE` (8-bit bit pattern (byte)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AB)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AB)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AB)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AB)
- **IN6**: OR input 6 (Type: adapter::types::unidirectional::AB)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AB)

Functionality

As soon as an event arrives at one of the 6 input adapters (`IN1` … `IN6`), the block combines the bit patterns of all 6 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / `0` (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AB_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AB` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AB_OR_6_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

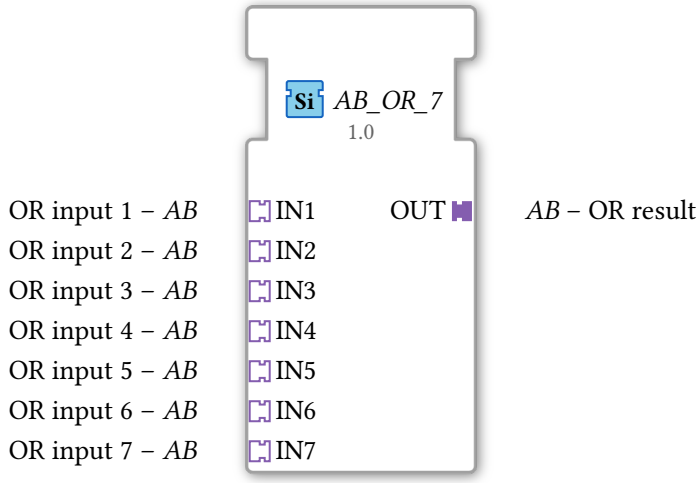
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_6`, which combines individual Boolean truth values, `AB_OR_6_UNGATED` operates on the full bit pattern of a `BYTE` value. Compared to the standard block OR_2, `AB_OR_6_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AB_OR_6`: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AB_OR_6_UNGATED offers a reliable, generic implementation of the bitwise OR function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AB_OR_7

• – ◦ • – ◦ • – ◦ •

Introduction

AB_OR_7 is a generic function block for the bitwise OR operation across 7 input values of type `BYTE` (8-bit bit pattern (byte)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AB)
- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AB)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AB)

Functionality

As soon as an event arrives at one of the 2 input adapters (IN1 … IN2), the block combines the bit patterns of all 2 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter OUT. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on OUT is OUT rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (GEN_AB_XOR) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean AX_XOR blocks, every bit of the BYTE data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type unidirectional::AB – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AB_XOR_2 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type BYTE into a single result.
- **Signal aggregation**: Merging multiple BYTE data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

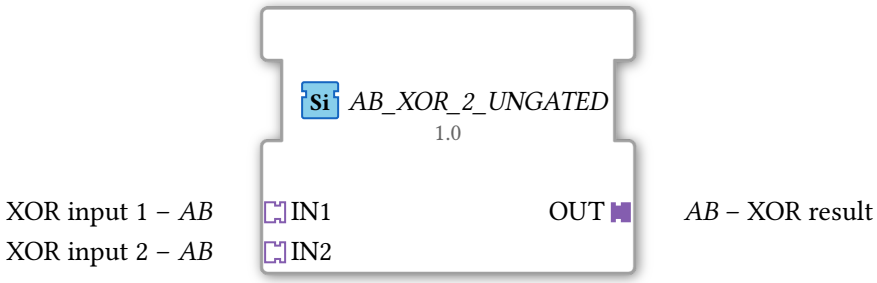
⚖️ Comparison with Similar Blocks

Unlike AX_XOR_2, which combines individual Boolean truth values, AB_XOR_2 operates on the full bit pattern of a BYTE value. Compared to the standard block XOR_2, AB_XOR_2 uses adapter-based interfaces

instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AB_XOR_2_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AB_XOR_2 offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AB_XOR_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AB_XOR_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AB_XOR_2_UNGATED is a generic function block for the bitwise XOR (exclusive OR) operation across 2 input values of type `BYTE` (8-bit bit pattern (byte)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

Adapters

Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AB)

- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AB)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AB)

Functionality

As soon as an event arrives at one of the 2 input adapters (`IN1` … `IN2`), the block combines the bit patterns of all 2 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AB_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AB` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AB_XOR_2_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

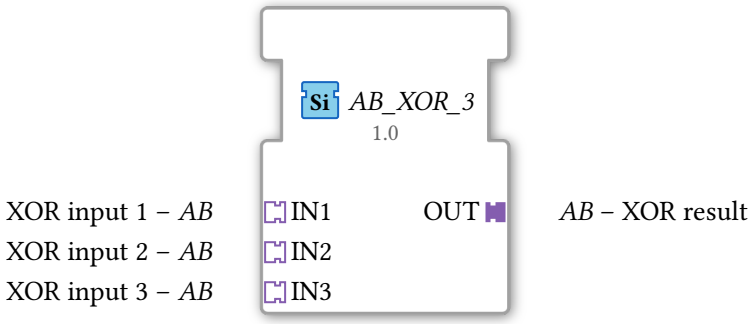
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_XOR_2`, which combines individual Boolean truth values, `AB_XOR_2_UNGATED` operates on the full bit pattern of a `BYTE` value. Compared to the standard block XOR_2, `AB_XOR_2_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AB_XOR_2`**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AB_XOR_2_UNGATED offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AB_XOR_3

• – ◦ • – ◦ • – ◦ •

Introduction

AB_XOR_3 is a generic function block for the bitwise XOR (exclusive OR) operation across 3 input values of type `BYTE` (8-bit bit pattern (byte)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AB)

Functionality

As soon as an event arrives at one of the 6 input adapters (`IN1` … `IN6`), the block combines the bit patterns of all 6 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AB_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AB` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AB_XOR_6 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

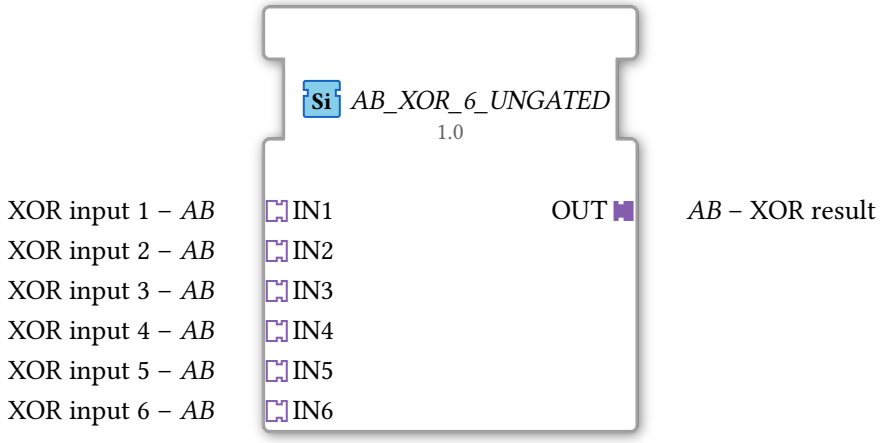
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_XOR_6`, which combines individual Boolean truth values, `AB_XOR_6` operates on the full bit pattern of a `BYTE` value. Compared to the standard block XOR_2, `AB_XOR_6` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AB_XOR_6_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AB_XOR_6 offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AB_XOR_6_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AB_XOR_6`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AB_XOR_6_UNGATED is a generic function block for the bitwise XOR (exclusive OR) operation across 6 input values of type `BYTE` (8-bit bit pattern (byte)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

Adapters

Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AB)
- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AB)
- **IN3**: XOR (exclusive OR) input 3 (Type: adapter::types::unidirectional::AB)
- **IN4**: XOR (exclusive OR) input 4 (Type: adapter::types::unidirectional::AB)
- **IN5**: XOR (exclusive OR) input 5 (Type: adapter::types::unidirectional::AB)
- **IN6**: XOR (exclusive OR) input 6 (Type: adapter::types::unidirectional::AB)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AB)

Functionality

As soon as an event arrives at one of the 6 input adapters (`IN1` … `IN6`), the block combines the bit patterns of all 6 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AB_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AB` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AB_XOR_6_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

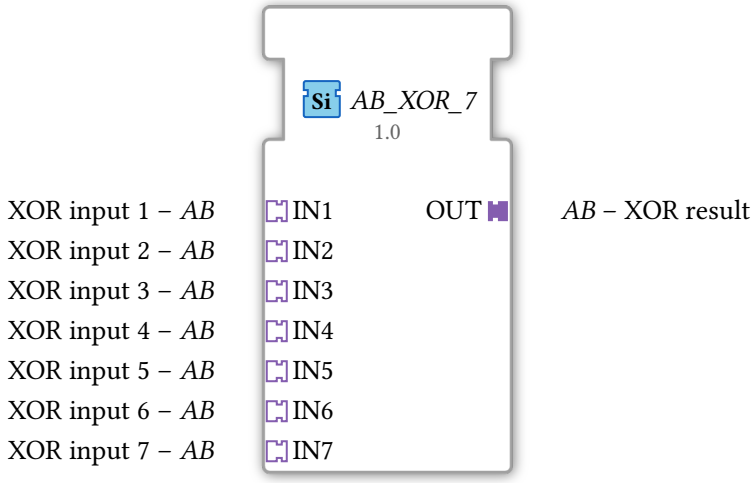
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_XOR_6`, which combines individual Boolean truth values, `AB_XOR_6_UNGATED` operates on the full bit pattern of a `BYTE` value. Compared to the standard block XOR_2, `AB_XOR_6_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AB_XOR_6`: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AB_XOR_6_UNGATED offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AB_XOR_7

• – ◦ • – ◦ • – ◦ •

Introduction

AB_XOR_7 is a generic function block for the bitwise XOR (exclusive OR) operation across 7 input values of type `BYTE` (8-bit bit pattern (byte)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

AD_AND_2

• – ◦ • – ◦ • – ◦ •

Introduction

AD_AND_2 is a generic function block for the bitwise AND operation across 2 input values of type `DWORD` (32-bit bit pattern (double word)). Unlike the Boolean operation on single truth values (as in the `AX_AND` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs
No event inputs available

Event Outputs
No event outputs available

Data Inputs
No direct data inputs available

Data Outputs
No direct data outputs available

Adapters
Input Adapters:

- **IN1**: AND input 1 (Type: adapter::types::unidirectional::AD)
- **IN2**: AND input 2 (Type: adapter::types::unidirectional::AD)

Output Adapter:

- **OUT**: AND result (Type: adapter::types::unidirectional::AD)

Functionality
As soon as an event arrives at one of the 2 input adapters (`IN1` … `IN2`), the block combines the bit patterns of all 2 inputs bitwise using **AND** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits set (identity element of the AND operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features
- **Generic function block**: The FB is defined as a generic type (`GEN_AD_AND`) and covers all arities (2 to 4 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_AND` blocks, every bit of the `DWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AD` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

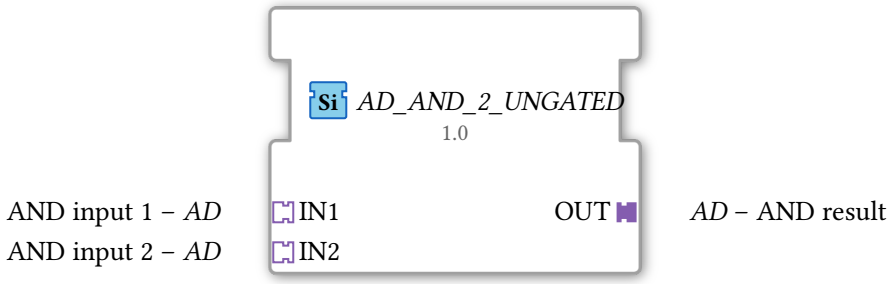
State Overview
Since this is a combinational logic block, AD_AND_2 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `DWORD` into a single result.
- **Signal aggregation**: Merging multiple `DWORD` data sources (e.g., from different modules) via a shared AND operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks
Unlike `AX_AND_2`, which combines individual Boolean truth values, `AD_AND_2` operates on the full bit pattern of a `DWORD` value. Compared to the standard block AND_2, `AD_AND_2` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AD_AND_2_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AD_AND_2 offers a reliable, generic implementation of the bitwise AND function for `DWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AD_AND_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AD_AND_2`. No direct data outputs available

Adapters

Input Adapters:

- **IN1**: AND input 1 (Type: adapter::types::unidirectional::AD)
- **IN2**: AND input 2 (Type: adapter::types::unidirectional::AD)
- **IN3**: AND input 3 (Type: adapter::types::unidirectional::AD)

Output Adapter:

- **OUT**: AND result (Type: adapter::types::unidirectional::AD)

Functionality

As soon as an event arrives at one of the 3 input adapters (`IN1` … `IN3`), the block combines the bit patterns of all 3 inputs bitwise using **AND** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits set (identity element of the AND operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AD_AND`) and covers all arities (2 to 4 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_AND` blocks, every bit of the `DWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AD` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AD_AND_3 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

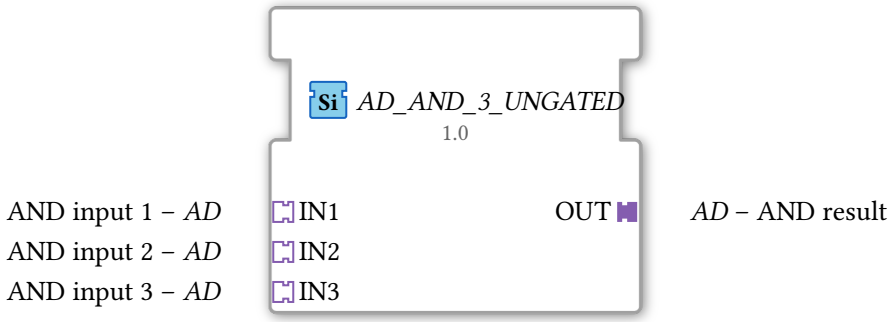
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `DWORD` into a single result.
- **Signal aggregation**: Merging multiple `DWORD` data sources (e.g., from different modules) via a shared AND operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_AND_3`, which combines individual Boolean truth values, `AD_AND_3` operates on the full bit pattern of a `DWORD` value. Compared to the standard block AND_2, `AD_AND_3` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AD_AND_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AD_AND_3 offers a reliable, generic implementation of the bitwise AND function for `DWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AD_AND_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AD_AND_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AD_AND_3_UNGATED is a generic function block for the bitwise AND operation across 3 input values of type `DWORD` (32-bit bit pattern (double word)). Unlike the Boolean operation on single truth values (as in the `AX_AND` blocks), every bit of the data word is combined independently here.

Interface Structure

Adapters

Input Adapters:

- **IN1**: AND input 1 (Type: adapter::types::unidirectional::AD)
- **IN2**: AND input 2 (Type: adapter::types::unidirectional::AD)
- **IN3**: AND input 3 (Type: adapter::types::unidirectional::AD)

Output Adapter:

- **OUT**: AND result (Type: adapter::types::unidirectional::AD)

Functionality

As soon as an event arrives at one of the 3 input adapters (`IN1` … `IN3`), the block combines the bit patterns of all 3 inputs bitwise using **AND** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits set (identity element of the AND operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AD_AND`) and covers all arities (2 to 4 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_AND` blocks, every bit of the `DWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AD` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AD_AND_3_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

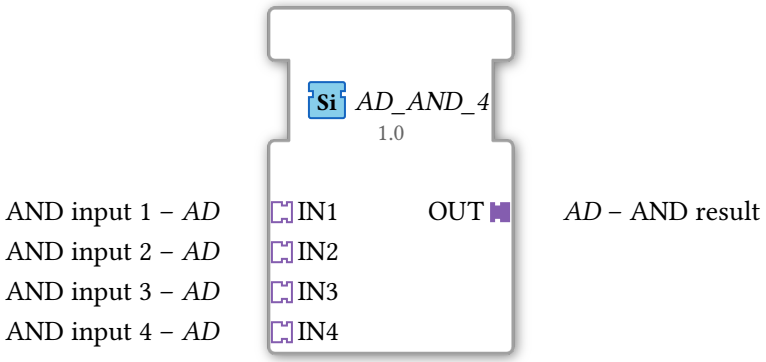
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `DWORD` into a single result.
- **Signal aggregation**: Merging multiple `DWORD` data sources (e.g., from different modules) via a shared AND operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_AND_3`, which combines individual Boolean truth values, `AD_AND_3_UNGATED` operates on the full bit pattern of a `DWORD` value. Compared to the standard block AND_2, `AD_AND_3_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AD_AND_3`**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AD_AND_3_UNGATED offers a reliable, generic implementation of the bitwise AND function for `DWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AD_AND_4

• – ◦ • – ◦ • – ◦ •

Introduction

AD_AND_4 is a generic function block for the bitwise AND operation across 4 input values of type `DWORD` (32-bit bit pattern (double word)). Unlike the Boolean operation on single truth values (as in the `AX_AND` blocks), every bit of the data word is combined independently here.

- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AD)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AD)

Functionality

As soon as an event arrives at one of the 3 input adapters (`IN1` … `IN3`), the block combines the bit patterns of all 3 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / `0` (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AD_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `DWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AD` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AD_OR_3 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

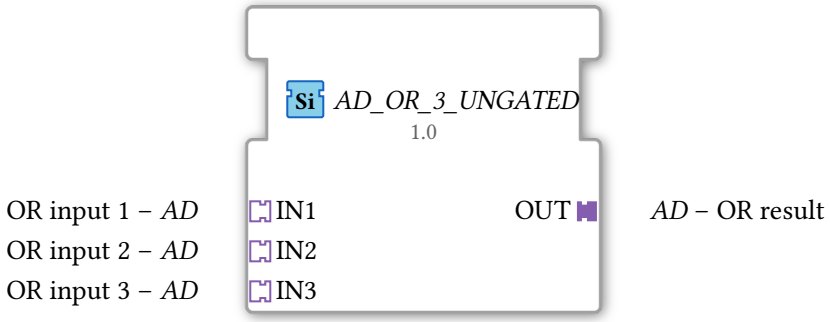
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `DWORD` into a single result.
- **Signal aggregation**: Merging multiple `DWORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_3`, which combines individual Boolean truth values, `AD_OR_3` operates on the full bit pattern of a `DWORD` value. Compared to the standard block OR_2, `AD_OR_3` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AD_OR_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AD_OR_3 offers a reliable, generic implementation of the bitwise OR function for `DWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AD_OR_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of AD_OR_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AD_OR_3_UNGATED is a generic function block for the bitwise OR operation across 3 input values of type `DWORD` (32-bit bit pattern (double word)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AD)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AD)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AD)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AD)

Functionality

As soon as an event arrives at one of the 3 input adapters (`IN1` … `IN3`), the block combines the bit patterns of all 3 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AD_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `DWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AD` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AD_OR_3_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

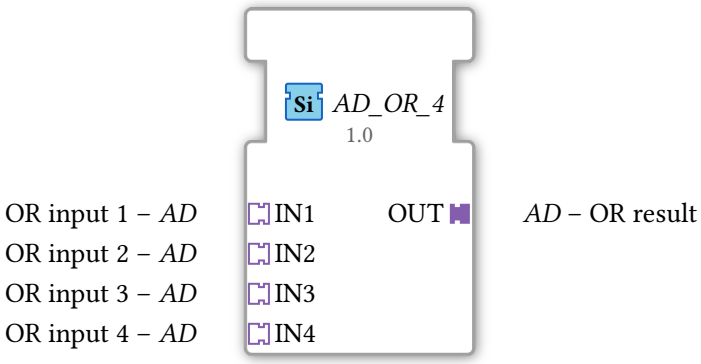
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `DWORD` into a single result.
- **Signal aggregation**: Merging multiple `DWORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_3`, which combines individual Boolean truth values, `AD_OR_3_UNGATED` operates on the full bit pattern of a `DWORD` value. Compared to the standard block OR_2, `AD_OR_3_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AD_OR_3`**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AD_OR_3_UNGATED offers a reliable, generic implementation of the bitwise OR function for `DWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AD_OR_4

• – ◦ • – ◦ • – ◦ •

Introduction

AD_OR_4 is a generic function block for the bitwise OR operation across 4 input values of type `DWORD` (32-bit bit pattern (double word)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AD)

Functionality

As soon as an event arrives at one of the 7 input adapters (`IN1` … `IN7`), the block combines the bit patterns of all 7 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / `0` (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AD_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `DWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AD` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AD_OR_7 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

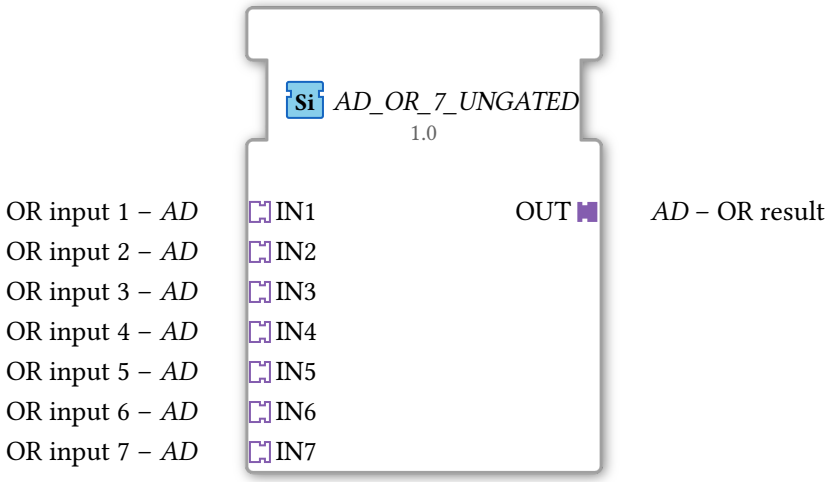
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `DWORD` into a single result.
- **Signal aggregation**: Merging multiple `DWORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike AX_OR_7, which combines individual Boolean truth values, AD_OR_7 operates on the full bit pattern of a DWORD value. Compared to the standard block OR_2, AD_OR_7 uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **AD_OR_7_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (OUT) and its adapter event only sent if the newly computed value differs from the value currently held on OUT. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AD_OR_7 offers a reliable, generic implementation of the bitwise OR function for DWORD values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AD_OR_7_UNGATED

> **i UNGATED variant:** This block is the ungated version of AD_OR_7. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AD_OR_7_UNGATED is a generic function block for the bitwise OR operation across 7 input values of type DWORD (32-bit bit pattern (double word)). Unlike the Boolean operation on single truth values (as in the AX_OR blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AD)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AD)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AD)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AD)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AD)
- **IN6**: OR input 6 (Type: adapter::types::unidirectional::AD)
- **IN7**: OR input 7 (Type: adapter::types::unidirectional::AD)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AD)

Functionality

As soon as an event arrives at one of the 7 input adapters (`IN1` … `IN7`), the block combines the bit patterns of all 7 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AD_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `DWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AD` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AD_OR_7_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

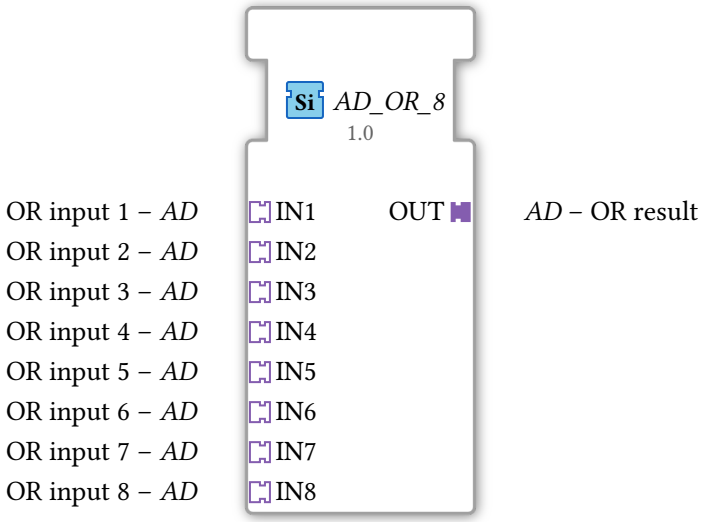
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `DWORD` into a single result.
- **Signal aggregation**: Merging multiple `DWORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_7`, which combines individual Boolean truth values, `AD_OR_7_UNGATED` operates on the full bit pattern of a `DWORD` value. Compared to the standard block OR_2, `AD_OR_7_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AD_OR_7`: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AD_OR_7_UNGATED offers a reliable, generic implementation of the bitwise OR function for `DWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AD_OR_8

• – ◦ • – ◦ • – ◦ •

Introduction

AD_OR_8 is a generic function block for the bitwise OR operation across 8 input values of type `DWORD` (32-bit bit pattern (double word)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AD)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AD)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AD)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AD)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AD)
- **IN6**: OR input 6 (Type: adapter::types::unidirectional::AD)
- **IN7**: OR input 7 (Type: adapter::types::unidirectional::AD)
- **IN8**: OR input 8 (Type: adapter::types::unidirectional::AD)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AD)

Functionality

As soon as an event arrives at one of the 8 input adapters (`IN1` … `IN8`), the block combines the bit patterns of all 8 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / `0` (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AD_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `DWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AD` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AD_OR_8 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

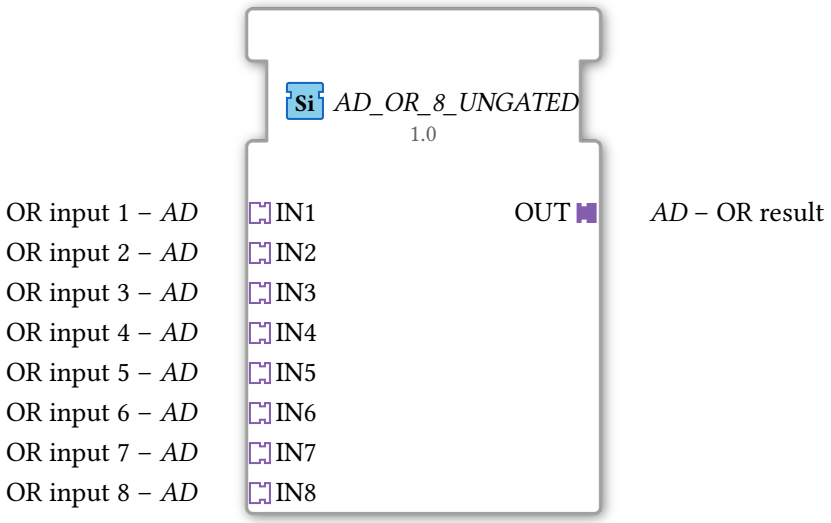
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `DWORD` into a single result.
- **Signal aggregation**: Merging multiple `DWORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_8`, which combines individual Boolean truth values, `AD_OR_8` operates on the full bit pattern of a `DWORD` value. Compared to the standard block OR_2, `AD_OR_8` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AD_OR_8_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AD_OR_8 offers a reliable, generic implementation of the bitwise OR function for `DWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AD_OR_8_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AD_OR_8`. Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AD)

Functionality

As soon as an event arrives at one of the 3 input adapters (`IN1` … `IN3`), the block combines the bit patterns of all 3 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AD_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `DWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AD` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AD_XOR_3 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

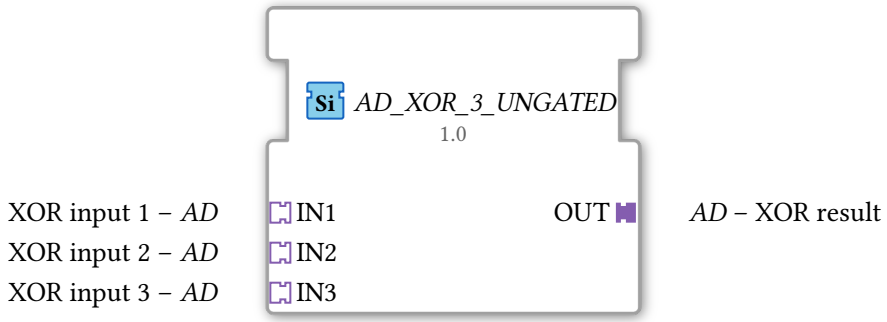
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `DWORD` into a single result.
- **Signal aggregation**: Merging multiple `DWORD` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_XOR_3`, which combines individual Boolean truth values, `AD_XOR_3` operates on the full bit pattern of a `DWORD` value. Compared to the standard block XOR_2, `AD_XOR_3` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AD_XOR_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AD_XOR_3 offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `DWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AD_XOR_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of AD_XOR_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AD_XOR_3_UNGATED is a generic function block for the bitwise XOR (exclusive OR) operation across 3 input values of type `DWORD` (32-bit bit pattern (double word)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs
No event inputs available

Event Outputs
No event outputs available

Data Inputs
No direct data inputs available

Data Outputs
No direct data outputs available

Adapters
Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AD)
- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AD)
- **IN3**: XOR (exclusive OR) input 3 (Type: adapter::types::unidirectional::AD)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AD)

Functionality
As soon as an event arrives at one of the 3 input adapters (`IN1` … `IN3`), the block combines the bit patterns of all 3 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / `0` (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

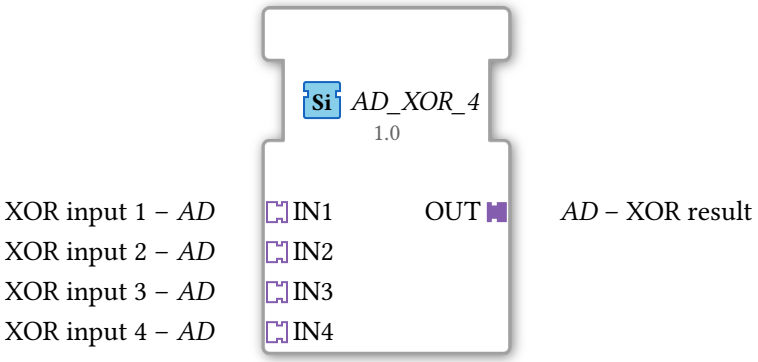
Technical Features
- **Generic function block**: The FB is defined as a generic type (`GEN_AD_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `DWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AD` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview
Since this is a combinational logic block, AD_XOR_3_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `DWORD` into a single result.
- **Signal aggregation**: Merging multiple `DWORD` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks
Unlike `AX_XOR_3`, which combines individual Boolean truth values, `AD_XOR_3_UNGATED` operates on the full bit pattern of a `DWORD` value. Compared to the standard block XOR_2, `AD_XOR_3_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AD_XOR_3`**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AD_XOR_3_UNGATED offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `DWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AD_XOR_4

• – ◦ • – ◦ • – ◦ •

Introduction

AD_XOR_4 is a generic function block for the bitwise XOR (exclusive OR) operation across 4 input values of type `DWORD` (32-bit bit pattern (double word)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AD)
- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AD)
- **IN3**: XOR (exclusive OR) input 3 (Type: adapter::types::unidirectional::AD)
- **IN4**: XOR (exclusive OR) input 4 (Type: adapter::types::unidirectional::AD)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AD)

Functionality

As soon as an event arrives at one of the 4 input adapters (`IN1` … `IN4`), the block combines the bit patterns of all 4 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The

starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AD_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `DWORD` data word is combined individually here, not just a single truth value.

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AD)

Functionality

As soon as an event arrives at one of the 7 input adapters (`IN1` … `IN7`), the block combines the bit patterns of all 7 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AD_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `DWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AD` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AD_XOR_7 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

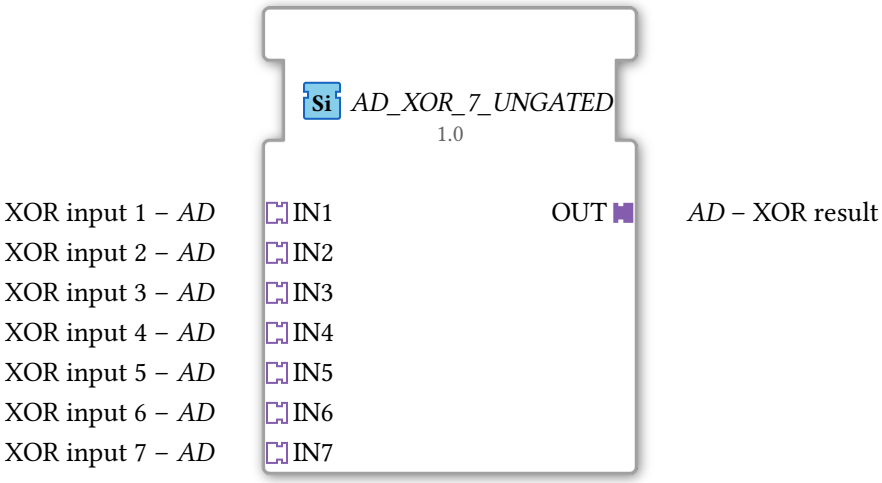
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `DWORD` into a single result.
- **Signal aggregation**: Merging multiple `DWORD` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike AX_XOR_7, which combines individual Boolean truth values, AD_XOR_7 operates on the full bit pattern of a DWORD value. Compared to the standard block XOR_2, AD_XOR_7 uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **AD_XOR_7_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (OUT) and its adapter event only sent if the newly computed value differs from the value currently held on OUT. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AD_XOR_7 offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for DWORD values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AD_XOR_7_UNGATED

> **i UNGATED variant:** This block is the ungated version of AD_XOR_7. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AD_XOR_7_UNGATED is a generic function block for the bitwise XOR (exclusive OR) operation across 7 input values of type DWORD (32-bit bit pattern (double word)). Unlike the Boolean operation on single truth values (as in the AX_XOR blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AD)
- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AD)
- **IN3**: XOR (exclusive OR) input 3 (Type: adapter::types::unidirectional::AD)
- **IN4**: XOR (exclusive OR) input 4 (Type: adapter::types::unidirectional::AD)
- **IN5**: XOR (exclusive OR) input 5 (Type: adapter::types::unidirectional::AD)
- **IN6**: XOR (exclusive OR) input 6 (Type: adapter::types::unidirectional::AD)
- **IN7**: XOR (exclusive OR) input 7 (Type: adapter::types::unidirectional::AD)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AD)

Functionality

As soon as an event arrives at one of the 7 input adapters (`IN1` … `IN7`), the block combines the bit patterns of all 7 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AD_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `DWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AD` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AD_XOR_7_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

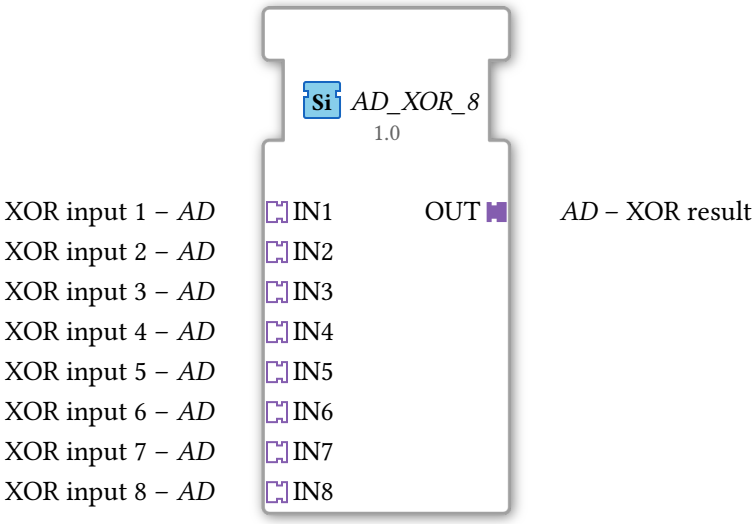
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `DWORD` into a single result.
- **Signal aggregation**: Merging multiple `DWORD` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_XOR_7`, which combines individual Boolean truth values, `AD_XOR_7_UNGATED` operates on the full bit pattern of a `DWORD` value. Compared to the standard block XOR_2, `AD_XOR_7_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AD_XOR_7`**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AD_XOR_7_UNGATED offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `DWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AD_XOR_8

• – ◦ • – ◦ • – ◦ •

Introduction

AD_XOR_8 is a generic function block for the bitwise XOR (exclusive OR) operation across 8 input values of type `DWORD` (32-bit bit pattern (double word)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

- **IN4**: AND input 4 (Type: adapter::types::unidirectional::AL)

Output Adapter:

- **OUT**: AND result (Type: adapter::types::unidirectional::AL)

Functionality

As soon as an event arrives at one of the 4 input adapters (`IN1` … `IN4`), the block combines the bit patterns of all 4 inputs bitwise using **AND** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits set (identity element of the AND operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AL_AND`) and covers all arities (2 to 4 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_AND` blocks, every bit of the `LWORD` data word is combined individually here, not just a single truth value.

- **Unidirectional adapters**: All adapters are of type `unidirectional::AL` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AL_AND_4 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

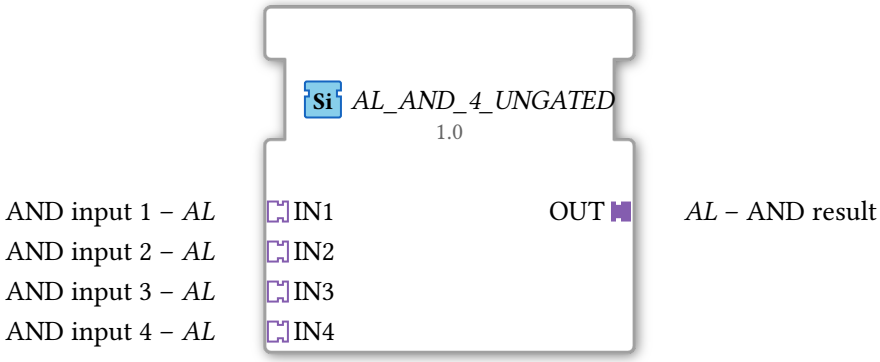
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `LWORD` into a single result.
- **Signal aggregation**: Merging multiple `LWORD` data sources (e.g., from different modules) via a shared AND operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_AND_4`, which combines individual Boolean truth values, `AL_AND_4` operates on the full bit pattern of a `LWORD` value. Compared to the standard block AND_2, `AL_AND_4` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AL_AND_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AL_AND_4 offers a reliable, generic implementation of the bitwise AND function for `LWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AL_AND_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AL_AND_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AL_AND_4_UNGATED is a generic function block for the bitwise AND operation across 4 input values of type `LWORD` (64-bit bit pattern (long word)). Unlike the Boolean operation on single truth values (as in the `AX_AND` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: AND input 1 (Type: adapter::types::unidirectional::AL)
- **IN2**: AND input 2 (Type: adapter::types::unidirectional::AL)
- **IN3**: AND input 3 (Type: adapter::types::unidirectional::AL)
- **IN4**: AND input 4 (Type: adapter::types::unidirectional::AL)

Output Adapter:

- **OUT**: AND result (Type: adapter::types::unidirectional::AL)

Functionality

As soon as an event arrives at one of the 4 input adapters (`IN1` … `IN4`), the block combines the bit patterns of all 4 inputs bitwise using **AND** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits set (identity element of the AND operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AL_AND`) and covers all arities (2 to 4 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_AND` blocks, every bit of the `LWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AL` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AL_AND_4_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

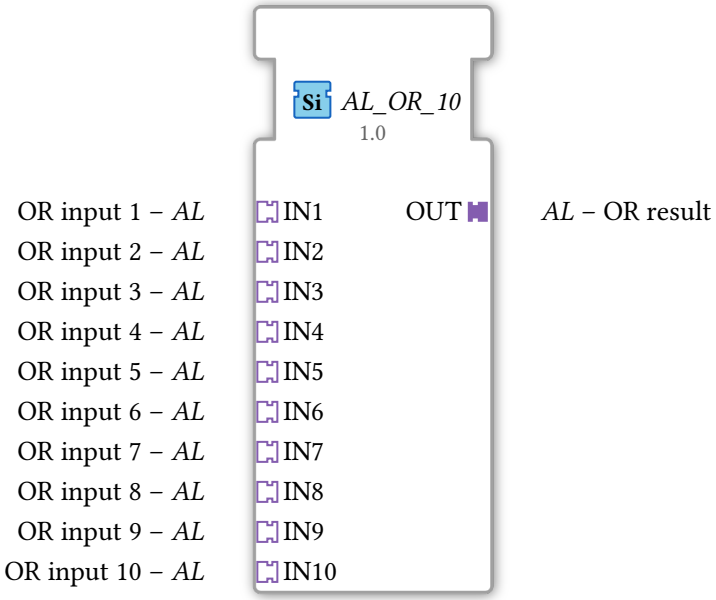
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `LWORD` into a single result.
- **Signal aggregation**: Merging multiple `LWORD` data sources (e.g., from different modules) via a shared AND operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike AX_AND_4, which combines individual Boolean truth values, AL_AND_4_UNGATED operates on the full bit pattern of a LWORD value. Compared to the standard block AND_2, AL_AND_4_UNGATED uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **AL_AND_4**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AL_AND_4_UNGATED offers a reliable, generic implementation of the bitwise AND function for LWORD values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AL_OR_10

• – ◦ • – ◦ • – ◦ •

Introduction

AL_OR_10 is a generic function block for the bitwise OR operation across 10 input values of type LWORD (64-bit bit pattern (long word)). Unlike the Boolean operation on single truth values (as in the AX_OR blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AL)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AL)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AL)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AL)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AL)
- **IN6**: OR input 6 (Type: adapter::types::unidirectional::AL)
- **IN7**: OR input 7 (Type: adapter::types::unidirectional::AL)
- **IN8**: OR input 8 (Type: adapter::types::unidirectional::AL)
- **IN9**: OR input 9 (Type: adapter::types::unidirectional::AL)
- **IN10**: OR input 10 (Type: adapter::types::unidirectional::AL)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AL)

Functionality

As soon as an event arrives at one of the 10 input adapters (`IN1` … `IN10`), the block combines the bit patterns of all 10 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AL_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `LWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AL` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AL_OR_10 has no internal states. The output is recalculated directly from the current input values on every incoming event.

- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AL)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AL)

Functionality

As soon as an event arrives at one of the 4 input adapters (`IN1` … `IN4`), the block combines the bit patterns of all 4 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AL_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `LWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AL` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AL_OR_4 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

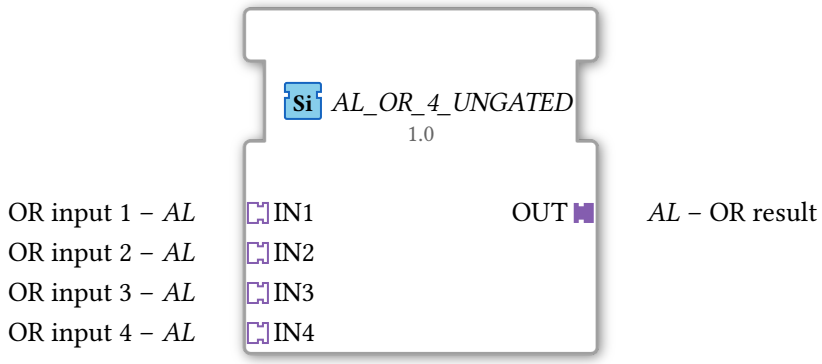
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `LWORD` into a single result.
- **Signal aggregation**: Merging multiple `LWORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ **Comparison with Similar Blocks**

Unlike `AX_OR_4`, which combines individual Boolean truth values, `AL_OR_4` operates on the full bit pattern of a `LWORD` value. Compared to the standard block OR_2, `AL_OR_4` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AL_OR_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AL_OR_4 offers a reliable, generic implementation of the bitwise OR function for `LWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AL_OR_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AL_OR_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AL_OR_4_UNGATED is a generic function block for the bitwise OR operation across 4 input values of type `LWORD` (64-bit bit pattern (long word)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AL)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AL)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AL)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AL)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AL)

Functionality

As soon as an event arrives at one of the 4 input adapters (`IN1` … `IN4`), the block combines the bit patterns of all 4 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AL_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `LWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AL` – data flows only from the socket to the plug.

- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AL_OR_4_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

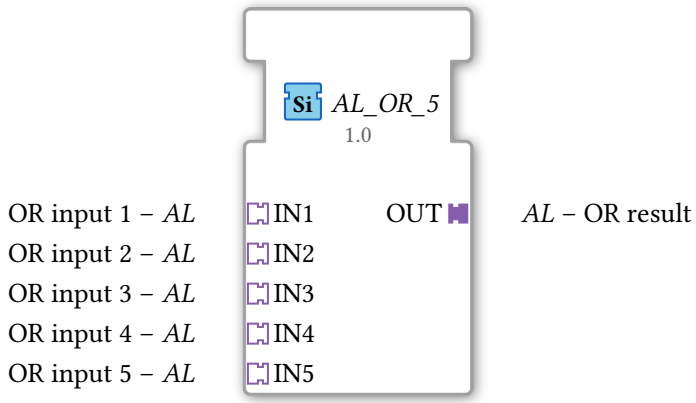
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `LWORD` into a single result.
- **Signal aggregation**: Merging multiple `LWORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ **Comparison with Similar Blocks**

Unlike `AX_OR_4`, which combines individual Boolean truth values, `AL_OR_4_UNGATED` operates on the full bit pattern of a `LWORD` value. Compared to the standard block OR_2, `AL_OR_4_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AL_OR_4`**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AL_OR_4_UNGATED offers a reliable, generic implementation of the bitwise OR function for `LWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AL_OR_5

• – ◦ • – ◦ • – ◦ •

Introduction

AL_OR_5 is a generic function block for the bitwise OR operation across 5 input values of type `LWORD` (64-bit bit pattern (long word)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AL)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AL)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AL)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AL)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AL)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AL)

Functionality

As soon as an event arrives at one of the 5 input adapters (`IN1` … `IN5`), the block combines the bit patterns of all 5 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / `0` (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AL_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `LWORD` data word is combined individually here, not just a single truth value.

- **IN7**: OR input 7 (Type: adapter::types::unidirectional::AL)
- **IN8**: OR input 8 (Type: adapter::types::unidirectional::AL)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AL)

Functionality

As soon as an event arrives at one of the 8 input adapters (`IN1` … `IN8`), the block combines the bit patterns of all 8 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AL_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `LWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AL` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AL_OR_8 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

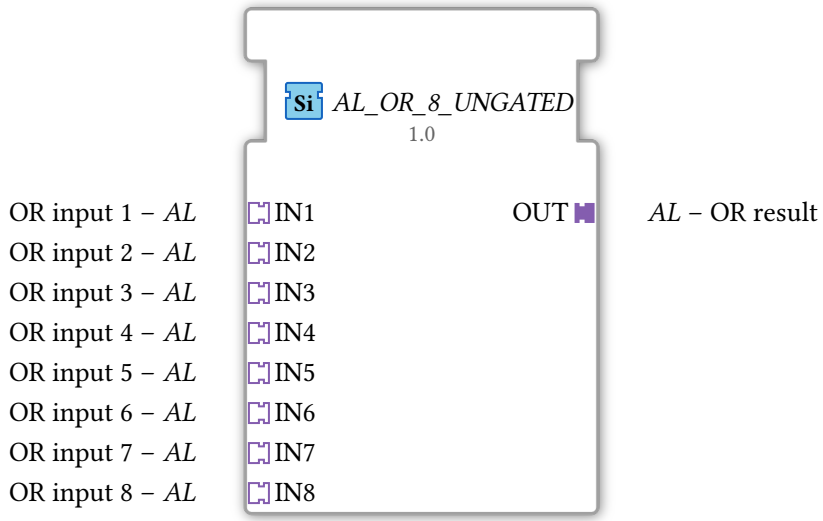
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `LWORD` into a single result.
- **Signal aggregation**: Merging multiple `LWORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_8`, which combines individual Boolean truth values, `AL_OR_8` operates on the full bit pattern of a `LWORD` value. Compared to the standard block OR_2, `AL_OR_8` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AL_OR_8_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AL_OR_8 offers a reliable, generic implementation of the bitwise OR function for `LWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AL_OR_8_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AL_OR_8`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AL_OR_8_UNGATED is a generic function block for the bitwise OR operation across 8 input values of type `LWORD` (64-bit bit pattern (long word)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AL)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AL)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AL)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AL)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AL)
- **IN6**: OR input 6 (Type: adapter::types::unidirectional::AL)
- **IN7**: OR input 7 (Type: adapter::types::unidirectional::AL)
- **IN8**: OR input 8 (Type: adapter::types::unidirectional::AL)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AL)

Functionality

As soon as an event arrives at one of the 8 input adapters (`IN1` … `IN8`), the block combines the bit patterns of all 8 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / `0` (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AL_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `LWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AL` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AL_OR_8_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

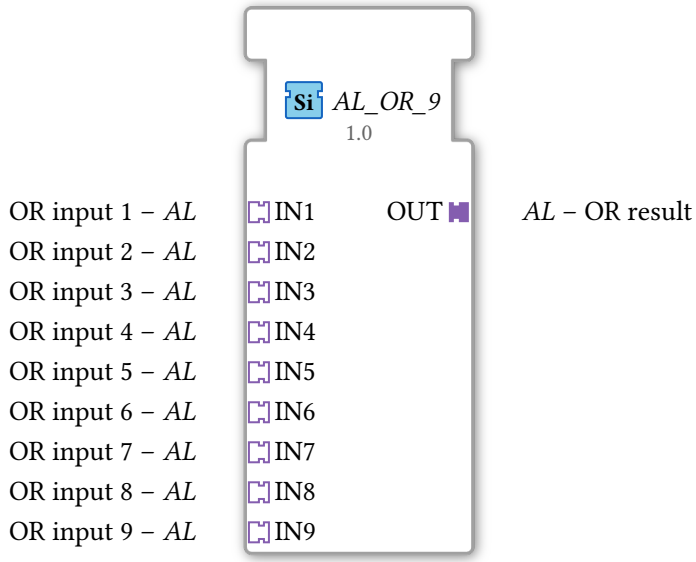
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `LWORD` into a single result.
- **Signal aggregation**: Merging multiple `LWORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_8`, which combines individual Boolean truth values, `AL_OR_8_UNGATED` operates on the full bit pattern of a `LWORD` value. Compared to the standard block OR_2, `AL_OR_8_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AL_OR_8`**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AL_OR_8_UNGATED offers a reliable, generic implementation of the bitwise OR function for `LWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AL_OR_9

• – ◦ • – ◦ • – ◦ •

Introduction

AL_OR_9 is a generic function block for the bitwise OR operation across 9 input values of type `LWORD` (64-bit bit pattern (long word)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AL)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AL)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AL)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AL)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AL)
- **IN6**: OR input 6 (Type: adapter::types::unidirectional::AL)
- **IN7**: OR input 7 (Type: adapter::types::unidirectional::AL)
- **IN8**: OR input 8 (Type: adapter::types::unidirectional::AL)
- **IN9**: OR input 9 (Type: adapter::types::unidirectional::AL)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AL)

Functionality

As soon as an event arrives at one of the 9 input adapters (`IN1` … `IN9`), the block combines the bit patterns of all 9 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / `0` (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AL_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `LWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AL` – data flows only from the socket to the plug.

- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AL)
- **IN3**: XOR (exclusive OR) input 3 (Type: adapter::types::unidirectional::AL)
- **IN4**: XOR (exclusive OR) input 4 (Type: adapter::types::unidirectional::AL)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AL)

Functionality

As soon as an event arrives at one of the 4 input adapters (`IN1` … `IN4`), the block combines the bit patterns of all 4 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The

starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on OUT is OUT rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (GEN_AL_XOR) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean AX_XOR blocks, every bit of the LWORD data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type unidirectional::AL – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AL_XOR_4 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

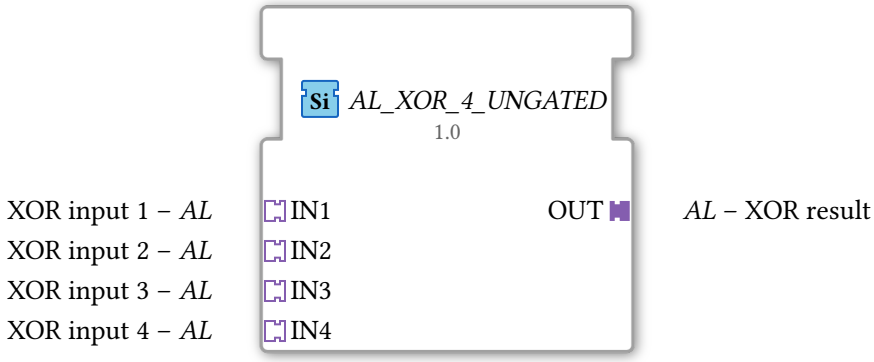
- **Bit mask combination**: Combining multiple status registers or flag bytes of type LWORD into a single result.
- **Signal aggregation**: Merging multiple LWORD data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike AX_XOR_4, which combines individual Boolean truth values, AL_XOR_4 operates on the full bit pattern of a LWORD value. Compared to the standard block XOR_2, AL_XOR_4 uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **AL_XOR_4_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (OUT) and its adapter event only sent if the newly computed value differs from the value currently held on OUT. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AL_XOR_4 offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for LWORD values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AL_XOR_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AL_XOR_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AL_XOR_4_UNGATED is a generic function block for the bitwise XOR (exclusive OR) operation across 4 input values of type `LWORD` (64-bit bit pattern (long word)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AL)
- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AL)
- **IN3**: XOR (exclusive OR) input 3 (Type: adapter::types::unidirectional::AL)
- **IN4**: XOR (exclusive OR) input 4 (Type: adapter::types::unidirectional::AL)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AL)

Functionality

As soon as an event arrives at one of the 4 input adapters (`IN1` … `IN4`), the block combines the bit patterns of all 4 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AL_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `LWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AL` – data flows only from the socket to the plug.

- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AL_XOR_4_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `LWORD` into a single result.
- **Signal aggregation**: Merging multiple `LWORD` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_XOR_4`, which combines individual Boolean truth values, `AL_XOR_4_UNGATED` operates on the full bit pattern of a `LWORD` value. Compared to the standard block XOR_2, `AL_XOR_4_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AL_XOR_4`**: The gated variant – updates the output only on an actual value change.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AL_XOR_4_UNGATED offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `LWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AL_XOR_5

• – ◦ • – ◦ • – ◦ •

Introduction

AL_XOR_5 is a generic function block for the bitwise XOR (exclusive OR) operation across 5 input values of type `LWORD` (64-bit bit pattern (long word)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AL)
- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AL)
- **IN3**: XOR (exclusive OR) input 3 (Type: adapter::types::unidirectional::AL)
- **IN4**: XOR (exclusive OR) input 4 (Type: adapter::types::unidirectional::AL)
- **IN5**: XOR (exclusive OR) input 5 (Type: adapter::types::unidirectional::AL)
- **IN6**: XOR (exclusive OR) input 6 (Type: adapter::types::unidirectional::AL)
- **IN7**: XOR (exclusive OR) input 7 (Type: adapter::types::unidirectional::AL)
- **IN8**: XOR (exclusive OR) input 8 (Type: adapter::types::unidirectional::AL)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AL)

Functionality

As soon as an event arrives at one of the 8 input adapters (`IN1` … `IN8`), the block combines the bit patterns of all 8 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AL_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `LWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AL` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AL_XOR_8 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

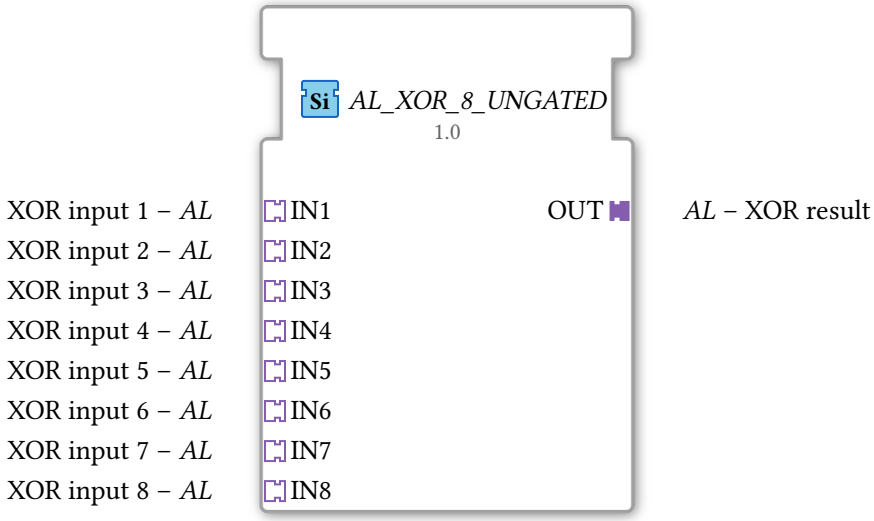
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `LWORD` into a single result.
- **Signal aggregation**: Merging multiple `LWORD` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ **Comparison with Similar Blocks**

Unlike `AX_XOR_8`, which combines individual Boolean truth values, `AL_XOR_8` operates on the full bit pattern of a `LWORD` value. Compared to the standard block XOR_2, `AL_XOR_8` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AL_XOR_8_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AL_XOR_8 offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `LWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AL_XOR_8_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AL_XOR_8`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AL_XOR_8_UNGATED is a generic function block for the bitwise XOR (exclusive OR) operation across 8 input values of type `LWORD` (64-bit bit pattern (long word)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AL)
- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AL)
- **IN3**: XOR (exclusive OR) input 3 (Type: adapter::types::unidirectional::AL)
- **IN4**: XOR (exclusive OR) input 4 (Type: adapter::types::unidirectional::AL)
- **IN5**: XOR (exclusive OR) input 5 (Type: adapter::types::unidirectional::AL)
- **IN6**: XOR (exclusive OR) input 6 (Type: adapter::types::unidirectional::AL)
- **IN7**: XOR (exclusive OR) input 7 (Type: adapter::types::unidirectional::AL)
- **IN8**: XOR (exclusive OR) input 8 (Type: adapter::types::unidirectional::AL)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AL)

Functionality

As soon as an event arrives at one of the 8 input adapters (`IN1` … `IN8`), the block combines the bit patterns of all 8 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AL_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `LWORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AL` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AL_XOR_8_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

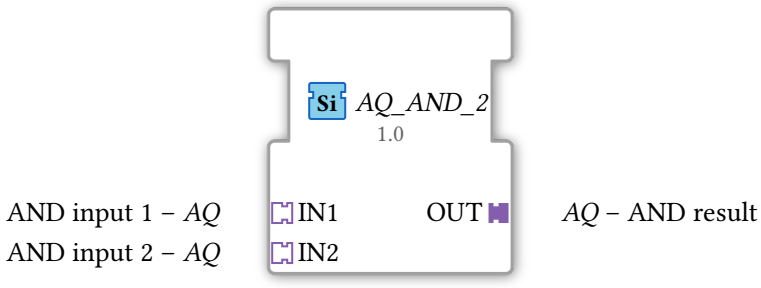
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `LWORD` into a single result.
- **Signal aggregation**: Merging multiple `LWORD` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ **Comparison with Similar Blocks**

Unlike `AX_XOR_8`, which combines individual Boolean truth values, `AL_XOR_8_UNGATED` operates on the full bit pattern of a `LWORD` value. Compared to the standard block XOR_2, `AL_XOR_8_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AL_XOR_8`: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AL_XOR_8_UNGATED offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `LWORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AQ_AND_2

• – ◦ • – ◦ • – ◦ •

Introduction

AQ_AND_2 is a generic function block for the bitwise AND operation across 2 input values of type `BYTE` (2-bit value (quarter byte, transmitted as a byte)). Unlike the Boolean operation on single truth values (as in the `AX_AND` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: AND input 1 (Type: adapter::types::unidirectional::AQ)
- **IN2**: AND input 2 (Type: adapter::types::unidirectional::AQ)

Output Adapter:

- **OUT**: AND result (Type: adapter::types::unidirectional::AQ)

Functionality

As soon as an event arrives at one of the 2 input adapters (`IN1` … `IN2`), the block combines the bit patterns of all 2 inputs bitwise using **AND** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits set (identity element of the AND operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AQ_AND`) and covers all arities (2 to 4 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_AND` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AQ` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AQ_AND_2 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

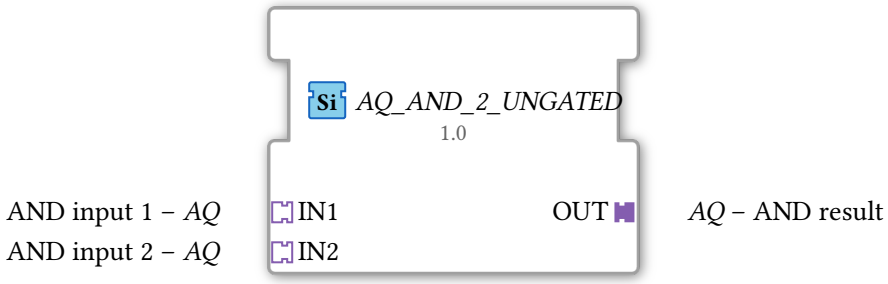
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared AND operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_AND_2`, which combines individual Boolean truth values, `AQ_AND_2` operates on the full bit pattern of a `BYTE` value. Compared to the standard block AND_2, `AQ_AND_2` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AQ_AND_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AQ_AND_2 offers a reliable, generic implementation of the bitwise AND function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AQ_AND_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AQ_AND_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. - **IN10**: OR input 10 (Type: adapter::types::unidirectional::AQ)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AQ)

Functionality

As soon as an event arrives at one of the 10 input adapters (`IN1` … `IN10`), the block combines the bit patterns of all 10 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AQ_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AQ` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AQ_OR_10 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

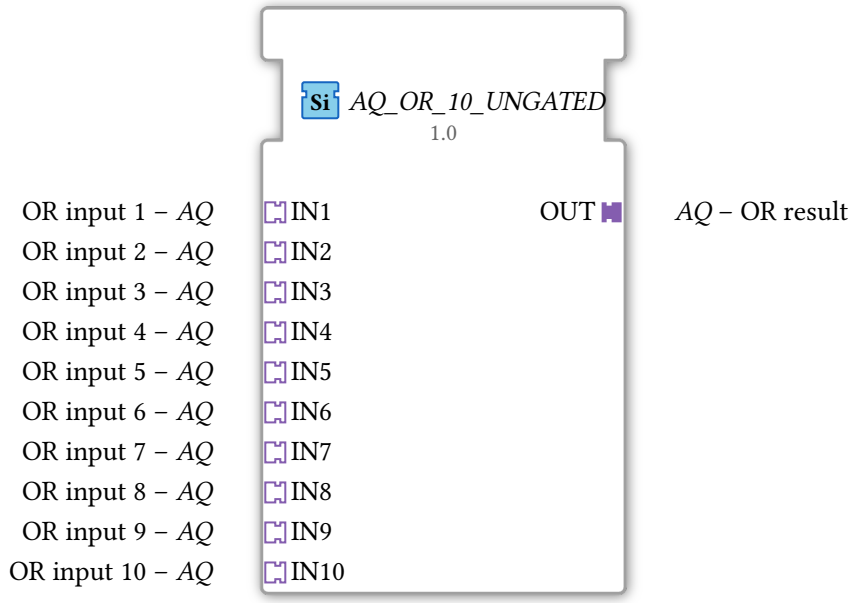
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_10`, which combines individual Boolean truth values, `AQ_OR_10` operates on the full bit pattern of a `BYTE` value. Compared to the standard block OR_2, `AQ_OR_10` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AQ_OR_10_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AQ_OR_10 offers a reliable, generic implementation of the bitwise OR function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AQ_OR_10_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AQ_OR_10`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AQ_OR_10_UNGATED is a generic function block for the bitwise OR operation across 10 input values of type `BYTE` (2-bit value (quarter byte, transmitted as a byte)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AQ)

- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AQ)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AQ)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AQ)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AQ)
- **IN6**: OR input 6 (Type: adapter::types::unidirectional::AQ)
- **IN7**: OR input 7 (Type: adapter::types::unidirectional::AQ)
- **IN8**: OR input 8 (Type: adapter::types::unidirectional::AQ)
- **IN9**: OR input 9 (Type: adapter::types::unidirectional::AQ)
- **IN10**: OR input 10 (Type: adapter::types::unidirectional::AQ)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AQ)

Functionality

As soon as an event arrives at one of the 10 input adapters (`IN1` … `IN10`), the block combines the bit patterns of all 10 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AQ_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AQ` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AQ_OR_10_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

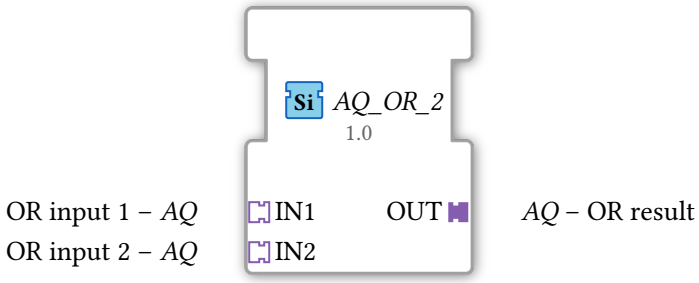
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_10`, which combines individual Boolean truth values, `AQ_OR_10_UNGATED` operates on the full bit pattern of a `BYTE` value. Compared to the standard block OR_2, `AQ_OR_10_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AQ_OR_10`**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AQ_OR_10_UNGATED offers a reliable, generic implementation of the bitwise OR function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AQ_OR_2

• – ◦ • – ◦ • – ◦ •

Introduction

AQ_OR_2 is a generic function block for the bitwise OR operation across 2 input values of type `BYTE` (2-bit value (quarter byte, transmitted as a byte)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AQ)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AQ)

Functionality

As soon as an event arrives at one of the 5 input adapters (`IN1` … `IN5`), the block combines the bit patterns of all 5 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / `0` (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AQ_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AQ` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AQ_OR_5 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

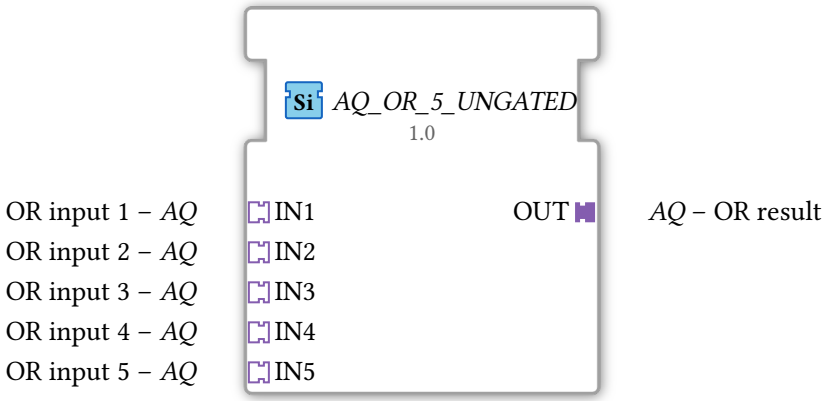
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_5`, which combines individual Boolean truth values, `AQ_OR_5` operates on the full bit pattern of a `BYTE` value. Compared to the standard block OR_2, `AQ_OR_5` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AQ_OR_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AQ_OR_5 offers a reliable, generic implementation of the bitwise OR function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AQ_OR_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AQ_OR_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AQ_OR_5_UNGATED is a generic function block for the bitwise OR operation across 5 input values of type `BYTE` (2-bit value (quarter byte, transmitted as a byte)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AQ)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AQ)

- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AQ)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AQ)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AQ)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AQ)

Functionality

As soon as an event arrives at one of the 5 input adapters (`IN1` … `IN5`), the block combines the bit patterns of all 5 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AQ_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AQ` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AQ_OR_5_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

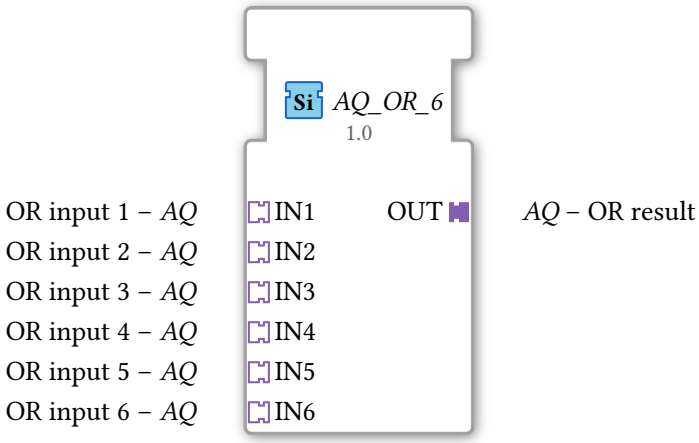
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_5`, which combines individual Boolean truth values, `AQ_OR_5_UNGATED` operates on the full bit pattern of a `BYTE` value. Compared to the standard block OR_2, `AQ_OR_5_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AQ_OR_5`: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AQ_OR_5_UNGATED offers a reliable, generic implementation of the bitwise OR function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AQ_OR_6

• – ◦ • – ◦ • – ◦ •

Introduction

AQ_OR_6 is a generic function block for the bitwise OR operation across 6 input values of type `BYTE` (2-bit value (quarter byte, transmitted as a byte)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AQ)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AQ)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AQ)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AQ)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AQ)
- **IN6**: OR input 6 (Type: adapter::types::unidirectional::AQ)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AQ)

Functionality

As soon as an event arrives at one of the 6 input adapters (`IN1` … `IN6`), the block combines the bit patterns of all 6 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AQ_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AQ` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AQ_OR_6 has no internal states. The output is recalculated directly from the current input values on every incoming event.

- **IN9**: OR input 9 (Type: adapter::types::unidirectional::AQ)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AQ)

Functionality

As soon as an event arrives at one of the 9 input adapters (`IN1` … `IN9`), the block combines the bit patterns of all 9 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AQ_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AQ` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AQ_OR_9 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

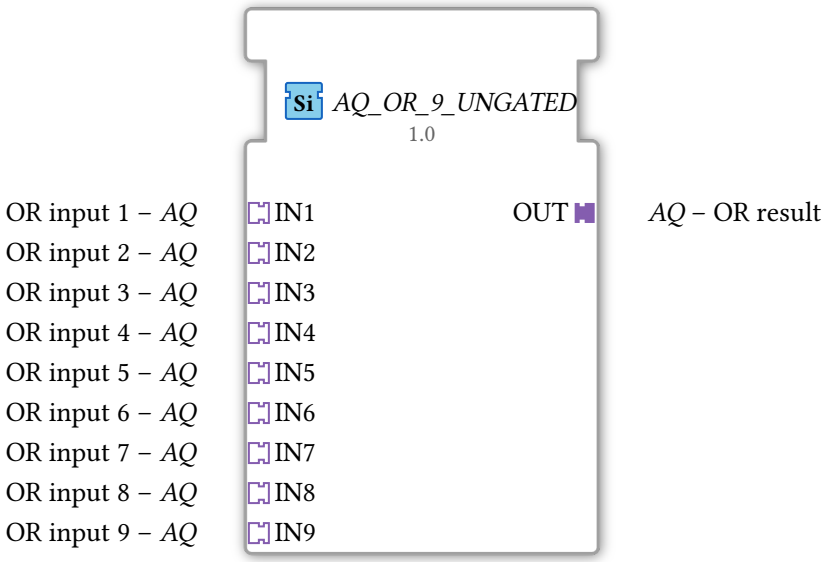
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_9`, which combines individual Boolean truth values, `AQ_OR_9` operates on the full bit pattern of a `BYTE` value. Compared to the standard block OR_2, `AQ_OR_9` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AQ_OR_9_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AQ_OR_9 offers a reliable, generic implementation of the bitwise OR function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AQ_OR_9_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AQ_OR_9`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AQ_OR_9_UNGATED is a generic function block for the bitwise OR operation across 9 input values of type `BYTE` (2-bit value (quarter byte, transmitted as a byte)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AQ)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AQ)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AQ)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AQ)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AQ)
- **IN6**: OR input 6 (Type: adapter::types::unidirectional::AQ)
- **IN7**: OR input 7 (Type: adapter::types::unidirectional::AQ)
- **IN8**: OR input 8 (Type: adapter::types::unidirectional::AQ)
- **IN9**: OR input 9 (Type: adapter::types::unidirectional::AQ)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AQ)

Functionality

As soon as an event arrives at one of the 9 input adapters (`IN1` … `IN9`), the block combines the bit patterns of all 9 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the

operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AQ_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AQ` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AQ_OR_9_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

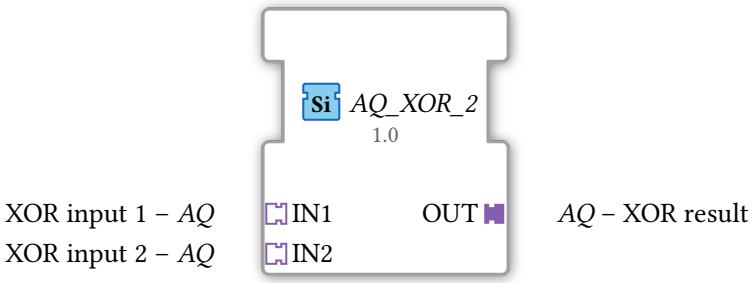
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_9`, which combines individual Boolean truth values, `AQ_OR_9_UNGATED` operates on the full bit pattern of a `BYTE` value. Compared to the standard block OR_2, `AQ_OR_9_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AQ_OR_9`: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AQ_OR_9_UNGATED offers a reliable, generic implementation of the bitwise OR function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AQ_XOR_2

• – ◦ • – ◦ • – ◦ •

Introduction

AQ_XOR_2 is a generic function block for the bitwise XOR (exclusive OR) operation across 2 input values of type `BYTE` (2-bit value (quarter byte, transmitted as a byte)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

- **IN5**: XOR (exclusive OR) input 5 (Type: adapter::types::unidirectional::AQ)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AQ)

Functionality

As soon as an event arrives at one of the 5 input adapters (`IN1` … `IN5`), the block combines the bit patterns of all 5 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AQ_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AQ` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AQ_XOR_5 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

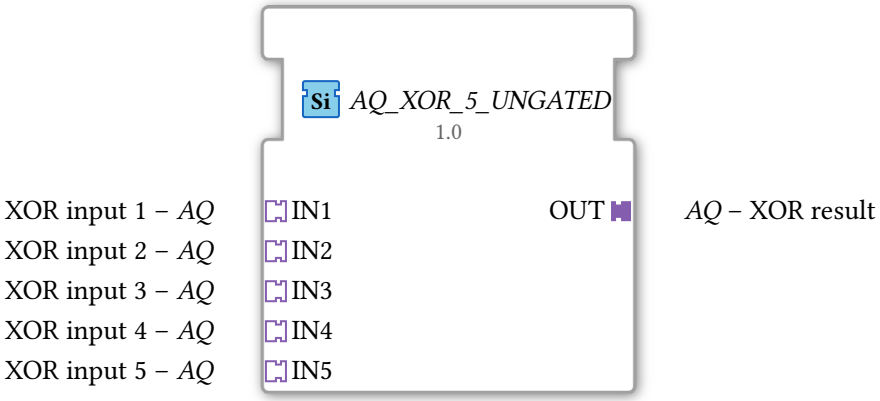
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_XOR_5`, which combines individual Boolean truth values, `AQ_XOR_5` operates on the full bit pattern of a `BYTE` value. Compared to the standard block XOR_2, `AQ_XOR_5` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AQ_XOR_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AQ_XOR_5 offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AQ_XOR_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AQ_XOR_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AQ_XOR_5_UNGATED is a generic function block for the bitwise XOR (exclusive OR) operation across 5 input values of type `BYTE` (2-bit value (quarter byte, transmitted as a byte)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

Adapters

Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AQ)

- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AQ)
- **IN3**: XOR (exclusive OR) input 3 (Type: adapter::types::unidirectional::AQ)
- **IN4**: XOR (exclusive OR) input 4 (Type: adapter::types::unidirectional::AQ)
- **IN5**: XOR (exclusive OR) input 5 (Type: adapter::types::unidirectional::AQ)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AQ)

Functionality

As soon as an event arrives at one of the 5 input adapters (`IN1` … `IN5`), the block combines the bit patterns of all 5 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AQ_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `BYTE` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AQ` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AQ_XOR_5_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

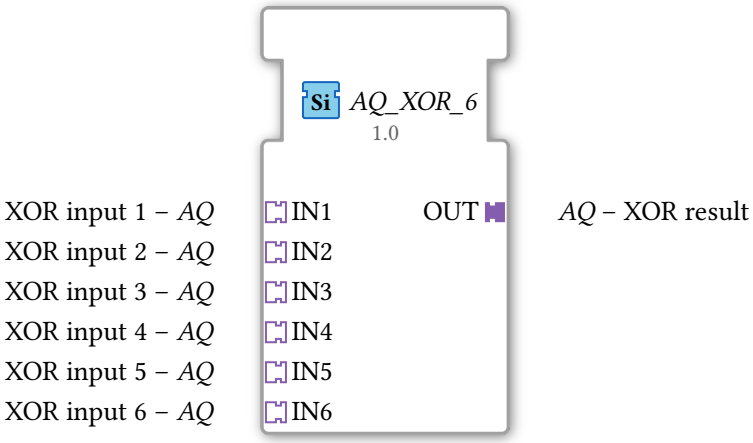
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `BYTE` into a single result.
- **Signal aggregation**: Merging multiple `BYTE` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_XOR_5`, which combines individual Boolean truth values, `AQ_XOR_5_UNGATED` operates on the full bit pattern of a `BYTE` value. Compared to the standard block XOR_2, `AQ_XOR_5_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AQ_XOR_5`**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AQ_XOR_5_UNGATED offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AQ_XOR_6

• – ◦ • – ◦ • – ◦ •

Introduction

AQ_XOR_6 is a generic function block for the bitwise XOR (exclusive OR) operation across 6 input values of type `BYTE` (2-bit value (quarter byte, transmitted as a byte)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

Conclusion

AQ_XOR_8_UNGATED offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `BYTE` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AW_AND_2

• – ◦ • – ◦ • – ◦ •

Introduction

AW_AND_2 is a generic function block for the bitwise AND operation across 2 input values of type `WORD` (16-bit bit pattern (word)). Unlike the Boolean operation on single truth values (as in the `AX_AND` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs
No event inputs available

Event Outputs
No event outputs available

Data Inputs
No direct data inputs available

Data Outputs
No direct data outputs available

Adapters
Input Adapters:

- **IN1**: AND input 1 (Type: adapter::types::unidirectional::AW)
- **IN2**: AND input 2 (Type: adapter::types::unidirectional::AW)

Output Adapter:

- **OUT**: AND result (Type: adapter::types::unidirectional::AW)

Functionality
As soon as an event arrives at one of the 2 input adapters (`IN1` … `IN2`), the block combines the bit patterns of all 2 inputs bitwise using **AND** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits set (identity element of the AND operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features
- **Generic function block**: The FB is defined as a generic type (`GEN_AW_AND`) and covers all arities (2 to 4 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_AND` blocks, every bit of the `WORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AW` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

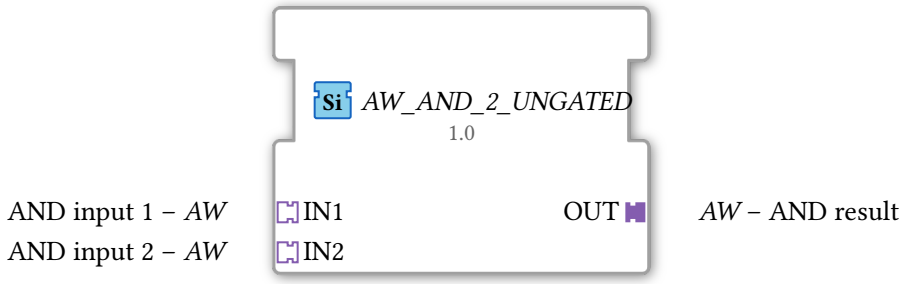
State Overview
Since this is a combinational logic block, AW_AND_2 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `WORD` into a single result.
- **Signal aggregation**: Merging multiple `WORD` data sources (e.g., from different modules) via a shared AND operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks
Unlike `AX_AND_2`, which combines individual Boolean truth values, `AW_AND_2` operates on the full bit pattern of a `WORD` value. Compared to the standard block AND_2, `AW_AND_2` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AW_AND_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AW_AND_2 offers a reliable, generic implementation of the bitwise AND function for `WORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AW_AND_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AW_AND_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AW_AND_2_UNGATED is a generic function block for the bitwise AND operation across 2 input values of type `WORD` (16-bit bit pattern (word)). Unlike the Boolean operation on single truth values (as in the `AX_AND` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

Input Adapters:

- **IN1**: AND input 1 (Type: adapter::types::unidirectional::AW)
- **IN2**: AND input 2 (Type: adapter::types::unidirectional::AW)

Output Adapter:

- **OUT**: AND result (Type: adapter::types::unidirectional::AW)

Functionality

As soon as an event arrives at one of the 2 input adapters (`IN1` … `IN2`), the block combines the bit patterns of all 2 inputs bitwise using **AND** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits set (identity element of the AND operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AW_AND`) and covers all arities (2 to 4 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_AND` blocks, every bit of the `WORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AW` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AW_AND_2_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

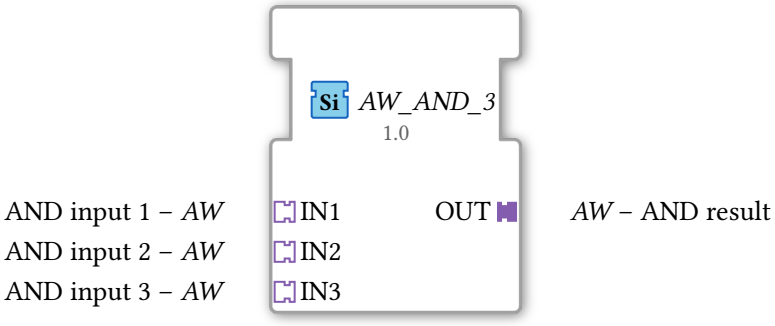
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `WORD` into a single result.
- **Signal aggregation**: Merging multiple `WORD` data sources (e.g., from different modules) via a shared AND operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_AND_2`, which combines individual Boolean truth values, `AW_AND_2_UNGATED` operates on the full bit pattern of a `WORD` value. Compared to the standard block AND_2, `AW_AND_2_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AW_AND_2`**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AW_AND_2_UNGATED offers a reliable, generic implementation of the bitwise AND function for `WORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AW_AND_3

• – ◦ • – ◦ • – ◦ •

Introduction

AW_AND_3 is a generic function block for the bitwise AND operation across 3 input values of type `WORD` (16-bit bit pattern (word)). Unlike the Boolean operation on single truth values (as in the `AX_AND` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AW)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AW)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AW)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AW)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AW)
- **IN6**: OR input 6 (Type: adapter::types::unidirectional::AW)
- **IN7**: OR input 7 (Type: adapter::types::unidirectional::AW)
- **IN8**: OR input 8 (Type: adapter::types::unidirectional::AW)
- **IN9**: OR input 9 (Type: adapter::types::unidirectional::AW)
- **IN10**: OR input 10 (Type: adapter::types::unidirectional::AW)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AW)

Functionality

As soon as an event arrives at one of the 10 input adapters (`IN1` … `IN10`), the block combines the bit patterns of all 10 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AW_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `WORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AW` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AW_OR_10 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AW)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AW)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AW)

Functionality

As soon as an event arrives at one of the 2 input adapters (`IN1` … `IN2`), the block combines the bit patterns of all 2 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AW_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `WORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AW` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AW_OR_2 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

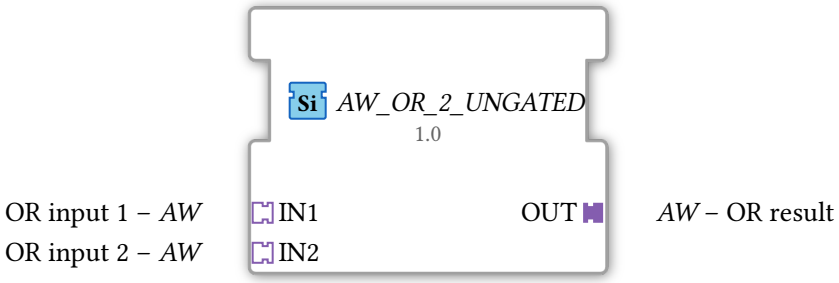
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `WORD` into a single result.
- **Signal aggregation**: Merging multiple `WORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_2`, which combines individual Boolean truth values, `AW_OR_2` operates on the full bit pattern of a `WORD` value. Compared to the standard block OR_2, `AW_OR_2` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AW_OR_2_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AW_OR_2 offers a reliable, generic implementation of the bitwise OR function for `WORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AW_OR_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AW_OR_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AW_OR_2_UNGATED is a generic function block for the bitwise OR operation across 2 input values of type `WORD` (16-bit bit pattern (word)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AW)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AW)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AW)

Functionality

As soon as an event arrives at one of the 2 input adapters (`IN1` … `IN2`), the block combines the bit patterns of all 2 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AW_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `WORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AW` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AW_OR_2_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

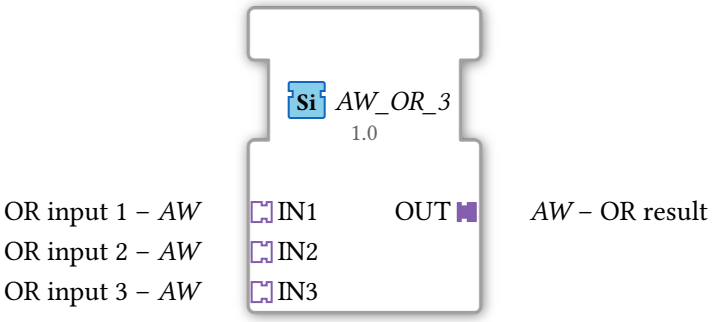
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `WORD` into a single result.
- **Signal aggregation**: Merging multiple `WORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_2`, which combines individual Boolean truth values, `AW_OR_2_UNGATED` operates on the full bit pattern of a `WORD` value. Compared to the standard block OR_2, `AW_OR_2_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AW_OR_2`: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AW_OR_2_UNGATED offers a reliable, generic implementation of the bitwise OR function for `WORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AW_OR_3

• – ◦ • – ◦ • – ◦ •

Introduction

AW_OR_3 is a generic function block for the bitwise OR operation across 3 input values of type `WORD` (16-bit bit pattern (word)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

State Overview

Since this is a combinational logic block, AW_OR_6 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

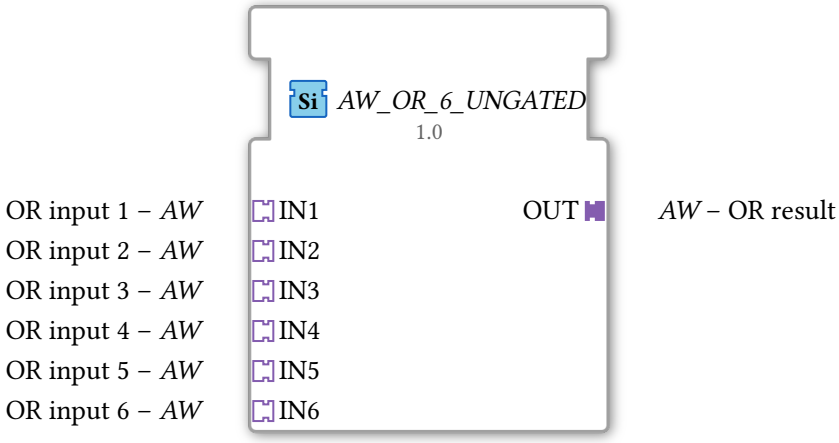
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `WORD` into a single result.
- **Signal aggregation**: Merging multiple `WORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_6`, which combines individual Boolean truth values, `AW_OR_6` operates on the full bit pattern of a `WORD` value. Compared to the standard block OR_2, `AW_OR_6` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AW_OR_6_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AW_OR_6 offers a reliable, generic implementation of the bitwise OR function for `WORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AW_OR_6_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AW_OR_6`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AW_OR_6_UNGATED is a generic function block for the bitwise OR operation across 6 input values of type `WORD` (16-bit bit pattern (word)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AW)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AW)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AW)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AW)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AW)
- **IN6**: OR input 6 (Type: adapter::types::unidirectional::AW)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AW)

Functionality

As soon as an event arrives at one of the 6 input adapters (`IN1` … `IN6`), the block combines the bit patterns of all 6 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / `0` (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AW_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `WORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AW` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AW_OR_6_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

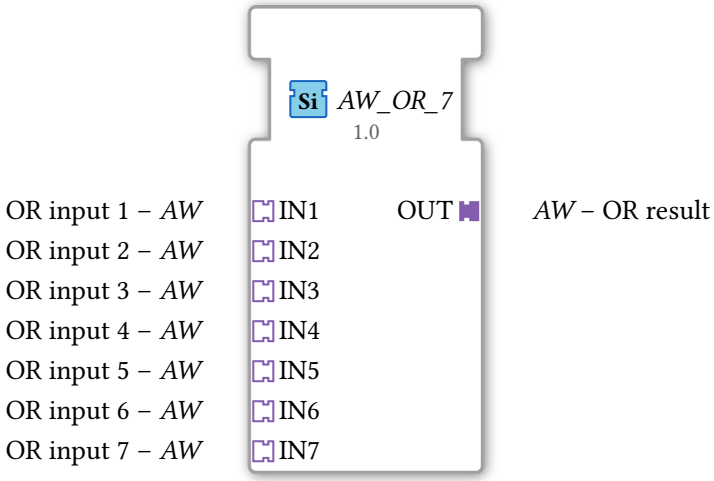
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `WORD` into a single result.
- **Signal aggregation**: Merging multiple `WORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_OR_6`, which combines individual Boolean truth values, `AW_OR_6_UNGATED` operates on the full bit pattern of a `WORD` value. Compared to the standard block OR_2, `AW_OR_6_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AW_OR_6`: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AW_OR_6_UNGATED offers a reliable, generic implementation of the bitwise OR function for `WORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AW_OR_7

• – ◦ • – ◦ • – ◦ •

Introduction

AW_OR_7 is a generic function block for the bitwise OR operation across 7 input values of type `WORD` (16-bit bit pattern (word)). Unlike the Boolean operation on single truth values (as in the `AX_OR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: OR input 1 (Type: adapter::types::unidirectional::AW)
- **IN2**: OR input 2 (Type: adapter::types::unidirectional::AW)
- **IN3**: OR input 3 (Type: adapter::types::unidirectional::AW)
- **IN4**: OR input 4 (Type: adapter::types::unidirectional::AW)
- **IN5**: OR input 5 (Type: adapter::types::unidirectional::AW)
- **IN6**: OR input 6 (Type: adapter::types::unidirectional::AW)
- **IN7**: OR input 7 (Type: adapter::types::unidirectional::AW)

Output Adapter:

- **OUT**: OR result (Type: adapter::types::unidirectional::AW)

Functionality

As soon as an event arrives at one of the 7 input adapters (`IN1` … `IN7`), the block combines the bit patterns of all 7 inputs bitwise using **OR** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / `0` (identity element of the OR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AW_OR`) and covers all arities (2 to 10 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_OR` blocks, every bit of the `WORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AW` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AW_OR_7 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

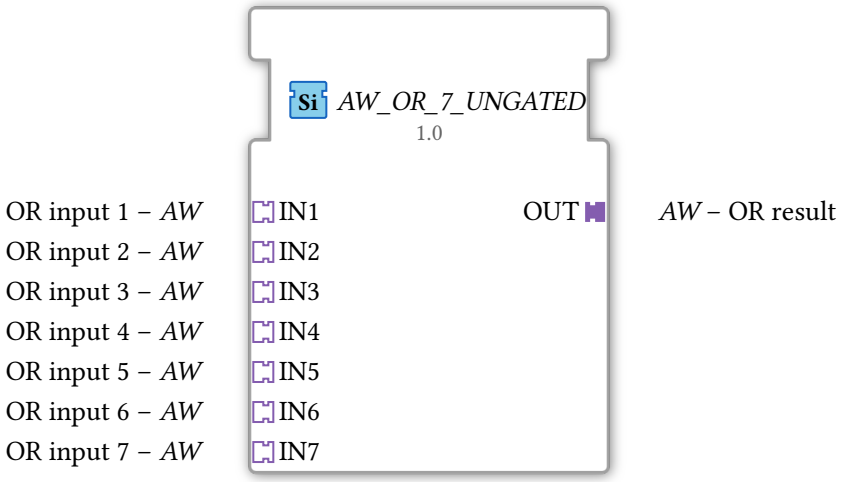
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `WORD` into a single result.
- **Signal aggregation**: Merging multiple `WORD` data sources (e.g., from different modules) via a shared OR operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike AX_OR_7, which combines individual Boolean truth values, AW_OR_7 operates on the full bit pattern of a WORD value. Compared to the standard block OR_2, AW_OR_7 uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **AW_OR_7_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (OUT) and its adapter event only sent if the newly computed value differs from the value currently held on OUT. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AW_OR_7 offers a reliable, generic implementation of the bitwise OR function for WORD values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AW_OR_7_UNGATED

> **i UNGATED variant:** This block is the ungated version of AW_OR_7. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AW)
- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AW)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AW)

Functionality

As soon as an event arrives at one of the 2 input adapters (`IN1` … `IN2`), the block combines the bit patterns of all 2 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AW_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `WORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AW` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AW_XOR_2 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `WORD` into a single result.
- **Signal aggregation**: Merging multiple `WORD` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

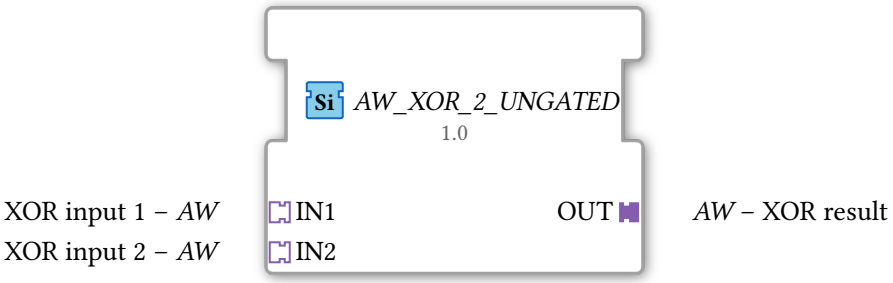
⚖️ Comparison with Similar Blocks

Unlike `AX_XOR_2`, which combines individual Boolean truth values, `AW_XOR_2` operates on the full bit pattern of a `WORD` value. Compared to the standard block XOR_2, `AW_XOR_2` uses adapter-based interfaces

instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AW_XOR_2_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AW_XOR_2 offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `WORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AW_XOR_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AW_XOR_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AW_XOR_2_UNGATED is a generic function block for the bitwise XOR (exclusive OR) operation across 2 input values of type `WORD` (16-bit bit pattern (word)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AW)

- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AW)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AW)

Functionality

As soon as an event arrives at one of the 2 input adapters (`IN1` … `IN2`), the block combines the bit patterns of all 2 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AW_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `WORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AW` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AW_XOR_2_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

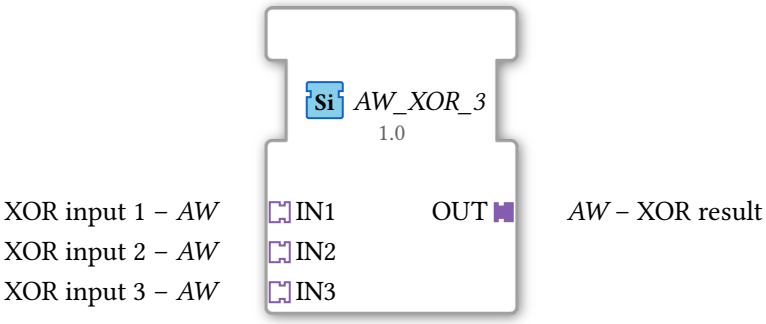
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `WORD` into a single result.
- **Signal aggregation**: Merging multiple `WORD` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_XOR_2`, which combines individual Boolean truth values, `AW_XOR_2_UNGATED` operates on the full bit pattern of a `WORD` value. Compared to the standard block XOR_2, `AW_XOR_2_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AW_XOR_2`**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AW_XOR_2_UNGATED offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `WORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AW_XOR_3

• – ◦ • – ◦ • – ◦ •

Introduction

AW_XOR_3 is a generic function block for the bitwise XOR (exclusive OR) operation across 3 input values of type `WORD` (16-bit bit pattern (word)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AW)

Functionality

As soon as an event arrives at one of the 6 input adapters (`IN1` … `IN6`), the block combines the bit patterns of all 6 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AW_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `WORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AW` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AW_XOR_6 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

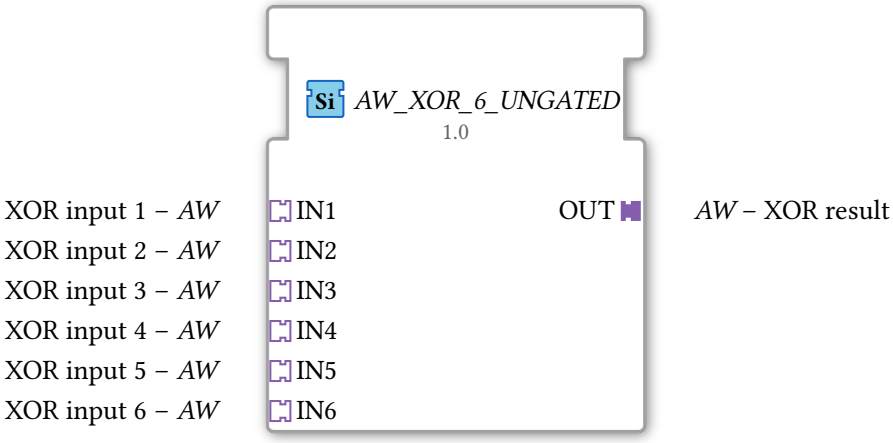
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `WORD` into a single result.
- **Signal aggregation**: Merging multiple `WORD` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_XOR_6`, which combines individual Boolean truth values, `AW_XOR_6` operates on the full bit pattern of a `WORD` value. Compared to the standard block XOR_2, `AW_XOR_6` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **`AW_XOR_6_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AW_XOR_6 offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `WORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AW_XOR_6_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AW_XOR_6`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AW_XOR_6_UNGATED is a generic function block for the bitwise XOR (exclusive OR) operation across 6 input values of type `WORD` (16-bit bit pattern (word)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AW)
- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AW)
- **IN3**: XOR (exclusive OR) input 3 (Type: adapter::types::unidirectional::AW)
- **IN4**: XOR (exclusive OR) input 4 (Type: adapter::types::unidirectional::AW)
- **IN5**: XOR (exclusive OR) input 5 (Type: adapter::types::unidirectional::AW)
- **IN6**: XOR (exclusive OR) input 6 (Type: adapter::types::unidirectional::AW)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AW)

Functionality

As soon as an event arrives at one of the 6 input adapters (`IN1` … `IN6`), the block combines the bit patterns of all 6 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AW_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `WORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AW` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AW_XOR_6_UNGATED has no internal states. The output is recalculated directly from the current input values on every incoming event.

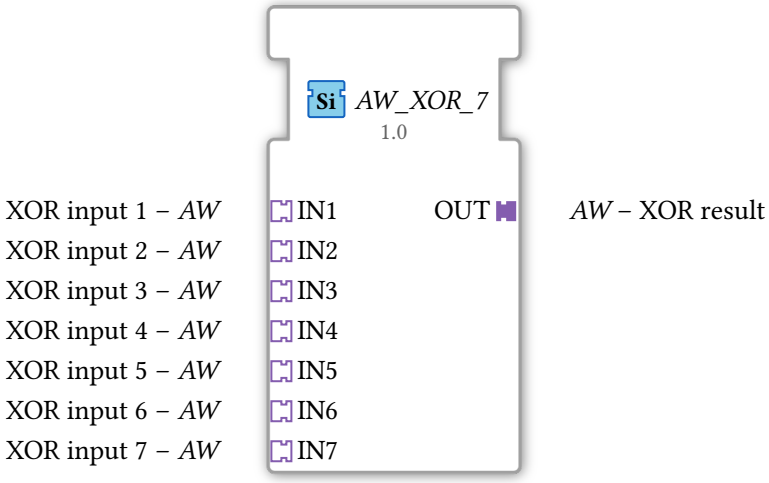
Application Scenarios

- **Bit mask combination**: Combining multiple status registers or flag bytes of type `WORD` into a single result.
- **Signal aggregation**: Merging multiple `WORD` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike `AX_XOR_6`, which combines individual Boolean truth values, `AW_XOR_6_UNGATED` operates on the full bit pattern of a `WORD` value. Compared to the standard block XOR_2, `AW_XOR_6_UNGATED` uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- `AW_XOR_6`: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AW_XOR_6_UNGATED offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `WORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AW_XOR_7

• – ◦ • – ◦ • – ◦ •

Introduction

AW_XOR_7 is a generic function block for the bitwise XOR (exclusive OR) operation across 7 input values of type `WORD` (16-bit bit pattern (word)). Unlike the Boolean operation on single truth values (as in the `AX_XOR` blocks), every bit of the data word is combined independently here.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN1**: XOR (exclusive OR) input 1 (Type: adapter::types::unidirectional::AW)
- **IN2**: XOR (exclusive OR) input 2 (Type: adapter::types::unidirectional::AW)
- **IN3**: XOR (exclusive OR) input 3 (Type: adapter::types::unidirectional::AW)
- **IN4**: XOR (exclusive OR) input 4 (Type: adapter::types::unidirectional::AW)
- **IN5**: XOR (exclusive OR) input 5 (Type: adapter::types::unidirectional::AW)
- **IN6**: XOR (exclusive OR) input 6 (Type: adapter::types::unidirectional::AW)
- **IN7**: XOR (exclusive OR) input 7 (Type: adapter::types::unidirectional::AW)

Output Adapter:

- **OUT**: XOR (exclusive OR) result (Type: adapter::types::unidirectional::AW)

Functionality

As soon as an event arrives at one of the 7 input adapters (`IN1` … `IN7`), the block combines the bit patterns of all 7 inputs bitwise using **XOR (exclusive OR)** and writes the result to the output adapter `OUT`. The starting value of the operation is the identity element (all bits cleared / 0 (identity element of the XOR operation)), so that with only one input actually connected, its value is passed through unchanged.

Only if the newly computed result differs from the value currently held on `OUT` is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

Technical Features

- **Generic function block**: The FB is defined as a generic type (`GEN_AW_XOR`) and covers all arities (2 to 8 inputs) of the same underlying logic via the GenericClassName mechanism.
- **Bitwise operation**: Unlike the Boolean `AX_XOR` blocks, every bit of the `WORD` data word is combined individually here, not just a single truth value.
- **Unidirectional adapters**: All adapters are of type `unidirectional::AW` – data flows only from the socket to the plug.
- **Standard compliance**: The block implements the operation according to IEC 61499-2 / IEC 61131-3.

State Overview

Since this is a combinational logic block, AW_XOR_7 has no internal states. The output is recalculated directly from the current input values on every incoming event.

Application Scenarios

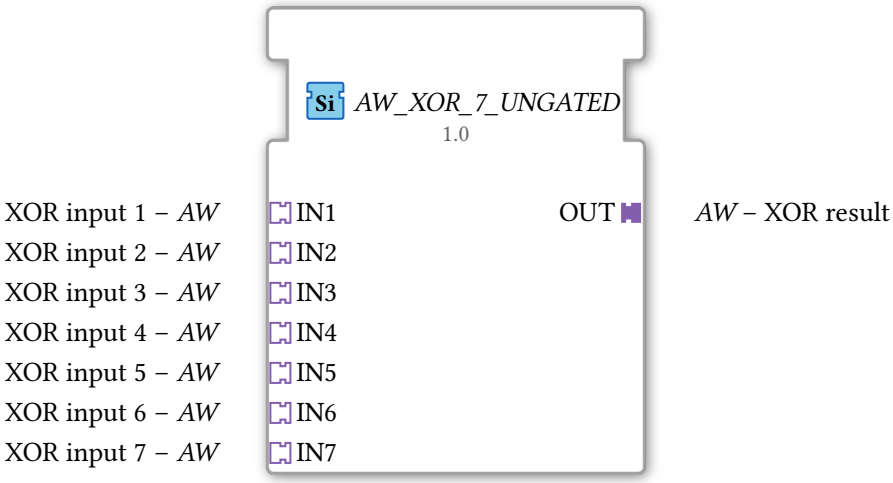
- **Bit mask combination**: Combining multiple status registers or flag bytes of type `WORD` into a single result.
- **Signal aggregation**: Merging multiple `WORD` data sources (e.g., from different modules) via a shared XOR (exclusive OR) operation.
- **Diagnostics and status evaluation**: Checking bit patterns for commonly or differently set bits.

⚖️ Comparison with Similar Blocks

Unlike AX_XOR_7, which combines individual Boolean truth values, AW_XOR_7 operates on the full bit pattern of a WORD value. Compared to the standard block XOR_2, AW_XOR_7 uses adapter-based interfaces instead of direct data/event inputs/outputs, enabling more flexible integration into adapter-based system architectures.

- **AW_XOR_7_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (OUT) and its adapter event only sent if the newly computed value differs from the value currently held on OUT. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AW_XOR_7 offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for WORD values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

AW_XOR_7_UNGATED

> **i UNGATED variant:** This block is the ungated version of AW_XOR_7. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. AW_XOR_8_UNGATED offers a reliable, generic implementation of the bitwise XOR (exclusive OR) function for `WORD` values with adapter-based interfaces. Its generic nature makes it versatile for use in automation projects developed according to the IEC 61499 standard that need to combine multiple bit patterns of the same data type.

2.1.11.7 booleanOperators

A2X_AND_2

• – ○ • – ○ • – ○ •

Introduction

The A2X_AND_2 function block computes the logical AND of two A2X adapters — separately for the UP and DOWN channels. Unlike the single-channel, generic `AX_AND` blocks, A2X_AND_2 is a hand-built composite function block that internally wires two standard `AND_BOOL_2` blocks, one per channel.

Interface Structure

Event Inputs

The function block has no direct event inputs — events flow through the `IN1`/`IN2` adapters.

Event Outputs

The function block has no direct event outputs — events flow through the `OUT` adapter.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

Input Adapters:

- **IN1**: AND input 1 (type: `adapter::types::unidirectional::A2X`)
- **IN2**: AND input 2 (type: `adapter::types::unidirectional::A2X`)

Output Adapter:

- **OUT**: AND result (type: `adapter::types::unidirectional::A2X`)

Functionality

The block contains two internal instances of `iec61131::booleanOperators::AND_BOOL_2`: `AND_UP` combines the UP channels of `IN1` and `IN2`, `AND_DOWN` the DOWN channels. When a UP event (`E_UP`) arrives on `IN1` or `IN2`, `AND_UP.REQ` is triggered, the result of `IN1.UP AND IN2.UP` is computed, and it is output via `OUT.E_UP`/`OUT.UP`. The DOWN channel runs the same logic independently through `AND_DOWN`. Because an event destination — unlike a data destination — may have multiple sources, both `IN1.E_UP` and `IN2.E_UP` are allowed to feed into `AND_UP.REQ`; the result is recomputed on either triggering event.

Technical Details

- A genuine composite block (not the `GenericClassName` mechanism used by `AX_AND_2`), built from two standard `AND_BOOL_2` instances
- Two independent channels (UP/DOWN), each with its own event pair — no shared state between channels
- Since IEC 61499 allows multiple sources on an event destination but not on a data destination, one logic block is inserted per channel instead of wiring the two input values directly onto a shared variable

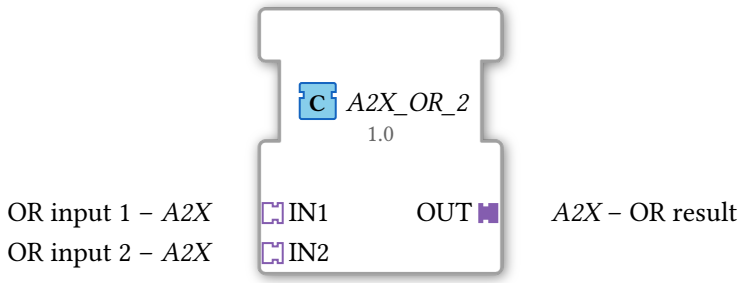
State Overview

The block is a combinational logic block with no internal state; every incoming event recomputes the result directly:

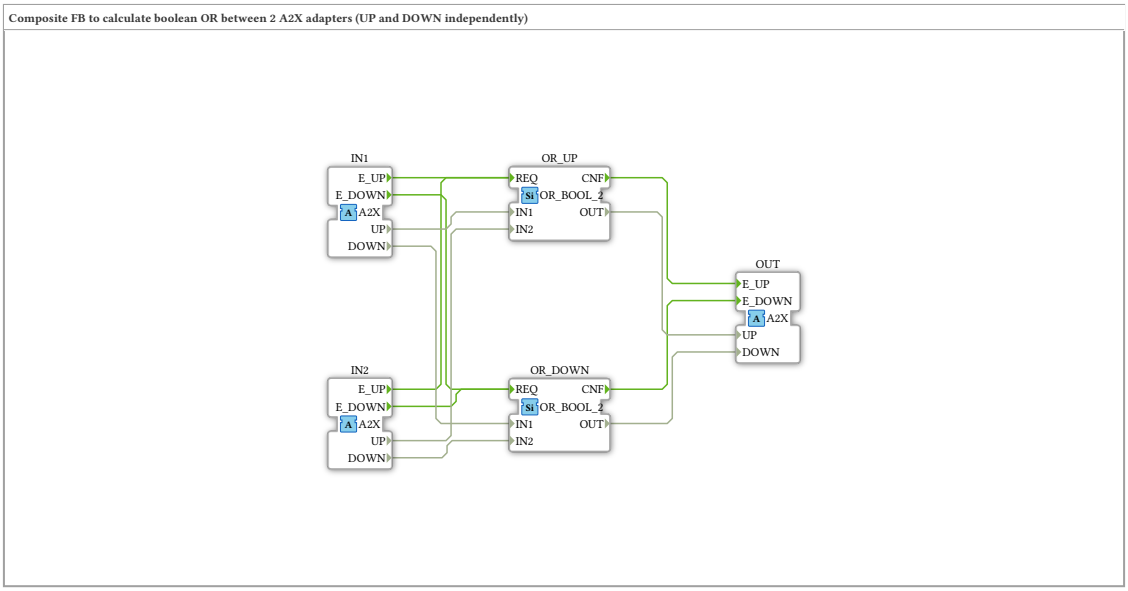
- IN1.E_UP, IN2.E_UP → AND_UP.REQ; IN1.UP, IN2.UP → AND_UP.IN1/IN2; AND_UP.CNF → OUT.E_UP; AND_UP.OUT → OUT.UP
- IN1.E_DOWN, IN2.E_DOWN → AND_DOWN.REQ; IN1.DOWN, IN2.DOWN → AND_DOWN.IN1/IN2; AND_DOWN.CNF → OUT.E_DOWN; AND_DOWN.OUT → OUT.DOWN

Application Scenarios

- Safety logic where two UP/DOWN signal sources must be active simultaneously before an actuator is enabled
- Interlocks between two redundant A2X signal sources
- Combinational logic in controllers built on A2X adapters instead of plain BOOL signals



⚖️ Comparison with Similar Blocks



A2X_OR_2 and A2X_XOR_2 are structurally identical but use `OR_BOOL_2` and `XOR_BOOL_2` instead of `AND_BOOL_2`. The single-channel predecessor AX_AND_2 combines only a single Boolean signal and, unlike A2X_AND_2, is implemented as a generic block (`GEN_AX_AND`). Unlike AB_AND_2, which combines a complete `BYTE` bit pattern, A2X_AND_2 processes individual Boolean truth values per channel.

Conclusion

A2X_AND_2 brings the logical AND operation to the two-channel A2X world: two independent, event-driven AND combinations for UP and DOWN, cleanly separated and without multiple writers on a shared variable.

A2X_OR_2

• – ○ • – ○ • – ○ •

Introduction

The A2X_OR_2 function block computes the logical OR of two A2X adapters — separately for the UP and DOWN channels. Like A2X_AND_2, it is a hand-built composite function block that internally wires two standard `OR_BOOL_2` blocks, one per channel.

Interface Structure

Event Inputs

The function block has no direct event inputs — events flow through the `IN1`/`IN2` adapters.

Event Outputs

The function block has no direct event outputs — events flow through the `OUT` adapter.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

Input Adapters:

- **IN1**: OR input 1 (type: `adapter::types::unidirectional::A2X`)
- **IN2**: OR input 2 (type: `adapter::types::unidirectional::A2X`)

Output Adapter:

- **OUT**: OR result (type: `adapter::types::unidirectional::A2X`)

Functionality

The block contains two internal instances of `iec61131::booleanOperators::OR_BOOL_2`: `OR_UP` combines the UP channels of `IN1` and `IN2`, `OR_DOWN` the DOWN channels. When a UP event (`E_UP`) arrives on `IN1` or `IN2`, `OR_UP.REQ` is triggered, the result of `IN1.UP OR IN2.UP` is computed, and it is output via `OUT.E_UP`/`OUT.UP`. The DOWN channel runs the same logic independently through `OR_DOWN`.

Technical Details

- A genuine composite block (not the `GenericClassName` mechanism), built from two standard `OR_BOOL_2` instances

- Two independent channels (UP/DOWN), each with its own event pair — no shared state between channels
- Since IEC 61499 allows multiple sources on an event destination but not on a data destination, one logic block is inserted per channel instead of wiring the two input values directly onto a shared variable

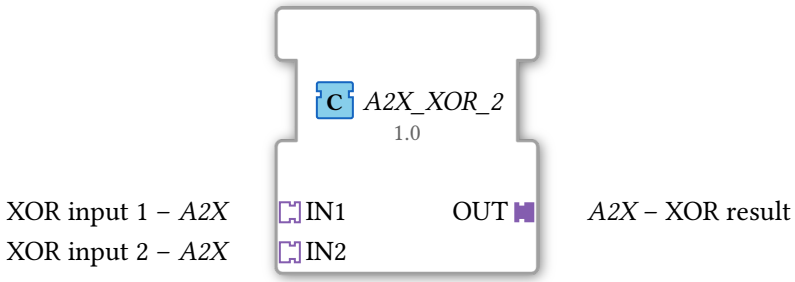
State Overview

The block is a combinational logic block with no internal state; every incoming event recomputes the result directly:

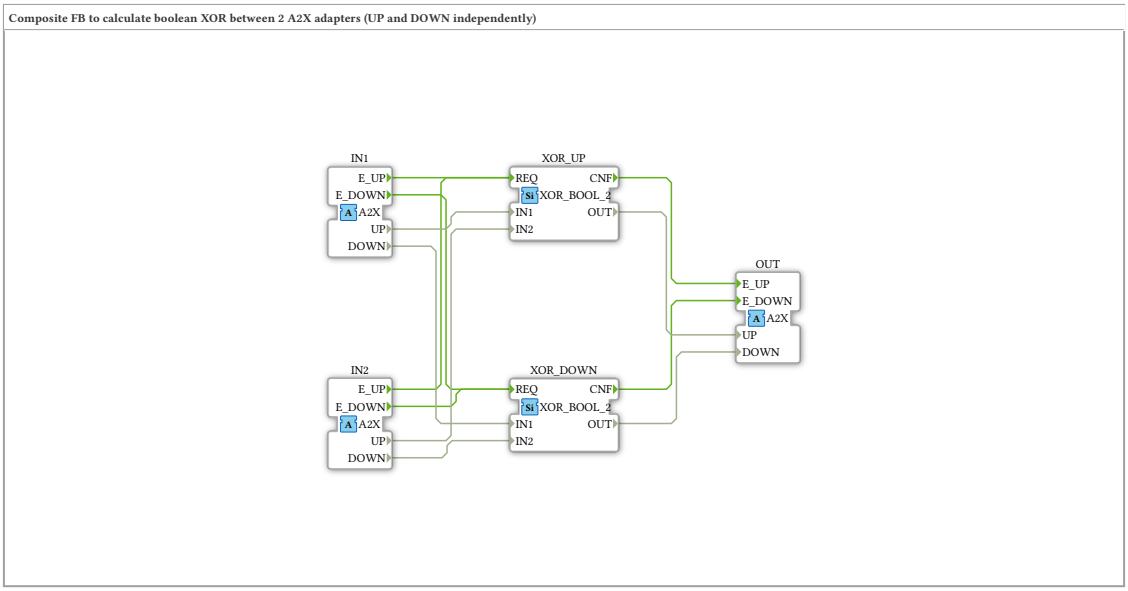
- IN1.E_UP, IN2.E_UP ⟶ OR_UP.REQ; IN1.UP, IN2.UP ⟶ OR_UP.IN1/IN2; OR_UP.CNF ⟶ OUT.E_UP; OR_UP.OUT ⟶ OUT.UP
- IN1.E_DOWN, IN2.E_DOWN ⟶ OR_DOWN.REQ; IN1.DOWN, IN2.DOWN ⟶ OR_DOWN.IN1/IN2; OR_DOWN.CNF ⟶ OUT.E_DOWN; OR_DOWN.OUT ⟶ OUT.DOWN

Application Scenarios

- Merging two redundant or alternative UP/DOWN signal sources into a single result
- Group alarms where triggering any one of several A2X signal sources is sufficient
- Combinational logic in controllers built on A2X adapters instead of plain BOOL signals



⚖️ Comparison with Similar Blocks



A2X_AND_2 and A2X_XOR_2 are structurally identical but use `AND_BOOL_2` and `XOR_BOOL_2` instead of `OR_BOOL_2`. The single-channel predecessor AX_OR_2 combines only a single Boolean signal and, unlike A2X_OR_2, is implemented as a generic block. Unlike bitwise blocks such as AB_AND_2, A2X_OR_2 processes individual Boolean truth values per channel.

Conclusion

A2X_OR_2 brings the logical OR operation to the two-channel A2X world: two independent, event-driven OR combinations for UP and DOWN, cleanly separated and without multiple writers on a shared variable.

A2X_XOR_2

• – ○ • – ○ • – ○ •

Introduction

The A2X_XOR_2 function block computes the logical exclusive-OR of two A2X adapters — separately for the UP and DOWN channels. Like A2X_AND_2 and A2X_OR_2, it is a hand-built composite function block that internally wires two standard `XOR_BOOL_2` blocks, one per channel.

Interface Structure

Event Inputs

The function block has no direct event inputs — events flow through the `IN1`/`IN2` adapters.

Event Outputs

The function block has no direct event outputs — events flow through the `OUT` adapter.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

Input Adapters:

- **IN1**: XOR input 1 (type: `adapter::types::unidirectional::A2X`)
- **IN2**: XOR input 2 (type: `adapter::types::unidirectional::A2X`)

Output Adapter:

- **OUT**: XOR result (type: `adapter::types::unidirectional::A2X`)

Functionality

The block contains two internal instances of `iec61131::booleanOperators::XOR_BOOL_2`: `XOR_UP` combines the UP channels of `IN1` and `IN2`, `XOR_DOWN` the DOWN channels. When a UP event (`E_UP`) arrives on `IN1` or `IN2`, `XOR_UP.REQ` is triggered, the result of `IN1.UP XOR IN2.UP` is computed, and it is output via `OUT.E_UP`/`OUT.UP`. The DOWN channel runs the same logic independently through `XOR_DOWN`.

Technical Details

- A genuine composite block (not the `GenericClassName` mechanism), built from two standard `XOR_BOOL_2` instances

- Two independent channels (UP/DOWN), each with its own event pair — no shared state between channels
- Since IEC 61499 allows multiple sources on an event destination but not on a data destination, one logic block is inserted per channel instead of wiring the two input values directly onto a shared variable

State Overview

The block is a combinational logic block with no internal state; every incoming event recomputes the result directly:

- IN1.E_UP, IN2.E_UP → XOR_UP.REQ; IN1.UP, IN2.UP → XOR_UP.IN1/IN2; XOR_UP.CNF → OUT.E_UP; XOR_UP.OUT → OUT.UP
- IN1.E_DOWN, IN2.E_DOWN → XOR_DOWN.REQ; IN1.DOWN, IN2.DOWN → XOR_DOWN.IN1/IN2; XOR_DOWN.CNF → OUT.E_DOWN; XOR_DOWN.OUT → OUT.DOWN

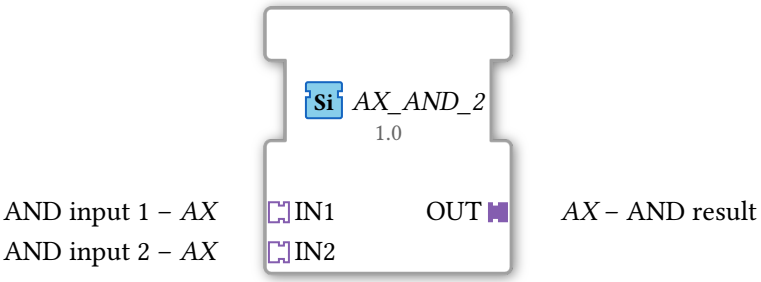
Application Scenarios

- Detecting contradictions between two UP/DOWN signal sources that should normally run in sync
- Toggle or exclusive-select logic where exactly one signal is allowed to be active
- Combinational logic in controllers built on A2X adapters instead of plain BOOL signals

⚖️ Comparison with Similar Blocks

A2X_AND_2 and A2X_OR_2 are structurally identical but use `AND_BOOL_2` and `OR_BOOL_2` instead of `XOR_BOOL_2`. The single-channel predecessor AX_XOR_2 combines only a single Boolean signal. Unlike bitwise blocks such as AB_AND_2, A2X_XOR_2 processes individual Boolean truth values per channel.

Conclusion



A2X_XOR_2 brings the logical exclusive-OR operation to the two-channel A2X world: two independent, event-driven XOR combinations for UP and DOWN, cleanly separated and without multiple writers on a shared variable.

AX_AND_2

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_AND_2 is a generic function block for calculating the logical AND operation. The block processes two Boolean input signals and outputs the logical AND result.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapter:

- **IN1** - AND input 1 (Adapter type: adapter::types::unidirectional::AX)
- **IN2** - AND input 2 (Adapter type: adapter::types::unidirectional::AX)

Output Adapter:

- **OUT** - AND result (Adapter type: adapter::types::unidirectional::AX)

Functionality

The function block performs a logical AND operation on the two input signals IN1 and IN2. The result is output via the output adapter OUT. Processing is unidirectional via the adapter interfaces.

Technical Features

- Generic function block with the specific class name 'GEN_AX_AND'
- Uses unidirectional adapters for signal transmission
- Implemented according to the IEC 61499-2 standard

State Overview

Since it is a combinational logic block, the AX_AND_2 has no internal states. The output is calculated directly from the current input values.

Application Scenarios

- Safety-critical controllers where two conditions must be met simultaneously
- Linking sensor signals in industrial automation systems
- Logical operations in control systems
- Safety shutdowns with multiple conditions

⚖️ Comparison with Similar Blocks

Compared to standard AND blocks, the AX_AND_2 uses adapter-based interfaces instead of direct data and event inputs/outputs. This enables more flexible integration into adapter-based system architectures.
Comparison AND_2

- `AX_AND_2_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

🛠️ Related Exercises

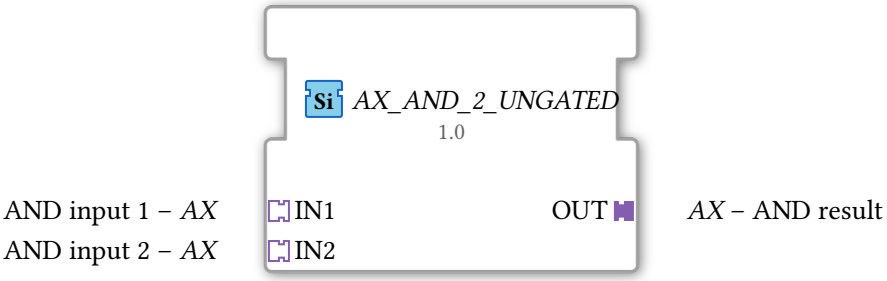
- Exercise_002a_AX
- Exercise_002b3_AX
- Exercise_006a3_AX

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_AND_2 offers a reliable and standards-compliant implementation of the logical AND function with adapter-based interfaces. Its generic nature makes it versatile for use in various automation projects developed according to the IEC 61499 standard.



AX_AND_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_AND_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

AX_AND_3

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_AND_3 is a generic function block for calculating a three-input logical AND operation. The block performs a Boolean AND operation on three independent input signals and outputs the result via an adapter output.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters (Sockets):

- **IN1** - AND Input 1 (Type: adapter::types::unidirectional::AX)

- **IN2** - AND Input 2 (Type: adapter::types::unidirectional::AX)
- **IN3** - AND Input 3 (Type: adapter::types::unidirectional::AX)

Output Adapters (Plugs):

- **OUT** - AND Result (Type: adapter::types::unidirectional::AX)

Functionality

The AX_AND_3 block performs a logical AND operation on the three input signals. The output signal is only active (TRUE) if all three input signals are active (TRUE) simultaneously. Processing is continuous based on the current input values.

Technical Features

- Uses unidirectional adapters for signal transmission
- Implemented as a generic function block with the generic class 'GEN_AX_AND'
- Works with AX-type adapters for standardized signal transmission
- No event-driven control - continuous evaluation

State Overview

The function block does not have an internal state machine, as it operates as a combinational logic circuit. The output is calculated directly from the current combination of input values. ...

Application Scenarios

- Safety controllers where multiple conditions must be met simultaneously
- Linking sensor signals in industrial controllers
- Logical processing in automation systems
- Monitoring systems with multiple conditions

⚖️ Comparison with similar function blocks

Compared to standard AND blocks, AX_AND_3 offers:

- Three inputs instead of the typical two inputs
- Adapter-based interface instead of direct data inputs/outputs
- Specific AX type compatibility
- Unidirectional signal transmission

Comparison with AND_3

🛠️ Related Exercises

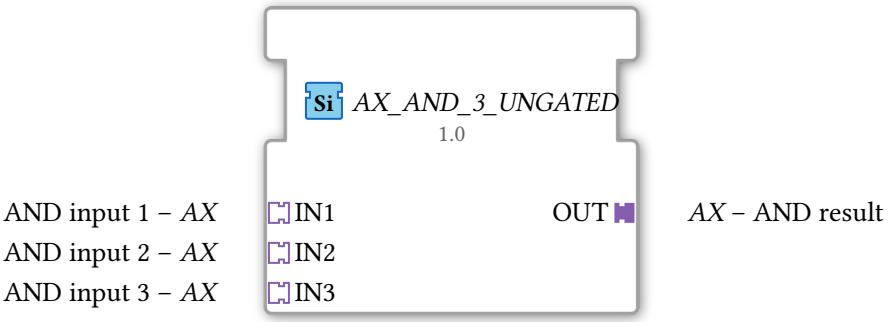
- Exercise_002a6_AX

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_AND_3 is a specialized logic function block for applications requiring triple AND operation with standardized AX adapters. Its adapter-based architecture enables easy integration into existing control systems and offers a reliable solution for complex logical connections.



AX_AND_3_UNGATED

AX_AND_4

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_AND_4 function block is a generic function block for calculating a four-input logical AND operation. It is used to process Boolean signals in automation systems and allows the combination of multiple input signals into a single output signal.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Plug Adapter:

- **OUT**: AND result (Adapter type: adapter::types::unidirectional::AX)

Socket Adapter:

- **IN1**: AND input 1 (Adapter type: adapter::types::unidirectional::AX)
- **IN2**: AND input 2 (Adapter type: adapter::types::unidirectional::AX)
- **IN3**: AND input 3 (Adapter type: adapter::types::unidirectional::AX)
- **IN4**: AND input 4 (Adapter type: adapter::types::unidirectional::AX)

Functionality

This function block performs a logical AND operation across four inputs. The output signal is only active (TRUE) if all four input signals are active (TRUE) simultaneously. As soon as at least one of the four inputs is inactive (FALSE), the output also becomes inactive.

Technical Features

- Generic function block with predefined class name 'GEN_AX_AND'
- Uses unidirectional adapters for signal transmission
- Implemented as part of the "adapter::booleanOperators" package
- Supports four independent input signals

State Overview

Since it is a combinational logic block, the AX_AND_4 has no internal states. The output is determined solely by the current input values.

Application Scenarios

- Safety controllers where multiple conditions must be met simultaneously
- Monitoring of multiple sensors
- Linking enable signals in process controllers
- Logical linking of control commands

Comparison with AND_4

⚖️ Comparison with similar function blocks

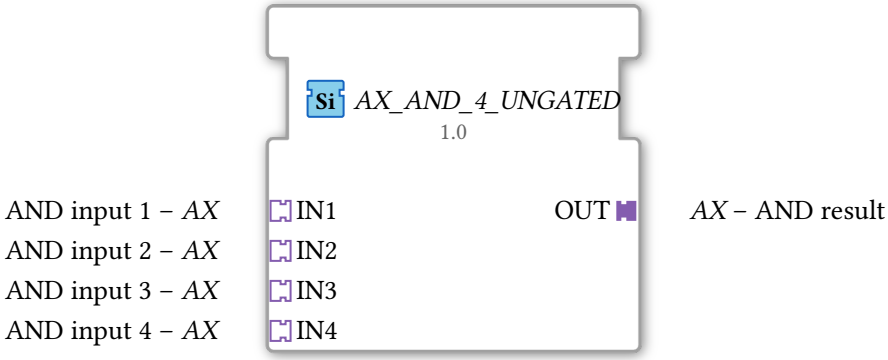
Compared to simple AND blocks with fewer inputs, AX_AND_4 offers the ability to directly link four signals without additional chaining. Compared to OR operations, the AND operation places stricter demands on activation.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_AND_4 function block provides an efficient solution for linking four Boolean input signals using a logical AND operation. Through the use of adapters, it enables flexible integration into various control systems and is particularly suitable for applications where multiple safety or enable conditions must be met simultaneously.



AX_AND_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_AND_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

AX_AND_6

Introduction

The `AX_AND_6` function block is a generic block for calculating a logical AND operation across six unidirectional AX adapter inputs. It is used to aggregate and monitor up to 6 input signals (e.g., emergency stop chains, enable or status signals) into a single adapter output signal.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Plug Adapter (Output):

- **OUT** – AND result (Adapter type: `adapter::types::unidirectional::AX`)

Socket Adapters (Inputs):

- **IN1** – AND input 1 (Adapter type: `adapter::types::unidirectional::AX`)
- **IN2** – AND input 2 (Adapter type: `adapter::types::unidirectional::AX`)
- **IN3** – AND input 3 (Adapter type: `adapter::types::unidirectional::AX`)
- **IN4** – AND input 4 (Adapter type: `adapter::types::unidirectional::AX`)
- **IN5** – AND input 5 (Adapter type: `adapter::types::unidirectional::AX`)
- **IN6** – AND input 6 (Adapter type: `adapter::types::unidirectional::AX`)

How It Works

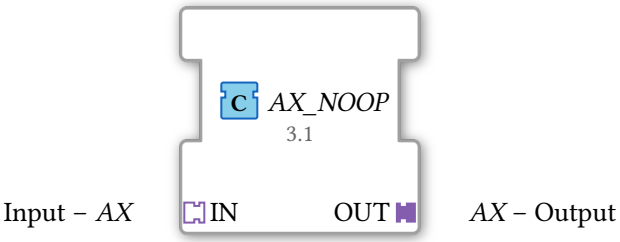
The function block evaluates the logical AND operation of all 6 AX inputs. The output `OUT.D1` is `TRUE` only when all six sockets `IN1.D1` through `IN6.D1` are simultaneously `TRUE`. If at least one input is `FALSE`, the output switches to `FALSE`.

Change Filtering

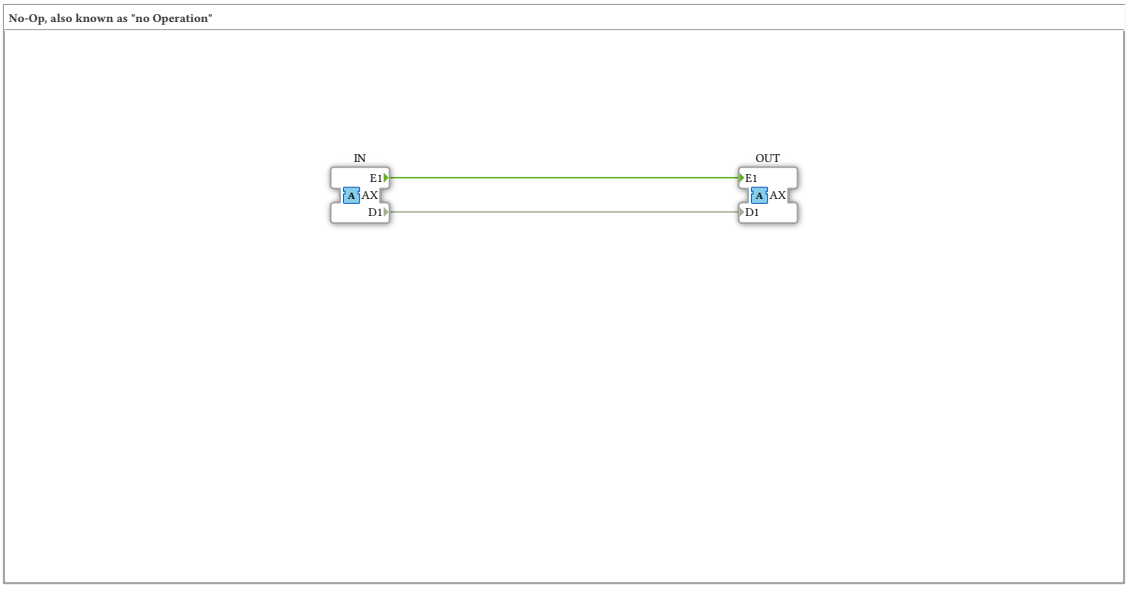
The result is written to output plug `OUT` and its adapter event `OUT.E1` is fired only when the newly calculated value differs from the currently held value. If the logical result remains unchanged, no adapter event is generated – preventing event flooding in downstream SubApps.

Technical Features

- **Generic Function Block**: Utilizes system class name `GEN_AX_AND` within the `adapter::booleanOperators` package.
- **Pure Adapter Interface**: Enables direct connection without manual event/data extraction.



Application Scenarios



- Aggregated monitoring of up to 6 emergency stop or safety channels (e.g., STG1 I1–I6 emergency stop monitoring).
- Grouping multiple safety and interlock criteria.

See Also

- `AX_AND_2` – 2-input AND block.
- `AX_AND_3` – 3-input AND block.
- `AX_AND_4` – 4-input AND block.

AX_NOOP

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_NOOP** (No Operation) serves as a pure pass-through function. It connects an incoming adapter (`IN`) directly to an outgoing adapter (`OUT`) without modifying data or processing events. This function block is designed as a basic block for testing, debugging, and placeholder purposes.

Interface Structure

Event Inputs

No direct event inputs are available.
Events are received via the adapter `IN`.

Event Outputs

No direct event outputs are available.
Events are passed on via the adapter `OUT`.

Data Inputs

No direct data inputs available.
Data is received via the `IN` adapter.

Data Outputs

No direct data outputs available.
Data is passed on via the `OUT` adapter.

Adapters

Type	Name	Direction	Comment
`adapter::types::unidirectional::AX`	IN	Socket (Input)	Receives events and data
`adapter::types::unidirectional::AX`	OUT	Plug (Output)	Passes on events and data unchanged

Functionality

This module establishes a point-to-point connection between the input adapter `IN` and the output adapter `OUT`. Internally, the following connections are implemented:

- **Event Connection**: `IN.E1` ⟶ `OUT.E1`
- **Data Connection**: `IN.D1` ⟶ `OUT.D1`

Every incoming event at `IN.E1` is immediately forwarded to `OUT.E1`. Every data value at `IN.D1` is passed on unchanged to `OUT.D1`. No logic, delay, or state change occurs.

Technical Features

- Pure passthrough without processing.
- Uses the adapter type `AX` for communication.
- No modifiable parameters or configurations.
- Ideally suited as a placeholder or for debugging adapter connections in the 4diac IDE.

State Overview

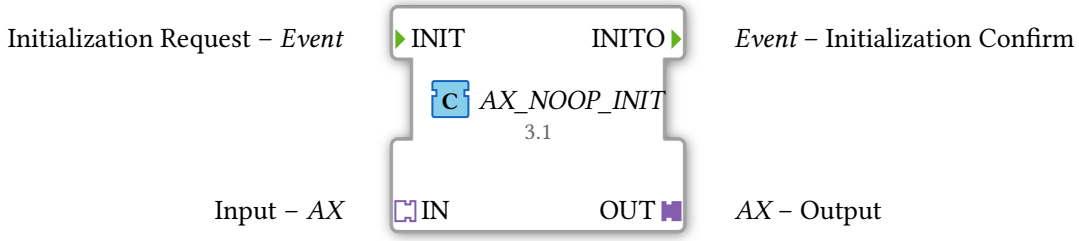
The function block does not have its own state machine. Its behavior is static and corresponds to direct wiring.

Application Scenarios

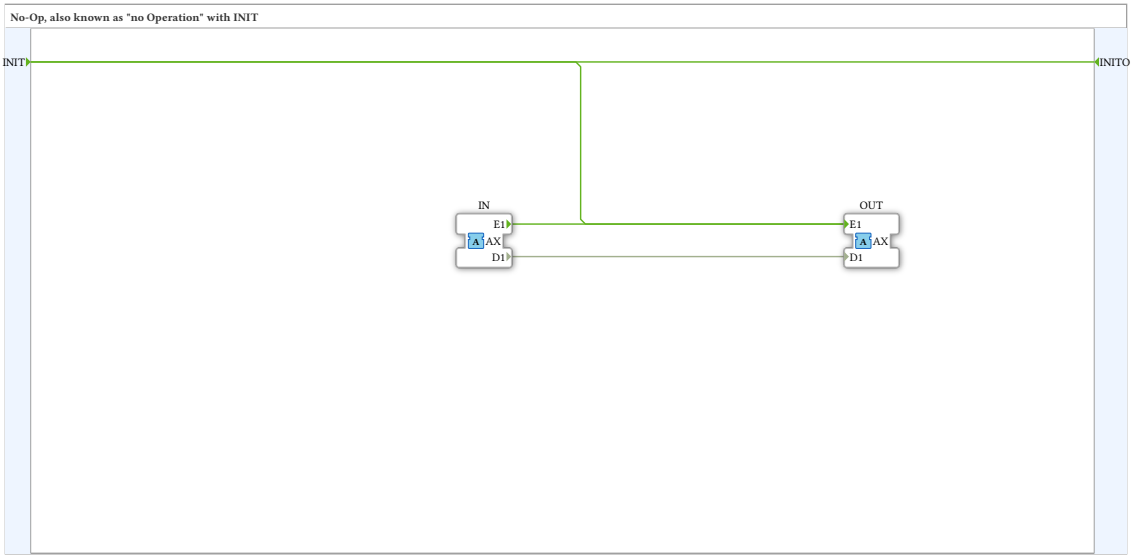
- **Test Environments**: Replacing a complex function block during the test phase to check the wiring.
- **Debugging**: Injecting a measurement or trace point into an adapter path.
- **Placeholder**: Temporarily inserting during the step-by-step implementation of a larger system.
- **Adapter Transparency**: Checking whether an adapter type is correctly connected without functional logic.

Comparison with Similar Function Blocks

Function Block	Description	Difference
`E_NOP`	Event NOP with direct event/data inputs/outputs	Uses standard I/O instead of adapters
`MUX`	Selection between multiple data sources	Provides selection, not pure passthrough
`BYE`	Explicit end-of-service marker	Has special semantics, not passthrough
AX_NOOP	Pure adapter passthrough	Specifically designed for the adapter type `AX`



Conclusion



The **AX_NOOP** is a minimalist yet useful component for working with adapter interfaces. Thanks to its simple pass-through functionality, it is ideally suited for testing, debugging, and as a placeholder in the 4diac IDE. Despite lacking its own logic, it plays a crucial role in the step-by-step development and verification of connection-intensive applications.

AX_NOOP_INIT

• – ○ • – ○ • – ○ •

Introduction

The function block `AX_NOOP_INIT` is a no-operation block that forwards incoming events and data from an adapter interface unchanged to an output interface. It also has an initialization function that, upon arrival of the INIT event, triggers both the INITO acknowledgment and the adapter's output event. It serves as a simple pass-through or placeholder block in automation technology.

Interface Structure

Event Inputs

- **INIT** (Type: `EInit`): Initialization request. Upon arrival, it triggers the event outputs `INITO` and `OUT.E1`.

Event Outputs

- **INITO** (Type: `EInit`): Initialization confirmation. Triggered directly by `INIT`.

Data Inputs

This function block does not have separate data inputs at the top level. All data is transmitted via the incoming adapter (`IN`).

Data Outputs

This function block does not have separate data outputs at the top level. All data is transmitted via the outgoing adapter (`OUT`).

Adapters

- **IN** (Socket): Input adapter of type `adapter::types::unidirectional::AX`. Provides an event interface `E1` and a data interface `D1`.
- **OUT** (Plug): Output adapter of type `adapter::types::unidirectional::AX`. Provides an event interface `E1` and a data interface `D1`.

Functionality

The function block operates as a simple pass-through module:

1. **Event Forwarding**:

- The INIT event is forwarded to `INITO` and to `OUT.E1`.
- The event `IN.E1` is passed directly to `OUT.E1`.

1. **Data Forwarding**:

- The value of `IN.D1` is copied unchanged to `OUT.D1`.

No processing or modification of the data takes place. The function block is stateless and simply combines the signal and data paths.

Technical Features

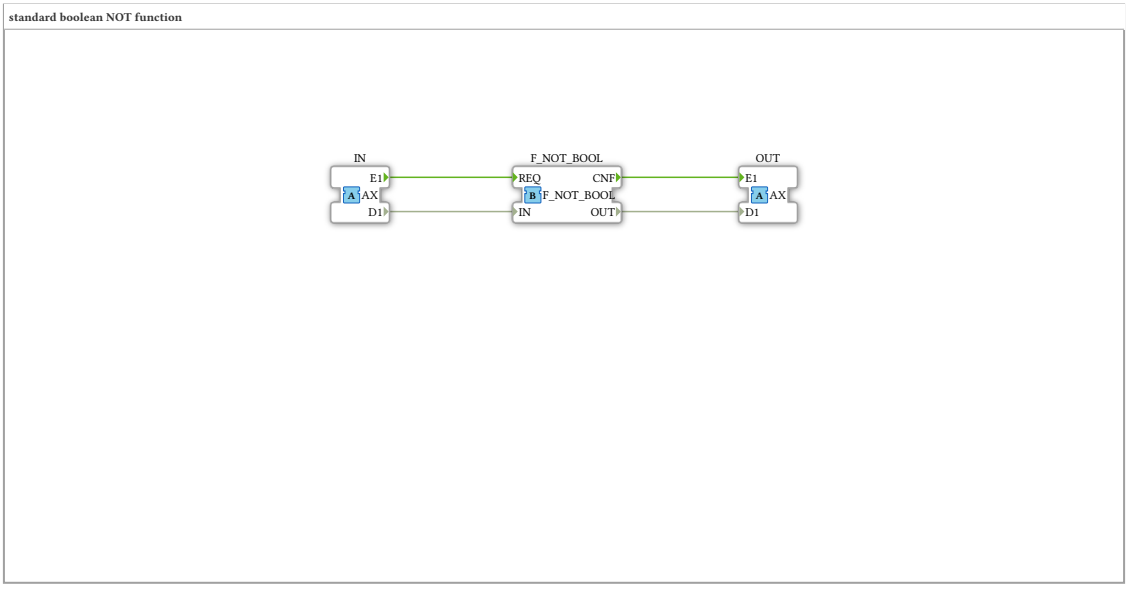
- The function block combines the pure pass-through function of a no-operation function block with an initialization-controlled output to the output adapter.
- The use of adapters (plug/socket) enables clean encapsulation and reusability of the interface definition.
- There are no internal states or timing behaviors – the response occurs immediately upon event input.

State Overview

The `AX_NOOP_INIT` has no states of its own. It reacts immediately to every incoming event and forwards it along with the associated data. A state machine is not present.

Application Scenarios

- **Initialization Cascades**: When multiple components in a chain need to be initialized, `AX_NOOP_INIT` can serve as a link, both acknowledging an INIT request and passing it on to the subsequent component.
- **Test and Simulation Environments**: As a placeholder to bridge interfaces and test functionalities without actual logic.
- **Adapter Passthrough**: When an adapter signal needs to be passed unchanged from a source to a destination without additional processing.

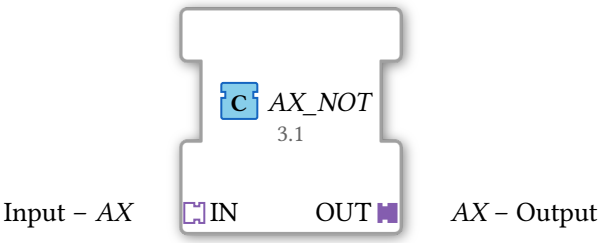


Comparison with Similar Components

A simple `AX_NOOP` (without INIT) would only pass through the IN/OUT events and data, but would not generate a separate initialization acknowledgment (`INITO`). The `AX_NOOP_INIT` extends this functionality with INIT handling, allowing it to be used directly in initialization processes.

Conclusion

The `AX_NOOP_INIT` is a simple yet useful function block for passing events and data at the adapter level. Its INIT functionality makes it particularly valuable in initialization chains or as a replacement for a test block. Its stateless nature makes it easy to understand and resource-efficient.



AX_NOT

• – ○ • – ○ • – ○ •

Introduction

The AX_NOT function block is a standardized Boolean NOT operator implemented according to the IEC 61131-3 standard. This block performs a logical negation (NOT operation) on the input values and outputs the inverted result.

Interface Structure

Event Inputs

The function block has no direct event inputs.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **IN** (Socket): Input adapter of type `adapter::types::unidirectional::AX` - used to transmit input data
- **OUT** (Plug): Output adapter of type `adapter::types::unidirectional::AX` - used to output the processed data

Functionality

The AX_NOT function block performs a logical negation on the Boolean values received via the IN adapter. The result of the NOT operation is output via the OUT adapter. Processing is bidirectional between the application and resource layers.

Technical Features

- Implemented according to the IEC 61131-3 standard for Boolean functions
- Uses unidirectional AX adapters for data transmission
- Works with the `adapter::booleanOperators` package
- Supports TypeHash functionality for type identification

State Overview

The function block operates statelessly and performs the NOT operation directly on the incoming data without storing any internal state.

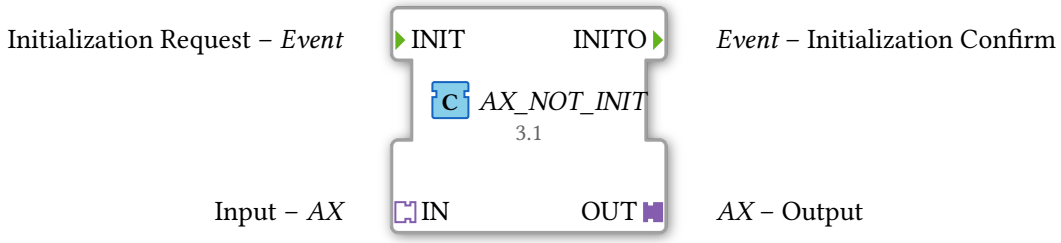
Application Scenarios

- Logical inversion of Boolean signals in control applications
- Signal reversal in automation systems
- Use in combinational circuits
- Integration into larger control logic for signal processing

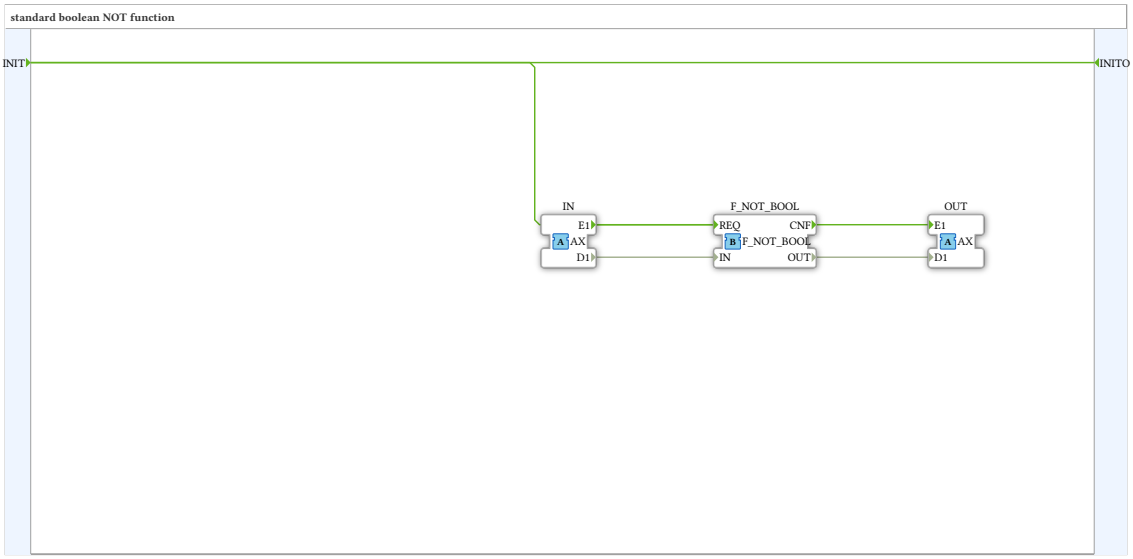
⚖️ Comparison with Similar Function Blocks

Compared to other Boolean operators such as AND or OR, AX_NOT performs only the negation operation. The use of adapters instead of direct inputs/outputs allows for more flexible integration into more complex system architectures.

Comparison with F_NOT



🛠️ Related Exercises



- Exercise_006a3_sub_AX

Conclusion

The AX_NOT function block offers a reliable and standards-compliant implementation of the Boolean NOT operation. Its adapter-based interface design makes it particularly suitable for modular system designs and enables easy integration into existing automation solutions.

AX_NOT_INIT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AX_NOT_INIT** implements a Boolean negation (NOT function) based on an adapter type. Unlike classic NOT blocks, it operates via a standardized adapter interface and is specifically designed for use in modular automation systems. Initialization occurs via the INIT event input, which triggers the first calculation.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization Request

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Confirmation

Data Inputs

This function block has no direct data inputs. Input data is obtained via the **IN** adapter.

Data Outputs

This function block has no direct data outputs. Output data is provided via the **OUT** adapter.

Adapters

Name	Type	Comment	Direction
IN	adapter::types::unidirectional::AX	Input Value	Socket
OUT	adapter::types::unidirectional::AX	Output Value (Negated)	Plug

Functionality

The function block performs a bitwise negation of the value provided via the **IN** adapter and outputs the result via the **OUT** adapter. Processing is initiated by an event at **IN.E1** (an event from the IN adapter) or by the INIT event. Internal steps:

1. An event at **INIT** or **IN.E1** activates the embedded function block **F_NOT_BOOL**.
2. **F_NOT_BOOL** retrieves the value from **IN.D1**, inverts it, and writes the result to **OUT.D1**.
3. Upon completion, an event is output via **OUT.E1** (to the OUT adapter) as well as **INITO**.

If the INIT event is received, **INITO** and **OUT.E1** are triggered immediately – the first negation occurs without a prior input event.

Technical Features

- **Adapter-Based Communication**: The function block uses exclusively unidirectional adapters of type `AX`, which modularly encapsulates the data and event interfaces. This facilitates communication between components using standardized protocols.
- **Initialization Behavior**: The INIT input performs an immediate initial calculation and outputs an acknowledgment event, which is useful for initial value settings or reset processes.
- **Reuse**: Internally, the IEC 61131-3 function block `F_NOT_BOOL` is used, which implements simple negation on Boolean values.

State Overview

The function block does not have an explicit state machine – it reacts event-driven. Simplified process:
Ereignis (INIT oder IN.E1) ⟶ Erfasse IN.D1 ⟶ Berechne NOT ⟶ Setze OUT.D1 ⟶ Sende INITO und/oder OUT.E1 The function block is **stateless**, meaning that each new request is processed independently of previous values.

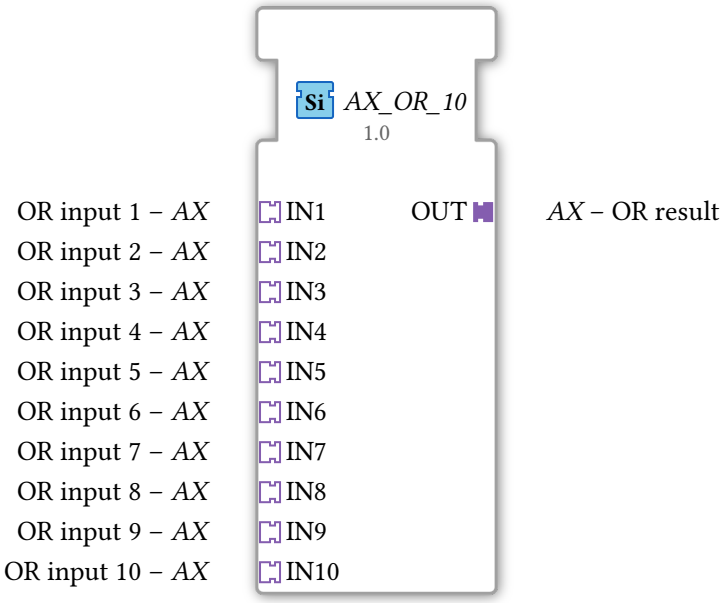
Application Scenarios

- **Signal Negation in Modular Systems**: If inputs and outputs are defined via adapters, the function block can be used as a universal NOT gate, e.g., for inverting actuator or sensor values.
- **Initialization Logic**: The INIT input ensures that the output provides a defined negated value at startup.
- **Adapter Compatibility**: In systems using the `AX` adapter protocol, the function block serves as a basic functional building block for logic operations.

Comparison with Similar Function Blocks

- **F_NOT_BOOL**: Standard IEC 61131-3 NOT function without an adapter. **AX_NOT_INIT** encapsulates this functionality in an adapter interface and adds initialization behavior.
- **AX_AND / AX_OR**: Analog adapter blocks for AND and OR, respectively. **AX_NOT_INIT** is specific for negation and has only one input.
- **F_TRIG / R_TRIG**: Edge detection that also uses events but does not perform logical negation.

Conclusion



The **AX_NOT_INIT** function block offers an efficient and standardized way to negate Boolean values via the `AX` adapter. By integrating initialization logic, it is particularly suitable for systems that require a defined initial state at startup. It complements the family of adapter-based logic blocks and simplifies the modular structuring of automation solutions.

AX_OR_10

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_OR_10 is a generic function block for calculating the logical OR operation of 10 inputs.

Interface Structure

Adapters

Input Adapters:

- **IN1** to **IN10** (adapter::types::unidirectional::AX)

Output Adapters:

- **OUT** (adapter::types::unidirectional::AX)

Functionality

The function block performs a logical OR operation on the 10 input signals.

Technical Features

- Generic function block with the specific class name 'GEN_AX_OR'
- Uses unidirectional adapters.

State Overview

Combinatory logic block without states.

Application Scenarios

Logical logic gates with many inputs.

⚖️ **Comparison with similar building blocks**

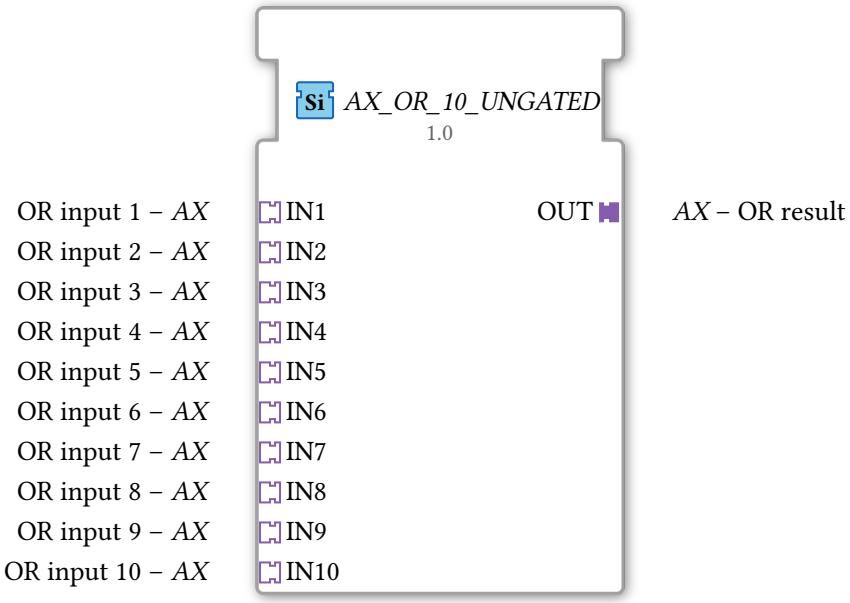
- **AX_OR_2...9**: Variants with fewer inputs.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

Adapter-based OR gate with 10 inputs.



AX_OR_10_UNGATED

i UNGATED variant: This block is the ungated version of `AX_OR_10`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_OR_10_UNGATED is a generic function block for calculating the logical OR operation of 10 inputs.

Interface Structure

Adapters

Input Adapters:

- **IN1** to **IN10** (adapter::types::unidirectional::AX)

Output Adapters:

- **OUT** (adapter::types::unidirectional::AX)

Functionality

The function block performs a logical OR operation on the 10 input signals.

Technical Features

- Generic function block with the specific class name 'GEN_AX_OR'
- Uses unidirectional adapters.

State Overview

Combinatory logic block without states.

Application Scenarios

Logical logic gates with many inputs.

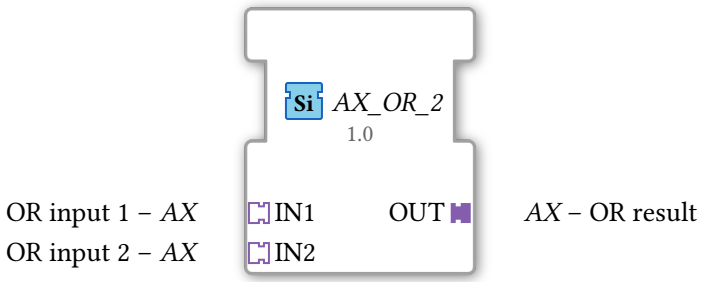
⚖️ Comparison with similar building blocks

- **AX_OR_2...9**: Variants with fewer inputs.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



Adapter-based OR gate with 10 inputs.

AX_OR_2

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_OR_2 function block is a generic function block for calculating Boolean OR operations. It processes two input signals and outputs the logical OR result. This function block is specifically designed for use in automation systems.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapter:

- **IN1** - OR Input 1 (Adapter Type: adapter::types::unidirectional::AX)
- **IN2** - OR Input 2 (Adapter Type: adapter::types::unidirectional::AX)

Output Adapter:

- **OUT** - OR Result (Adapter Type: adapter::types::unidirectional::AX)

Functionality

The AX_OR_2 function block performs a logical OR operation between the two input signals IN1 and IN2. The result is output via the output adapter OUT. Processing occurs continuously as soon as input signals are available.

Technical Features

- Generic function block with the class 'GEN_AX_OR'
- Uses unidirectional adapters for signal transmission

- Implemented as part of the “adapter::booleanOperators” package
- Supports the Eclipse 4diac standard specification 61499-2

State Overview

Since it is a combinational logic block, AX_OR_2 has no internal state. The output is determined solely by the current input values.

Application Scenarios

- Safety circuits with redundant sensors
- Parallel control commands
- Monitoring systems with multiple input signals
- Logical operations in control algorithms

⚖️ Comparison with similar components

Compared to other OR components, AX_OR_2 is distinguished by its adapter-based interface, which enables flexible integration into various system architectures. The unidirectional adapters ensure a clear signal flow direction.

Comparison with OR_2

AX_OR_3

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_OR_3 function block is a generic function block for calculating the logical OR operation with three inputs. It is used to process Boolean signals in control applications and allows the flexible combination of multiple input signals into a single output signal.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapter

Input Adapter:

- **IN1**: OR Input 1 (Type: adapter::types::unidirectional::AX)
- **IN2**: OR Input 2 (Type: adapter::types::unidirectional::AX)
- **IN3**: OR Input 3 (Type: adapter::types::unidirectional::AX)

Output Adapter:

- **OUT**: OR Result (Type: adapter::types::unidirectional::AX)

Functionality

The function block continuously calculates the logical OR operation of the three input signals. The output signal is true (TRUE) if at least one of the three inputs is true. Only if all three inputs are false (FALSE) will the output also be false.

The logical function can be represented as follows:
OUT = IN1 OR IN2 OR IN3

Technical Features

- Uses unidirectional adapters for signal transmission
- Implemented as a generic function block with the class 'GEN_AX_OR'
- Operates without event control, computs continuously
- Optimized for use in adapter-based architectures

State Overview

Since it is a combinational function block without a memory function, AX_OR_3 has no internal states. The output is determined solely by the current input values.

Application Scenarios

- Safety circuits with multiple emergency stop buttons
- Monitoring systems with multiple sensors
- Control logic with alternative activation conditions
- Linking status messages from various sources

⚖️ Comparison with Similar Function Blocks

Compared to standard OR blocks, AX_OR_3 offers the advantage of three inputs in a single block, which simplifies wiring. Compared to function blocks with a variable number of inputs, AX_OR_3 is specifically optimized for triple OR operation.

Comparison with OR_3

🛠️ Related Exercises

- Exercise_002a5_AX
- Exercise_002a5b_AX

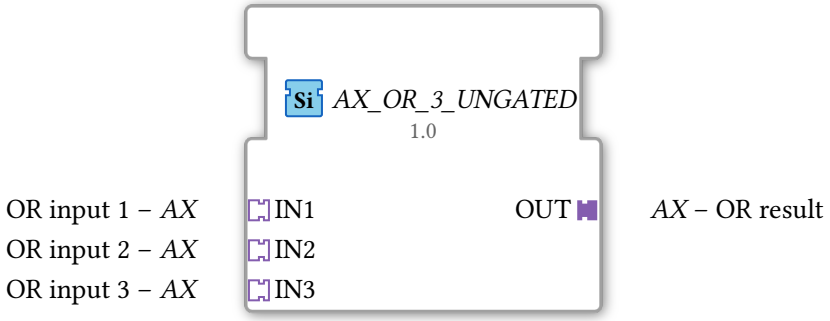
Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_OR_3 function block provides an efficient solution for three-input OR logic operations. Its adapter-based interface allows for flexible integration into various control architectures and makes it particularly suitable for applications where multiple conditions can be met alternatively.

AX_OR_3_UNGATED



> **i UNGATED variant:** This block is the ungated version of `AX_OR_3`. AX_OR_4

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_OR_4 is a generic function block for calculating a four-input logical OR operation. The block processes Boolean signals and outputs the result of the OR operation via an adapter output.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Incoming Adapters (Sockets):

- **IN1**: OR Input 1 (Type: adapter::types::unidirectional::AX)
- **IN2**: OR Input 2 (Type: adapter::types::unidirectional::AX)
- **IN3**: OR Input 3 (Type: adapter::types::unidirectional::AX)
- **IN4**: OR Input 4 (Type: adapter::types::unidirectional::AX)

Outgoing Adapters (Plugs):

- **OUT**: OR Result (Type: adapter::types::unidirectional::AX)

Functionality

This function block continuously calculates the logical OR operation of the four input signals. The result is output via the outgoing adapter OUT. The OR operation returns a logical TRUE if at least one of the four inputs is TRUE. Only if all four inputs are FALSE will the result be FALSE.

Technical Features

- Uses unidirectional adapters for communication
- Implemented as a generic function block with the class 'GEN_AX_OR'
- Works with the AX adapter type for Boolean values
- No event control - operates continuously

State Overview

Since it is a combinational function block without event control, the AX_OR_4 does not have a state machine. The output is calculated continuously based on the current input values.

Application Scenarios

- Safety circuits with multiple emergency stop buttons
- Monitoring systems with multiple sensors
- Control logic with parallel conditions
- Alarm systems with multiple triggers

⚖️ Comparison with Similar Function Blocks

Compared to simpler OR function blocks, the AX_OR_4 offers the advantage of four inputs in a single block, which simplifies wiring and saves space. Compared to event-driven function blocks, AX_OR_4 operates continuously without explicit trigger events.

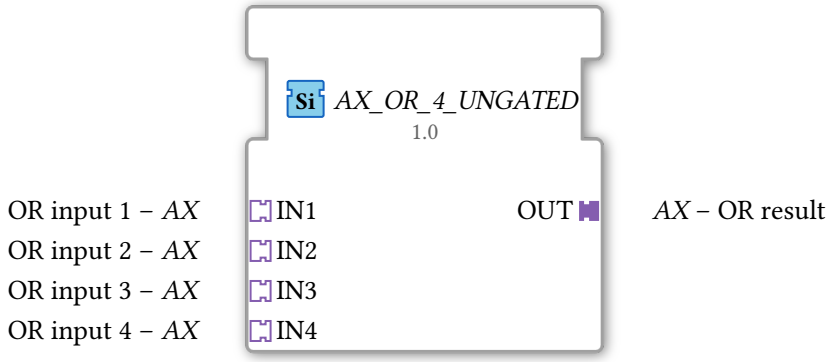
Comparison with OR_4

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_OR_4 is an efficient and compact function block for four-input logical OR gates. Its adapter-based interface allows for flexible integration into larger control systems, while its continuous operation ensures an immediate response to input changes.



AX_OR_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_OR_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

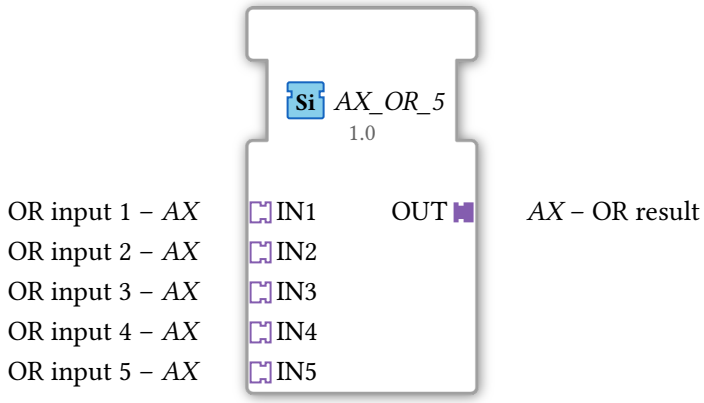
Conclusion



The AX_OR_4_UNGATED is an efficient and compact function block for four-input logical OR gates. Its adapter-based interface allows for flexible integration into larger control systems, while its continuous operation ensures an immediate response to input changes.

AX_OR_5

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_OR_5 function block is a generic block for calculating Boolean OR operations with five inputs. It is used for the logical processing of signals in automation systems and allows the combination of multiple input signals into a single output signal.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Plug Adapter:

- **OUT**: Unidirectional adapter for the OR result

Socket Adapter:

- **IN1**: Unidirectional adapter for OR input 1
- **IN2**: Unidirectional adapter for OR input 2
- **IN3**: Unidirectional adapter for OR input 3
- **IN4**: Unidirectional adapter for OR input 4
- **IN5**: Unidirectional adapter for OR input 5

Functionality

This function block calculates the logical OR operation of the five input signals. The output signal is TRUE if at least one of the five inputs is TRUE. If all inputs are FALSE, the output signal is also FALSE. Processing is performed via adapter interfaces, with all inputs and outputs configured unidirectionally.

Technical Features

- Generic function block with five inputs
- Uses unidirectional adapters for all interfaces
- Implemented as a five-operand OR gate
- No event-driven logic, continuous signal processing

State Overview

The block has no internal state and operates stateless. The output is continuously calculated based on the current input values.

Application Scenarios

- Safety circuits with multiple emergency stop buttons
- Monitoring systems with multiple sensors
- Control logic with parallel conditions
- Alarm systems with multiple triggers

⚖️ Comparison with Similar Blocks

Compared to standard OR blocks with fewer inputs, AX_OR_5 offers the ability to process five signals simultaneously, simplifying wiring and saving space. Compared to cascaded OR gates, this block provides an integrated solution.

Comparison with OR_5

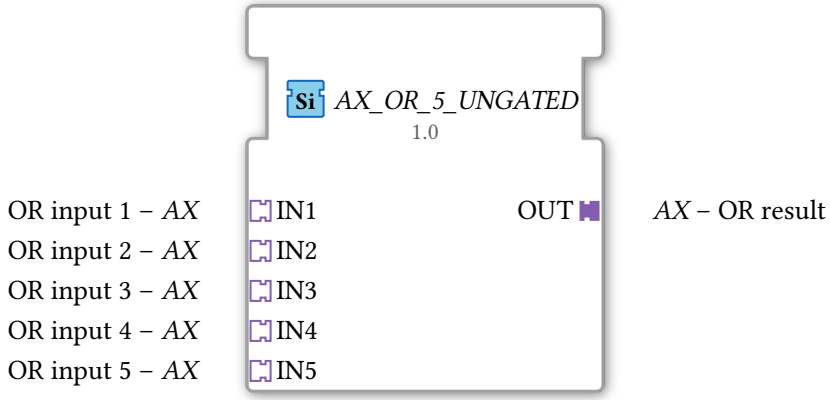
- `AX_OR_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_OR_5 function block provides an efficient solution for five-input OR logic operations. Using adapters, it allows for flexible integration into various system architectures and is particularly suitable for applications requiring logical combinations of multiple signals.



AX_OR_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_OR_5`. - **IN2**: Unidirectional adapter for OR input 2
- **IN3**: Unidirectional adapter for OR input 3
- **IN4**: Unidirectional adapter for OR input 4
- **IN5**: Unidirectional adapter for OR input 5

Functionality

This function block calculates the logical OR operation of the five input signals. The output signal is TRUE if at least one of the five inputs is TRUE. If all inputs are FALSE, the output signal is also FALSE. Processing is performed via adapter interfaces, with all inputs and outputs configured unidirectionally.

Technical Features

- Generic function block with five inputs
- Uses unidirectional adapters for all interfaces
- Implemented as a five-operand OR gate
- No event-driven logic, continuous signal processing

State Overview

The block has no internal state and operates stateless. The output is continuously calculated based on the current input values.

Application Scenarios

- Safety circuits with multiple emergency stop buttons
- Monitoring systems with multiple sensors
- Control logic with parallel conditions
- Alarm systems with multiple triggers

⚖️ Comparison with Similar Blocks

Compared to standard OR blocks with fewer inputs, AX_OR_5_UNGATED offers the ability to process five signals simultaneously, simplifying wiring and saving space. Compared to cascaded OR gates, this block provides an integrated solution.

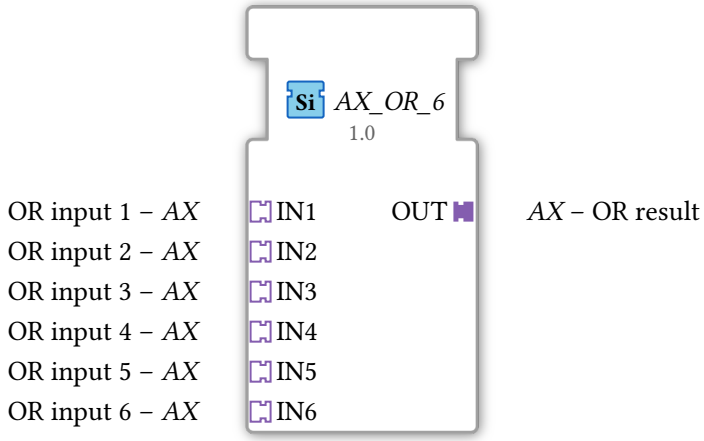
Comparison with OR_5

- **AX_OR_5**: The gated variant – updates the output only on an actual value change.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The AX_OR_5_UNGATED function block provides an efficient solution for five-input OR logic operations. Using adapters, it allows for flexible integration into various system architectures and is particularly suitable for applications requiring logical combinations of multiple signals.

AX_OR_6

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_OR_6 is a generic function block for calculating a logical OR operation with six inputs. This block is used to process Boolean signals in automation systems and outputs the result of the OR operation via an adapter output.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

Input Adapters:

- **IN1** - OR Input 1 (Type: adapter::types::unidirectional::AX)
- **IN2** - OR Input 2 (Type: adapter::types::unidirectional::AX)
- **IN3** - OR Input 3 (Type: adapter::types::unidirectional::AX)
- **IN4** - OR Input 4 (Type: adapter::types::unidirectional::AX)
- **IN5** - OR Input 5 (Type: adapter::types::unidirectional::AX)
- **IN6** - OR input 6 (Type: adapter::types::unidirectional::AX)

Output adapter:

- **OUT** - OR result (Type: adapter::types::unidirectional::AX)

Functionality

The function block continuously calculates the logical OR operation of all six input signals. The output signal is TRUE if at least one of the six inputs is TRUE. Only if all six inputs are FALSE will the output also be FALSE.

Technical Features

- Generic function block with the class 'GEN_AX_OR'
- Uses unidirectional AX adapters for signal transmission
- Six independent inputs for flexible applications
- Real-time processing without event control

State Overview

The function block has no internal state and operates stateless. The output is continuously calculated based on the current input values.

Application Scenarios

- Safety circuits with multiple emergency stop buttons
- Monitoring systems with multiple sensors
- Control logic with alternative activation conditions
- Linking multiple status messages

⚖️ Comparison with similar components

Compared to simpler OR components with fewer inputs, the AX_OR_6 offers greater flexibility thanks to its six separate inputs. The exclusive use of adapters instead of conventional data inputs/outputs enables a modular system architecture.

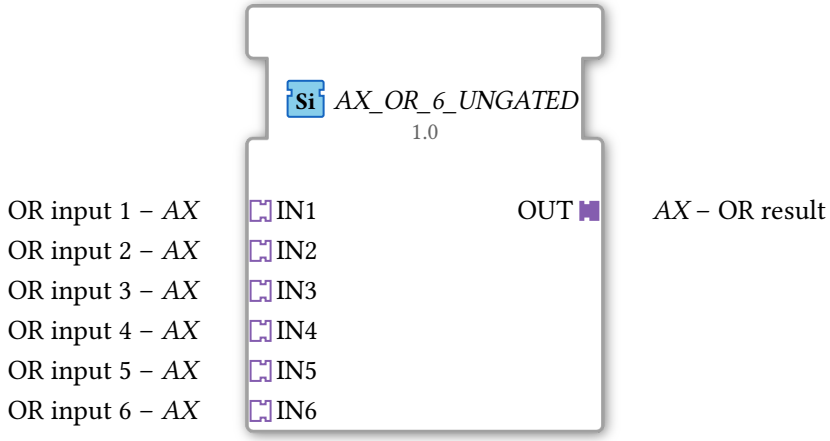
Comparison with OR_6

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_OR_6 is a specialized logic component for applications requiring a multi-input OR gate. Its adapter-based interface makes it particularly suitable for modular system designs and allows for clear separation of signal paths.



AX_OR_6_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_OR_6`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

- **IN6** - OR input 6 (Type: adapter::types::unidirectional::AX)

Output adapter:

- **OUT** - OR result (Type: adapter::types::unidirectional::AX)

Functionality

The function block continuously calculates the logical OR operation of all six input signals. The output signal is TRUE if at least one of the six inputs is TRUE. Only if all six inputs are FALSE will the output also be FALSE.

Technical Features

- Generic function block with the class ‘GEN_AX_OR’
- Uses unidirectional AX adapters for signal transmission
- Six independent inputs for flexible applications
- Real-time processing without event control

State Overview

The function block has no internal state and operates stateless. The output is continuously calculated based on the current input values.

Application Scenarios

- Safety circuits with multiple emergency stop buttons
- Monitoring systems with multiple sensors
- Control logic with alternative activation conditions
- Linking multiple status messages

⚖️ Comparison with similar components

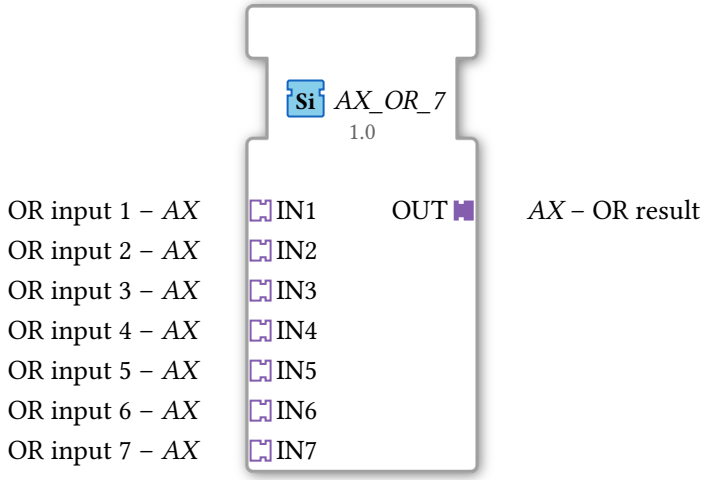
Compared to simpler OR components with fewer inputs, the AX_OR_6_UNGATED offers greater flexibility thanks to its six separate inputs. The exclusive use of adapters instead of conventional data inputs/outputs enables a modular system architecture.

Comparison with OR_6

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The AX_OR_6_UNGATED is a specialized logic component for applications requiring a multi-input OR gate. Its adapter-based interface makes it particularly suitable for modular system designs and allows for clear separation of signal paths.

AX_OR_7

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_OR_7 function block is a generic function block for calculating Boolean OR operations. It has seven inputs and calculates the logical OR of all input signals.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Input Adapter:

- **IN1** - OR Input 1
- **IN2** - OR Input 2
- **IN3** - OR Input 3
- **IN4** - OR Input 4
- **IN5** - OR Input 5
- **IN6** - OR Input 6
- **IN7** - OR Input 7

Output Adapter:

- **OUT** - OR Result

All adapters use the type `adapter::types::unidirectional::AX`.

Functionality

The function block continuously calculates the Boolean OR operation of all seven input signals. The result is output via the output adapter OUT. The output signal is TRUE if at least one of the seven inputs is TRUE.

Technical Features

- Generic function block with the class 'GEN_AX_OR'
- Uses unidirectional AX adapters for all interfaces
- No event control - operates continuously
- Seven independent inputs for maximum flexibility

State Overview

Since it is a purely combinational function block without event control, the AX_OR_7 does not have a state machine. The output is calculated directly from the current input values.

Application Scenarios

- Safety circuits with multiple emergency stop buttons
- Multiple operator stations in machine controls
- Monitoring systems with multiple sensors
- Linking multiple enable signals

⚖️ Comparison with Similar Function Blocks

Compared to standard OR blocks, the AX_OR_7 offers the unique feature of seven inputs, which simplifies wiring because fewer blocks need to be connected in series. The use of adapters instead of direct data connections allows for more flexible integration into various system architectures.

Comparison with OR_7

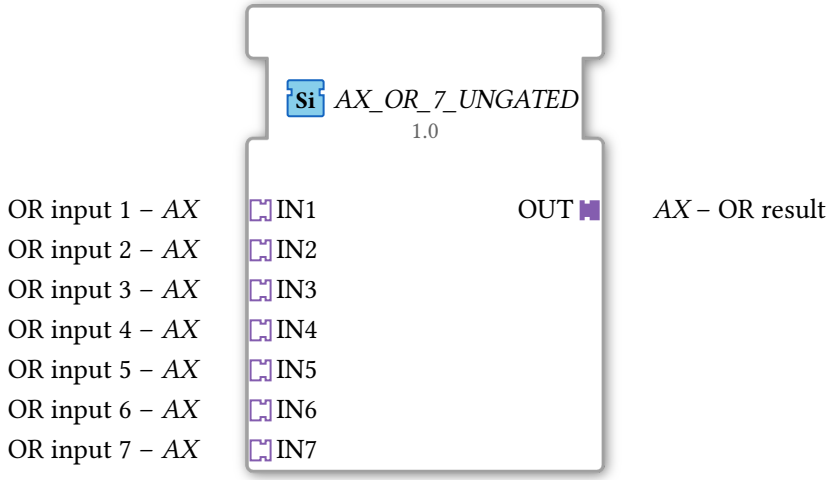
Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_OR_7 is a specialized OR gate for applications with many input signals. With its seven inputs and adapter-based interface, it is particularly suitable for complex control tasks where multiple signals need to be logically combined.

AX_OR_7_UNGATED



> **i UNGATED variant:** This block is the ungated version of `AX_OR_7`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change.

This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_OR_7_UNGATED function block is a generic function block for calculating Boolean OR operations. It has seven inputs and calculates the logical OR of all input signals.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Input Adapter:

- **IN1** - OR Input 1
- **IN2** - OR Input 2
- **IN3** - OR Input 3
- **IN4** - OR Input 4
- **IN5** - OR Input 5
- **IN6** - OR Input 6
- **IN7** - OR Input 7

Output Adapter:

- **OUT** - OR Result

All adapters use the type `adapter::types::unidirectional::AX`.

Functionality

The function block continuously calculates the Boolean OR operation of all seven input signals. The result is output via the output adapter OUT. The output signal is TRUE if at least one of the seven inputs is TRUE.

Technical Features

- Generic function block with the class ‘GEN_AX_OR’
- Uses unidirectional AX adapters for all interfaces
- No event control - operates continuously
- Seven independent inputs for maximum flexibility

State Overview

Since it is a purely combinational function block without event control, the AX_OR_7_UNGATED does not have a state machine. The output is calculated directly from the current input values.

Application Scenarios

- Safety circuits with multiple emergency stop buttons
- Multiple operator stations in machine controls
- Monitoring systems with multiple sensors
- Linking multiple enable signals

⚖ Comparison with Similar Function Blocks

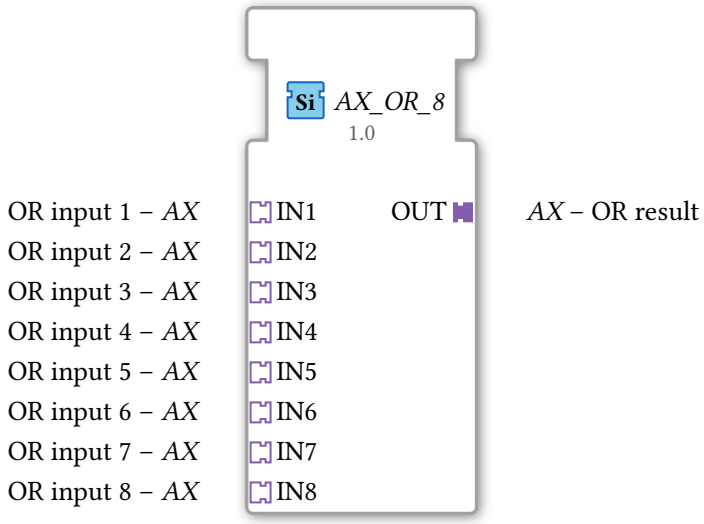
Compared to standard OR blocks, the AX_OR_7_UNGATED offers the unique feature of seven inputs, which simplifies wiring because fewer blocks need to be connected in series. The use of adapters instead of direct data connections allows for more flexible integration into various system architectures.

Comparison with OR_7

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The AX_OR_7_UNGATED is a specialized OR gate for applications with many input signals. With its seven inputs and adapter-based interface, it is particularly suitable for complex control tasks where multiple signals need to be logically combined.

AX_OR_8

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_OR_8 function block is a generic function block for calculating an eight-input logical OR operation. It is used to process Boolean signals in control applications and allows the combination of multiple input signals into a single output signal.

Interface Structure

Event Inputs
No event inputs available

Event Outputs
No event outputs available

Data Inputs
No direct data inputs available

Data Outputs
No direct data outputs available

Adapters
Input Adapters:

- **IN1** - OR input 1 (unidirectional AX adapter)
- **IN2** - OR input 2 (unidirectional AX adapter)
- **IN3** - OR input 3 (unidirectional AX adapter)
- **IN4** - OR input 4 (unidirectional AX adapter)
- **IN5** - OR input 5 (unidirectional AX adapter)
- **IN6** - OR input 6 (unidirectional AX adapter) AX Adapter
- **IN7** - OR input 7 (unidirectional AX adapter)
- **IN8** - OR input 8 (unidirectional AX adapter)

Output Adapter:

- **OUT** - OR result (unidirectional AX adapter)

Functionality
The AX_OR_8 block performs a logical OR operation on all eight inputs. The output signal is set to TRUE if at least one of the eight inputs is TRUE. Only if all inputs are FALSE will the output also be FALSE.

The functionality corresponds to the Boolean equation:
OUT = IN1 ∨ IN2 ∨ IN3 ∨ IN4 ∨ IN5 ∨ IN6 ∨ IN7 ∨ IN8

Technical Features
- Generic function block with the class name identifier ‘GEN_AX_OR’
- Uses unidirectional AX adapters for all interfaces
- No internal states or memory functions
- Immediate processing without delay
- Part of the “adapter::booleanOperators” package

State Overview
The function block is stateless and performs the OR operation immediately upon any change to the inputs. No internal states are stored.

Application Scenarios
- Safety circuits with multiple emergency stop buttons
- Monitoring systems with multiple sensors
- Control logic with parallel conditions
- Alarm systems with multiple triggers
- Linking multiple enable signals

⚖️ Comparison with similar function blocks
Compared to simple OR function blocks with fewer inputs, AX_OR_8 offers the ability to directly link up to eight signals without additional chaining of multiple function blocks. The use of adapters instead of direct data connections enables more flexible integration into various system architectures.

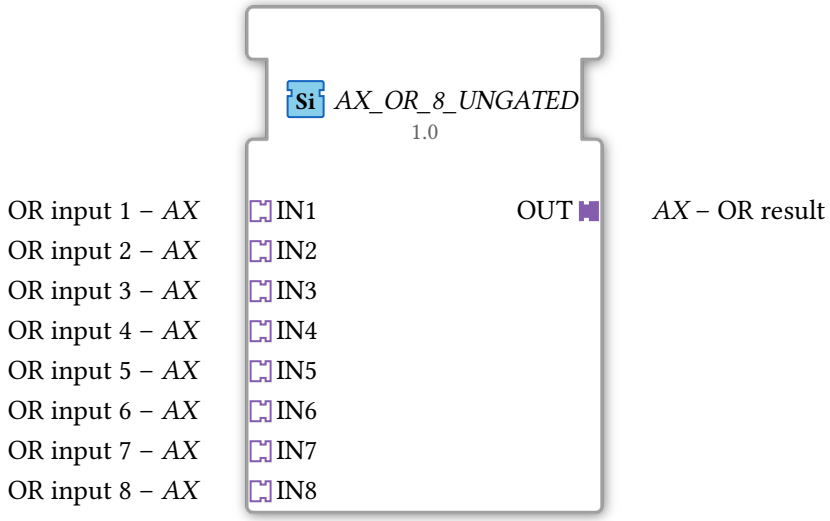
Comparison with OR_8

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_OR_8 function block represents an efficient solution for complex OR logic operations with up to eight inputs. Due to the use of standard adapters and its generic implementation, it is particularly suitable for reusable control logic in industrial automation applications.



AX_OR_8_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_OR_8`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

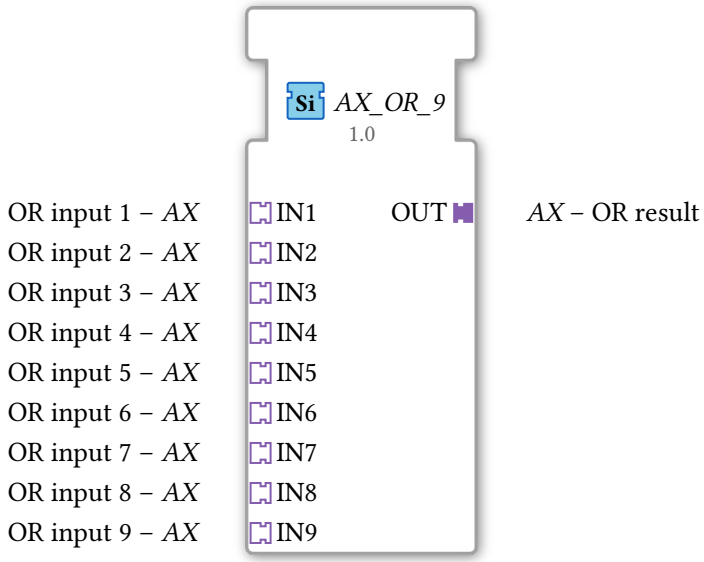
Conclusion



The AX_OR_8_UNGATED function block represents an efficient solution for complex OR logic operations with up to eight inputs. Due to the use of standard adapters and its generic implementation, it is particularly suitable for reusable control logic in industrial automation applications.

AX_OR_9

• − ◦ • − ◦ • − ◦ •

Introduction

The AX_OR_9 is a generic function block for calculating the Boolean OR operation with nine inputs. This block is used for the logical processing of signals in automation systems and outputs the result of the OR operation on all input signals.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Sockets (Inputs):

- **IN1** - OR Input 1
- **IN2** - OR Input 2
- **IN3** - OR Input 3
- **IN4** - OR Input 4
- **IN5** - OR Input 5
- **IN6** - OR Input 6
- **IN7** - OR Input 7
- **IN8** - OR Input 8
- **IN9** - OR Input 9

Plugs (Outputs):

- **OUT** - OR Result

Functionality

The function block continuously calculates the Boolean OR operation of all nine input signals. The output signal is TRUE (1) if at least one of the nine inputs is TRUE (1). Only if all inputs are FALSE (0) will the output also be FALSE (0).

Technical Features

- Generic function block with a fixed number of 9 inputs
- Uses unidirectional AX adapters for inputs and outputs
- No event-driven control - operates continuously
- Implemented as a generic function block with a specific class name

State Overview

The function block has no internal state and operates stateless. The output is calculated solely based on the current input values.

Application Scenarios

- Safety circuits with multiple emergency stop buttons
- Monitoring systems with multiple sensors
- Control logic with redundant input signals
- Alarm systems with multiple triggers

⚖️ Comparison with similar function blocks

Compared to standard OR function blocks with fewer inputs, AX_OR_9 offers the ability to process up to nine signals simultaneously, simplifying the wiring of more complex logic. Unlike configurable OR function blocks, this block has a fixed number of inputs, simplifying configuration for known requirements.

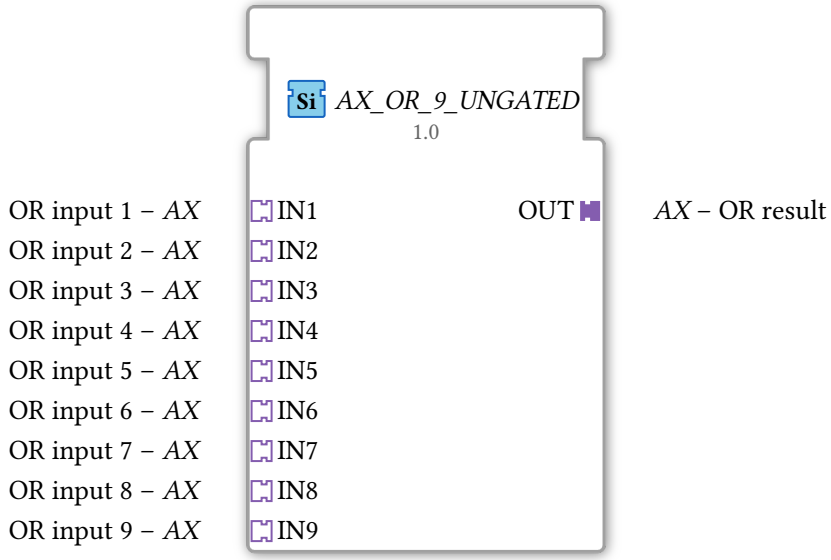
Comparison with OR_9

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_OR_9 is a specialized OR function block for applications that need to logically combine exactly nine input signals. Its fixed number of inputs and simple operation make it particularly suitable for clearly defined control tasks with redundant input signals.



AX_OR_9_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_OR_9`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. - Control logic with redundant input signals
- Alarm systems with multiple triggers

⚖️ Comparison with similar function blocks

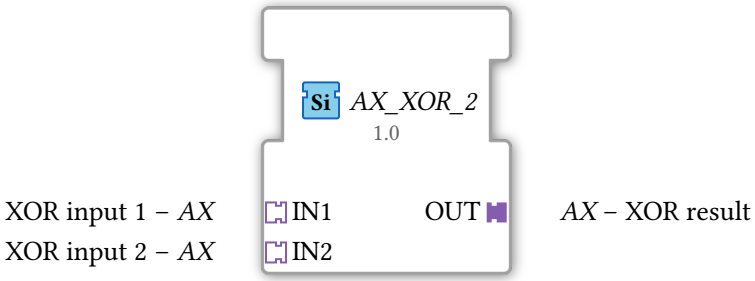
Compared to standard OR function blocks with fewer inputs, AX_OR_9_UNGATED offers the ability to process up to nine signals simultaneously, simplifying the wiring of more complex logic. Unlike configurable OR function blocks, this block has a fixed number of inputs, simplifying configuration for known requirements.

Comparison with OR_9

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The AX_OR_9_UNGATED is a specialized OR function block for applications that need to logically combine exactly nine input signals. Its fixed number of inputs and simple operation make it particularly suitable for clearly defined control tasks with redundant input signals.

AX_XOR_2

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_XOR_2 function block is a generic function block for calculating the Boolean XOR operation (exclusive OR). It processes two input signals and outputs the logical XOR result.

Interface Structure

Event Inputs

No direct event inputs are available – processing is handled via adapter interfaces.

Event Outputs

No direct event outputs are available – output is handled via adapter interfaces.

Data Inputs

No direct data inputs are available – input is handled via adapter interfaces.

Data Outputs

No direct data outputs are available – output is handled via adapter interfaces.

Adapter

- **IN1** (Socket): XOR Input 1 - Receives the first input signal
- **IN2** (Socket): XOR Input 2 - Receives the second input signal
- **OUT** (Plug): XOR Result - Outputs the calculated XOR result

All adapters use the type `adapter::types::unidirectional::AX` for unidirectional communication.

Functionality

The function block continuously calculates the XOR operation between the two input signals IN1 and IN2. The XOR function outputs a true signal (TRUE) if and only if exactly one of the two inputs is true (TRUE). If both inputs are the same (both TRUE or both FALSE), a false signal (FALSE) is output.

Technical Features

- Generic function block with the class `GEN_AX_XOR`
- Uses unidirectional adapters for inputs and outputs
- Implemented according to the IEC 61499-2 standard
- Part of the `adapter::booleanOperators` package

State Overview

The function block has a continuous operating state and constantly calculates the XOR result based on the current input values.

Application Scenarios

- Logic circuits in control systems
- Comparison of two binary signals
- Detection of signal differences
- Safety-related circuits
- Digital signal processing

⚖️ Comparison with similar function blocks

Compared to other logical operators such as AND or OR, XOR has the unique feature that a TRUE signal is only generated when the input values are different. This makes it particularly suitable for comparison and difference detection tasks.

Comparison with XOR_2

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_XOR_2 function block provides an efficient and reliable solution for XOR operations in 4diac-based control systems. Its use of adapter interfaces allows for flexible integration into various system architectures and makes it particularly suitable for applications where signal differences need to be detected.

AX_XOR_3

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_XOR_3 function block is a generic function block for calculating the Boolean XOR operation with three inputs. It implements the exclusive OR operation for three binary input signals and outputs the corresponding result.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Sockets (Inputs):

- **IN1**: XOR input 1 (Adapter type: unidirectional::AX)
- **IN2**: XOR input 2 (Adapter type: unidirectional::AX)
- **IN3**: XOR input 3 (Adapter type: unidirectional::AX)

Plugs (Outputs):

- **OUT**: XOR result (Adapter type: unidirectional::AX)

Functionality

This function block calculates the XOR operation for three input signals. The XOR operation outputs a "true" signal if and only if an odd number of the inputs are "true". With three inputs, this means:

- The result is true if exactly one or all three inputs are true.
- The result is false if none or exactly two inputs are true.

Technical Features

- Generic function block with the class name identifier 'GEN_AX_XOR'
- Uses unidirectional adapters for communication
- Implemented according to the IEC 61499-2 standard
- No internal states or storage required

State Overview

The function block has no internal states and operates statically. The output is calculated solely based on the current input values.

Application Scenarios

- Three-input switching networks
- Parity checks
- Safety-critical controllers where odd-numbered activation is required
- Logical operations in automation systems

⚖️ Comparison with similar function blocks

Compared to standard two-input XOR blocks, AX_XOR_3 offers the extension to three inputs. While a two-input XOR only returns true if the inputs are unequal, the three-input XOR takes the parity of all three signals into account.

Comparison with XOR_3

🛠️ Related Exercises

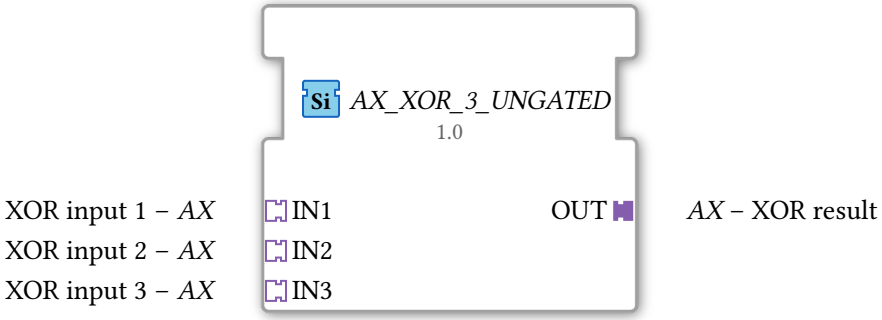
- Exercise_002a7_AX

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_XOR_3 function block provides a reliable and efficient solution for triple XOR operations in IEC 61499-based control systems. By using adapters, it enables flexible integration into different system architectures and is particularly suitable for applications that require parity checking or special logical conditions with three input signals.



AX_XOR_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_XOR_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. AX_XOR_4

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_XOR_4 function block is a generic function block for calculating the Boolean XOR operation with four inputs. It implements the exclusive OR operation for up to four different input signals.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Plug Adapter:

- **OUT**: Unidirectional adapter for the XOR result

Socket Adapter:

- **IN1**: Unidirectional adapter for XOR input 1
- **IN2**: Unidirectional adapter for XOR input 2
- **IN3**: Unidirectional adapter for XOR input 3
- **IN4**: Unidirectional adapter for XOR input 4

Functionality

The function block calculates the XOR operation across four inputs. The XOR operation returns a "true" signal if and only if an odd number of inputs are active. With four inputs, this means:

- Result = 1 if 1 or 3 inputs are active
- Result = 0 if 0, 2, or 4 inputs are active

Communication occurs exclusively via the defined adapter interfaces.

Technical Features

- Generic function block with the class 'GEN_AX_XOR'
- Uses unidirectional adapters for all inputs and outputs
- No direct event or data interfaces
- Fully adapter-based architecture

State Overview

Since it is a combinational logic block, the AX_XOR_4 has no internal states. The output is determined solely by the current input values.

Application Scenarios

- Parity check in control systems
- Odd parity check
- Safety-critical circuits with multiple inputs
- Distributed logic operations in automation systems

⚖️ Comparison with similar function blocks

Compared to standard XOR function blocks, AX_XOR_4 offers:

- Four inputs instead of the typical two inputs
- A purely adapter-based interface
- Specialization for unidirectional AX adapters
- No event-driven control, but continuous operation

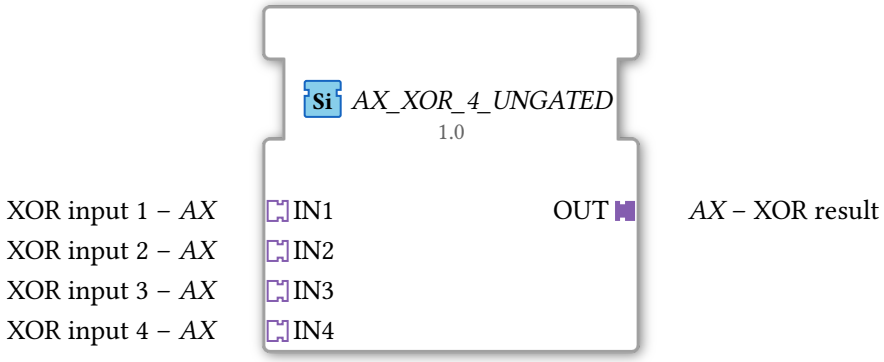
Comparison with XOR_4

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_XOR_4 function block represents a specialized solution for four-input XOR operations in adapter-based system architectures. Its purely adapter-based interface makes it particularly suitable for modular system designs where communication takes place via standardized adapters.



AX_XOR_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_XOR_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

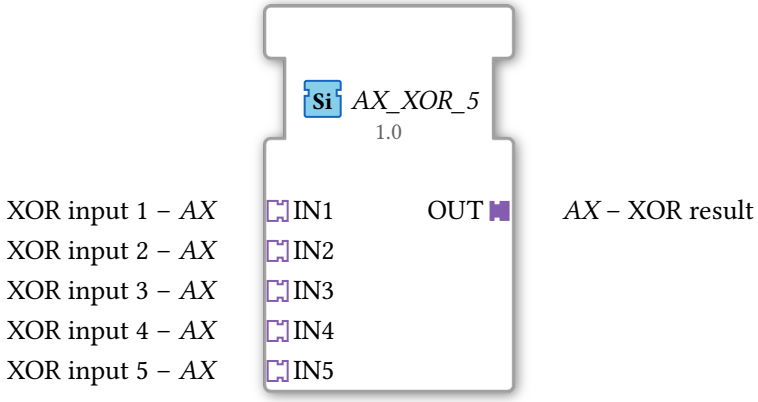
This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The AX_XOR_4_UNGATED function block represents a specialized solution for four-input XOR operations in adapter-based system architectures. Its purely adapter-based interface makes it particularly suitable for modular system designs where communication takes place via standardized adapters.

AX_XOR_5

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_XOR_5 is a generic function block for calculating the Boolean XOR operation with five inputs. The block implements the exclusive OR operation for up to five input signals and outputs the result via an adapter output.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Input Adapters:

- **IN1**: XOR Input 1 (unidirectional AX adapter)
- **IN2**: XOR Input 2 (unidirectional AX adapter)
- **IN3**: XOR Input 3 (unidirectional AX adapter)
- **IN4**: XOR Input 4 (unidirectional AX adapter)
- **IN5**: XOR Input 5 (unidirectional AX adapter)

Output Adapters:

- **OUT**: XOR Result (unidirectional AX adapter)

Functionality

This function block calculates the XOR operation across all five inputs. The XOR operation (exclusive OR) returns a "true" signal if and only if an odd number of inputs are active. With an even number of active inputs, it returns "false".

The mathematical formula is:
OUT = IN1 XOR IN2 XOR IN3 XOR IN4 XOR IN5

Technical Features

- Uses unidirectional AX adapters for all interfaces
- Implemented as a generic function block named 'GEN_AX_XOR'
- Supports up to five independent input signals
- No event control - operates continuously based on the adapter inputs

State Overview

Since it is a combinational logic block without memory, the AX_XOR_5 has no internal states. The output is determined solely by the current input values.

Application Scenarios

- Parity checking in digital circuits
- Fault detection in safety systems
- Control logic with multiple conditions
- Distributed decision-making in automation systems
- Safety-critical applications with redundant sensors

⚖️ Comparison with Similar Blocks

Compared to standard XOR blocks with fewer inputs, the AX_XOR_5 offers the ability to process up to five signals simultaneously. While simple XOR blocks typically have only two inputs, this function block enables more complex logical operations without additional nesting.

Comparison with XOR_5

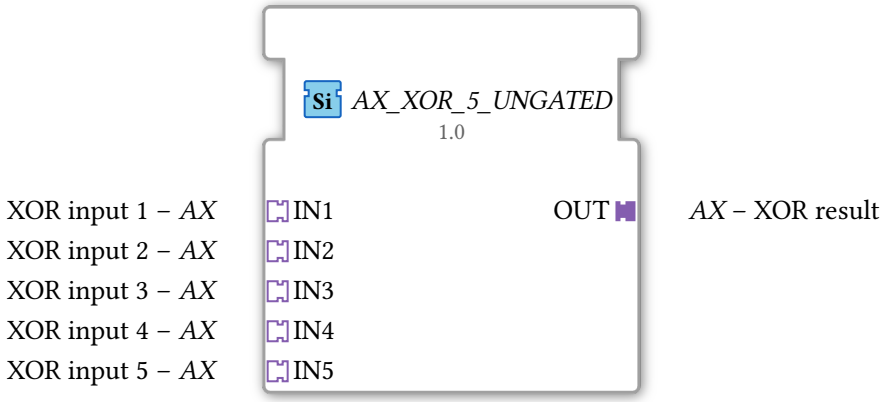
- `AX_XOR_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_XOR_5 function block provides a flexible solution for multi-input XOR operations. Its adapter-based interface allows for easy integration into existing control systems, while its generic implementation ensures reusability and extensibility.



AX_XOR_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of AX_XOR_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_XOR_5_UNGATED is a generic function block for calculating the Boolean XOR operation with five inputs. The block implements the exclusive OR operation for up to five input signals and outputs the result via an adapter output.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Input Adapters:

- **IN1**: XOR Input 1 (unidirectional AX adapter)
- **IN2**: XOR Input 2 (unidirectional AX adapter)
- **IN3**: XOR Input 3 (unidirectional AX adapter)
- **IN4**: XOR Input 4 (unidirectional AX adapter)
- **IN5**: XOR Input 5 (unidirectional AX adapter)

Output Adapters:

- **OUT**: XOR Result (unidirectional AX adapter)

Functionality

This function block calculates the XOR operation across all five inputs. The XOR operation (exclusive OR) returns a “true” signal if and only if an odd number of inputs are active. With an even number of active inputs, it returns “false”.

The mathematical formula is:
OUT = IN1 XOR IN2 XOR IN3 XOR IN4 XOR IN5

Technical Features

- Uses unidirectional AX adapters for all interfaces
- Implemented as a generic function block named 'GEN_AX_XOR'
- Supports up to five independent input signals
- No event control - operates continuously based on the adapter inputs

State Overview

Since it is a combinational logic block without memory, the AX_XOR_5_UNGATED has no internal states. The output is determined solely by the current input values.

Application Scenarios

- Parity checking in digital circuits
- Fault detection in safety systems
- Control logic with multiple conditions
- Distributed decision-making in automation systems
- Safety-critical applications with redundant sensors

⚖️ Comparison with Similar Blocks

Compared to standard XOR blocks with fewer inputs, the AX_XOR_5_UNGATED offers the ability to process up to five signals simultaneously. While simple XOR blocks typically have only two inputs, this function block enables more complex logical operations without additional nesting.

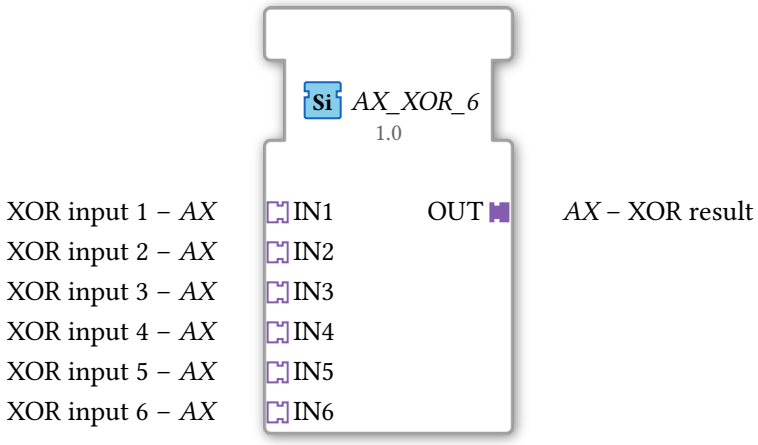
Comparison with XOR_5

- **AX_XOR_5**: The gated variant – updates the output only on an actual value change.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The AX_XOR_5_UNGATED function block provides a flexible solution for multi-input XOR operations. Its adapter-based interface allows for easy integration into existing control systems, while its generic implementation ensures reusability and extensibility.

AX_XOR_6

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_XOR_6 is a generic function block for calculating the Boolean XOR operation with six inputs. The block implements the exclusive OR operation for up to six binary input signals and outputs the result via an adapter output.

Interface Structure

Event Inputs
No event inputs available.

Event Outputs
No event outputs available.

Data Inputs
No direct data inputs available.

Data Outputs
No direct data outputs available.

Adapters
Plug Adapter:

- **OUT** (Type: adapter::types::unidirectional::AX) - XOR result

Socket Adapter:

- **IN1** (Type: adapter::types::unidirectional::AX) - XOR input 1
- **IN2** (Type: adapter::types::unidirectional::AX) - XOR input 2
- **IN3** (Type: adapter::types::unidirectional::AX) - XOR input 3
- **IN4** (Type: adapter::types::unidirectional::AX) - XOR input 4
- **IN5** (Type: adapter::types::unidirectional::AX) - XOR input 5
- **IN6** (Type: adapter::types::unidirectional::AX) - XOR input 6

Functionality
The function block calculates the XOR operation of all six inputs. The XOR operation returns a “TRUE” signal if and only if an odd number of inputs are set to “TRUE”. An even number of “TRUE” inputs returns “FALSE”.

Technical Features
- Generic function block with the generic class ‘GEN_AX_XOR’
- Uses unidirectional AX adapters for communication
- No event control - operates continuously based on the input values
- Supports six independent inputs for complex XOR calculations

State Overview
Since this is a purely combinational function block without event control, the AX_XOR_6 has no internal states. The output is determined solely by the current input values.

Application Scenarios
- Parity checking in data transmission systems
- Safety-critical controllers with multiple redundancy
- Error detection in binary signal chains
- Encryption algorithms with XOR operations
- Control systems with multi-input logic

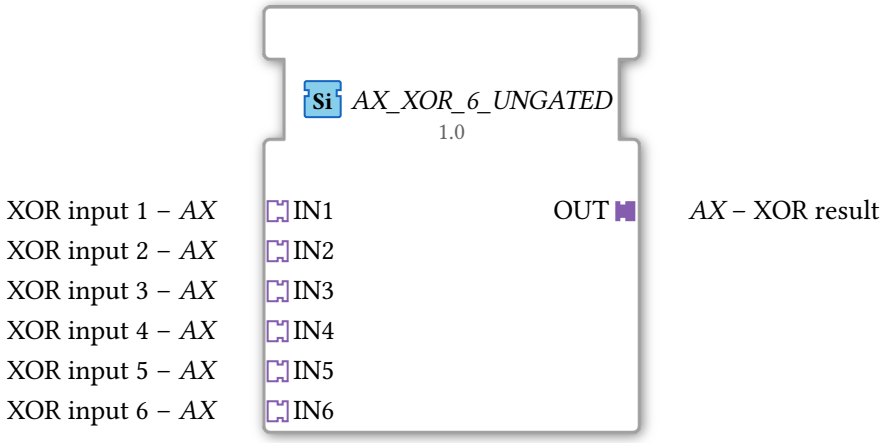
⚖️ Comparison with similar function blocks
Compared to standard XOR function blocks with fewer inputs, the AX_XOR_6 offers the ability to process up to six signals simultaneously. While simple XOR blocks typically only have two inputs, this function block enables more complex logical operations without the need for additional nesting of multiple blocks.

Comparison with XOR_6

Change Detection
The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_XOR_6 is a specialized function block for demanding multi-input XOR operations. Its adapter-based interface allows for easy integration into existing control systems and provides an efficient solution for complex Boolean operations without additional wiring complexity.



AX_XOR_6_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_XOR_6`. The AX_XOR_6_UNGATED is a specialized function block for demanding multi-input XOR operations. Its adapter-based interface allows for easy integration into existing control systems and provides an efficient solution for complex Boolean operations without additional wiring complexity.

AX_XOR_7

• − ◦ • − ◦ • − ◦ •

Introduction

The AX_XOR_7 function block is a generic function block for calculating the Boolean XOR operation with seven inputs. It allows the processing of up to seven input signals and outputs the result of the XOR operation.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Plug Adapter:

- `OUT` - XOR result (Adapter type: `adapter::types::unidirectional::AX`)

Socket Adapter:

- `IN1` - XOR input 1 (Adapter type: `adapter::types::unidirectional::AX`)
- `IN2` - XOR input 2 (Adapter type: `adapter::types::unidirectional::AX`)
- `IN3` - XOR input 3 (Adapter type: `adapter::types::unidirectional::AX`)
- `IN4` - XOR input 4 (Adapter type: `adapter::types::unidirectional::AX`)
- `IN5` - XOR input 5 (Adapter type: `adapter::types::unidirectional::AX`)
- `IN6` - XOR input 6 (Adapter type: `adapter::types::unidirectional::AX`)
- `IN7` - XOR input 7 (Adapter type: `adapter::types::unidirectional::AX`)

Functionality

This function block performs the XOR operation across all seven inputs. The XOR operation returns a "TRUE" signal if and only if an odd number of inputs are set to "TRUE". An even number of "TRUE" inputs results in a "FALSE" output.

Technical Features

- Generic function block with the generic class name `GEN_AX_XOR`
- Uses unidirectional AX adapters for inputs and outputs
- Supports exactly seven inputs for XOR calculations
- Implemented as an adapter-based solution without direct event or data interfaces

State Overview

The function block has no internal state and operates stateless. The output is calculated solely based on the current input values.

Application Scenarios

- Parity checking in data transmission systems
- Safety-critical controllers with majority voting
- Error detection in binary signal chains
- Logical operations in industrial automation systems

⚖️ Comparison with Similar Function Blocks

Compared to standard XOR blocks with fewer inputs, AX_XOR_7 offers the ability to perform XOR operations with up to seven inputs. While simple XOR blocks typically process only two inputs, this function block enables more complex logic operations within a single block.

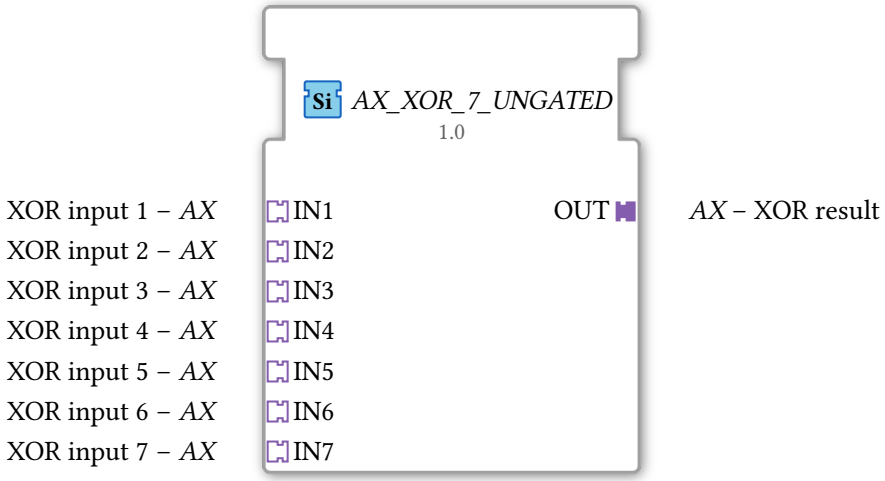
Comparison with XOR_7

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_XOR_7 function block provides an efficient solution for multi-input XOR operations. Its adapter-based architecture allows for flexible integration into various control systems and makes it particularly suitable for applications requiring odd parity checks across multiple signals.



AX_XOR_7_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_XOR_7`. The AX_XOR_7_UNGATED function block provides an efficient solution for multi-input XOR operations. Its adapter-based architecture allows for flexible integration into various control systems and makes it particularly suitable for applications requiring odd parity checks across multiple signals.

AX_XOR_8

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_XOR_8 function block is a generic block for calculating Boolean XOR operations with 8 inputs. It enables the processing of logic signals according to the exclusive-OR principle and is designed for use in control applications.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Plug Adapter:

- **OUT**: Unidirectional adapter for the XOR result

Socket Adapter:

- **IN1**: Unidirectional adapter for XOR input 1
- **IN2**: Unidirectional adapter for XOR input 2
- **IN3**: Unidirectional adapter for XOR input 3
- **IN4**: Unidirectional adapter for XOR input 4
- **IN5**: Unidirectional adapter for XOR input 5
- **IN6**: Unidirectional adapter for XOR input 6
- **IN7**: Unidirectional adapter for XOR input 7
- **IN8**: Unidirectional adapter for XOR input 8

Functionality

This function block calculates the XOR operation across all 8 inputs. The XOR operation (exclusive OR) returns a TRUE signal if and only if an odd number of inputs are TRUE. If an even number of inputs are TRUE, FALSE is output.

Technical Features

- Generic function block with the class 'GEN_AX_XOR'
- Uses unidirectional adapters for all inputs and outputs
- No direct event or data interfaces
- Adapter-based architecture for flexible connectivity

State Overview

Since it is a combinational logic block, AX_XOR_8 has no internal state. The output is determined solely by the current input values.

Application Scenarios

- Parity checking in data transmission systems
- Safety-critical controllers with multiple redundancy
- Logical operations in automation systems
- Error detection in binary signal chains

⚖️ Comparison with similar components

Compared to simple XOR components with fewer inputs, AX_XOR_8 offers the ability to combine up to 8 signals simultaneously. The exclusive use of adapters instead of direct data and event inputs enables greater flexibility in complex system architectures.

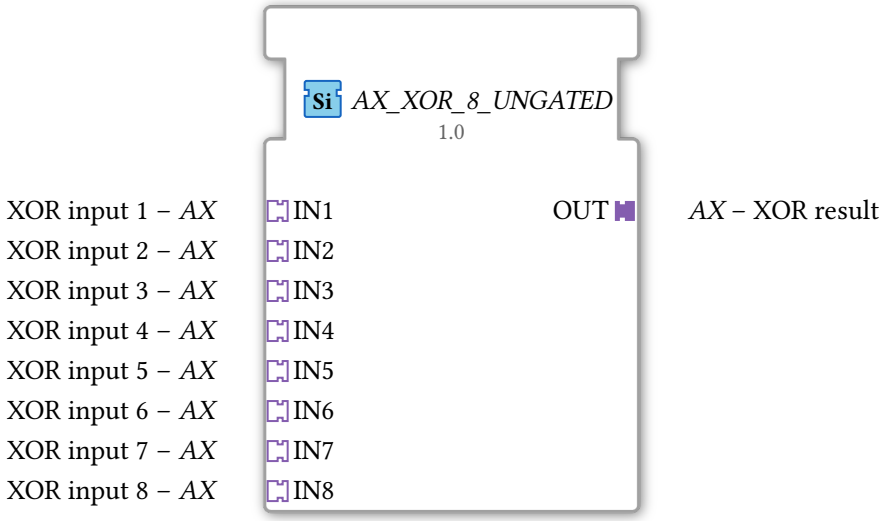
Comparison with XOR_8

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AX_XOR_8 is a specialized logic component for demanding multi-input XOR operations. Its adapter-based interface makes it particularly suitable for modular system designs where flexible connections between functional blocks are required.



AX_XOR_8_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_XOR_8`. bidirectional

Numerical Index (bidirectional)

Here you will find all exercises from the `bidirectional` workspace in ascending order. ...

A2X2_2AX2_TO_2X

• – ○ • – ○ • – ○ •

Introduction

The A2X2_2AX2_TO_2X function block composes an A2X2 plug from two AX2 sockets — one for the UP channel, one for the DOWN channel. Since AX2 is itself already bidirectional (1 event/1 bool per direction), a single AX2 per channel is enough to cover both directions of A2X2.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **A2X2_OUT** (Plug): composed output of type `adapter::types::bidirectional::A2X2`
- **UP** (Socket): UP channel, of type `adapter::types::bidirectional::AX2` — TRUE = forward, up, right, clockwise
- **DOWN** (Socket): DOWN channel, of type `adapter::types::bidirectional::AX2` — TRUE = backward, down, left, counter-clockwise

Functionality

For each channel, the full bidirectional wiring between A2X2 and the corresponding AX2 socket is established: whatever `A2X2_OUT` receives on its request side (`EI_UP`/`DI_UP`) is forwarded to `UP.EI1`/`UP.DI1`; whatever `UP` delivers on its indication side (`EO1`/`DO1`) appears on `A2X2_OUT.EO_UP`/`DO_UP`. The same wiring applies to DOWN via the `DOWN` socket. Both channels are fully independent.

Technical Details

- Directly exploits AX2's bidirectionality — each channel needs only a single adapter, not two
- Pure wiring, no logic or state
- Every destination variable has exactly one writer, no fan-in on data connections

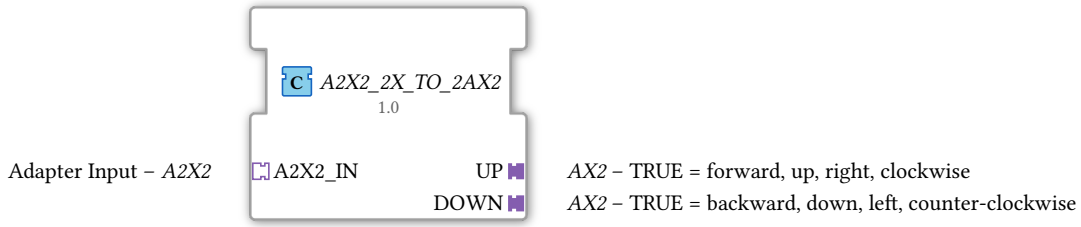
State Overview

The block is stateless:

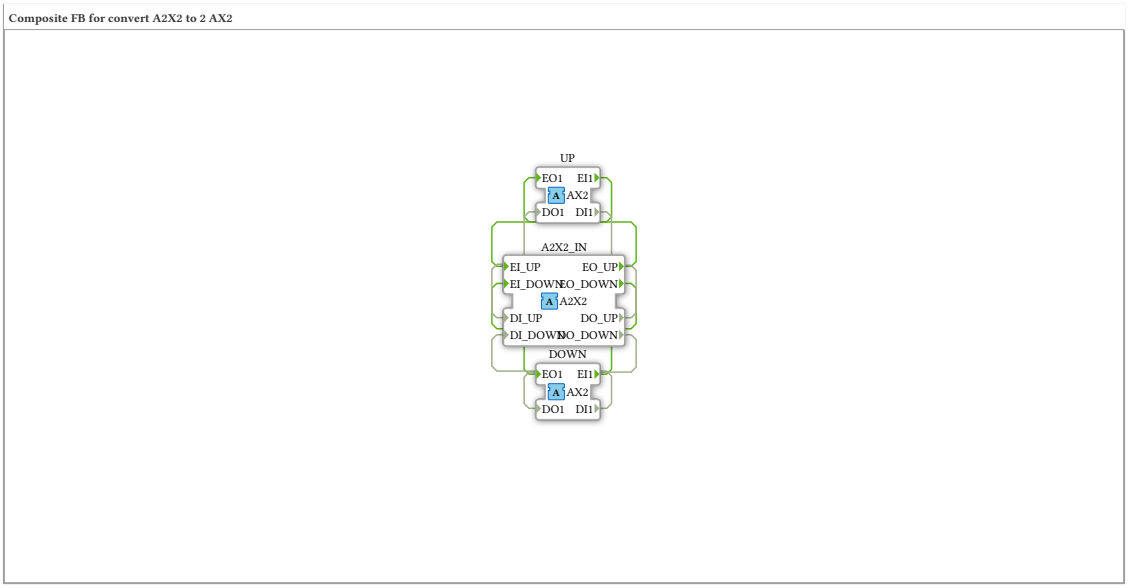
- A2X2_OUT.EI_UP ⟶ UP.EI1, A2X2_OUT.DI_UP ⟶ UP.DI1
- UP.EO1 ⟶ A2X2_OUT.EO_UP, UP.DO1 ⟶ A2X2_OUT.DO_UP
- A2X2_OUT.EI_DOWN ⟶ DOWN.EI1, A2X2_OUT.DI_DOWN ⟶ DOWN.DI1
- DOWN.EO1 ⟶ A2X2_OUT.EO_DOWN, DOWN.DO1 ⟶ A2X2_OUT.DO_DOWN

Application Scenarios

- Building an A2X2 endpoint from two already existing, independent AX2 channels
- Systems where UP and DOWN are historically wired separately as AX2 but should present themselves as a single A2X2 externally
- Modular composition of larger adapters from smaller, reusable blocks



⚖️ Comparison with Similar Blocks



The counterpart A2X2_2X_TO_2AX2 decomposes instead of composing. For the same task, A2X2_4AX_TO_2X offers an alternative that uses four unidirectional AX adapters instead of two bidirectional AX2 (two per channel, one per direction) — useful when only unidirectional AX infrastructure is available. The unidirectional predecessor A2X_2AX_TO_2X composes analogously from two plain AX adapters.

Conclusion

A2X2_2AX2_TO_2X is the most efficient way to build an A2X2 from two existing AX2 channels, since both adapters are already bidirectional and no extra logic is needed.

A2X2_2X_TO_2AX2

• – ○ • – ○ • – ○ •

Introduction

The A2X2_2X_TO_2AX2 function block is the inverse of A2X2_2AX2_TO_2X: it decomposes an A2X2 socket into two AX2 plugs — one for UP, one for DOWN.

Interface Structure

Event Inputs
The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs
The function block has no direct event outputs.

Data Inputs
The function block has no direct data inputs.

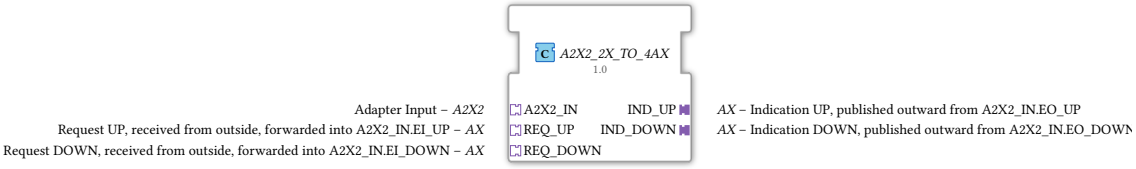
Data Outputs
The function block has no direct data outputs.

Adapters
- **A2X2_IN** (Socket): input to be decomposed, of type `adapter::types::bidirectional::A2X2`
- **UP** (Plug): UP channel, of type `adapter::types::bidirectional::AX2` — TRUE = forward, up, right, clockwise
- **DOWN** (Plug): DOWN channel, of type `adapter::types::bidirectional::AX2` — TRUE = backward, down, left, counter-clockwise

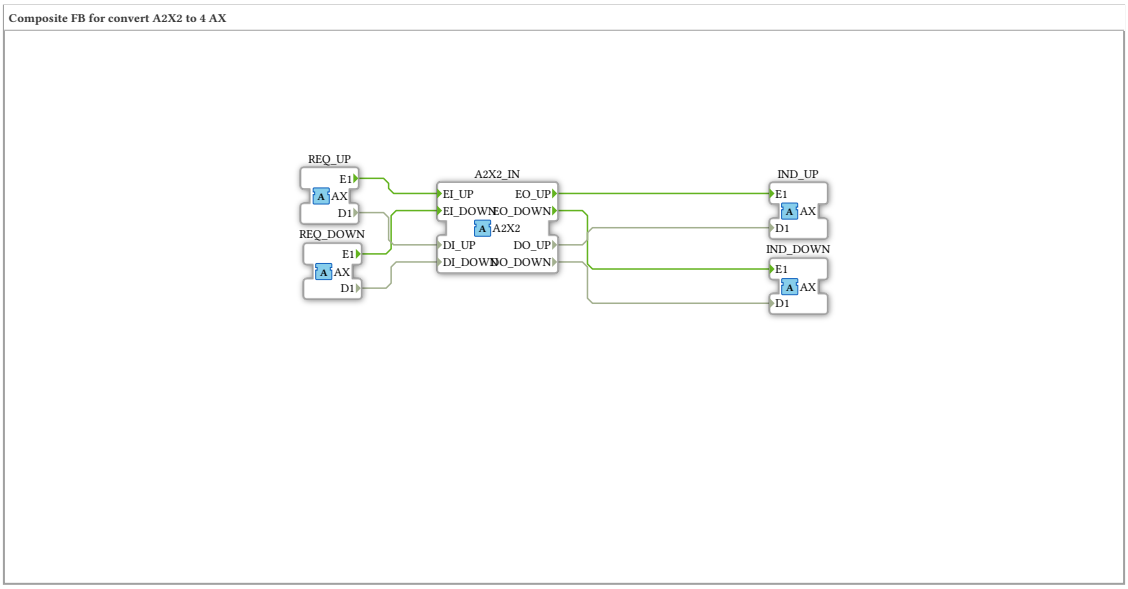
Functionality
For each channel, the full bidirectional wiring between the A2X2 socket and the corresponding AX2 plug is established: whatever `A2X2_IN` receives on its indication side (`EO_UP`/`DO_UP`) is passed to `UP.EO1`/`UP.DO1`; whatever arrives at the `UP` plug on its request side (`EI1`/`DI1`) is reported back to `A2X2_IN.EI_UP`/`DI_UP`. The same wiring applies to DOWN via the `DOWN` plug. Both channels are fully independent.

Technical Details
- Directly exploits AX2's bidirectionality — each channel needs only a single adapter, not two
- Pure wiring, no logic or state
- Every destination variable has exactly one writer, no fan-in on data connections

State Overview
The block is stateless:



- A2X2_IN.EO_UP ⟶ UP.EO1, A2X2_IN.DO_UP ⟶ UP.DO1
- UP.EI1 ⟶ A2X2_IN.EI_UP, UP.DI1 ⟶ A2X2_IN.DI_UP
- A2X2_IN.EO_DOWN ⟶ DOWN.EO1, A2X2_IN.DO_DOWN ⟶ DOWN.DO1
- DOWN.EI1 ⟶ A2X2_IN.EI_DOWN, DOWN.DI1 ⟶ A2X2_IN.DI_DOWN



Application Scenarios
- Splitting an A2X2 bus signal into two independently processable AX2 channels
- Connecting existing AX2-based subsystems to a central A2X2
- Test setups that need to observe or control each channel individually

⚖️ Comparison with Similar Blocks
The counterpart A2X2_2AX2_TO_2X composes instead of decomposing. For the same task, A2X2_4AX_TO_2X / A2X2_2X_TO_4AX offer an alternative with four unidirectional AX adapters instead of two bidirectional AX2. The unidirectional predecessor A2X_2X_TO_2AX decomposes analogously into two plain AX adapters.

Conclusion
A2X2_2X_TO_2AX2 is the most efficient way to split an A2X2 signal into two independent AX2 channels, since both adapters are already bidirectional and no extra logic is needed.

A2X2_2X_TO_4AX

• – ○ • – ○ • – ○ •

Introduction

The A2X2_2X_TO_4AX function block decomposes an A2X2 socket into **four** unidirectional AX adapters. Since A2X2 has two channels (UP/DOWN) and each of them is itself bidirectional, representing it with unidirectional AX needs two AX per channel to cover both directions — one for the indication direction, one for the request direction. 2 channels × 2 directions = 4 AX.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **A2X2_IN** (Socket): input to be decomposed, of type `adapter::types::bidirectional::A2X2`
- **REQ_UP** (Socket): UP request, received from outside and forwarded to `A2X2_IN.EI_UP`, of type `adapter::types::unidirectional::AX`
- **REQ_DOWN** (Socket): DOWN request, received from outside and forwarded to `A2X2_IN.EI_DOWN`, of type `adapter::types::unidirectional::AX`
- **IND_UP** (Plug): UP indication, published outward from `A2X2_IN.EO_UP`, of type `adapter::types::unidirectional::AX`
- **IND_DOWN** (Plug): DOWN indication, published outward from `A2X2_IN.EO_DOWN`, of type `adapter::types::unidirectional::AX`

Functionality

Whatever the A2X2 socket receives on its indication side (`EO_UP`/`DO_UP` or `EO_DOWN`/`DO_DOWN`) is published unchanged via the unidirectional plugs `IND_UP`/`IND_DOWN`. Conversely, whatever arrives from outside at the unidirectional sockets `REQ_UP`/`REQ_DOWN` is forwarded to the request side of the A2X2 socket (`EI_UP`/`DI_UP` or `EI_DOWN`/`DI_DOWN`). This makes both directions of each channel available as their own plain unidirectional AX adapter.

Technical Details

- Four separate AX adapters instead of two AX2, because AX does not combine an `EventInputs`/`EventOutputs` pair in one adapter — each direction needs its own adapter
- Pure wiring, no logic or state
- Every destination variable has exactly one writer, no fan-in on data connections

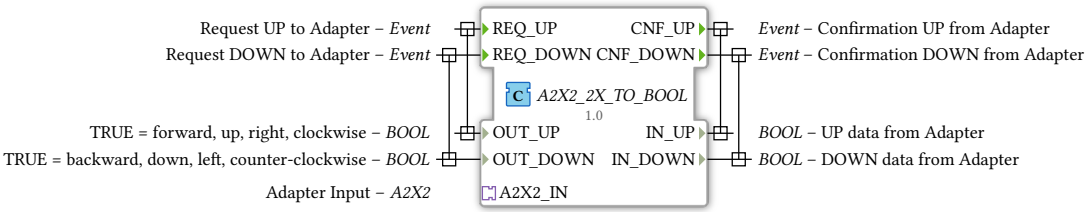
State Overview

The block is stateless:

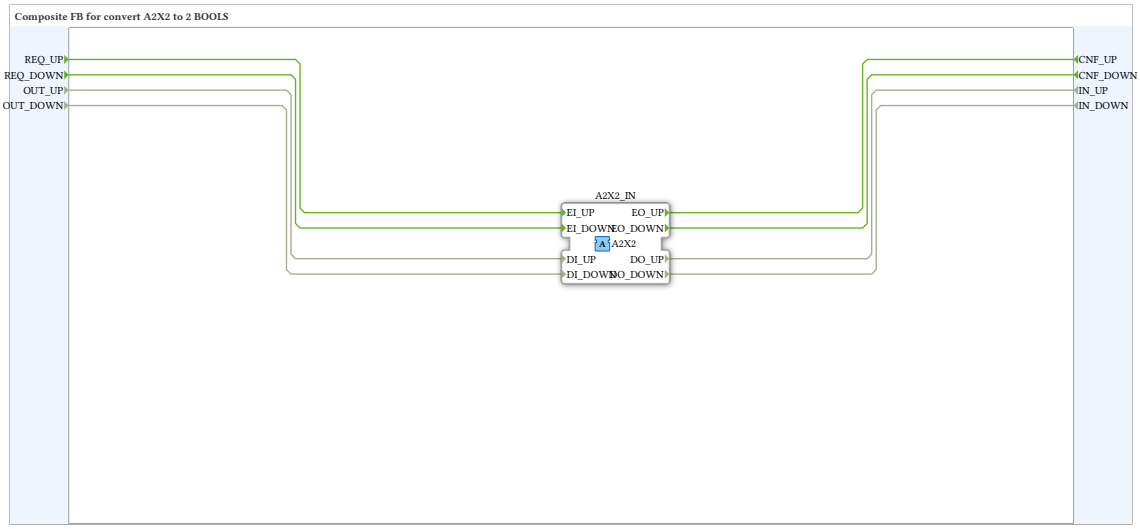
- A2X2_IN.EO_UP ⟶ IND_UP.E1, A2X2_IN.DO_UP ⟶ IND_UP.D1
- A2X2_IN.EO_DOWN ⟶ IND_DOWN.E1, A2X2_IN.DO_DOWN ⟶ IND_DOWN.D1
- REQ_UP.E1 ⟶ A2X2_IN.EI_UP, REQ_UP.D1 ⟶ A2X2_IN.DI_UP
- REQ_DOWN.E1 ⟶ A2X2_IN.EI_DOWN, REQ_DOWN.D1 ⟶ A2X2_IN.DI_DOWN

Application Scenarios

- Connecting an A2X2 signal to infrastructure that only knows unidirectional AX adapters (e.g. older subsystems)
- Processing the request and indication directions separately, e.g. for independent logging or filtering
- Systems where bidirectional AX2 adapters are unavailable or undesired



⚖️ Comparison with Similar Blocks



For the same task (decomposing A2X2), A2X2_2X_TO_2AX2 offers a simpler alternative that only needs two bidirectional AX2 instead of four unidirectional AX — where AX2 infrastructure is available, that is the leaner solution. The counterpart to this block is A2X2_4AX_TO_2X, which recomposes an A2X2 from four AX.

Conclusion

A2X2_2X_TO_4AX is the right choice when an A2X2 signal must be integrated into a purely unidirectional AX landscape — at the cost of twice as many adapters as the AX2-based alternative.

A2X2_2X_TO_BOOL

• – ○ • – ○ • – ○ •

Introduction

The A2X2_2X_TO_BOOL function block is the socket counterpart of A2X2_BOOL_TO_2X: it translates the bidirectional A2X2 adapter format back into two plain BOOL channels (UP and DOWN) by exposing an A2X2 socket.

Interface Structure

Event Inputs

- **REQ_UP**: request event for the UP channel, delivers `OUT_UP`
- **REQ_DOWN**: request event for the DOWN channel, delivers `OUT_DOWN`

Event Outputs

- **CNF_UP**: confirmation event for the UP channel, delivers `IN_UP`
- **CNF_DOWN**: confirmation event for the DOWN channel, delivers `IN_DOWN`

Data Inputs

- **OUT_UP**: BOOL, TRUE = forward, up, right, clockwise
- **OUT_DOWN**: BOOL, TRUE = backward, down, left, counter-clockwise

Data Outputs

- **IN_UP**: BOOL, UP data from the adapter
- **IN_DOWN**: BOOL, DOWN data from the adapter

Adapters

- **A2X2_IN** (Socket): input adapter of type `adapter::types::bidirectional::A2X2`

Functionality

When the socket `A2X2_IN` receives events on its indication side (`EO_UP`/`DO_UP` or `EO_DOWN`/`DO_DOWN`), they are immediately reported outward as `CNF_UP`/`IN_UP` or `CNF_DOWN`/`IN_DOWN`. Conversely, when a `REQ_UP` or `REQ_DOWN` event arrives, the corresponding `OUT_UP`/`OUT_DOWN` value is sent out via the socket (`EI_UP`/`DI_UP` or `EI_DOWN`/`DI_DOWN`). Both channels operate completely independently of each other.

Technical Details

- Pure 1:1 pass-through, no internal state, no gates or logic blocks needed
- Uses an A2X2 socket, i.e. this block is the counterpart that an A2X2 plug connects to
- Identical interface to A2X2_BOOL_TO_2X, only the adapter role (socket instead of plug) differs

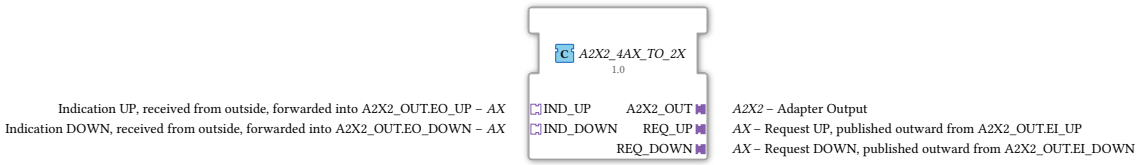
State Overview

The block is stateless; every connection acts immediately and directly:

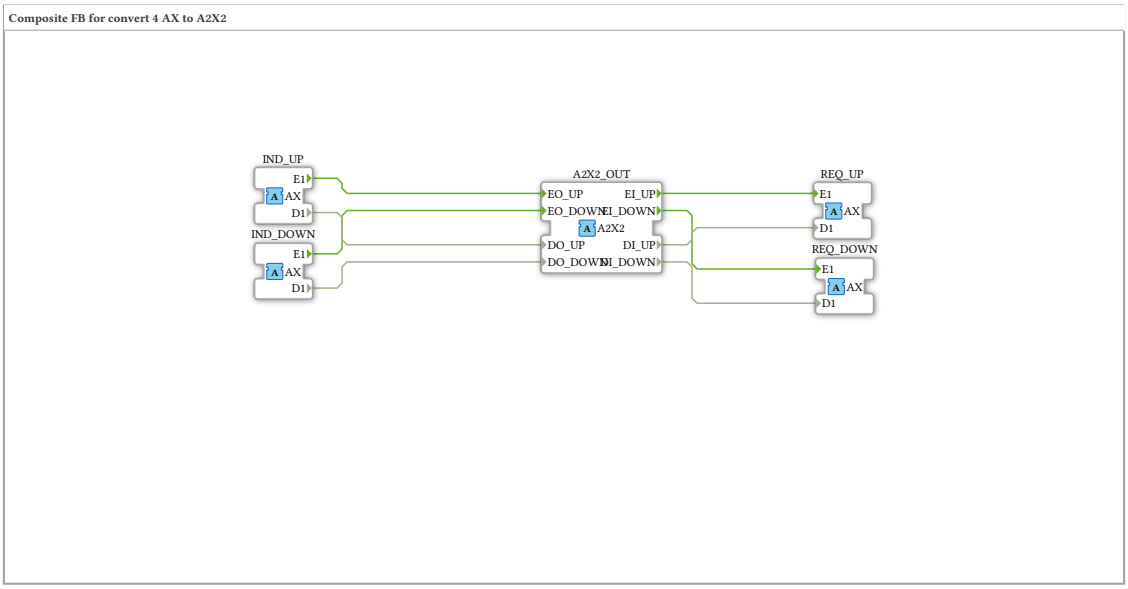
- A2X2_IN.EO_UP ⟶ CNF_UP, A2X2_IN.DO_UP ⟶ IN_UP
- A2X2_IN.EO_DOWN ⟶ CNF_DOWN, A2X2_IN.DO_DOWN ⟶ IN_DOWN
- REQ_UP ⟶ A2X2_IN.EI_UP, OUT_UP ⟶ A2X2_IN.DI_UP
- REQ_DOWN ⟶ A2X2_IN.EI_DOWN, OUT_DOWN ⟶ A2X2_IN.DI_DOWN

Application Scenarios

- Reading the UP/DOWN channels of an A2X2 bus participant as plain BOOL signals
- Integrating an A2X2 endpoint into a classically wired controller
- Test blocks acting as the counterpart of A2X2_BOOL_TO_2X



⚖ Comparison with Similar Blocks



The plug counterpart is A2X2_BOOL_TO_2X. For the unidirectional case, see A2X_2X_TO_BOOL. The single-channel bidirectional predecessor is AX2_X_TO_BOOL.

Conclusion

A2X2_2X_TO_BOOL is the direct counterpart of A2X2_BOOL_TO_2X and makes an A2X2 bus signal usable as two plain BOOL channels for the rest of the application.

A2X2_4AX_TO_2X

• – ○ • – ○ • – ○ •

Introduction

The A2X2_4AX_TO_2X function block is the inverse of A2X2_2X_TO_4AX: it composes an A2X2 plug from **four** unidirectional AX adapters. Two channels (UP/DOWN) × two directions (indication/request) = four AX.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **A2X2_OUT** (Plug): composed output of type `adapter::types::bidirectional::A2X2`
- **REQ_UP** (Plug): UP request, published outward from `A2X2_OUT.EI_UP`, of type `adapter::types::unidirectional::AX`
- **REQ_DOWN** (Plug): DOWN request, published outward from `A2X2_OUT.EI_DOWN`, of type `adapter::types::unidirectional::AX`
- **IND_UP** (Socket): UP indication, received from outside and forwarded to `A2X2_OUT.EO_UP`, of type `adapter::types::unidirectional::AX`
- **IND_DOWN** (Socket): DOWN indication, received from outside and forwarded to `A2X2_OUT.EO_DOWN`, of type `adapter::types::unidirectional::AX`

Functionality

Whatever arrives from outside at the unidirectional sockets `IND_UP`/`IND_DOWN` is passed through to the indication side of the A2X2 plug (`EO_UP`/`DO_UP` or `EO_DOWN`/`DO_DOWN`). Conversely, whatever the A2X2 plug receives on its request side (`EI_UP`/`DI_UP` or `EI_DOWN`/`DI_DOWN`) is published via the unidirectional plugs `REQ_UP`/`REQ_DOWN`.

Technical Details

- Four separate AX adapters instead of two AX2, because AX does not combine an `EventInputs`/`EventOutputs` pair in one adapter — each direction needs its own adapter
- Pure wiring, no logic or state
- Every destination variable has exactly one writer, no fan-in on data connections

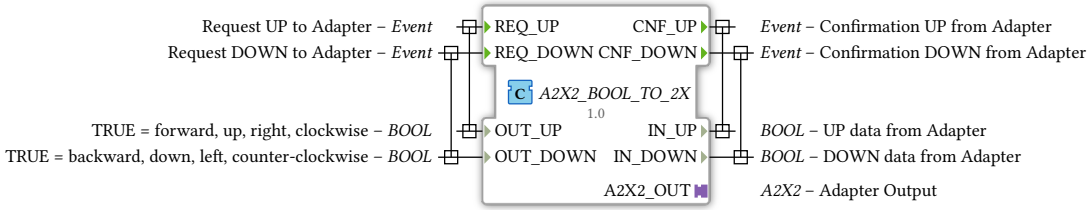
State Overview

The block is stateless:

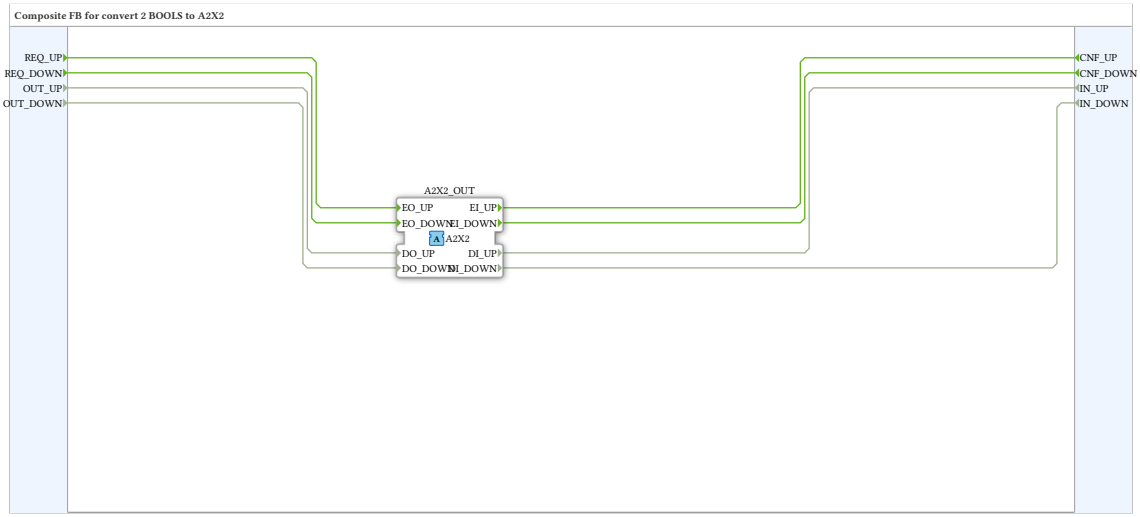
- IND_UP.E1 ⟶ A2X2_OUT.EO_UP, IND_UP.D1 ⟶ A2X2_OUT.DO_UP
- IND_DOWN.E1 ⟶ A2X2_OUT.EO_DOWN, IND_DOWN.D1 ⟶ A2X2_OUT.DO_DOWN
- A2X2_OUT.EI_UP ⟶ REQ_UP.E1, A2X2_OUT.DI_UP ⟶ REQ_UP.D1
- A2X2_OUT.EI_DOWN ⟶ REQ_DOWN.E1, A2X2_OUT.DI_DOWN ⟶ REQ_DOWN.D1

Application Scenarios

- Building an A2X2 endpoint from four already existing unidirectional AX signals
- Migration scenarios where an existing AX infrastructure is gradually converted to A2X2
- Systems where bidirectional AX2 adapters are unavailable or undesired



⚖️ Comparison with Similar Blocks



For the same task (composing A2X2), A2X2_2AX2_TO_2X offers a simpler alternative that only needs two bidirectional AX2 instead of four unidirectional AX — where AX2 infrastructure is available, that is the leaner solution. The counterpart to this block is A2X2_2X_TO_4AX, which decomposes an A2X2 back into four AX.

Conclusion

A2X2_4AX_TO_2X is the right choice when an A2X2 endpoint must be built from purely unidirectional AX infrastructure — at the cost of twice as many adapters as the AX2-based alternative.

A2X2_BOOL_TO_2X

• – ○ • – ○ • – ○ •

Introduction

The A2X2_BOOL_TO_2X function block is a composite function block that translates two plain BOOL channels (UP and DOWN) into the bidirectional A2X2 adapter format. It exposes an A2X2 plug and maps each of the two channels independently through its own request/confirmation event pair.

Interface Structure

Event Inputs

- **REQ_UP**: request event for the UP channel, delivers `OUT_UP`
- **REQ_DOWN**: request event for the DOWN channel, delivers `OUT_DOWN`

Event Outputs

- **CNF_UP**: confirmation event for the UP channel, delivers `IN_UP`
- **CNF_DOWN**: confirmation event for the DOWN channel, delivers `IN_DOWN`

Data Inputs

- **OUT_UP**: BOOL, TRUE = forward, up, right, clockwise
- **OUT_DOWN**: BOOL, TRUE = backward, down, left, counter-clockwise

Data Outputs

- **IN_UP**: BOOL, UP data from the adapter
- **IN_DOWN**: BOOL, DOWN data from the adapter

Adapters

- **A2X2_OUT** (Plug): output adapter of type `adapter::types::bidirectional::A2X2`

Functionality

When a `REQ_UP` event arrives, the current value of `OUT_UP` is sent out via `A2X2_OUT.EO_UP`/`A2X2_OUT.DO_UP`; the same happens for `REQ_DOWN`/`OUT_DOWN` via `EO_DOWN`/`DO_DOWN`. Conversely, whatever the adapter receives on its confirmation side (`A2X2_OUT.EI_UP`/`A2X2_OUT.EI_DOWN` with `DI_UP`/`DI_DOWN`)

is forwarded unchanged as `CNF_UP`/`IN_UP` and `CNF_DOWN`/`IN_DOWN` respectively. Both channels operate completely independently of each other.

Technical Details

- Pure 1:1 pass-through, no internal state, no gates or logic blocks needed
- Each channel (UP/DOWN) has its own event pair — there is no shared variable that two sources would need to write at once
- Uses the A2X2 plug, i.e. this block acts as the "endpoint" that an A2X2 socket connects to

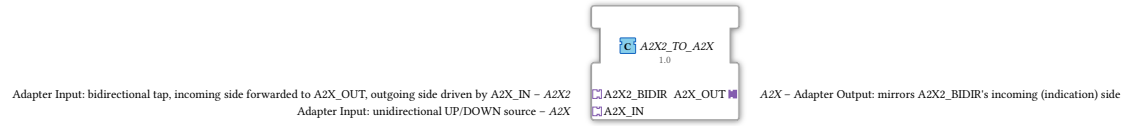
State Overview

The block is stateless; every connection acts immediately and directly:

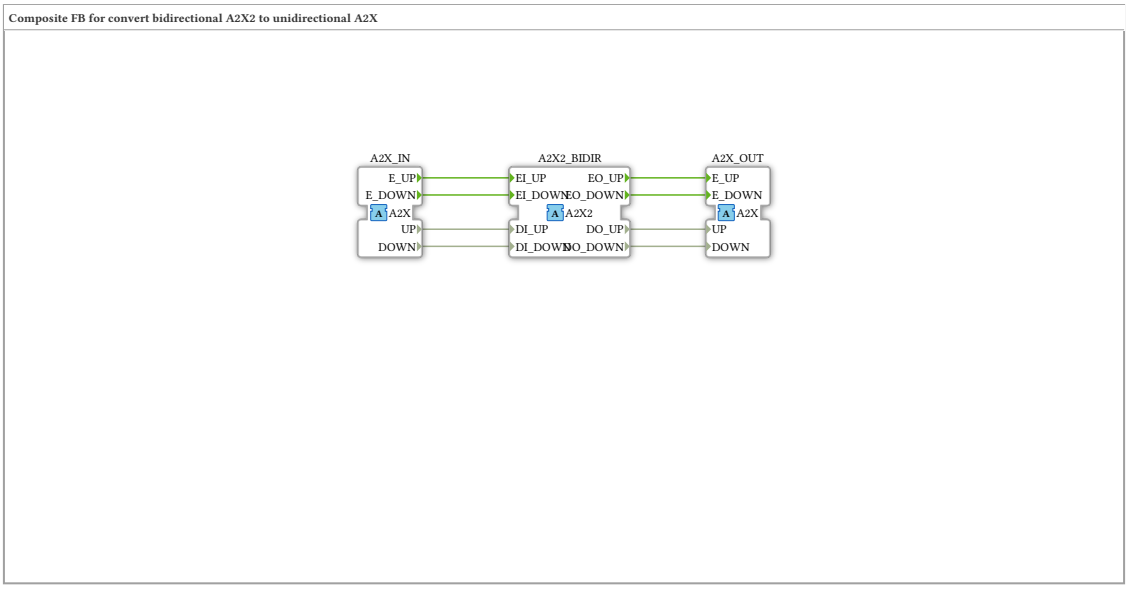
- REQ_UP ⟶ A2X2_OUT.EO_UP, OUT_UP ⟶ A2X2_OUT.DO_UP
- REQ_DOWN ⟶ A2X2_OUT.EO_DOWN, OUT_DOWN ⟶ A2X2_OUT.DO_DOWN
- A2X2_OUT.EI_UP ⟶ CNF_UP, A2X2_OUT.DI_UP ⟶ IN_UP
- A2X2_OUT.EI_DOWN ⟶ CNF_DOWN, A2X2_OUT.DI_DOWN ⟶ IN_DOWN

Application Scenarios

- Connecting two plain BOOL signals (e.g. two buttons or limit switches for UP/DOWN) to an A2X2 bus system
- Test blocks that simulate A2X2 traffic without real hardware
- Bridging classic BOOL wiring and adapter-based subnetworks



⚖️ Comparison with Similar Blocks



The socket counterpart A2X2_2X_TO_BOOL has the same interface but uses an A2X2 socket instead of a plug. For the unidirectional case, A2X_BOOL_TO_2X implements the same basic idea but without a request side (only `E_UP`/`E_DOWN`). The single-channel bidirectional predecessor is AX2_BOOL_TO_X, whose pattern this block doubles onto two independent channels.

Conclusion

A2X2_BOOL_TO_2X is the simplest way to connect plain BOOL signals to an A2X2 adapter — no state, no logic, a direct 1:1 pass-through per channel.

A2X2_TO_A2X

• — ○ • — ○ • — ○ •

Introduction

The A2X2_TO_A2X function block is the mirror image of A2X_TO_A2X2: here the bidirectional A2X2 tap sits as a socket on the left (input) side, complemented by a second unidirectional A2X socket and a unidirectional A2X plug.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **A2X2_BIDIR** (Socket): bidirectional tap whose incoming side is forwarded to `A2X_OUT` and whose outgoing side is fed by `A2X_IN`, of type `adapter::types::bidirectional::A2X2`
- **A2X_IN** (Socket): unidirectional UP/DOWN source, of type `adapter::types::unidirectional::A2X`
- **A2X_OUT** (Plug): mirrors the incoming (indication) side of `A2X2_BIDIR` as a unidirectional signal, of type `adapter::types::unidirectional::A2X`

Functionality

The block operates in two directions at once: whatever the socket `A2X2_BIDIR` receives on its indication side (`EO_UP`/`DO_UP`, `EO_DOWN`/`DO_DOWN` — i.e. whatever a bidirectional peer attached to A2X2_BIDIR reports) is output unchanged as a standalone unidirectional signal via the plug `A2X_OUT`. Conversely, whatever arrives at the socket `A2X_IN` (`E_UP`/`UP`, `E_DOWN`/`DOWN`) is published onto the request side of `A2X2_BIDIR` (`EI_UP`/`DI_UP`, `EI_DOWN`/`DI_DOWN`) — so A2X2_BIDIR forwards the same UP/DOWN signal to the attached bidirectional peer.

Technical Details

- Three adapters instead of two: the direction received from the tap and the separately injected direction are deliberately kept apart rather than mixed
- Pure wiring, no logic or state, every destination variable has exactly one writer
- `A2X_OUT` only reflects what is reported via `A2X2_BIDIR` by an attached bidirectional peer — without such a peer, `A2X_OUT` stays idle

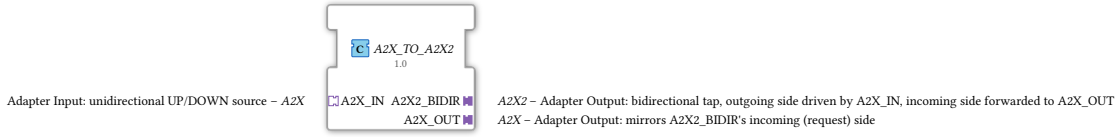
State Overview

The block is stateless:

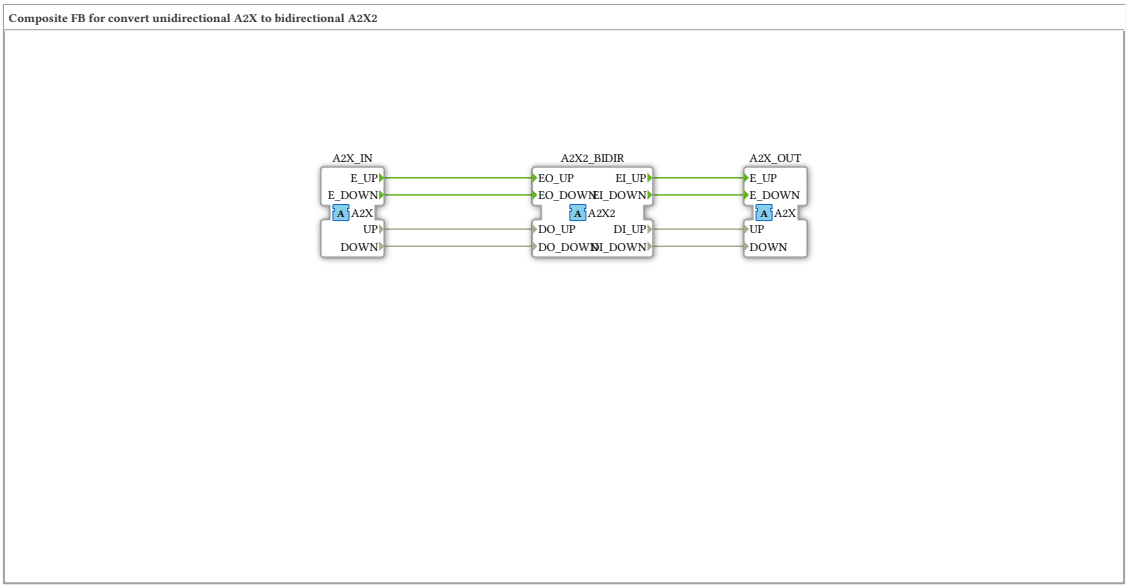
- A2X2_BIDIR.EO_UP ⟶ A2X_OUT.E_UP, A2X2_BIDIR.DO_UP ⟶ A2X_OUT.UP
- A2X2_BIDIR.EO_DOWN ⟶ A2X_OUT.E_DOWN, A2X2_BIDIR.DO_DOWN ⟶ A2X_OUT.DOWN
- A2X_IN.E_UP ⟶ A2X2_BIDIR.EI_UP, A2X_IN.UP ⟶ A2X2_BIDIR.DI_UP
- A2X_IN.E_DOWN ⟶ A2X2_BIDIR.EI_DOWN, A2X_IN.DOWN ⟶ A2X2_BIDIR.DI_DOWN

Application Scenarios

- Reading the status of a bidirectional A2X2 peer as a plain unidirectional A2X signal, combined with injecting a separate unidirectional command signal
- Systems where a bidirectional peer needs to be monitored without converting the rest of the control logic to A2X2
- Bridging a bidirectional A2X2 zone and a unidirectional A2X zone



⚖️ Comparison with Similar Blocks



A2X_TO_A2X2 is the mirror image of this block — there, `A2X2_BIDIR` sits as a plug on the right side. For a pure, non-tapping 1:1 conversion between the single-channel adapters, see the conversion blocks between AX and AX2 in the same library.

Conclusion

A2X2_TO_A2X is not a simple converter but a tap point: it makes the state of a bidirectional A2X2 peer visible as a standalone unidirectional A2X signal while simultaneously injecting a separate unidirectional signal into the bidirectional side.

A2X_TO_A2X2

• – ○ • – ○ • – ○ •

Introduction

The A2X_TO_A2X2 function block inserts a bidirectional A2X2 tap into a unidirectional A2X chain. Rather than a simple 1:1 conversion, it uses **three** adapters: an incoming unidirectional A2X signal is both published onto the bidirectional A2X2 interface and — whatever A2X2 returns on its request side — output again as a standalone unidirectional A2X signal.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **A2X_IN** (Socket): unidirectional UP/DOWN source, of type `adapter::types::unidirectional::A2X`
- **A2X2_BIDIR** (Plug): bidirectional tap whose outgoing side is fed by `A2X_IN` and whose incoming side is forwarded to `A2X_OUT`, of type `adapter::types::bidirectional::A2X2`
- **A2X_OUT** (Plug): mirrors the incoming (request) side of `A2X2_BIDIR` as a unidirectional signal, of type `adapter::types::unidirectional::A2X`

Functionality

The block operates in two directions at once: whatever arrives at the socket `A2X_IN` (`E_UP`/`UP`, `E_DOWN`/`DOWN`) is published directly onto the outgoing side of `A2X2_BIDIR` (`EO_UP`/`DO_UP`, `EO_DOWN`/`DO_DOWN`) — so A2X2_BIDIR reports outward the same UP/DOWN signal coming in via A2X_IN. Conversely, whatever `A2X2_BIDIR` receives on its request side (`EI_UP`/`DI_UP`, `EI_DOWN`/`DI_DOWN` — i.e. whatever a bidirectional peer attached to A2X2_BIDIR "sends back") is output unchanged as a standalone unidirectional signal via the plug `A2X_OUT`. A2X2_BIDIR thus acts as a tap point that doesn't break the unidirectional chain but extends it with a bidirectional observation/injection point.

Technical Details

- Three adapters instead of two: the incoming signal direction and the direction coming back from the tap are deliberately kept separate rather than mixed
- Pure wiring, no logic or state, every destination variable has exactly one writer
- `A2X_OUT` only reflects what comes back via `A2X2_BIDIR` from an attached bidirectional peer — without such a peer, `A2X_OUT` stays idle

State Overview

The block is stateless:

- A2X_IN.E_UP ⟶ A2X2_BIDIR.EO_UP, A2X_IN.UP ⟶ A2X2_BIDIR.DO_UP
- A2X_IN.E_DOWN ⟶ A2X2_BIDIR.EO_DOWN, A2X_IN.DOWN ⟶ A2X2_BIDIR.DO_DOWN
- A2X2_BIDIR.EI_UP ⟶ A2X_OUT.E_UP, A2X2_BIDIR.DI_UP ⟶ A2X_OUT.UP
- A2X2_BIDIR.EI_DOWN ⟶ A2X_OUT.E_DOWN, A2X2_BIDIR.DI_DOWN ⟶ A2X_OUT.DOWN

Application Scenarios

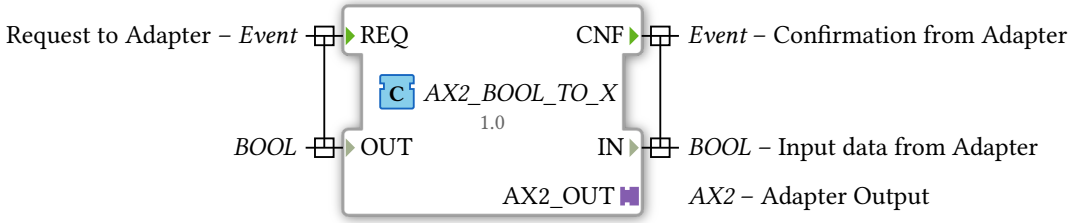
- Retrofitting a bidirectional diagnostic or control point into an existing unidirectional A2X signal chain without breaking it
- Systems where a bidirectional peer (e.g. an operator panel) needs to both display the status of a unidirectional signal source and send commands back
- Bridging a unidirectional A2X zone and a bidirectional A2X2 zone

⚖️ Comparison with Similar Blocks

A2X2_TO_A2X is the mirror image of this block — there, `A2X2_BIDIR` sits as a socket on the left side. For a pure, non-tapping 1:1 conversion between the single-channel adapters, see the conversion blocks between AX and AX2 in the same library.

Conclusion

A2X_TO_A2X2 is not a simple converter but a tap point: it makes a unidirectional A2X signal visible at a bidirectional A2X2 point without breaking the original unidirectional signal chain, while forwarding the request signal received there as a standalone A2X signal.



AX2_BOOL_TO_X

• – ○ • – ○ • – ○ •

Introduction

The AX2_BOOL_TO_X function block serves as a composite function block for converting BOOL values into the AX2 adapter format. It enables bidirectional communication between simple BOOL data and the specific AX2 adapter interface.

Interface Structure

Event Inputs

- **REQ**: Request event to activate the adapter
- Linked to data output OUT
- Y position: 46

Event Outputs

- **CNF**: Acknowledge event from the adapter
- Linked to data input IN
- Y position: 46

Data Inputs

- **OUT**: BOOL data input for output
- Y position: 31

Data Outputs

- **IN**: BOOL data output for input
- Receives data from the adapter
- Y position: 47

Adapter

- **AX2_OUT**: AX2 adapter for bidirectional communication
- Adapter type: adapter::types::bidirectional::AX2

- Position: x=−3900, y=−500

Functionality

This function block acts as a bridge between BOOL data and the AX2 adapter. Upon receiving a REQ event, the OUT value is sent via the AX2_OUT adapter. Simultaneously, incoming data can be received via the same adapter and made available as an IN output with a CNF event.

Technical Features

- Implemented as a composite function block
- Supports bidirectional data transmission
- Uses a specific AX2 adapter interface
- Automatic event and data forwarding between the main interface and the adapter

State Overview

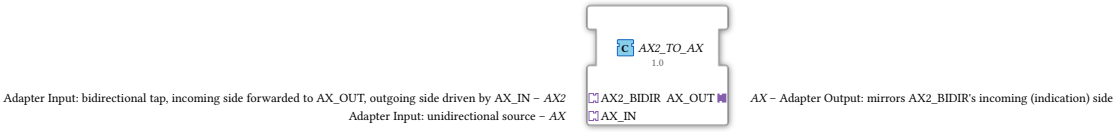
The function block operates statelessly and forwards events and data directly between the interfaces:

- REQ ⟶ AX2_OUT.EO1
- AX2_OUT.EI1 ⟶ CNF
- OUT ⟶ AX2_OUT.DO1
- AX2_OUT.DI1 ⟶ IN

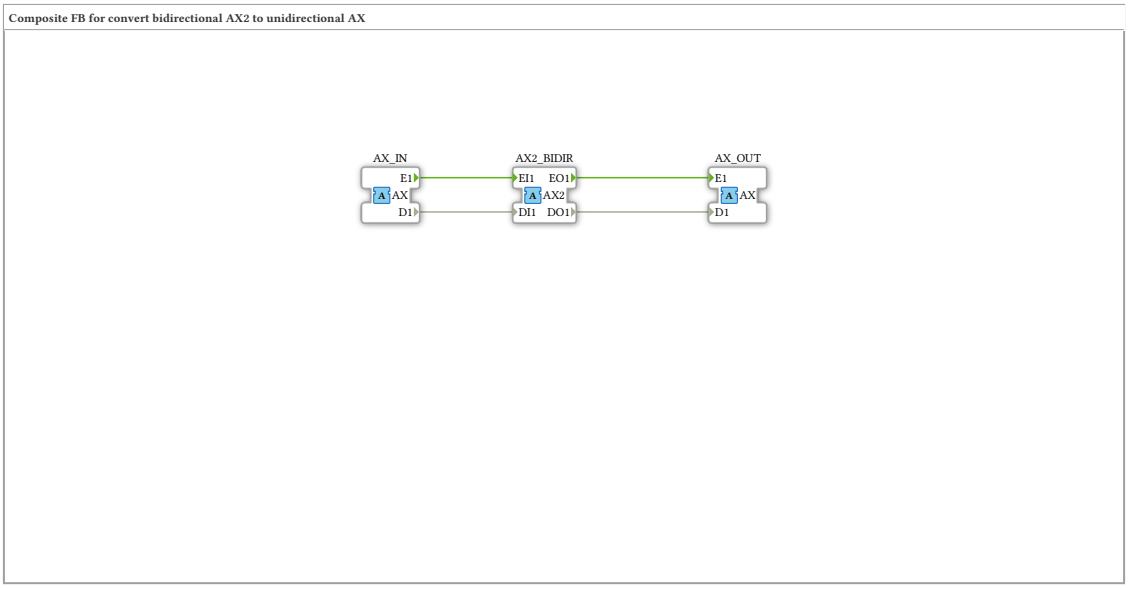
Application Scenarios

- Integration of BOOL signals into AX2-based systems
- Protocol translation between different automation levels
- Bidirectional data exchange scenarios
- Adapter-based system integration

⚖️ Comparison with Similar Blocks



Compared to simple conversion blocks, AX2_BOOL_TO_X offers:



- Bidirectional functionality
- Integrated adapter interface
- Complete event handling
- Higher level of abstraction Composite Design

Conclusion

AX2_BOOL_TO_X is a specialized composite function block that efficiently bridges BOOL data and the AX2 adapter protocol. Its bidirectional architecture and integrated event handling make it ideal for systems requiring seamless integration between different protocol layers.

AX2_TO_AX

• – ○ • – ○ • – ○ •

Introduction

The AX2_TO_AX function block is the mirror image of AX_TO_AX2: here the bidirectional AX2 tap sits as a socket on the left (input) side, complemented by a second unidirectional AX socket and a unidirectional AX plug.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AX2_BIDIR** (Socket): bidirectional tap whose incoming side is forwarded to `AX_OUT` and whose outgoing side is fed by `AX_IN`, of type `adapter::types::bidirectional::AX2`
- **AX_IN** (Socket): unidirectional BOOL source, of type `adapter::types::unidirectional::AX`
- **AX_OUT** (Plug): mirrors the incoming (indication) side of `AX2_BIDIR` as a unidirectional signal, of type `adapter::types::unidirectional::AX`

Functionality

The block operates in two directions at once: whatever the socket `AX2_BIDIR` receives on its indication side (`EO1`/`DO1` — i.e. whatever a bidirectional peer attached to AX2_BIDIR reports) is output unchanged as a standalone unidirectional signal via the plug `AX_OUT`. Conversely, whatever arrives at the socket `AX_IN` (`E1`/`D1`) is published onto the request side of `AX2_BIDIR` (`EI1`/`DI1`) — so AX2_BIDIR forwards the same signal to the attached bidirectional peer.

Technical Details

- Three adapters instead of two: the direction received from the tap and the separately injected direction are deliberately kept apart rather than mixed
- Pure wiring, no logic or state, every destination variable has exactly one writer

- `AX_OUT` only reflects what is reported via `AX2_BIDIR` by an attached bidirectional peer — without such a peer, `AX_OUT` stays idle

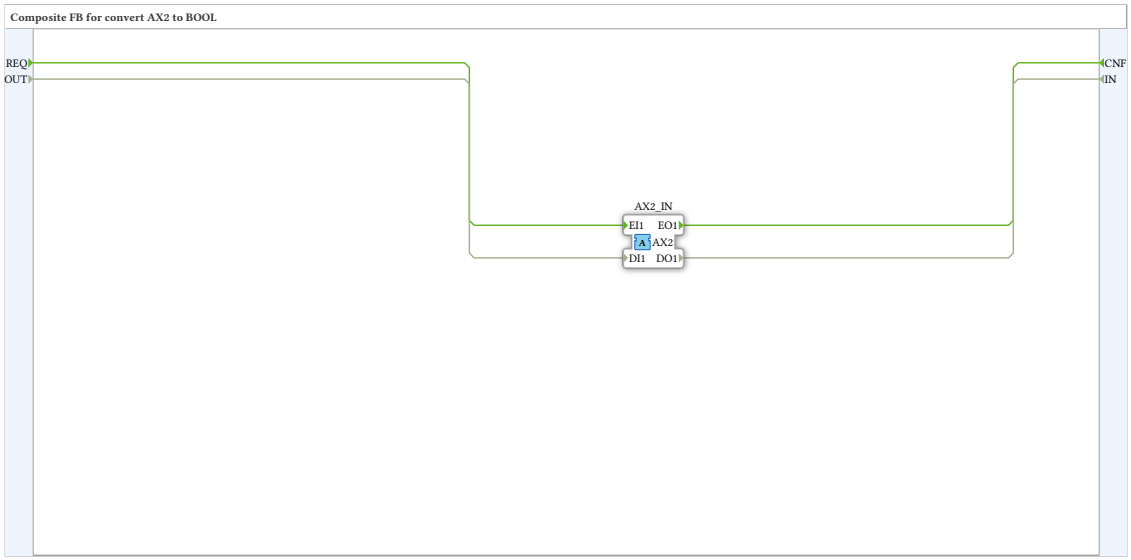
State Overview

The block is stateless:

- AX2_BIDIR.EO1 ⟶ AX_OUT.E1, AX2_BIDIR.DO1 ⟶ AX_OUT.D1
- AX_IN.E1 ⟶ AX2_BIDIR.EI1, AX_IN.D1 ⟶ AX2_BIDIR.DI1

Application Scenarios

- Reading the status of a bidirectional AX2 peer as a plain unidirectional AX signal, combined with injecting a separate unidirectional command signal
- Systems where a bidirectional peer needs to be monitored without converting the rest of the control logic to AX2
- Bridging a bidirectional AX2 zone and a unidirectional AX zone

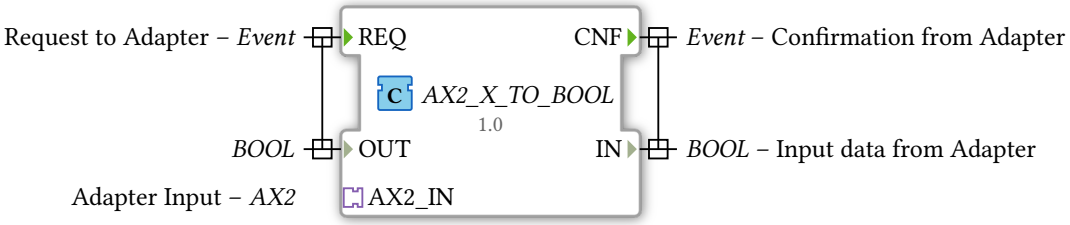


⚖️ Comparison with Similar Blocks

AX_TO_AX2 is the mirror image of this block — there, `AX2_BIDIR` sits as a plug on the right side. For a pure, non-tapping 1:1 conversion between AX2 and a plain BOOL signal, see AX2_X_TO_BOOL/ AX2_BOOL_TO_X. The 2-channel A2X2/A2X counterpart is A2X2_TO_A2X.

Conclusion

AX2_TO_AX is not a simple converter but a tap point: it makes the state of a bidirectional AX2 peer visible as a standalone unidirectional AX signal while simultaneously injecting a separate unidirectional signal into the bidirectional side.



AX2_X_TO_BOOL

• – ◦ • – ◦ • – ◦ •

Introduction

The AX2_X_TO_BOOL function block is a composite function block for converting AX2 data to BOOL values. It serves as a bidirectional adapter for data type conversion between different interfaces in automation systems.

Interface Structure

Event Inputs

- **REQ** (Request to Adapter): Initiates the conversion request to the adapter

Event Outputs

- **CNF** (Confirmation from Adapter): Confirms the completion of the conversion from the adapter

Data Inputs

- **OUT** (BOOL): Output data for transfer to the adapter

Data Outputs

- **IN** (BOOL): Input data from the adapter after successful conversion

Adapter

- **AX2_IN** (adapter::types::bidirectional::AX2): Bidirectional AX2 adapter for data type conversion

Functionality

The function block receives a conversion request via the REQ event and forwards it to the AX2 adapter. The adapter converts AX2 data to BOOL values. After successful conversion, the CNF event containing the converted data is output at the IN output. Simultaneously, BOOL data can be returned to the adapter via the OUT input.

Technical Features

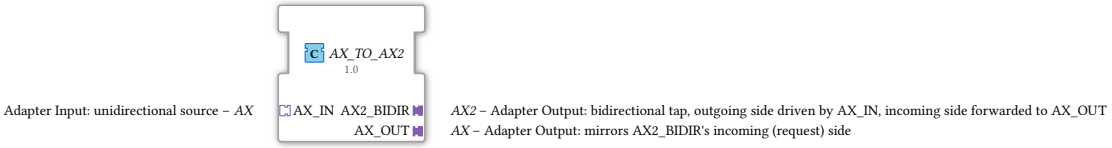
- Bidirectional data transfer between AX2 and BOOL data types
- Composite function block with integrated adapter
- Automatic event forwarding between interfaces
- Positioned elements for optimized display in the development environment

State Transitions

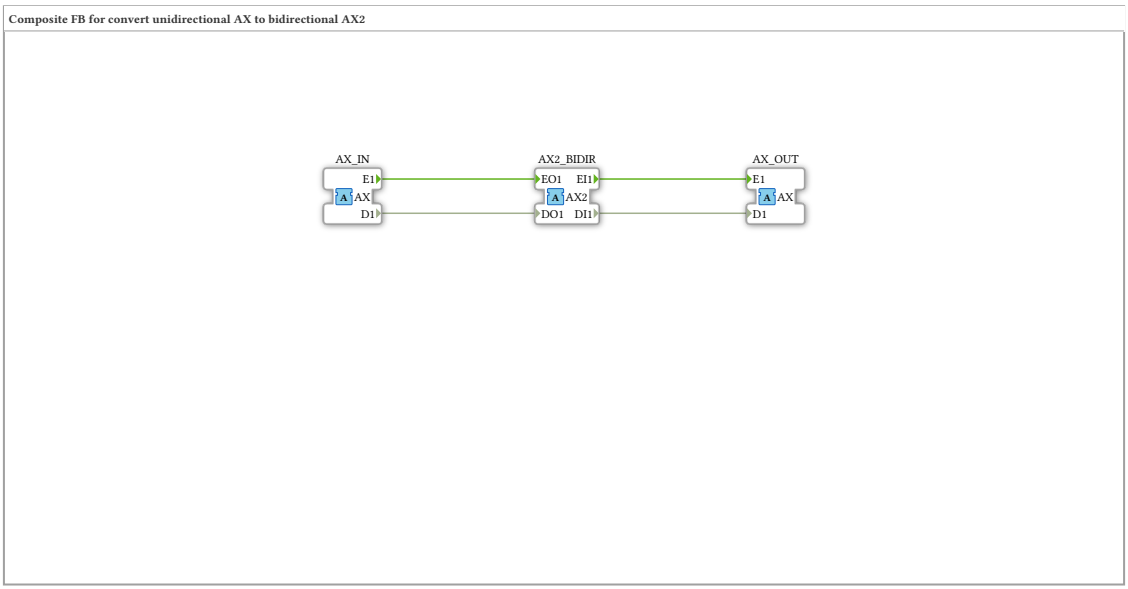
1. **Wait State**: No active conversion
2. **Active State**: On REQ event - data is forwarded to the adapter
3. **Confirmation State**: Upon completion of the conversion - CNF event is triggered

Application Scenarios

- Integration of AX2 sensor data into BOOL-based control systems
- Data type conversion in mixed automation environments
- Bidirectional communication between different protocols
- Adapter solutions for existing systems with different data types



⚖️ Comparison with similar blocks



Compared to simple conversion blocks, AX2_X_TO_BOOL offers bidirectional functionality with an integrated adapter interface. While simple converters typically only work in one direction, this block enables bidirectional data exchange.

Conclusion

The AX2_X_TO_BOOL function block provides a robust solution for bidirectional conversion between AX2 and BOOL data types. Its integrated adapter architecture and clear event handling make it particularly suitable for complex automation applications with mixed data type environments.

AX_TO_AX2

• – ○ • – ○ • – ○ •

Introduction

The AX_TO_AX2 function block inserts a bidirectional AX2 tap into a unidirectional AX chain. Rather than a simple 1:1 conversion, it uses **three** adapters: an incoming unidirectional AX signal is both published onto the bidirectional AX2 interface and — whatever AX2 returns on its request side — output again as a standalone unidirectional AX signal.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AX_IN** (Socket): unidirectional BOOL source, of type `adapter::types::unidirectional::AX`
- **AX2_BIDIR** (Plug): bidirectional tap whose outgoing side is fed by `AX_IN` and whose incoming side is forwarded to `AX_OUT`, of type `adapter::types::bidirectional::AX2`
- **AX_OUT** (Plug): mirrors the incoming (request) side of `AX2_BIDIR` as a unidirectional signal, of type `adapter::types::unidirectional::AX`

Functionality

The block operates in two directions at once: whatever arrives at the socket `AX_IN` (`E1`/`D1`) is published directly onto the outgoing side of `AX2_BIDIR` (`EO1`/`DO1`) — so AX2_BIDIR reports outward the same signal coming in via AX_IN. Conversely, whatever `AX2_BIDIR` receives on its request side (`EI1`/`DI1` — i.e.

whatever a bidirectional peer attached to AX2_BIDIR "sends back") is output unchanged as a standalone unidirectional signal via the plug `AX_OUT`. AX2_BIDIR thus acts as a tap point that doesn't break the unidirectional chain but extends it with a bidirectional observation/injection point.

Technical Details

- Three adapters instead of two: the incoming signal direction and the direction coming back from the tap are deliberately kept separate rather than mixed
- Pure wiring, no logic or state, every destination variable has exactly one writer
- `AX_OUT` only reflects what comes back via `AX2_BIDIR` from an attached bidirectional peer — without such a peer, `AX_OUT` stays idle

State Overview

The block is stateless:

- AX_IN.E1 ⟶ AX2_BIDIR.EO1, AX_IN.D1 ⟶ AX2_BIDIR.DO1
- AX2_BIDIR.EI1 ⟶ AX_OUT.E1, AX2_BIDIR.DI1 ⟶ AX_OUT.D1

Application Scenarios

- Retrofitting a bidirectional diagnostic or control point into an existing unidirectional AX signal chain without breaking it
- Systems where a bidirectional peer (e.g. an operator panel) needs to both display the status of a unidirectional signal source and send commands back
- Bridging a unidirectional AX zone and a bidirectional AX2 zone

⚖️ Comparison with Similar Blocks

AX2_TO_AX is the mirror image of this block — there, `AX2_BIDIR` sits as a socket on the left side. For a pure, non-tapping 1:1 conversion between a plain BOOL signal and AX2, see AX2_BOOL_TO_X/ AX2_X_TO_BOOL. The 2-channel A2X/A2X2 counterpart is A2X_TO_A2X2.

Conclusion

AX_TO_AX2 is not a simple converter but a tap point: it makes a unidirectional AX signal visible at a bidirectional AX2 point without breaking the original unidirectional signal chain, while forwarding the request signal received there as a standalone AX signal.

AB2_BYTE_TO_B

• – ○ • – ○ • – ○ •

Introduction

The AB2_BYTE_TO_B function block is a composite function block used for conversion between BYTE data types and the AB2 adapter. It acts as a bidirectional converter and enables communication between system components with different interfaces.

Interface Structure

Event Inputs

- **REQ** (Request to Adapter): Starts the conversion and data transfer to the adapter

Event Outputs

- **CNF** (Confirmation from Adapter): Signals the successful completion of the conversion and data transfer from the adapter

Data Inputs

- **OUT** (BYTE): Output data to be transferred to the adapter

Data Outputs

- **IN** (BYTE): Input data received by the adapter

Adapter

- **AB2_OUT** (adapter::types::bidirectional::AB2): Bidirectional adapter for data conversion

Functionality

The function block receives a conversion request via the REQ event and forwards the incoming BYTE data (OUT) to the AB2 adapter. The adapter performs the actual conversion and, upon successful completion, sends back a CNF event along with the converted BYTE data (IN). ...

Technical Features

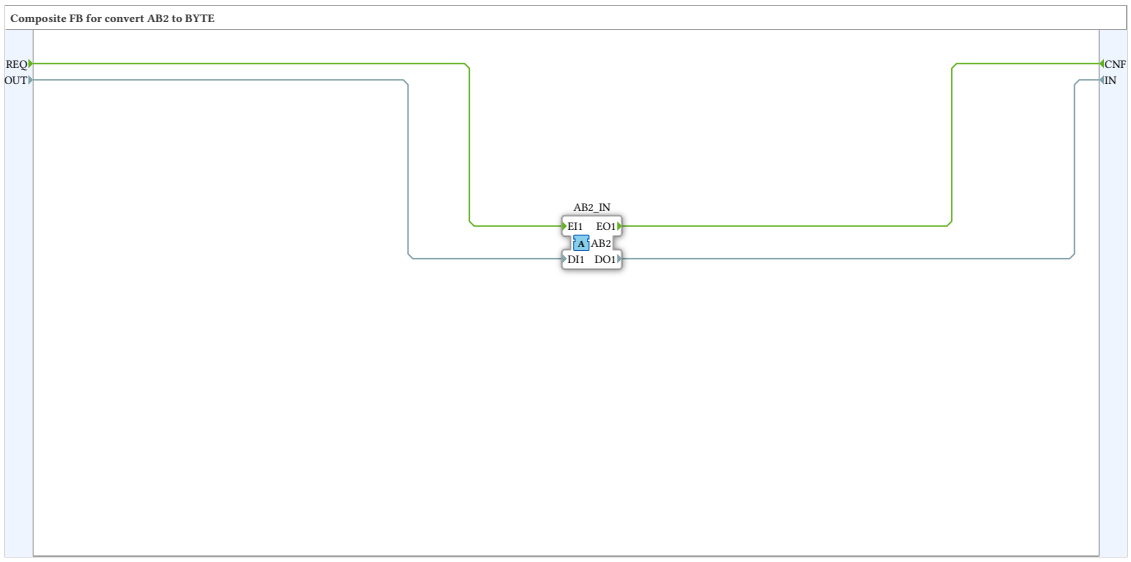
- Composite function block with integrated adapter
- Bidirectional data transmission
- Uses BYTE as the primary data type
- Positioned interfaces for optimized display in the development environment

State Transitions

1. **Idle State**: Waits for REQ event
2. **Processing State**: Upon REQ, data is forwarded to AB2_OUT
3. **Acknowledgement State**: Upon feedback from the adapter, CNF is triggered

Application Scenarios

- Integration of BYTE-based components into AB2-compatible systems
- Protocol conversion in distributed automation systems
- Bidirectional data exchange interfaces
- Adapter-based system integration

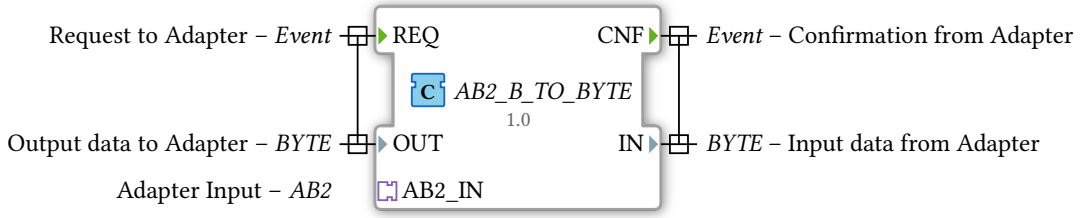


⚖️ Comparison with Similar Blocks

Compared to simple conversion blocks, AB2_BYTE_TO_B offers bidirectional functionality with adapter integration. While simple converters typically only operate in one direction, this block enables communication in both directions via standardized adapter interfaces.

Conclusion

AB2_BYTE_TO_B is a specialized composite function block that provides reliable bidirectional conversion between BYTE data and the AB2 adapter standard. Its structured interface and clear event control make it ideal for use in complex automation systems with standardized communication protocols.



AB2_B_TO_BYTE

• – ○ • – ○ • – ○ •

Introduction

The AB2_B_TO_BYTE is a composite function block used for bidirectional conversion between AB2 and BYTE data types. This function block acts as an adapter converter, enabling the seamless integration of different data types into automation systems.

Interface Structure

Event Inputs

- **REQ** (Request to Adapter): Starts the conversion operation and requests the data output

Event Outputs

- **CNF** (Confirmation from Adapter): Signals the successful completion of the conversion operation

Data Inputs

- **OUT** (BYTE): Output data to be sent to the adapter

Data Outputs

- **IN** (BYTE): Input data received by the adapter

Adapter

- **AB2_IN** (adapter::types::bidirectional::AB2): Bidirectional AB2 adapter for data type conversion

Functionality

This function block operates as a bidirectional converter between AB2 and BYTE data types. Upon receiving a REQ event, the BYTE data at OUT is converted via the AB2_IN adapter. After successful conversion, the CNF event is triggered, and the converted data is output to IN.

The internal networking shows the following signal flows:

- REQ → AB2_IN.EI1 (Adapter input event)
- AB2_IN.EO1 → CNF (Adapter output event)
- OUT → AB2_IN.DI1 (Adapter data input)
- AB2_IN.DO1 → IN (Adapter data output)

Technical Features

- Implemented as a composite function block with an integrated adapter
- Supports bidirectional data conversion
- Positioning attributes for graphical representation in the development environment
- Embedded in the “adapter::conversion::bidirectional” package

State Overview

The function block goes through the following states:

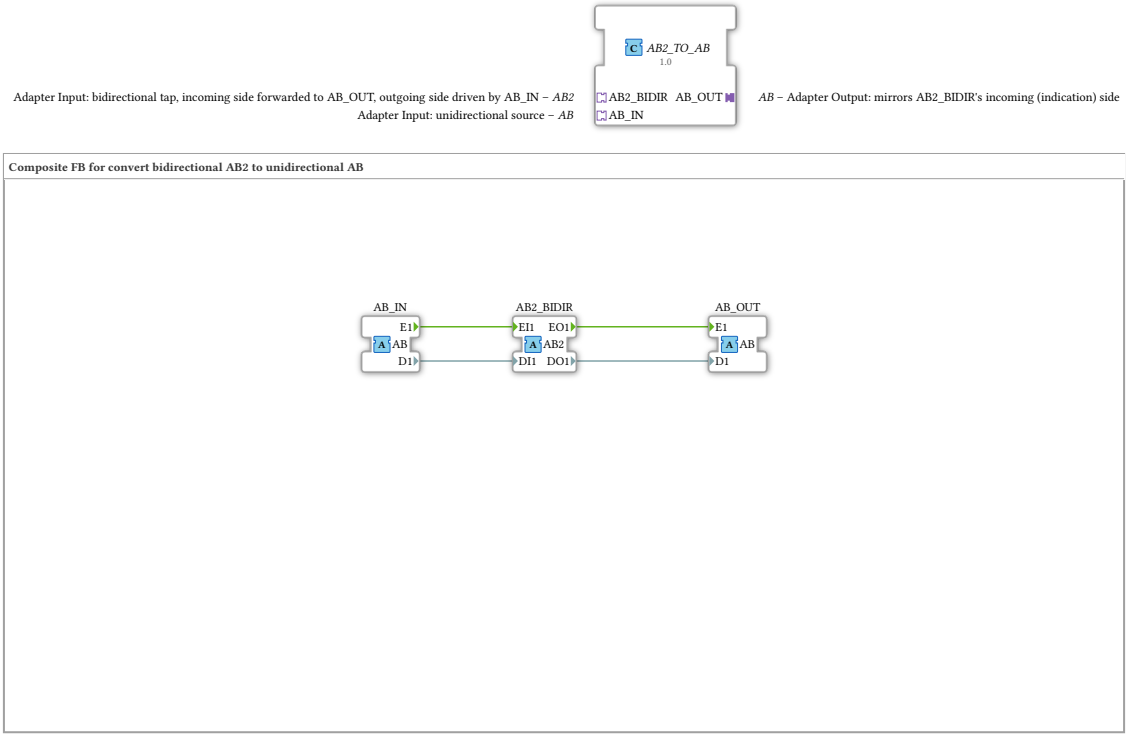
1. **Ready**: Waiting for a REQ event
2. **Conversion in progress**: Processing data via the AB2 adapter
3. **Acknowledgement**: Sends a CNF upon successful completion

Application Scenarios

- Integration of AB2 components into BYTE-based Control Systems
- Data Type Conversion in Heterogeneous Automation Networks
- Adapter Solutions for Legacy Systems with AB2 Interfaces
- Protocol Conversion Between Different Communication Standards

⚖️ Comparison with Similar Function Blocks

Compared to simple conversion blocks, AB2_B_TO_BYTE offers:



- Bidirectional functionality in a single block
- Integrated adapter interface for AB2 types

- Composite architecture with extended functionality
- Standardized event handling with REQ/CNF pair

Conclusion

The AB2_B_TO_BYTE function block provides a robust solution for bidirectional conversion between AB2 and BYTE data types. Its composite architecture with integrated adapter enables easy integration into existing automation systems and offers reliable data type compatibility.

AB2_TO_AB

• – ○ • – ○ • – ○ •

Introduction

The AB2_TO_AB function block is the mirror image of AB_TO_AB2: here the bidirectional AB2 tap sits as a socket on the left (input) side, complemented by a second unidirectional AB socket and a unidirectional AB plug.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AB2_BIDIR** (Socket): bidirectional tap whose incoming side is forwarded to `AB_OUT` and whose outgoing side is fed by `AB_IN`, of type `adapter::types::bidirectional::AB2`
- **AB_IN** (Socket): unidirectional BYTE source, of type `adapter::types::unidirectional::AB`

- **AB_OUT** (Plug): mirrors the incoming (indication) side of `AB2_BIDIR` as a unidirectional signal, of type `adapter::types::unidirectional::AB`

Functionality

The block operates in two directions at once: whatever the socket `AB2_BIDIR` receives on its indication side (`EO1`/`DO1` — i.e. whatever a bidirectional peer attached to AB2_BIDIR reports) is output unchanged as a standalone unidirectional signal via the plug `AB_OUT`. Conversely, whatever arrives at the socket `AB_IN` (`E1`/`D1`) is published onto the request side of `AB2_BIDIR` (`EI1`/`DI1`) — so AB2_BIDIR forwards the same signal to the attached bidirectional peer.

Technical Details

- Three adapters instead of two: the direction received from the tap and the separately injected direction are deliberately kept apart rather than mixed
- Pure wiring, no logic or state, every destination variable has exactly one writer
- `AB_OUT` only reflects what is reported via `AB2_BIDIR` by an attached bidirectional peer — without such a peer, `AB_OUT` stays idle

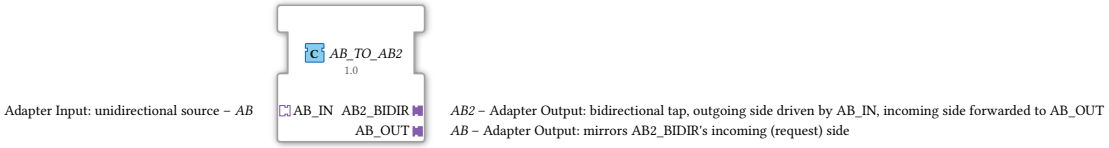
State Overview

The block is stateless:

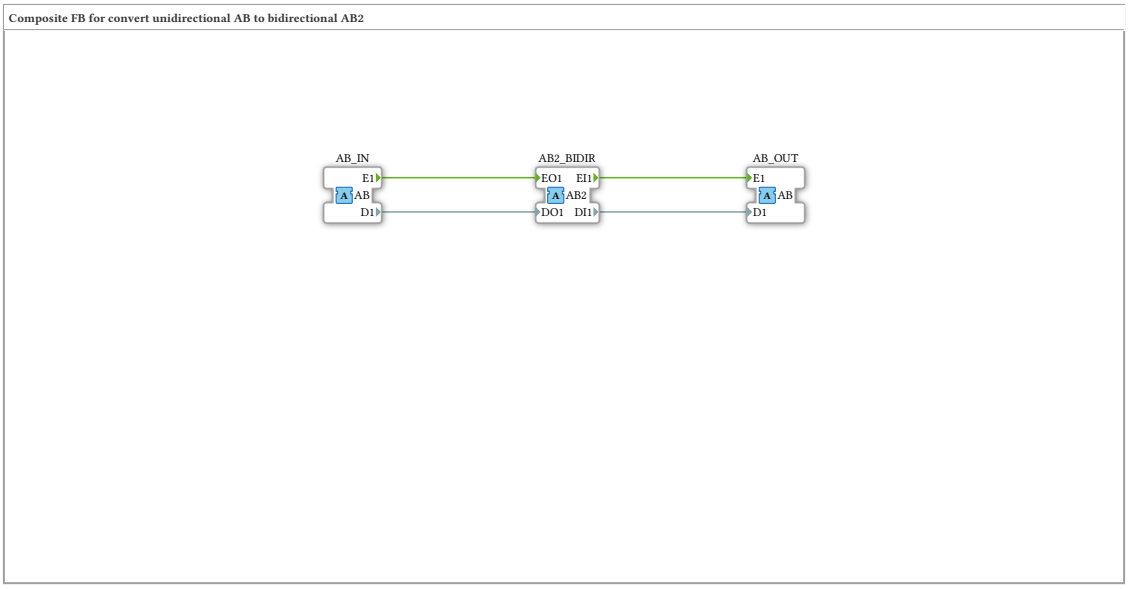
- AB2_BIDIR.EO1 ⟶ AB_OUT.E1, AB2_BIDIR.DO1 ⟶ AB_OUT.D1
- AB_IN.E1 ⟶ AB2_BIDIR.EI1, AB_IN.D1 ⟶ AB2_BIDIR.DI1

Application Scenarios

- Reading the status of a bidirectional AB2 peer as a plain unidirectional AB signal, combined with injecting a separate unidirectional command signal
- Systems where a bidirectional peer needs to be monitored without converting the rest of the control logic to AB2
- Bridging a bidirectional AB2 zone and a unidirectional AB zone



⚖️ Comparison with Similar Blocks



AB_TO_AB2 is the mirror image of this block — there, `AB2_BIDIR` sits as a plug on the right side. For a pure, non-tapping 1:1 conversion between AB2 and a plain BYTE signal, see AB2_BYTE_TO_B/ AB2_B_TO_BYTE.

Conclusion

AB2_TO_AB is not a simple converter but a tap point: it makes the state of a bidirectional AB2 peer visible as a standalone unidirectional AB signal while simultaneously injecting a separate unidirectional signal into the bidirectional side.

AB_TO_AB2

• – ○ • – ○ • – ○ •

Introduction

The AB_TO_AB2 function block inserts a bidirectional AB2 tap into a unidirectional AB chain. Rather than a simple 1:1 conversion, it uses **three** adapters: an incoming unidirectional AB signal is both published onto the bidirectional AB2 interface and — whatever AB2 returns on its request side — output again as a standalone unidirectional AB signal.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AB_IN** (Socket): unidirectional BYTE source, of type `adapter::types::unidirectional::AB`
- **AB2_BIDIR** (Plug): bidirectional tap whose outgoing side is fed by `AB_IN` and whose incoming side is forwarded to `AB_OUT`, of type `adapter::types::bidirectional::AB2`
- **AB_OUT** (Plug): mirrors the incoming (request) side of `AB2_BIDIR` as a unidirectional signal, of type `adapter::types::unidirectional::AB`

Functionality

The block operates in two directions at once: whatever arrives at the socket `AB_IN` (`E1`/`D1`) is published directly onto the outgoing side of `AB2_BIDIR` (`EO1`/`DO1`) — so AB2_BIDIR reports outward the same signal coming in via AB_IN. Conversely, whatever `AB2_BIDIR` receives on its request side (`EI1`/`DI1` — i.e. whatever a bidirectional peer attached to AB2_BIDIR "sends back") is output unchanged as a standalone unidirectional signal via the plug `AB_OUT`. AB2_BIDIR thus acts as a tap point that doesn't break the unidirectional chain but extends it with a bidirectional observation/injection point.

Technical Details

- Three adapters instead of two: the incoming signal direction and the direction coming back from the tap are deliberately kept separate rather than mixed
- Pure wiring, no logic or state, every destination variable has exactly one writer
- `AB_OUT` only reflects what comes back via `AB2_BIDIR` from an attached bidirectional peer — without such a peer, `AB_OUT` stays idle

State Overview

The block is stateless:

- AB_IN.E1 ⟶ AB2_BIDIR.EO1, AB_IN.D1 ⟶ AB2_BIDIR.DO1
- AB2_BIDIR.EI1 ⟶ AB_OUT.E1, AB2_BIDIR.DI1 ⟶ AB_OUT.D1

Application Scenarios

- Retrofitting a bidirectional diagnostic or control point into an existing unidirectional AB signal chain without breaking it
- Systems where a bidirectional peer (e.g. an operator panel) needs to both display the status of a unidirectional byte signal source and send commands back
- Bridging a unidirectional AB zone and a bidirectional AB2 zone

⚖️ Comparison with Similar Blocks

AB2_TO_AB is the mirror image of this block — there, `AB2_BIDIR` sits as a socket on the left side. For a pure, non-tapping 1:1 conversion between a plain BYTE signal and AB2, see AB2_B_TO_BYTE/ AB2_BYTE_TO_B.

Conclusion

AB_TO_AB2 is not a simple converter but a tap point: it makes a unidirectional AB signal visible at a bidirectional AB2 point without breaking the original unidirectional signal chain, while forwarding the request signal received there as a standalone AB signal.

DWORD

AD_TO_AD2

• – ○ • – ○ • – ○ •

Introduction

The AD_TO_AD2 function block inserts a bidirectional AD2 tap into a unidirectional AD chain. Rather than a simple 1:1 conversion, it uses **three** adapters: an incoming unidirectional AD signal is both published onto the bidirectional AD2 interface and — whatever AD2 returns on its request side — output again as a standalone unidirectional AD signal.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AD_IN** (Socket): unidirectional DWORD source, of type `adapter::types::unidirectional::AD`
- **AD2_BIDIR** (Plug): bidirectional tap whose outgoing side is fed by `AD_IN` and whose incoming side is forwarded to `AD_OUT`, of type `adapter::types::bidirectional::AD2`
- **AD_OUT** (Plug): mirrors the incoming (request) side of `AD2_BIDIR` as a unidirectional signal, of type `adapter::types::unidirectional::AD`

Functionality

The block operates in two directions at once: whatever arrives at the socket `AD_IN` (`E1`/`D1`) is published directly onto the outgoing side of `AD2_BIDIR` (`EO1`/`DO1`) — so AD2_BIDIR reports outward the same signal coming in via AD_IN. Conversely, whatever `AD2_BIDIR` receives on its request side (`EI1`/`DI1` — i.e. whatever a bidirectional peer attached to AD2_BIDIR "sends back") is output unchanged as a standalone unidirectional signal via the plug `AD_OUT`. AD2_BIDIR thus acts as a tap point that doesn't break the unidirectional chain but extends it with a bidirectional observation/injection point.

Technical Details

- Three adapters instead of two: the incoming signal direction and the direction coming back from the tap are deliberately kept separate rather than mixed
- Pure wiring, no logic or state, every destination variable has exactly one writer
- `AD_OUT` only reflects what comes back via `AD2_BIDIR` from an attached bidirectional peer — without such a peer, `AD_OUT` stays idle

State Overview

The block is stateless:

- AD_IN.E1 ⟶ AD2_BIDIR.EO1, AD_IN.D1 ⟶ AD2_BIDIR.DO1
- AD2_BIDIR.EI1 ⟶ AD_OUT.E1, AD2_BIDIR.DI1 ⟶ AD_OUT.D1

Application Scenarios

- Retrofitting a bidirectional diagnostic or control point into an existing unidirectional AD signal chain without breaking it
- Systems where a bidirectional peer (e.g. an operator panel) needs to both display the status of a unidirectional byte signal source and send commands back
- Bridging a unidirectional AD zone and a bidirectional AD2 zone

⚖️ Comparison with Similar Blocks

AD_TO_AD2 belongs to the conversion family of tap blocks (analogous to AB_TO_AB2 for BYTE): a unidirectional AD signal is tapped at a bidirectional AD2 point.

Conclusion

AD_TO_AD2 is not a simple converter but a tap point: it makes a unidirectional AD signal visible at a bidirectional AD2 point without breaking the original unidirectional signal chain, while forwarding the request signal received there as a standalone AD signal.

AE2_EVENT_TO_E

• – ◦ • – ◦ • – ◦ •

Introduction

The AE2_EVENT_TO_E function block is a composite function block used to convert EVENT signals into the AE2 adapter format. It enables bidirectional communication between standard events and the specific AE2 adapter.

Interface Structure

Event Inputs

- **REQ** (Request to Adapter): Starts the conversion and sends a request to the AE2 output adapter

Event Outputs

- **CNF** (Confirmation from Adapter): Confirms the successful completion of the conversion and receipt of the response from the AE2 adapter

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

- **AE2_OUT** (Adapter Output): Bidirectional AE2 output adapter for communication with AE2-compatible systems

Functionality

This function block forwards incoming REQ events directly to the AE2_OUT adapter (EO1 port). Simultaneously, incoming acknowledgments from the AE2 adapter (EI1 port) are output as CNF events. This enables transparent conversion between the standard EVENT format and the specific AE2 adapter protocol.

Technical Features

- Implemented as a composite function block
- Supports bidirectional communication
- Uses the AE2 adapter type from the adapter::types::bidirectional package
- Positioned adapter interface for optimized visualization

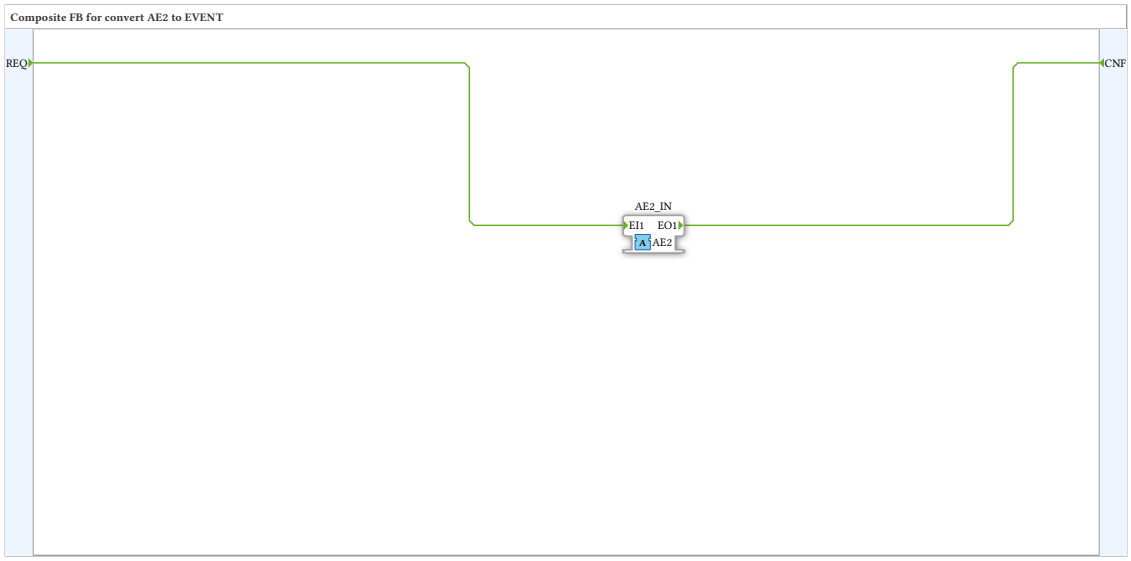
State Overview

The function block features a simple state machine:

1. **Idle State**: Waits for a REQ event
2. **Request State**: After REQ input, sends to AE2_OUT.EO1
3. **Confirmation State**: After receiving AE2_OUT.EI1, outputs CNF

Application Scenarios

- Integration of EVENT-based systems into AE2-compatible environments
- Protocol conversion in distributed automation systems
- Bidirectional communication bridges between different automation components
- Adapter-based system integration

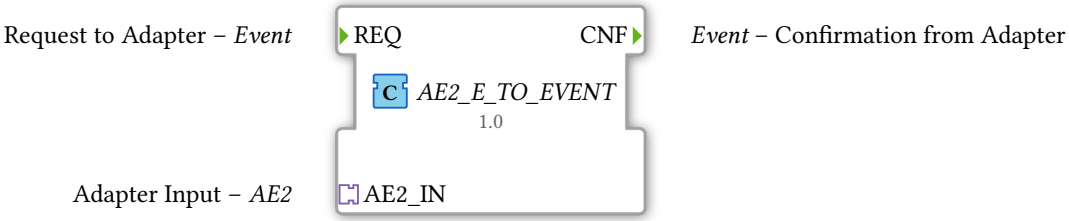


⚖️ Comparison with Similar Blocks

Compared to simple EVENT converters, this offers AE2_EVENT_TO_E provides specific AE2 adapter support with bidirectional communication. While standard converters often operate only unidirectionally, this block enables complete request-response cycles with the AE2 protocol.

Conclusion

The AE2_EVENT_TO_E function block offers a reliable solution for converting between standard event signals and the AE2 adapter protocol. Its bidirectional functionality and ease of integration make it particularly suitable for systems requiring seamless communication between different protocol environments.



AE2_E_TO_EVENT

• – ◦ • – ◦ • – ◦ •

Introduction

The AE2_E_TO_EVENT function block is a composite function block used to convert AE2 adapter signals into events. It enables bidirectional communication between adapter-based components and event-driven function blocks.

Interface Structure

Event Inputs

- **REQ** (Request to Adapter): Starts the conversion and sends a request to the adapter

Event Outputs

- **CNF** (Confirmation from Adapter): Confirms successful completion of the conversion

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapter

- **AE2_IN** (Adapter Input): Bidirectional AE2 adapter input for communication with AE2-compatible components

Functionality

This function block acts as a simple converter between the AE2 adapter protocol and the standard 4diac event system. Upon receiving a REQ event, a request is sent via the AE2 adapter. The adapter's response is received via the EO1 signal and output as a CNF event.

Technical Features

- Implemented as a composite function block
- Uses bidirectional AE2 adapter communication
- Simple event forwarding without data manipulation
- The CNF output position is fixed at Y position 46

State Overview

The function block has two main states:

1. **Wait State**: No active conversion
2. **Active State**: Conversion in progress (from REQ input to CNF output)

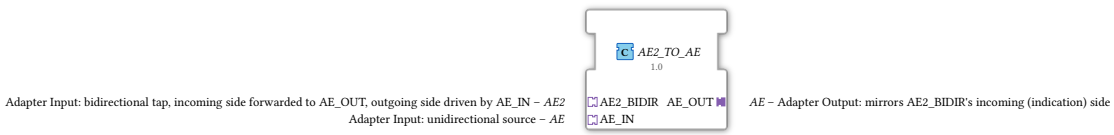
Application Scenarios

- Integration of AE2-compatible devices into 4diac controllers
- Bridge functionality between different communication protocols
- Simple event conversion in automation systems
- Protocol conversion in distributed control systems

⚖️ Comparison with Similar Blocks

Compared to other adapter converters, AE2_E_TO_EVENT stands out due to its specific focus on the AE2 adapter protocol. While general adapter converters support various protocols, this module is specifically optimized for bidirectional AE2 communication.

Conclusion



The AE2_E_TO_EVENT function block offers a reliable and simple solution for integrating AE2 adapters into event-driven 4diac systems. Its clear interface definition and straightforward functionality make it a practical tool for protocol conversions in industrial automation applications.

AE2_TO_AE

• – ○ • – ○ • – ○ •

Introduction

The AE2_TO_AE function block is the mirror image of AE_TO_AE2: here the bidirectional AE2 tap sits as a socket on the left (input) side, complemented by a second unidirectional AE socket and a unidirectional AE plug.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no data inputs or outputs at all — AE and AE2 carry only events, never payload data.

Data Outputs

The function block has no data inputs or outputs at all — AE and AE2 carry only events, never payload data.

Adapters

- **AE2_BIDIR** (Socket): bidirectional tap whose incoming side is forwarded to `AE_OUT` and whose outgoing side is fed by `AE_IN`, of type `adapter::types::bidirectional::AE2`
- **AE_IN** (Socket): unidirectional EVENT source, of type `adapter::types::unidirectional::AE`
- **AE_OUT** (Plug): mirrors the incoming (indication) side of `AE2_BIDIR` as a unidirectional event, of type `adapter::types::unidirectional::AE`

Functionality

The block operates in two directions at once: whatever the socket `AE2_BIDIR` receives on its indication side (`EO1` — i.e. whatever a bidirectional peer attached to AE2_BIDIR reports) is output unchanged as a standalone unidirectional event via the plug `AE_OUT`. Conversely, whatever arrives at the socket `AE_IN` (`E1`) is published onto the request side of `AE2_BIDIR` (`EI1`) — so AE2_BIDIR forwards the same event to the attached bidirectional peer. Since AE/AE2 are pure event adapters with no payload data, there are no DataConnections at all.

Technical Details

- Three adapters instead of two: the direction received from the tap and the separately injected direction are deliberately kept apart rather than mixed
- Pure wiring, no logic or state, every destination variable has exactly one writer
- No data transport: AE/AE2 carry only events, so this block has no DataConnections
- `AE_OUT` only reflects what is reported via `AE2_BIDIR` by an attached bidirectional peer — without such a peer, `AE_OUT` stays idle

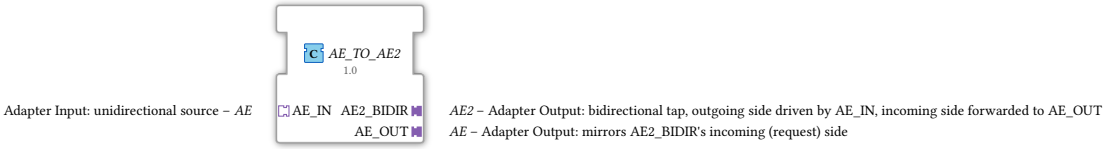
State Overview

The block is stateless:

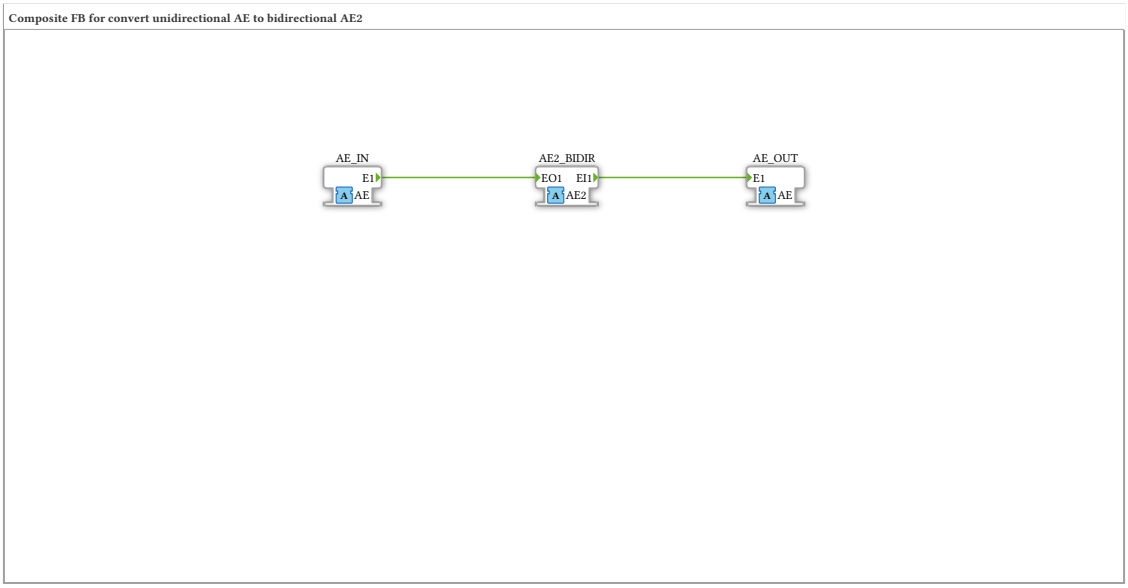
- AE2_BIDIR.EO1 ⟶ AE_OUT.E1
- AE_IN.E1 ⟶ AE2_BIDIR.EI1

Application Scenarios

- Reading a bidirectional AE2 peer as a plain unidirectional AE event, combined with injecting a separate unidirectional event
- Systems where a bidirectional peer needs to be monitored without converting the rest of the control logic to AE2
- Bridging a bidirectional AE2 zone and a unidirectional AE zone



⚖️ Comparison with Similar Blocks



AE_TO_AE2 is the mirror image of this block — there, `AE2_BIDIR` sits as a plug on the right side. For a pure, non-tapping 1:1 conversion between AE2 and a plain EVENT signal, see AE2_E_TO_EVENT/ AE2_EVENT_TO_E. For two coupled events (SET/RESET), see ASR2_TO_ASR.

Conclusion

AE2_TO_AE is not a simple converter but a tap point: it makes the state of a bidirectional AE2 peer visible as a standalone unidirectional AE event while simultaneously injecting a separate unidirectional event into the bidirectional side.

AE_TO_AE2

• – ○ • – ○ • – ○ •

Introduction

The AE_TO_AE2 function block inserts a bidirectional AE2 tap into a unidirectional AE event chain. Rather than a simple 1:1 conversion, it uses **three** adapters: an incoming unidirectional AE event is both published onto the bidirectional AE2 interface and — whatever AE2 returns on its request side — output again as a standalone unidirectional AE event.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no data inputs or outputs at all — AE and AE2 carry only events, never payload data.

Data Outputs

The function block has no data inputs or outputs at all — AE and AE2 carry only events, never payload data.

Adapters

- **AE_IN** (Socket): unidirectional EVENT source, of type `adapter::types::unidirectional::AE`
- **AE2_BIDIR** (Plug): bidirectional tap whose outgoing side is fed by `AE_IN` and whose incoming side is forwarded to `AE_OUT`, of type `adapter::types::bidirectional::AE2`
- **AE_OUT** (Plug): mirrors the incoming (request) side of `AE2_BIDIR` as a unidirectional event, of type `adapter::types::unidirectional::AE`

Functionality

The block operates in two directions at once: whatever arrives at the socket `AE_IN` (`E1`) is published directly onto the outgoing side of `AE2_BIDIR` (`EO1`) — so AE2_BIDIR reports outward the same event coming in via AE_IN. Conversely, whatever `AE2_BIDIR` receives on its request side (`EI1` — i.e. whatever a bidirectional peer attached to AE2_BIDIR "sends back") is output unchanged as a standalone unidirectional event via the plug `AE_OUT`. Since AE/AE2 are pure event adapters with no payload data, there are no DataConnections at all.

Technical Details

- Three adapters instead of two: the incoming event direction and the direction coming back from the tap are deliberately kept separate rather than mixed
- Pure wiring, no logic or state, every destination variable has exactly one writer
- No data transport: AE/AE2 carry only events, so this block has no DataConnections
- `AE_OUT` only reflects what comes back via `AE2_BIDIR` from an attached bidirectional peer — without such a peer, `AE_OUT` stays idle

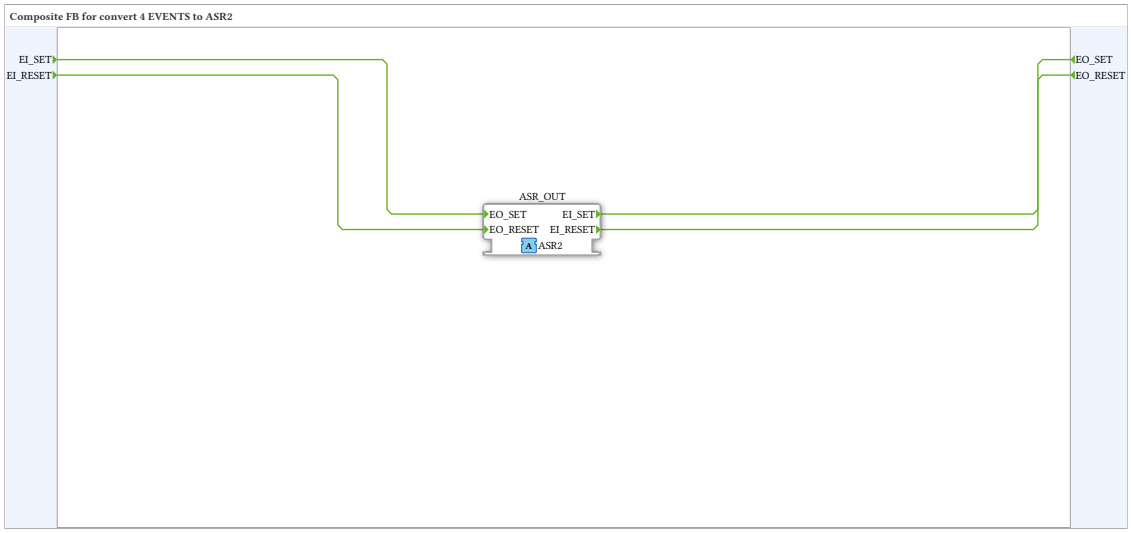
State Overview

The block is stateless:

- AE_IN.E1 → AE2_BIDIR.EO1
- AE2_BIDIR.EI1 → AE_OUT.E1

Application Scenarios

- Retrofitting a bidirectional diagnostic or control point into an existing unidirectional AE event chain without breaking it
- Systems where a bidirectional peer (e.g. an operator panel) needs to both display a unidirectional event and send an event back
- Bridging a unidirectional AE zone and a bidirectional AE2 zone

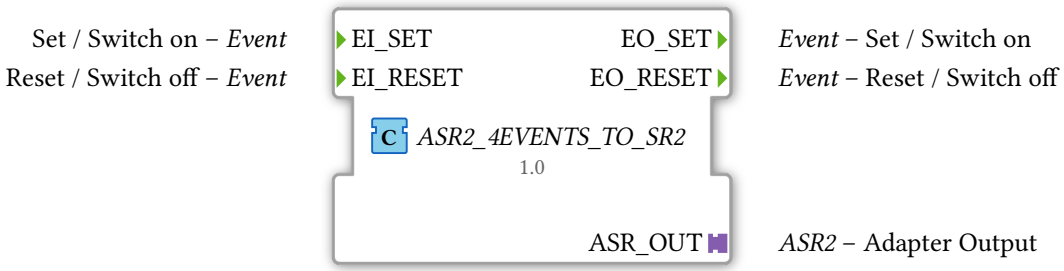


⚖️ Comparison with Similar Blocks

AE2_TO_AE is the mirror image of this block — there, `AE2_BIDIR` sits as a socket on the left side. For a pure, non-tapping 1:1 conversion between a plain EVENT signal and AE2, see AE2_EVENT_TO_E/ AE2_E_TO_EVENT. For two coupled events (SET/RESET), see ASR_TO_ASR2.

Conclusion

AE_TO_AE2 is not a simple converter but a tap point: it makes a unidirectional AE event visible at a bidirectional AE2 point without breaking the original unidirectional event chain, while forwarding the request event received there as a standalone AE event.



ASR2_4EVENTS_TO_SR2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block ASR2_4EVENTS_TO_SR2 is a composite function block used to convert four events into the ASR2 adapter format. It enables bidirectional conversion between individual set/reset events and the standardized ASR2 adapter.

Interface Structure

Event Inputs

- **EI_SET**: Set Event (Power On)
- **EI_RESET**: Reset Event (Power Off)

Event Outputs

- **EO_SET**: Set Event (Power On)
- **EO_RESET**: Reset Event (Power Off)

Adapters

- **ASR_OUT**: ASR2 Adapter Output (bidirectional)

Functionality

This function block acts as a bridge between individual events and the ASR2 adapter. It forwards incoming set and reset events to the ASR2 adapter and simultaneously passes corresponding events from the ASR2 adapter to the outputs. This enables seamless integration of individual events into systems that use the ASR2 adapter format.

Technical Features

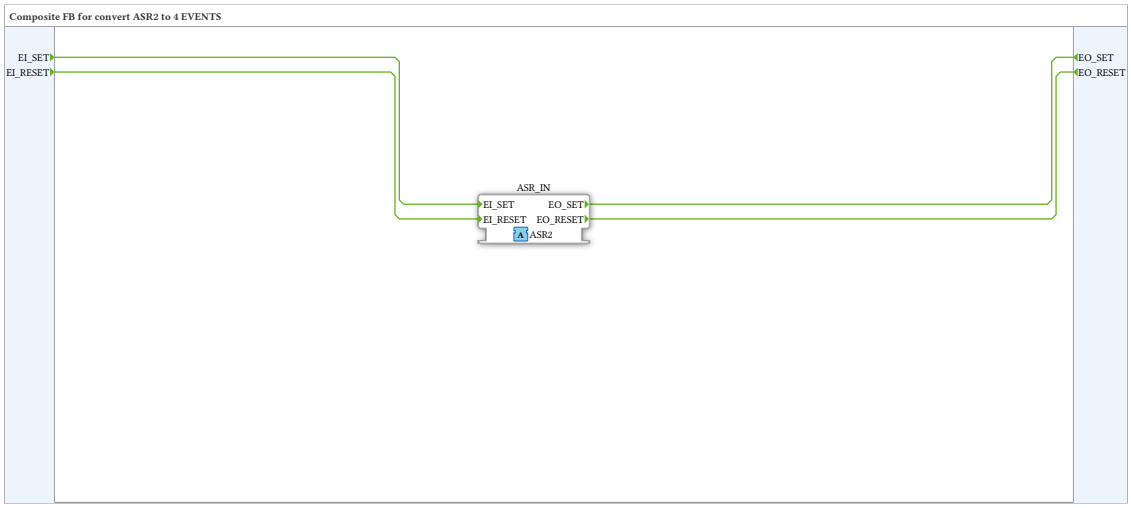
- Bidirectional signal transmission
- Direct event forwarding without data processing
- Compatible with the ASR2 adapter standard
- Composite function block implementation

State Overview

The function block has no internal state, as it functions solely as a pass-through element. All events are forwarded directly and without delay.

Application Scenarios

- Integration of single-event systems into ASR2-based architectures
- Protocol conversion between different control systems
- Adapter solutions for existing automation systems
- Bidirectional communication between different event formats

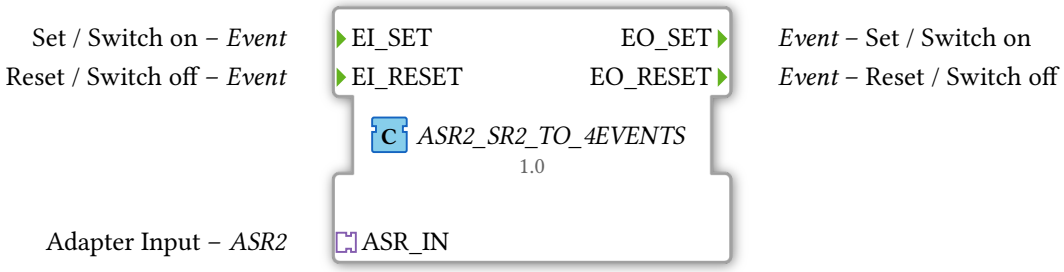


⚖️ Comparison with similar blocks

Compared to simple event blocks, ASR2_4EVENTS_TO_SR2 offers specific adapter functionality for the ASR2 format. While standard blocks typically only offer unidirectional signal processing, this block enables bidirectional communication with ASR2-compatible systems.

Conclusion

The ASR2_4EVENTS_TO_SR2 function block represents an efficient solution for integrating individual events into ASR2-based systems. Its bidirectional functionality and direct event forwarding make it a valuable component for system integration and protocol conversion in automated control systems.



ASR2_SR2_TO_4EVENTS

• – ○ • – ○ • – ○ •

Introduction

The ASR2_SR2_TO_4EVENTS function block is a composite function block that provides the ASR2 adapter signals as four discrete event endpoints. It enables bidirectional conversion between ASR2 adapter interfaces and discrete event inputs and outputs.

Interface Structure

Event Inputs

- **EI_SET**: Set / Turn On
- **EI_RESET**: Reset / Turn Off

Event Outputs

- **EO_SET**: Set / Turn On
- **EO_RESET**: Reset / Turn Off

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

- **ASR_IN**: Adapter input of type `adapter::types::bidirectional::ASR2`

Functionality

This function block acts as a bridge between the ASR2 adapter and discrete events. The event inputs EI_SET and EI_RESET are passed directly to the ASR2 adapter, while the event outputs EO_SET and EO_RESET are fed directly from the ASR2 adapter. This enables bidirectional communication between the two interfaces.

Technical Features

- Implemented as a composite function block
- Uses bidirectional adapter communication
- Contains no internal data processing logic, but primarily serves as a signal relay
- Supports Eclipse 4diac standard compliance

State Overview

This function block has no internal states, as it functions exclusively as a pass-through block for events. All incoming events are immediately forwarded to the corresponding interface.

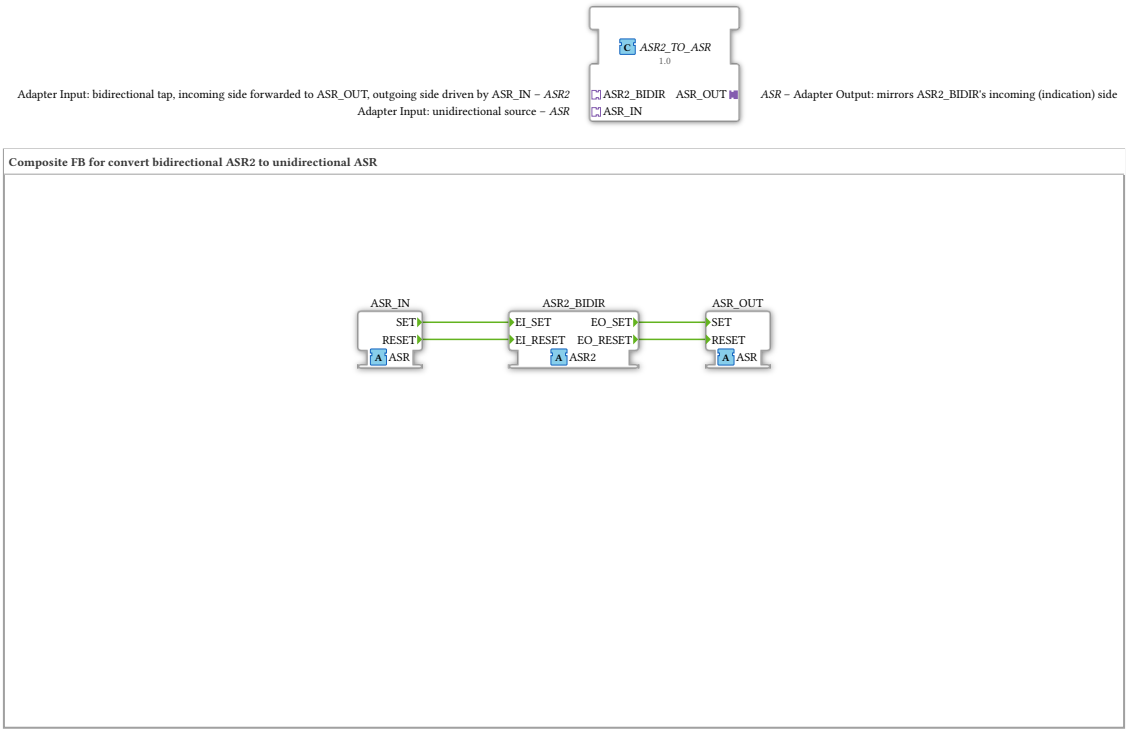
Application Scenarios

- Integration of ASR2-compatible components into 4diac systems
- Conversion between adapter-based and event-based interfaces
- Bidirectional signal transmission in automation systems
- Coupling of different communication protocols

⚖️ Comparison with similar modules

Compared to simple converter blocks, ASR2_SR2_TO_4EVENTS offers the unique feature of bidirectional communication and specific adaptation to ASR2 adapters. Other converter blocks are often unidirectional or support different adapter types.

Conclusion



The ASR2_SR2_TO_4EVENTS function block represents an efficient solution for integrating ASR2 interfaces into 4diac-based control systems. Its simple yet effective pass-through architecture enables seamless communication between different interface types without additional processing latency.

ASR2_TO_ASR

• — ○ • — ○ • — ○ •

Introduction

The ASR2_TO_ASR function block is the mirror image of ASR_TO_ASR2: here the bidirectional ASR2 tap sits as a socket on the left (input) side, complemented by a second unidirectional ASR socket and a unidirectional ASR plug.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no data inputs or outputs at all — ASR and ASR2 carry only the SET/RESET events, never payload data.

Data Outputs

The function block has no data inputs or outputs at all — ASR and ASR2 carry only the SET/RESET events, never payload data.

Adapters

- **ASR2_BIDIR** (Socket): bidirectional tap whose incoming side is forwarded to `ASR_OUT` and whose outgoing side is fed by `ASR_IN`, of type `adapter::types::bidirectional::ASR2`
- **ASR_IN** (Socket): unidirectional SET/RESET source, of type `adapter::types::unidirectional::ASR`
- **ASR_OUT** (Plug): mirrors the incoming (indication) side of `ASR2_BIDIR` as unidirectional SET/RESET events, of type `adapter::types::unidirectional::ASR`

Functionality

The block operates in two directions at once: whatever the socket `ASR2_BIDIR` receives on its indication side (`EO_SET`/`EO_RESET` — i.e. whatever a bidirectional peer attached to ASR2_BIDIR reports) is output unchanged as standalone unidirectional events via the plug `ASR_OUT` (`SET`/`RESET`). Conversely, whatever arrives at the socket `ASR_IN` (`SET`/`RESET`) is published onto the request side of `ASR2_BIDIR` (`EI_SET`/`EI_RESET`) — so ASR2_BIDIR forwards the same events to the attached bidirectional peer. Since ASR/ASR2 are pure event adapters with no payload data, there are no DataConnections at all.

Technical Details

- Three adapters instead of two: the direction received from the tap and the separately injected direction are deliberately kept apart rather than mixed
- Two parallel but independently routed event pairs (SET and RESET), never merged or combined
- Pure wiring, no logic or state, every destination variable has exactly one writer
- No data transport: ASR/ASR2 carry only SET/RESET events, so this block has no DataConnections
- `ASR_OUT` only reflects what is reported via `ASR2_BIDIR` by an attached bidirectional peer — without such a peer, `ASR_OUT` stays idle

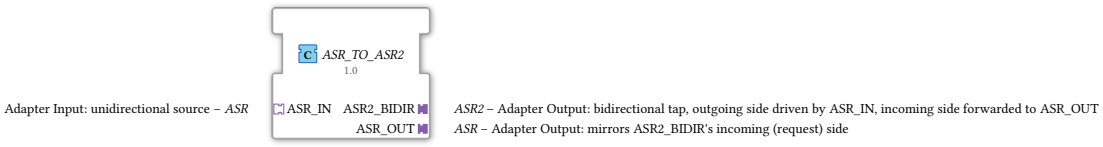
State Overview

The block is stateless:

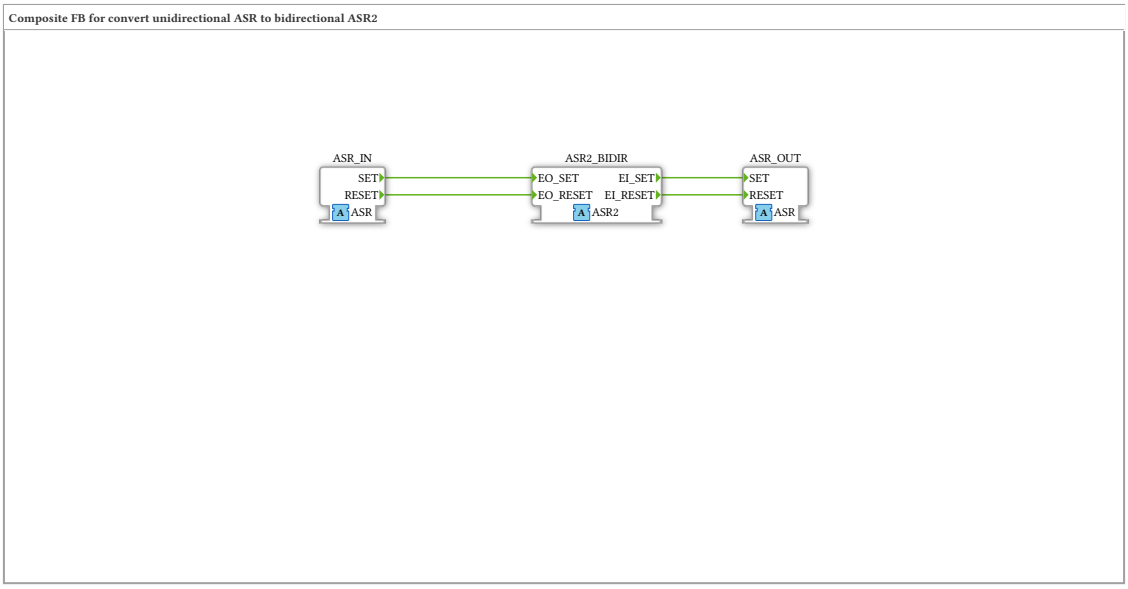
- ASR2_BIDIR.EO_SET ⟶ ASR_OUT.SET, ASR2_BIDIR.EO_RESET ⟶ ASR_OUT.RESET
- ASR_IN.SET ⟶ ASR2_BIDIR.EI_SET, ASR_IN.RESET ⟶ ASR2_BIDIR.EI_RESET

Application Scenarios

- Reading a bidirectional ASR2 peer as a plain unidirectional SET/RESET pair, combined with injecting a separate unidirectional SET/RESET pair
- Systems where a bidirectional peer needs to be monitored without converting the rest of the control logic to ASR2
- Bridging a bidirectional ASR2 zone and a unidirectional ASR zone



⚖️ Comparison with Similar Blocks



ASR_TO_ASR2 is the mirror image of this block — there, `ASR2_BIDIR` sits as a plug on the right side. For a pure, non-tapping 1:1 conversion between ASR2 and two plain EVENT signals, see ASR2_SR2_TO_4EVENTS/ASR2_4EVENTS_TO_SR2. For a single event without SET/RESET coupling, see AE2_TO_AE.

Conclusion

ASR2_TO_ASR is not a simple converter but a tap point: it makes the state of a bidirectional ASR2 peer visible as a standalone unidirectional SET/RESET pair while simultaneously injecting a separate unidirectional SET/RESET pair into the bidirectional side.

ASR_TO_ASR2

• – ○ • – ○ • – ○ •

Introduction

The ASR_TO_ASR2 function block inserts a bidirectional ASR2 tap into a unidirectional ASR chain. ASR/ASR2 carry two coupled events, SET and RESET, rather than a single E1. Like the other bridge blocks, ASR_TO_ASR2 uses **three** adapters: incoming unidirectional SET/RESET events are both published onto the bidirectional ASR2 interface and — whatever ASR2 returns on its request side — output again as standalone unidirectional SET/RESET events.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no data inputs or outputs at all — ASR and ASR2 carry only the SET/RESET events, never payload data.

Data Outputs

The function block has no data inputs or outputs at all — ASR and ASR2 carry only the SET/RESET events, never payload data.

Adapters

- **ASR_IN** (Socket): unidirectional SET/RESET source, of type `adapter::types::unidirectional::ASR`
- **ASR2_BIDIR** (Plug): bidirectional tap whose outgoing side is fed by `ASR_IN` and whose incoming side is forwarded to `ASR_OUT`, of type `adapter::types::bidirectional::ASR2`
- **ASR_OUT** (Plug): mirrors the incoming (request) side of `ASR2_BIDIR` as unidirectional SET/RESET events, of type `adapter::types::unidirectional::ASR`

Functionality

The block operates in two directions at once: whatever arrives at the socket `ASR_IN` (`SET`/`RESET`) is published directly onto the outgoing side of `ASR2_BIDIR` (`EO_SET`/`EO_RESET`) — so ASR2_BIDIR reports outward the same events coming in via ASR_IN. Conversely, whatever `ASR2_BIDIR` receives on its request side (`EI_SET`/`EI_RESET` — i.e. whatever a bidirectional peer attached to ASR2_BIDIR "sends back") is output unchanged as standalone unidirectional events via the plug `ASR_OUT` (`SET`/`RESET`). Since ASR/ASR2 are pure event adapters with no payload data, there are no DataConnections at all.

Technical Details

- Three adapters instead of two: the incoming event direction and the direction coming back from the tap are deliberately kept separate rather than mixed
- Two parallel but independently routed event pairs (SET and RESET), never merged or combined
- Pure wiring, no logic or state, every destination variable has exactly one writer
- No data transport: ASR/ASR2 carry only SET/RESET events, so this block has no DataConnections
- `ASR_OUT` only reflects what comes back via `ASR2_BIDIR` from an attached bidirectional peer — without such a peer, `ASR_OUT` stays idle

State Overview

The block is stateless:

- ASR_IN.SET ⟶ ASR2_BIDIR.EO_SET, ASR_IN.RESET ⟶ ASR2_BIDIR.EO_RESET
- ASR2_BIDIR.EI_SET ⟶ ASR_OUT.SET, ASR2_BIDIR.EI_RESET ⟶ ASR_OUT.RESET

Application Scenarios

- Retrofitting a bidirectional diagnostic or control point into an existing unidirectional ASR SET/RESET chain without breaking it
- Systems where a bidirectional peer (e.g. an operator panel) needs to both display SET/RESET state and send SET/RESET events back
- Bridging a unidirectional ASR zone and a bidirectional ASR2 zone

⚖️ Comparison with Similar Blocks

ASR2_TO_ASR is the mirror image of this block — there, `ASR2_BIDIR` sits as a socket on the left side. For a pure, non-tapping 1:1 conversion between two plain EVENT signals and ASR2, see ASR2_4EVENTS_TO_SR2/ASR2_SR2_TO_4EVENTS. For a single event without SET/RESET coupling, see AE_TO_AE2.

Conclusion

ASR_TO_ASR2 is not a simple converter but a tap point: it makes a unidirectional ASR SET/RESET pair visible at a bidirectional ASR2 point without breaking the original unidirectional chain, while forwarding the request SET/RESET pair received there as a standalone ASR signal.

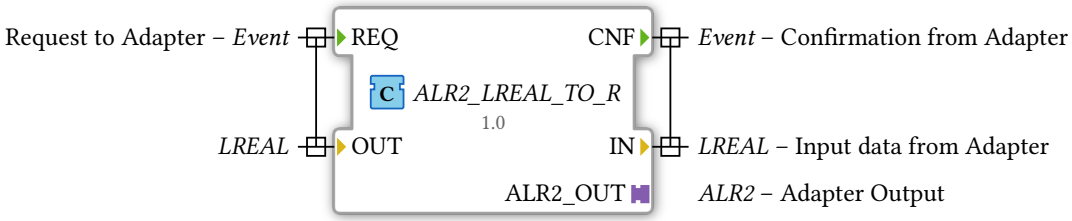
LREAL



ALR2_LREAL_TO_R

• – ◦ • – ◦ • – ◦ •

Introduction

`ALR2_LREAL_TO_R` is a composite FB that mediates between an `LREAL` data pair (`OUT`/`IN`) and the bidirectional adapter `ALR2`. It completes the conversion family analogously to `AR2`/`AB2`/`AE2`.

Interface Structure

Event Inputs

- `REQ`: Request to the adapter. Associated data: `OUT`.

Event Outputs

- `CNF`: Confirmation from the adapter. Associated data: `IN`.

Data Inputs

- `OUT` (`LREAL`): Value sent to the adapter.

Data Outputs

- `IN` (`LREAL`): Value received from the adapter.

Adapters

Direction	Name	Adapter type	Comment
Plug (output)	`ALR2_OUT`	`adapter::types::bidirectional::ALR2`	Adapter output.

Functionality

The block contains no internal FBs, only connections:

- `REQ` ⟶ `ALR2_OUT.EO1` and `OUT` ⟶ `ALR2_OUT.DO1`: a `REQ` event sends the value `OUT` through the adapter.

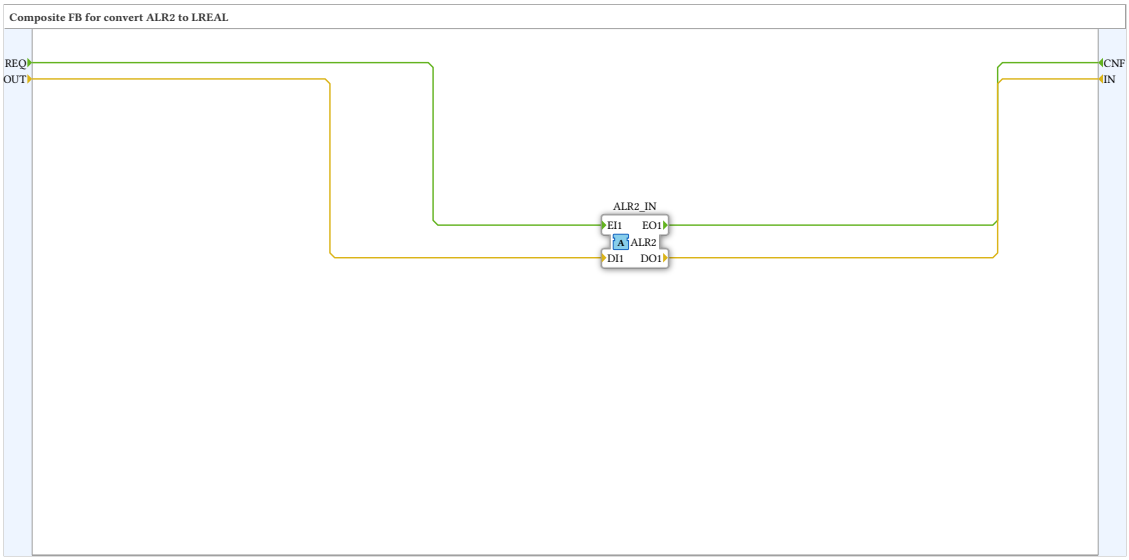
- `ALR2_OUT.EI1` ⟶ `CNF` and `ALR2_OUT.DI1` ⟶ `IN`: an event received through the adapter is output as `CNF`, and the received value appears at `IN`.

Technical Details

- Pure pass-through without logic.
- The data type is `LREAL` (64-bit floating point).
- The naming `OUT`/`IN` is chosen from the adapter's point of view: `OUT` goes out to the adapter, `IN` comes in from the adapter.

Application Scenarios

- Output an `LREAL` value to a bidirectional `ALR2` adapter and at the same time read its backward channel as a data output.



Summary

`ALR2_LREAL_TO_R` connects events and `LREAL` data 1:1 with the bidirectional adapter `ALR2`.

ALR2_R_TO_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

`ALR2_R_TO_LREAL` is a composite FB that mediates between a `LREAL` data pair (`OUT`/`IN`) and the bidirectional adapter `ALR2`. In contrast to the plug variant `ALR2_LREAL_TO_R` it has an adapter **socket** (input). It completes the conversion family analogously to `AR2`/`AB2`/`AE2`.

Interface Structure

Event Inputs

- `REQ`: Request to the adapter. Associated data: `OUT`.

Event Outputs

- `CNF`: Confirmation from the adapter. Associated data: `IN`.

Data Inputs

- `OUT` (`LREAL`): Value sent to the adapter.

Data Outputs

- `IN` (`LREAL`): Value received from the adapter.

Adapters

Direction	Name	Adapter type	Comment
Socket (input)	`ALR2_IN`	`adapter::types::bidirectional::ALR2`	Adapter input.

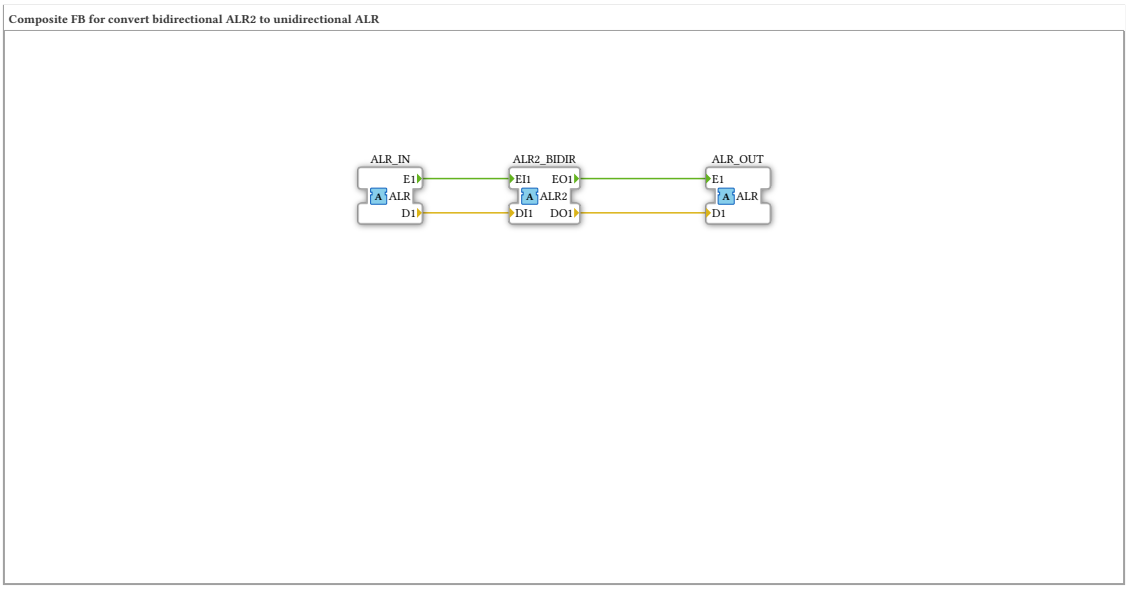
Functionality

The block contains no internal FBs, only connections:

- `REQ` ⟶ `ALR2_IN.EI1` and `OUT` ⟶ `ALR2_IN.DI1`: a `REQ` event sends the value `OUT` through the adapter.
- `ALR2_IN.EO1` ⟶ `CNF` and `ALR2_IN.DO1` ⟶ `IN`: an event coming from the adapter is output as `CNF`, and the received value appears at `IN`.

Technical Details

- Pure pass-through without logic and without internal state.
- The data type is `LREAL` (64-bit floating point).
- The naming `OUT`/`IN` is chosen from the adapter's point of view: `OUT` goes out to the adapter, `IN` comes in from the adapter.

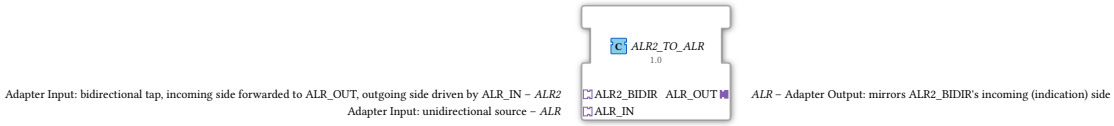


Application Scenarios

- Output a `LREAL` value to a bidirectional `ALR2` adapter and at the same time read its backward channel as a data output, when the adapter is present as a socket.

Summary

`ALR2_R_TO_LREAL` connects events and `LREAL` data 1:1 with the bidirectional adapter `ALR2` (socket variant).



ALR2_TO_ALR

• – ○ • – ○ • – ○ •

Introduction

ALR2_TO_ALR is a composite function block that connects a bidirectional ALR2 tap with unidirectional ALR adapters (LREAL): the incoming side of ALR2_BIDIR is output as a plain unidirectional signal via ALR_OUT, and ALR_IN is published onto the outgoing side of ALR2_BIDIR.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **ALR2_BIDIR** (Socket): bidirectional tap whose incoming side is forwarded to ALR_OUT and whose outgoing side is fed by ALR_IN, of type adapter::types::bidirectional::ALR2
- **ALR_IN** (Socket): unidirectional source, of type adapter::types::unidirectional::ALR
- **ALR_OUT** (Plug): mirrors the incoming (indication) side of ALR2_BIDIR, of type adapter::types::unidirectional::ALR

Functionality

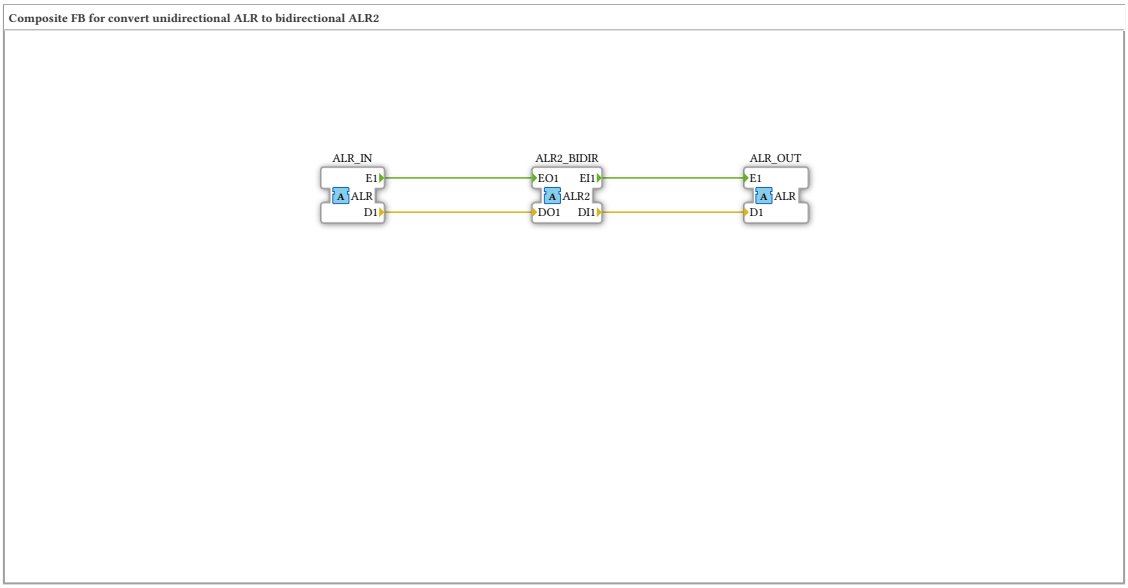
The block consists of just four connections:

- Event: ALR2_BIDIR.EO1 ⟶ ALR_OUT.E1; data: ALR2_BIDIR.DO1 ⟶ ALR_OUT.D1
- Event: ALR_IN.E1 ⟶ ALR2_BIDIR.EI1; data: ALR_IN.D1 ⟶ ALR2_BIDIR.DI1

Whatever a bidirectional peer attached to ALR2_BIDIR reports therefore appears unchanged at ALR_OUT; whatever arrives at ALR_IN is passed on to the bidirectional peer.

Technical Details

- Pure wiring, no logic or state
- Every destination variable has exactly one writer
- Without an attached bidirectional peer, ALR_OUT stays idle

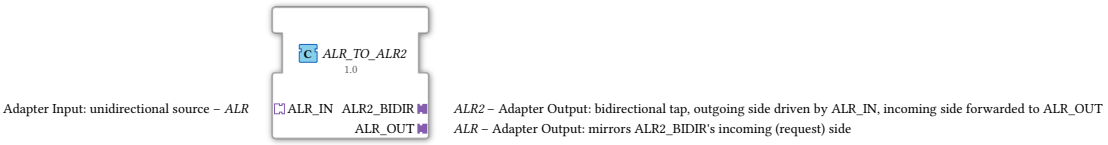


Application Scenarios

- Reading a bidirectional ALR2 peer as a plain unidirectional ALR signal while injecting a separate unidirectional signal
- Bridging a bidirectional ALR2 zone and a unidirectional ALR zone

Conclusion

ALR2_TO_ALR is a tap point without logic: it makes the incoming side of a bidirectional ALR2 peer visible as a unidirectional ALR signal and simultaneously feeds a unidirectional signal into the outgoing side.



ALR_TO_ALR2

• – ○ • – ○ • – ○ •

Introduction

`ALR_TO_ALR2` is a composite function block that converts a **unidirectional** `ALR` adapter into a **bidirectional** `ALR2` adapter. `ALR_IN` is written onto the outgoing side (`EO1`/`DO1`) of `ALR2_BIDIR`; whatever `ALR2_BIDIR` receives on its incoming side (`EI1`/`DI1`) is output again as a plain unidirectional signal via `ALR_OUT`.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

- **ALR_IN** (socket): Unidirectional adapter of type `adapter::types::unidirectional::ALR` - unidirectional source
- **ALR2_BIDIR** (plug): Bidirectional adapter of type `adapter::types::bidirectional::ALR2` - outgoing side driven by `ALR_IN`, incoming side forwarded to `ALR_OUT`
- **ALR_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::ALR` - mirrors the incoming (request) side of `ALR2_BIDIR`

How it works

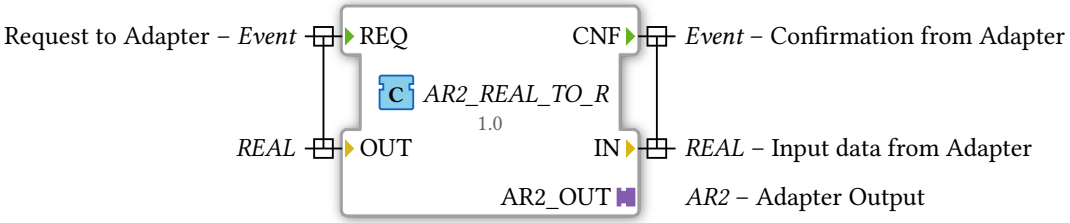
1. `ALR_IN.E1` is forwarded to `ALR2_BIDIR.EO1` and `ALR_IN.D1` to `ALR2_BIDIR.DO1`.
2. `ALR2_BIDIR.EI1` is forwarded to `ALR_OUT.E1` and `ALR2_BIDIR.DI1` to `ALR_OUT.D1`.

Technical Details

- Pure event/data connections (`FBNetwork`), no logic of its own and no internal state
- Part of the conversion family (analogous to `AR2`/`AB2`/`AE2`); the data type is `LREAL`

Application Scenarios

- Connecting unidirectional `ALR` sources and sinks to a bidirectional `ALR2` adapter



Summary

`ALR_TO_ALR2` combines a unidirectional `ALR` input and output into a bidirectional `ALR2` adapter.

Here you will find all exercises from the `bidirectional` workspace, listed in ascending order. …

AR2_REAL_TO_R

• – ○ • – ○ • – ○ •

Introduction

The function block `AR2_REAL_TO_R` is a composite function block (FB) for converting a REAL value into an AR2 format. It encapsulates a bidirectional adapter of type `adapter::types::bidirectional::AR2` and acts as a transparent interface between a simple REAL variable and the more complex AR2 data type. The conversion logic resides entirely within the adapter, while the FB only handles signal and data transmission.

Interface Structure

Event Inputs

Event	Comment
`REQ`	Request for processing via the adapter (triggers adapter output)

Event Outputs

Event	Comment
CNF	Confirmation after adapter processing is complete

Data Inputs

Variable	Type	Comment
OUT	REAL	Output data sent to the adapter (actually: input value for conversion)

Data Outputs

Variable	Type	Comment
IN	REAL	Input data returned by the adapter (actually: converted value)

Adapter

Adapter	Type	Comment
AR2_OUT	adapter::types::bidirectional::AR2	Bidirectional interface adapter for AR2 conversion

Functionality

The function block operates as a simple forwarding block:

1. An incoming event at the **event input REQ** is forwarded directly to the event output EO1 of the adapter AR2_OUT.
2. The current value of the **data input OUT** is simultaneously sent to the data output DO1 of the adapter.
3. The adapter internally performs the conversion from REAL to AR2 format (and back if necessary) and sends an acknowledgment event back via its event input EI1.
4. This event is passed on to the **event output CNF** of the function block.
5. The value provided by the adapter at its data input DI1 is transferred to the **data output IN** of the function block.

The actual conversion (REAL ↔ AR2) takes place exclusively within the adapter – the function block itself does not perform any arithmetic operations.

Technical Features

- **Composite Block**: The functionality is implemented through the internal wiring of an external adapter type. The function block is therefore dependent on the implementation of the adapter adapter::types::bidirectional::AR2.
- **Bidirectional Data Flow**: The variable names (OUT as input, IN as output) can be confusing. In reality, the data flows as follows:
- REAL value ⟶ Adapter ⟶ AR2 object (forward)
- AR2 object ⟶ Adapter ⟶ REAL value (reverse)

The function block provides both directions via the event handlers REQ / CNF.

- **No State Logic**: The function block (FB) does not have its own state machine – all processes are event-driven and direct.

State Overview

Since the FB does not have an internal state machine, there is no classic state overview. The process is purely sequential per event:

1. Wait for REQ
2. Send to adapter
3. Wait for adapter response
4. Output of CNF and updated IN

Application Scenarios

- **Interface to External Systems**: When an external device or another function block expects data in AR2 format, but the user code works with REAL values.
- **Data Preprocessing**: Integration into a chain of conversion blocks to convert REAL data into a specific binary or structured format (AR2).
- **Testing and Simulation**: Used in test environments to verify adapter functionality without requiring in-depth knowledge of the adapter itself.

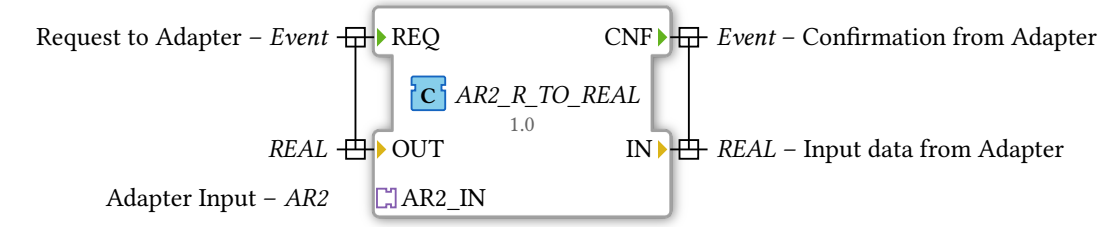
Comparison with Similar Function Blocks

- **AR2_REAL_TO_R vs. Simple Type Conversion (REAL_TO_INT etc.)**:

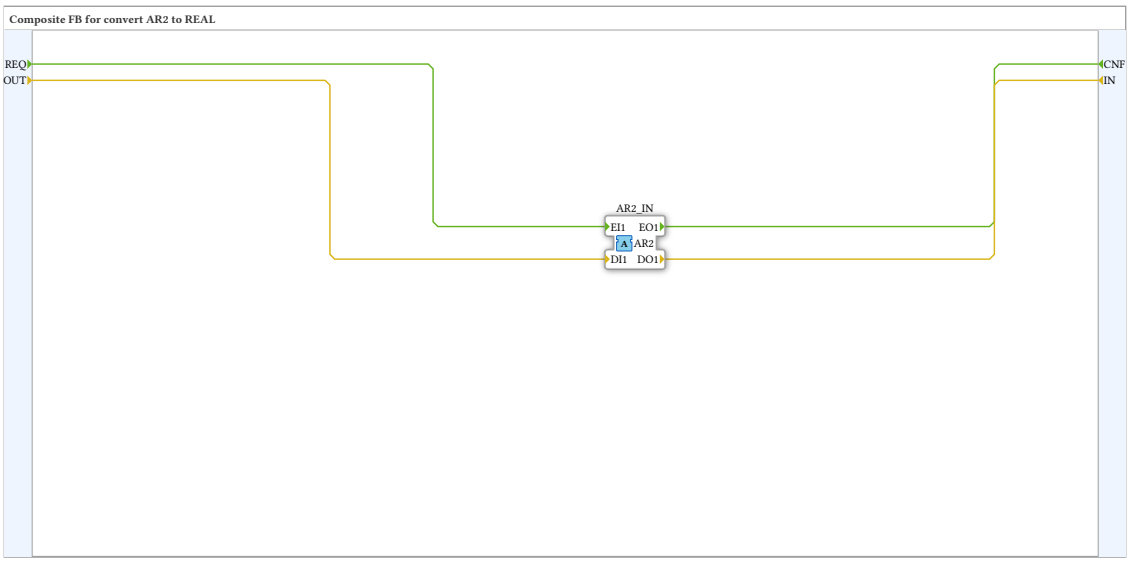
Simple converters work directly with elementary data types. `AR2_REAL_TO_R`, on the other hand, uses an adapter that encapsulates a complex conversion (e.g., to an array or structure).

- **AR2_REAL_TO_R vs. Direct Adapter Use**:

The function block simplifies handling by performing the signal wiring (event and data connections). The user only needs to instantiate the function block and connect it to their code.



- **AR2_REAL_TO_R vs. CONVERT Adapter Blocks**:



Similar blocks (e.g., from the IEC 61499 library) usually offer generic conversion. This function block is specifically for coupling REAL and AR2.

Conclusion

The function block `AR2_REAL_TO_R` provides a simple, event-driven interface for using a bidirectional AR2 adapter. It is ideal for all applications that require conversion between the standard REAL data type and a project-specific AR2 format. Its design keeps the complexity hidden within the adapter, and the block can be integrated into applications like a normal function block.

AR2_R_TO_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The **AR2_R_TO_REAL** function block is a composite module that acts as a bridge between an AR2 adapter interface and REAL values. It enables bidirectional data transfer and conversion, with the actual conversion being performed by an external adapter of type `adapter::types::bidirectional::AR2`.

Interface Structure

Event Inputs

Event	Description
`REQ`	Starts data transfer to the adapter. The data value `OUT` is sent.

Event Outputs

Event	Description
`CNF`	Acknowledges the adapter's response. The converted value is stored as `IN`.

Data Inputs

Variable	Type	Description
`OUT`	REAL	Data value passed to the adapter.

Data Outputs

Variable	Type	Description
`IN`	REAL	Converted value returned by the adapter.

Adapter

Name	Type	Direction	Description
`AR2_IN`	`adapter::types::bidirectional::AR2`	Socket	Bidirectional adapter for AR2 communication and conversion.

Functionality

The module functions purely as a mediation layer:

1. An incoming event `REQ` triggers the transfer of the value `OUT` (REAL) to the connected adapter (via `AR2_IN.DI1`).
2. The adapter performs the necessary conversion (e.g., AR2 ↔ REAL) and sends an acknowledgment event to its output `EO1`.
3. This event is forwarded externally as `CNF`, and the converted value is made available via `AR2_IN.DO1` as `IN` (REAL).

The actual conversion direction is determined by the implementation of the connected adapter. The name of the function block suggests a primary conversion from AR2 to REAL, but the bidirectional adapter interface also allows for the reverse direction.

Technical Features

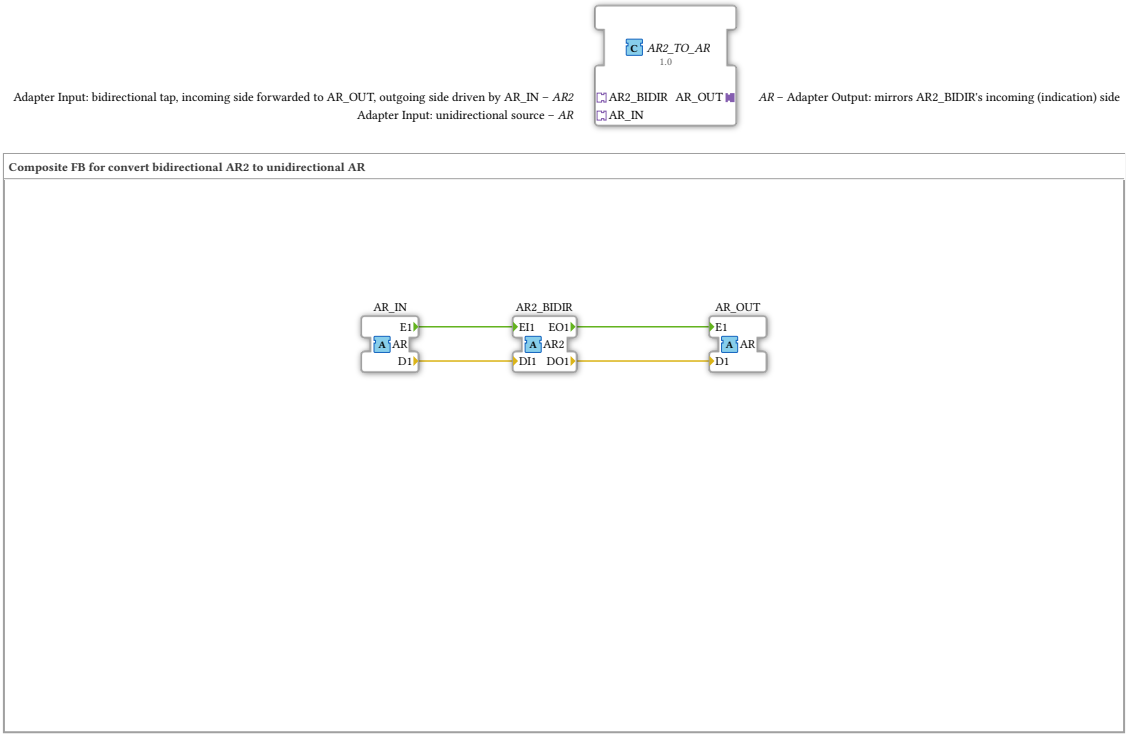
- **Composite Function Block**: Contains no internal logic; it simply combines an adapter socket with event and data connections.
- **Bidirectional Adapter**: The interface `AR2_IN` must provide an adapter of type `adapter::types::bidirectional::AR2`, which implements the actual conversion.
- **Simple Coupling**: The function block separates the REAL world from the AR2 world, thus enabling modular integration.

State Overview

The function block has no internal states of its own. Its behavior is entirely controlled by the external events `REQ` and the adapter's feedback.

Application Scenarios

- **Connecting AR2-based sensors/actuators** to a control system that uses REAL values.
- **Bidirectional data bridge** in mixed automation environments where AR2 and REAL protocols interact.
- **Test and simulation setups** where AR2 data needs to be replaced with easily manageable REAL values.



Comparison with Similar Components

While direct conversion components (e.g., AR2_TO_REAL) hardwire the conversion, this composite component allows for the flexible connection of an external adapter. This decouples the conversion logic, allowing it to be replaced depending on the application without changing the rest of the configuration.

Conclusion

The **AR2_R_TO_REAL** is a useful bridging component for systems that need to process both AR2 and REAL data. By using a bidirectional adapter, a clear separation between the interface and the conversion logic is achieved, which improves reusability and maintainability.

AR2_TO_AR

• — ○ • — ○ • — ○ •

Introduction

The AR2_TO_AR function block is the mirror image of AR_TO_AR2: here the bidirectional AR2 tap sits as a socket on the left (input) side, complemented by a second unidirectional AR socket and a unidirectional AR plug.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AR2_BIDIR** (Socket): bidirectional tap whose incoming side is forwarded to `AR_OUT` and whose outgoing side is fed by `AR_IN`, of type `adapter::types::bidirectional::AR2`
- **AR_IN** (Socket): unidirectional REAL source, of type `adapter::types::unidirectional::AR`
- **AR_OUT** (Plug): mirrors the incoming (indication) side of `AR2_BIDIR` as a unidirectional signal, of type `adapter::types::unidirectional::AR`

Functionality

The block operates in two directions at once: whatever the socket `AR2_BIDIR` receives on its indication side (`EO1`/`DO1` — i.e. whatever a bidirectional peer attached to AR2_BIDIR reports) is output unchanged as a standalone unidirectional signal via the plug `AR_OUT`. Conversely, whatever arrives at the socket `AR_IN` (`E1`/`D1`) is published onto the request side of `AR2_BIDIR` (`EI1`/`DI1`) — so AR2_BIDIR forwards the same signal to the attached bidirectional peer.

Technical Details

- Three adapters instead of two: the direction received from the tap and the separately injected direction are deliberately kept apart rather than mixed
- Pure wiring, no logic or state, every destination variable has exactly one writer
- `AR_OUT` only reflects what is reported via `AR2_BIDIR` by an attached bidirectional peer — without such a peer, `AR_OUT` stays idle

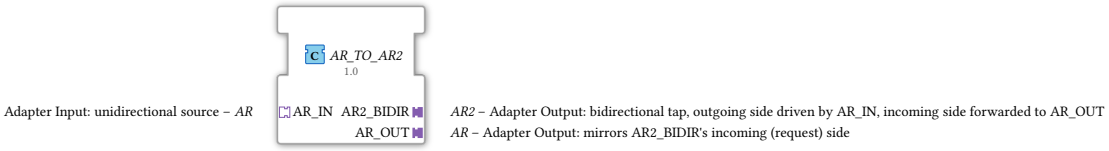
State Overview

The block is stateless:

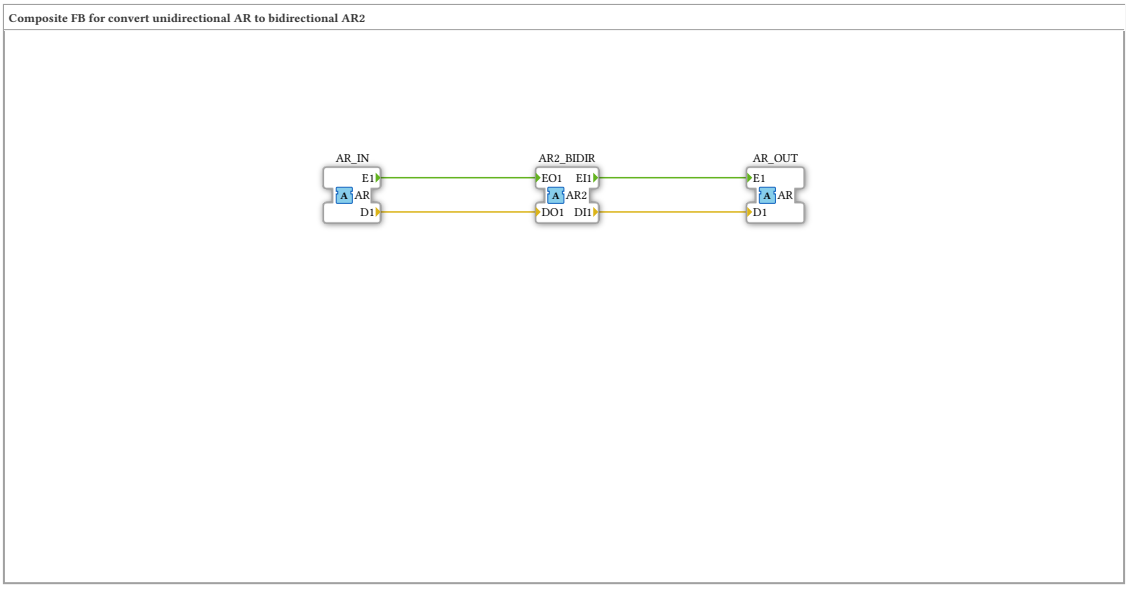
- AR2_BIDIR.EO1 ⟶ AR_OUT.E1, AR2_BIDIR.DO1 ⟶ AR_OUT.D1
- AR_IN.E1 ⟶ AR2_BIDIR.EI1, AR_IN.D1 ⟶ AR2_BIDIR.DI1

Application Scenarios

- Reading the status of a bidirectional AR2 peer as a plain unidirectional AR signal, combined with injecting a separate unidirectional setpoint signal
- Systems where a bidirectional peer needs to be monitored without converting the rest of the control logic to AR2
- Bridging a bidirectional AR2 zone and a unidirectional AR zone



⚖️ Comparison with Similar Blocks



AR_TO_AR2 is the mirror image of this block — there, `AR2_BIDIR` sits as a plug on the right side. For a pure, non-tapping 1:1 conversion between AR2 and a plain REAL signal, see AR2_REAL_TO_R/ AR2_R_TO_REAL.

Conclusion

AR2_TO_AR is not a simple converter but a tap point: it makes the state of a bidirectional AR2 peer visible as a standalone unidirectional AR signal while simultaneously injecting a separate unidirectional signal into the bidirectional side.

AR_TO_AR2

• – ○ • – ○ • – ○ •

Introduction

The AR_TO_AR2 function block inserts a bidirectional AR2 tap into a unidirectional AR chain. Rather than a simple 1:1 conversion, it uses **three** adapters: an incoming unidirectional AR signal is both published onto the bidirectional AR2 interface and — whatever AR2 returns on its request side — output again as a standalone unidirectional AR signal.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AR_IN** (Socket): unidirectional REAL source, of type `adapter::types::unidirectional::AR`
- **AR2_BIDIR** (Plug): bidirectional tap whose outgoing side is fed by `AR_IN` and whose incoming side is forwarded to `AR_OUT`, of type `adapter::types::bidirectional::AR2`
- **AR_OUT** (Plug): mirrors the incoming (request) side of `AR2_BIDIR` as a unidirectional signal, of type `adapter::types::unidirectional::AR`

Functionality

The block operates in two directions at once: whatever arrives at the socket `AR_IN` (`E1`/`D1`) is published directly onto the outgoing side of `AR2_BIDIR` (`EO1`/`DO1`) — so AR2_BIDIR reports outward the same signal coming in via AR_IN. Conversely, whatever `AR2_BIDIR` receives on its request side (`EI1`/`DI1` — i.e. whatever a bidirectional peer attached to AR2_BIDIR "sends back") is output unchanged as a standalone unidirectional signal via the plug `AR_OUT`. AR2_BIDIR thus acts as a tap point that doesn't break the unidirectional chain but extends it with a bidirectional observation/injection point.

Technical Details

- Three adapters instead of two: the incoming signal direction and the direction coming back from the tap are deliberately kept separate rather than mixed
- Pure wiring, no logic or state, every destination variable has exactly one writer
- `AR_OUT` only reflects what comes back via `AR2_BIDIR` from an attached bidirectional peer — without such a peer, `AR_OUT` stays idle

State Overview

The block is stateless:

- AR_IN.E1 ⟶ AR2_BIDIR.EO1, AR_IN.D1 ⟶ AR2_BIDIR.DO1
- AR2_BIDIR.EI1 ⟶ AR_OUT.E1, AR2_BIDIR.DI1 ⟶ AR_OUT.D1

Application Scenarios

- Retrofitting a bidirectional diagnostic or control point into an existing unidirectional AR signal chain without breaking it
- Systems where a bidirectional peer (e.g. an operator panel) needs to both display the status of a unidirectional measurement source and send setpoints back
- Bridging a unidirectional AR zone and a bidirectional AR2 zone

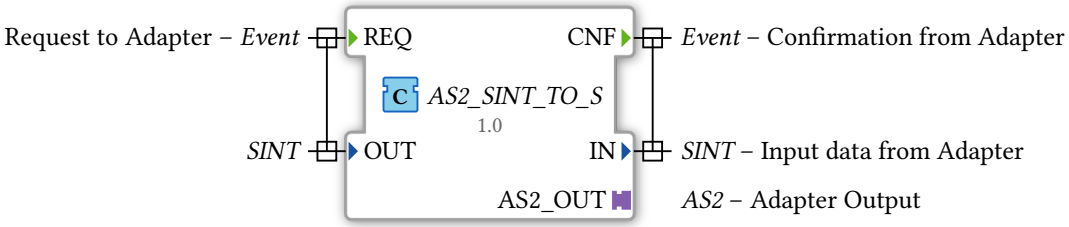
⚖️ Comparison with Similar Blocks

AR2_TO_AR is the mirror image of this block — there, `AR2_BIDIR` sits as a socket on the left side. For a pure, non-tapping 1:1 conversion between a plain REAL signal and AR2, see AR2_R_TO_REAL/ AR2_REAL_TO_R.

Conclusion

AR_TO_AR2 is not a simple converter but a tap point: it makes a unidirectional AR signal visible at a bidirectional AR2 point without breaking the original unidirectional signal chain, while forwarding the request signal received there as a standalone AR signal.

SINT



AS2_SINT_TO_S

• – ○ • – ○ • – ○ •

Introduction

`AS2_SINT_TO_S` is a composite function block that mediates between classic event/data connections of type `SINT` and a **bidirectional** `AS2` adapter. On `REQ`, the input `OUT` is written onto the outgoing side of the adapter plug `AS2_OUT`; the value reported via the adapter's backward direction appears at output `IN` and is acknowledged with `CNF`.

Interface Structure

Event Inputs

- **REQ**: Request to the adapter. Associated data: `OUT`

Event Outputs

- **CNF**: Confirmation from the adapter. Associated data: `IN`

Data Inputs

- **OUT** (`SINT`): Data sent to the adapter

Data Outputs

- **IN** (`SINT`): Data received from the adapter

Adapters

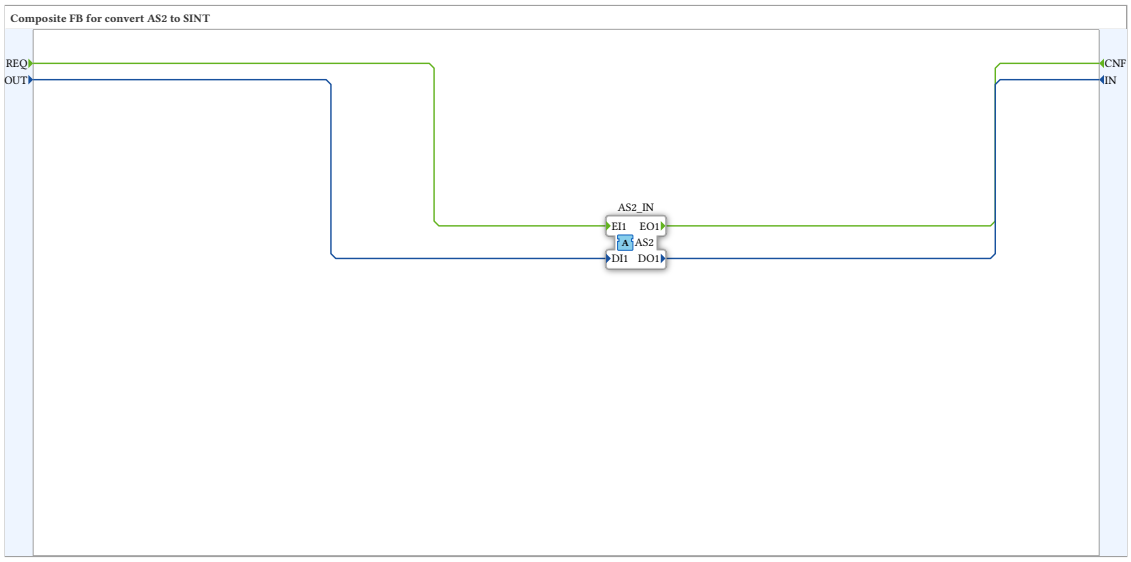
- **AS2_OUT** (plug): Bidirectional adapter of type `adapter::types::bidirectional::AS2` (adapter output)

How it works

1. `REQ` is forwarded to `AS2_OUT.EO1`, `OUT` to `AS2_OUT.DO1`.
2. `AS2_OUT.EI1` is forwarded to `CNF`, `AS2_OUT.DI1` to `IN`.

Technical Details

- Pure event/data connections (`FBNetwork`), no logic of its own and no internal state
- Part of the conversion family (analogous to `AR2`/`AB2`/`AE2`)

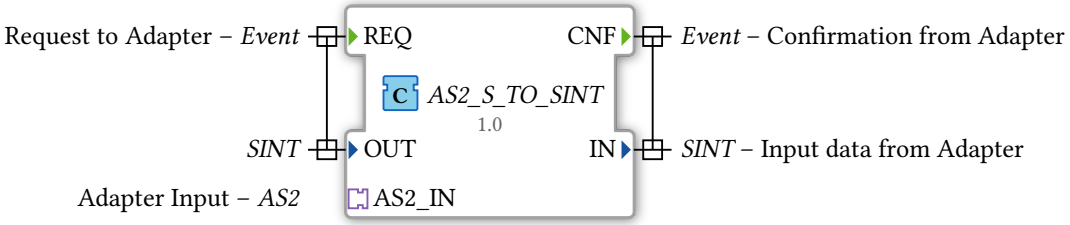


Application Scenarios

- Connecting `SINT` values from classic function block networks to a bidirectional `AS2` adapter

Summary

`AS2_SINT_TO_S` maps `SINT` event/data connections 1:1 onto the two directions of an `AS2` adapter.



AS2_S_TO_SINT

• – ○ • – ○ • – ○ •

Introduction

`AS2_S_TO_SINT` is a composite FB that mediates between a `SINT` data pair (`OUT`/`IN`) and the bidirectional adapter `AS2`. In contrast to the plug variant `AS2_SINT_TO_R` it has an adapter **socket** (input). It completes the conversion family analogously to `AR2`/`AB2`/`AE2`.

Interface Structure

Event Inputs

- `REQ`: Request to the adapter. Associated data: `OUT`.

Event Outputs

- `CNF`: Confirmation from the adapter. Associated data: `IN`.

Data Inputs

- `OUT` (`SINT`): Value sent to the adapter.

Data Outputs

- `IN` (`SINT`): Value received from the adapter.

Adapters

Direction	Name	Adapter type	Comment
Socket (input)	`AS2_IN`	`adapter::types::bidirectional::AS2`	Adapter input.

Functionality

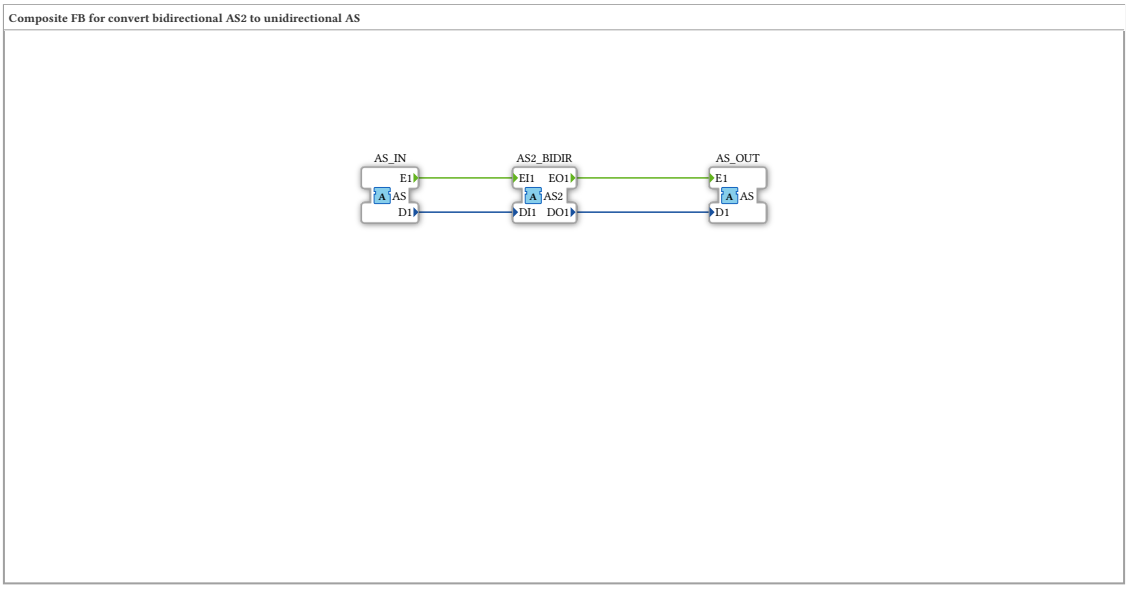
The block contains no internal FBs, only connections:

- `REQ` ⟶ `AS2_IN.EI1` and `OUT` ⟶ `AS2_IN.DI1`: a `REQ` event sends the value `OUT` through the adapter.

- `AS2_IN.EO1` ⟶ `CNF` and `AS2_IN.DO1` ⟶ `IN`: an event coming from the adapter is output as `CNF`, and the received value appears at `IN`.

Technical Details

- Pure pass-through without logic and without internal state.
- The data type is `SINT` (signed 8-bit integer).
- The naming `OUT`/`IN` is chosen from the adapter's point of view: `OUT` goes out to the adapter, `IN` comes in from the adapter.



Application Scenarios

- Output a `SINT` value to a bidirectional `AS2` adapter and at the same time read its backward channel as a data output, when the adapter is present as a socket.

Summary

`AS2_S_TO_SINT` connects events and `SINT` data 1:1 with the bidirectional adapter `AS2` (socket variant).

AS2_TO_AS

• – ○ • – ○ • – ○ •

Introduction

The AS2_TO_AS function block is the mirror image of AS_TO_AS2: here the bidirectional AS2 tap sits as a socket on the left (input) side, complemented by a second unidirectional AS socket and a unidirectional AS plug.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AS2_BIDIR** (Socket): bidirectional tap whose incoming side is forwarded to `AS_OUT` and whose outgoing side is fed by `AS_IN`, of type `adapter::types::bidirectional::AS2`
- **AS_IN** (Socket): unidirectional SINT source, of type `adapter::types::unidirectional::AS`
- **AS_OUT** (Plug): mirrors the incoming (indication) side of `AS2_BIDIR` as a unidirectional signal, of type `adapter::types::unidirectional::AS`

Functionality

The block operates in two directions at once: whatever the socket `AS2_BIDIR` receives on its indication side (`EO1`/`DO1` — i.e. whatever a bidirectional peer attached to AS2_BIDIR reports) is output unchanged as a standalone unidirectional signal via the plug `AS_OUT`. Conversely, whatever arrives at the socket `AS_IN` (`E1`/`D1`) is published onto the request side of `AS2_BIDIR` (`EI1`/`DI1`) — so AS2_BIDIR forwards the same signal to the attached bidirectional peer.

Technical Details

- Three adapters instead of two: the direction received from the tap and the separately injected direction are deliberately kept apart rather than mixed
- Pure wiring, no logic or state, every destination variable has exactly one writer
- `AS_OUT` only reflects what is reported via `AS2_BIDIR` by an attached bidirectional peer — without such a peer, `AS_OUT` stays idle

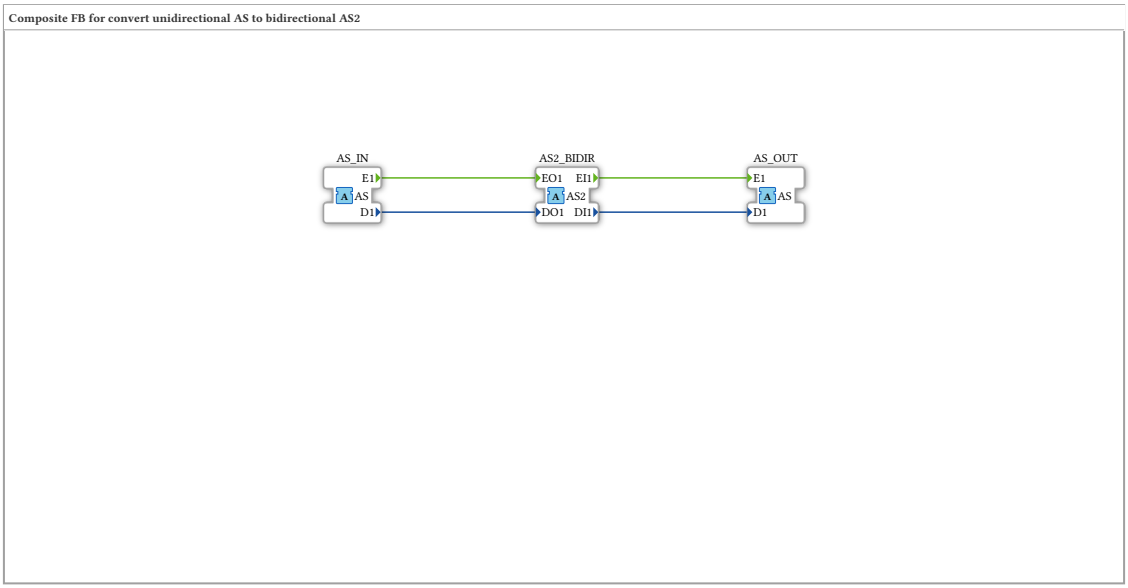
State Overview

The block is stateless:

- AS2_BIDIR.EO1 ⟶ AS_OUT.E1, AS2_BIDIR.DO1 ⟶ AS_OUT.D1
- AS_IN.E1 ⟶ AS2_BIDIR.EI1, AS_IN.D1 ⟶ AS2_BIDIR.DI1

Application Scenarios

- Reading the status of a bidirectional AS2 peer as a plain unidirectional AS signal, combined with injecting a separate unidirectional command signal
- Systems where a bidirectional peer needs to be monitored without converting the rest of the control logic to AS2
- Bridging a bidirectional AS2 zone and a unidirectional AS zone

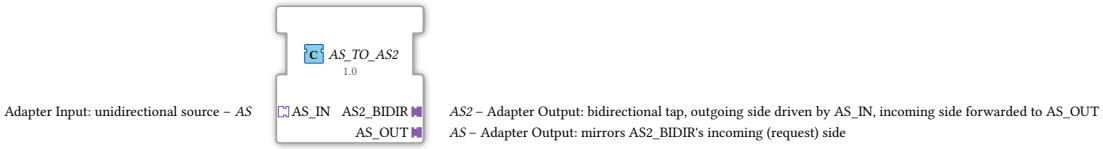


⚖️ Comparison with Similar Blocks

AS_TO_AS2 is the mirror image of this block — there, `AS2_BIDIR` sits as a plug on the right side.

Conclusion

AS2_TO_AS is not a simple converter but a tap point: it makes the state of a bidirectional AS2 peer visible as a standalone unidirectional AS signal while simultaneously injecting a separate unidirectional signal into the bidirectional side.



AS_TO_AS2

• – ○ • – ○ • – ○ •

Introduction

The `AS_TO_AS2` function block inserts a bidirectional `AS2` tap into a unidirectional `AS` chain (SINT). It uses **three** adapters: an incoming unidirectional AS signal is published onto the bidirectional AS2 interface, and whatever AS2 returns on its request side is output again as a standalone unidirectional AS signal.

Interface Structure

Event Inputs

The function block has no direct event inputs.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AS_IN** (socket): unidirectional SINT source, type `adapter::types::unidirectional::AS`
- **AS2_BIDIR** (plug): bidirectional tap whose outgoing side is fed by `AS_IN` and whose incoming side is forwarded to `AS_OUT`, type `adapter::types::bidirectional::AS2`
- **AS_OUT** (plug): mirrors the incoming (request) side of `AS2_BIDIR` as a unidirectional signal, type `adapter::types::unidirectional::AS`

Functionality

The block operates in two directions at once: whatever arrives at the socket `AS_IN` (`E1`/`D1`) is published directly onto the outgoing side of `AS2_BIDIR` (`EO1`/`DO1`). Conversely, whatever `AS2_BIDIR` receives on its request side (`EI1`/`DI1`) is output unchanged as a standalone unidirectional signal via the plug `AS_OUT`.

AS2_BIDIR thus acts as a tap point that does not break the unidirectional chain but extends it with a bidirectional observation/injection point.

Technical Details

- Three adapters instead of two: the incoming signal direction and the direction coming back from the tap are deliberately kept separate
- Pure wiring, no logic or state, every destination variable has exactly one writer
- AS_OUT only reflects what comes back via AS2_BIDIR from an attached bidirectional peer; without such a peer, AS_OUT stays idle

State Overview

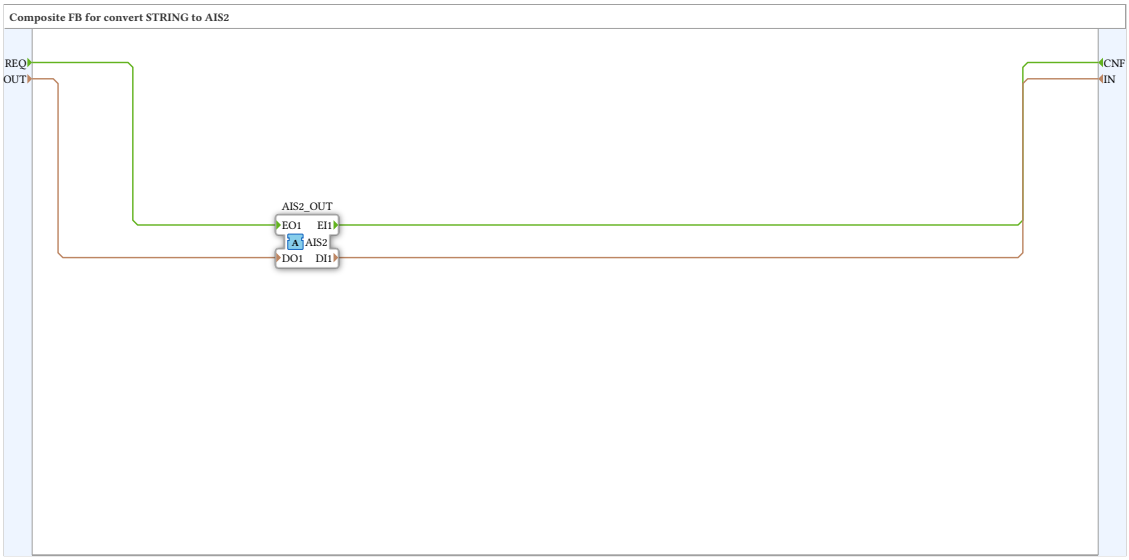
The block is stateless:

- AS_IN.E1 ⟶ AS2_BIDIR.EO1, AS_IN.D1 ⟶ AS2_BIDIR.DO1
- AS2_BIDIR.EI1 ⟶ AS_OUT.E1, AS2_BIDIR.DI1 ⟶ AS_OUT.D1

Application Scenarios

- Retrofitting a bidirectional diagnostic or control point into an existing unidirectional AS signal chain without breaking it
- Bridging a unidirectional AS zone and a bidirectional AS2 zone

⚖️ Comparison with Similar Blocks

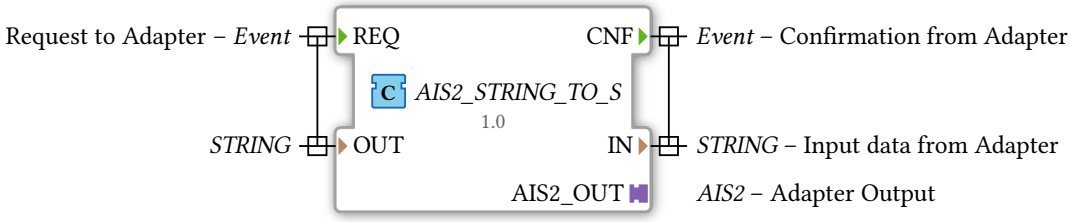


The counterpart in the opposite direction is the block AS2_TO_AS (there, AS2_BIDIR is a socket on the left side). The blocks of this conversion family exist analogously for the adapters AR/AR2, AB/AB2 and AE/AE2.

Conclusion

AS_TO_AS2 is not a simple converter but a tap point: it makes a unidirectional AS signal visible at a bidirectional AS2 point without breaking the original signal chain, while forwarding the request signal received there as a standalone AS signal.

STRING



AIS2_STRING_TO_S

• – ○ • – ○ • – ○ •

Introduction

AIS2_STRING_TO_S is a composite function block that connects a bidirectional AIS2 adapter (plug AIS2_OUT) to a classic event/data interface of type STRING. The event REQ with the data input OUT is written to the adapter; event and value coming from the adapter appear as CNF with the data output IN. The block belongs to the conversion family (analogous to AR2/AB2/AE2).

Interface Structure

Event Inputs

- **REQ**: Request to the adapter (associated data: `OUT`)

Event Outputs

- **CNF**: Confirmation from the adapter (associated data: `IN`)

Data Inputs

- **OUT** (`STRING`): Value sent to the adapter

Data Outputs

- **IN** (`STRING`): Value received from the adapter (input data from adapter)

Adapters

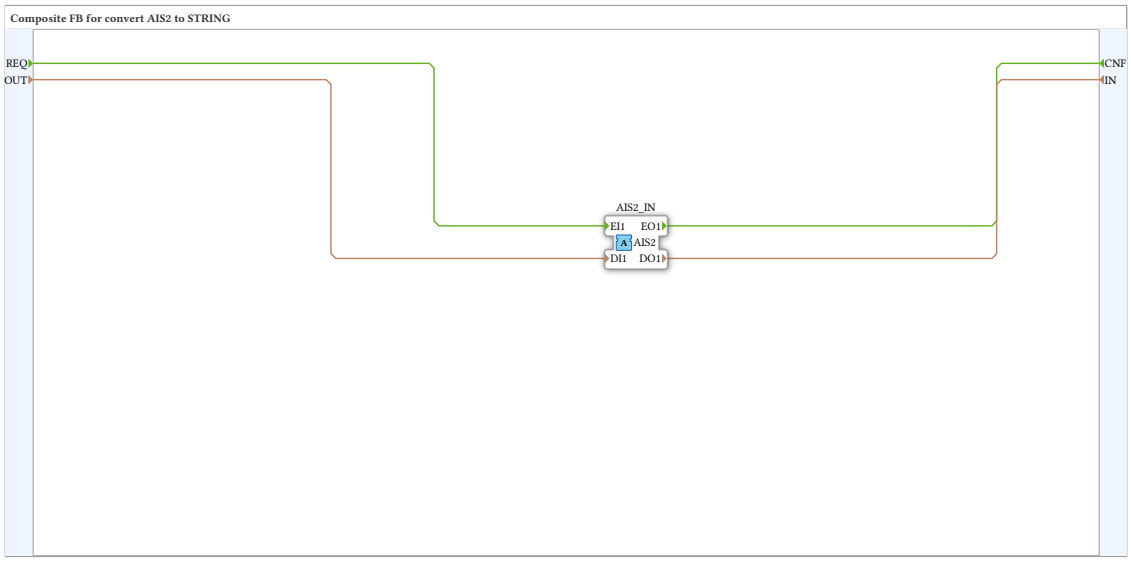
- **AIS2_OUT** (plug): Bidirectional adapter of type `adapter::types::bidirectional::AIS2` (adapter output)

How it works

1. **Send**: `REQ` is routed to `AIS2_OUT.EO1` and `OUT` to `AIS2_OUT.DO1`.
2. **Receive**: `AIS2_OUT.EI1` is routed to `CNF` and `AIS2_OUT.DI1` to `IN`.

Technical Details

- Pure event/data connections (`FBNetwork`), no logic of its own and no internal state
- The data type is `STRING` on both sides, no value conversion takes place
- Version 1.0 (2026-09-12): conversion family completed

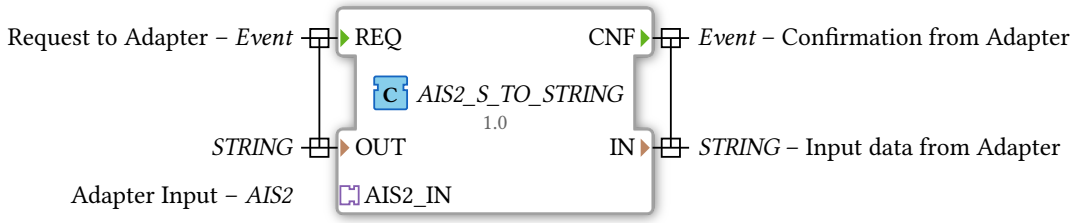


Application Scenarios

- Connecting a block with a simple `REQ`/`CNF` interface to a bidirectional `AIS2` adapter connection
- Bridge between event/data ports and adapter for `STRING` values

Summary

`AIS2_STRING_TO_S` translates a simple `STRING` event/data interface 1:1 into a bidirectional `AIS2` adapter and back.



AIS2_S_TO_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

`AIS2_S_TO_STRING` is a composite function block that maps the bidirectional adapter AIS2 onto plain event and STRING data ports. It belongs to the conversion family analogous to AR2/AB2/AE2.

Interface Structure

Event Inputs

- **REQ** (Request to Adapter): Sends the data `OUT` through the adapter (associated with `OUT`)

Event Outputs

- **CNF** (Confirmation from Adapter): Triggered when the adapter delivers an event on its incoming side (associated with `IN`)

Data Inputs

- **OUT** (STRING): Data sent to the adapter

Data Outputs

- **IN** (STRING): Data received from the adapter

Adapters

- **AIS2_IN** (Socket): Adapter of type `adapter::types::bidirectional::AIS2`

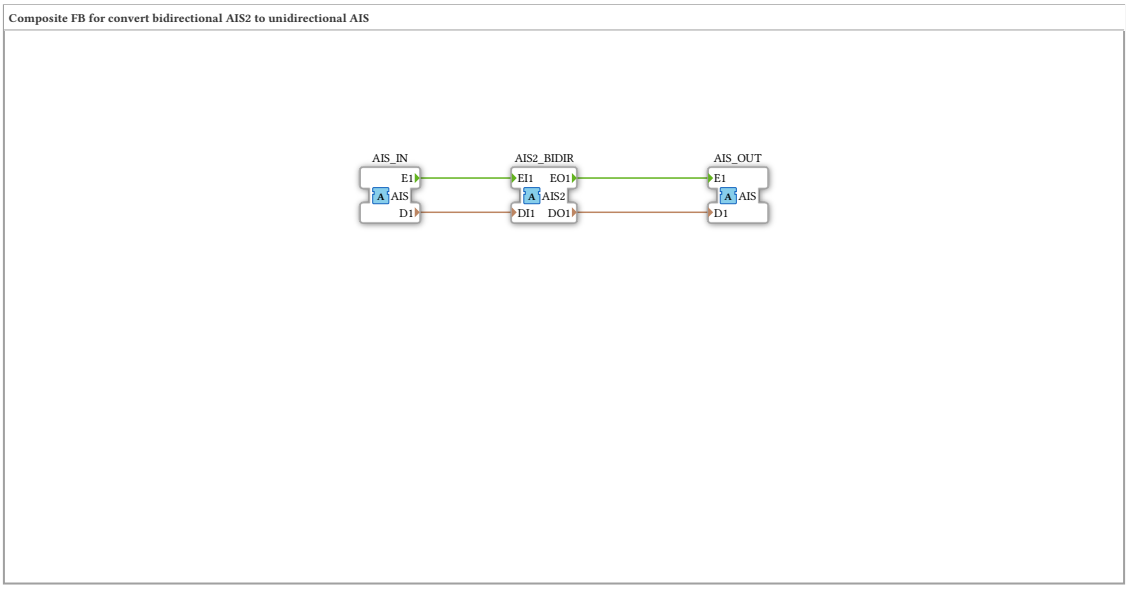
Functionality

The block consists of wiring only, without any logic of its own:

- `REQ` ⟶ `AIS2_IN.EI1` and `OUT` ⟶ `AIS2_IN.DI1`: The request event stream together with its data is published onto the outgoing side of the adapter.
- `AIS2_IN.EO1` ⟶ `CNF` and `AIS2_IN.DO1` ⟶ `IN`: Whatever is reported on the incoming side of the adapter appears as event `CNF` with the data `IN`.

Technical Details

- Stateless composite block without algorithms
- Every destination variable has exactly one writer
- The adapter data is passed through unchanged, no value conversion takes place

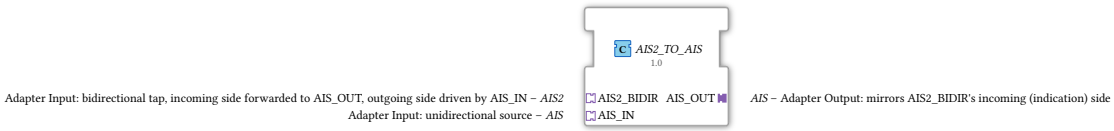


Application Scenarios

- Connecting classic event/data ports to a bidirectional AIS2 adapter
- Integrating blocks with STRING ports into adapter-based networks

Conclusion

`AIS2_S_TO_STRING` maps the bidirectional AIS2 adapter onto the ports `REQ`/`OUT` and `CNF`/`IN` without any logic.



AIS2_TO_AIS

• – ○ • – ○ • – ○ •

Introduction

`AIS2_TO_AIS` is a composite function block that converts a **bidirectional** `AIS2` adapter into a **unidirectional** `AIS` adapter. The incoming side (`EO1`/`DO1`) of the bidirectional adapter is output as a plain unidirectional signal via `AIS_OUT`; via `AIS_IN` a value is written onto the outgoing side (`EI1`/`DI1`) of the bidirectional adapter.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

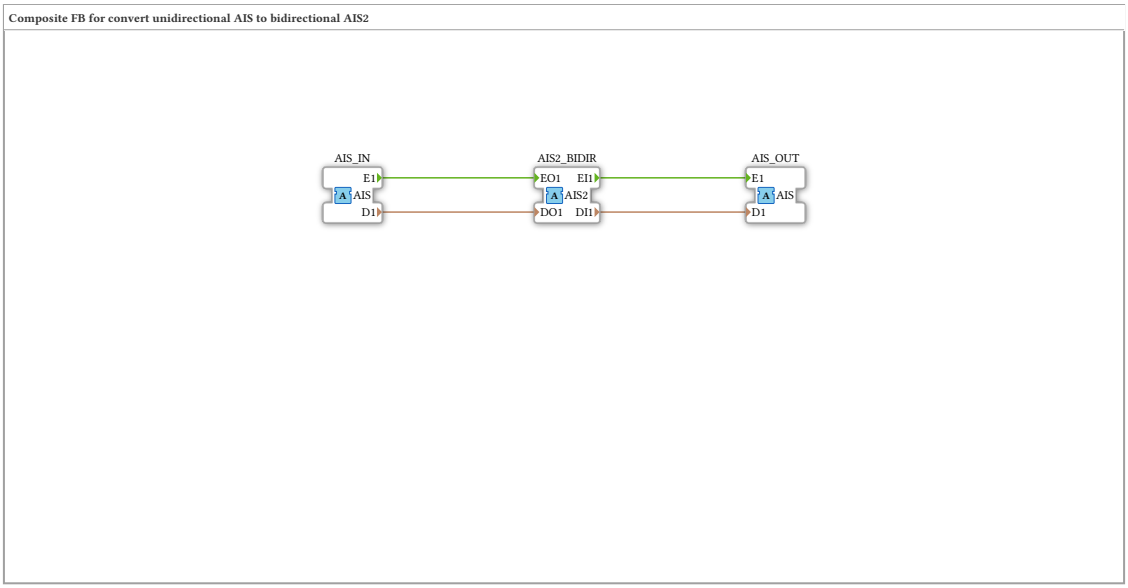
- **AIS2_BIDIR** (socket): Bidirectional adapter of type `adapter::types::bidirectional::AIS2` - the incoming side is forwarded to `AIS_OUT`, the outgoing side is driven by `AIS_IN`
- **AIS_IN** (socket): Unidirectional adapter of type `adapter::types::unidirectional::AIS` - unidirectional source
- **AIS_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::AIS` - mirrors the incoming (indication) side of `AIS2_BIDIR`

How it works

1. `AIS2_BIDIR.EO1` is forwarded to `AIS_OUT.E1` and `AIS2_BIDIR.DO1` to `AIS_OUT.D1`.
2. `AIS_IN.E1` is forwarded to `AIS2_BIDIR.EI1` and `AIS_IN.D1` to `AIS2_BIDIR.DI1`.

Technical Details

- Pure event/data connections (`FBNetwork`), no logic of its own and no internal state
- Part of the conversion family (analogous to `AR2`/`AB2`/`AE2`); the data type is `STRING`

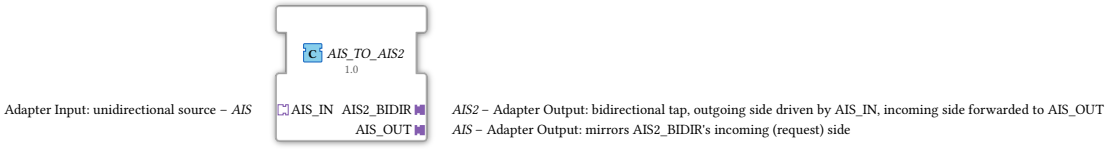


Application Scenarios

- Connecting a unidirectional `AIS` consumer or producer to a bidirectional `AIS2` adapter

Summary

`AIS2_TO_AIS` separates the two directions of a bidirectional `AIS2` adapter into a unidirectional output (`AIS_OUT`) and a unidirectional input (`AIS_IN`).



AIS_TO_AIS2

• – ○ • – ○ • – ○ •

Introduction

The `AIS_TO_AIS2` function block inserts a bidirectional `AIS2` tap into a unidirectional `AIS` chain (STRING). It uses **three** adapters: an incoming unidirectional AIS signal is published onto the bidirectional AIS2 interface, and whatever AIS2 returns on its request side is output again as a standalone unidirectional AIS signal.

Interface Structure

Event Inputs

The function block has no direct event inputs.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AIS_IN** (socket): unidirectional STRING source, type `adapter::types::unidirectional::AIS`
- **AIS2_BIDIR** (plug): bidirectional tap whose outgoing side is fed by `AIS_IN` and whose incoming side is forwarded to `AIS_OUT`, type `adapter::types::bidirectional::AIS2`
- **AIS_OUT** (plug): mirrors the incoming (request) side of `AIS2_BIDIR` as a unidirectional signal, type `adapter::types::unidirectional::AIS`

Functionality

The block operates in two directions at once: whatever arrives at the socket `AIS_IN` (`E1`/`D1`) is published directly onto the outgoing side of `AIS2_BIDIR` (`EO1`/`DO1`). Conversely, whatever `AIS2_BIDIR` receives on its request side (`EI1`/`DI1`) is output unchanged as a standalone unidirectional signal via the plug `AIS_OUT`. `AIS2_BIDIR` thus acts as a tap point that does not break the unidirectional chain but extends it with a bidirectional observation/injection point.

Technical Details

- Three adapters instead of two: the incoming signal direction and the direction coming back from the tap are deliberately kept separate
- Pure wiring, no logic or state, every destination variable has exactly one writer
- `AIS_OUT` only reflects what comes back via `AIS2_BIDIR` from an attached bidirectional peer; without such a peer, `AIS_OUT` stays idle

State Overview

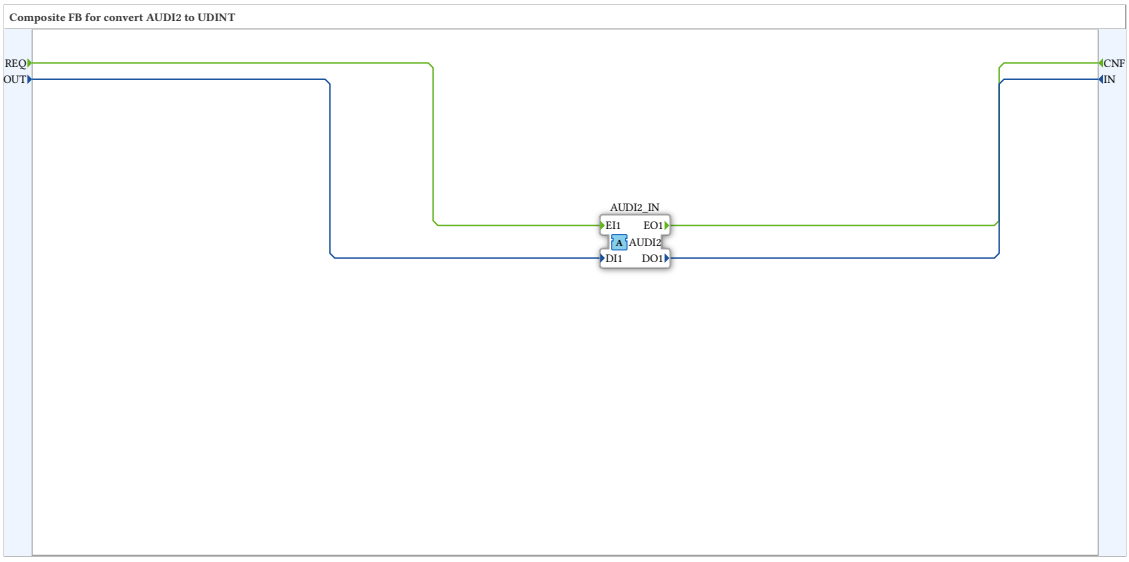
The block is stateless:

- AIS_IN.E1 ⟶ AIS2_BIDIR.EO1, AIS_IN.D1 ⟶ AIS2_BIDIR.DO1
- AIS2_BIDIR.EI1 ⟶ AIS_OUT.E1, AIS2_BIDIR.DI1 ⟶ AIS_OUT.D1

Application Scenarios

- Retrofitting a bidirectional diagnostic or control point into an existing unidirectional AIS signal chain without breaking it
- Bridging a unidirectional AIS zone and a bidirectional AIS2 zone

⚖️ Comparison with Similar Blocks

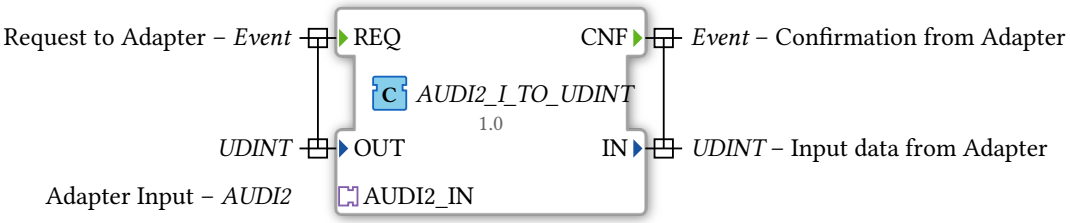


The counterpart in the opposite direction is the block `AIS2_TO_AIS` (there, `AIS2_BIDIR` is a socket on the left side). The blocks of this conversion family exist analogously for the adapters `AR`/`AR2`, `AB`/`AB2` and `AE`/`AE2`.

Conclusion

`AIS_TO_AIS2` is not a simple converter but a tap point: it makes a unidirectional AIS signal visible at a bidirectional AIS2 point without breaking the original signal chain, while forwarding the request signal received there as a standalone AIS signal.

UDINT



AUDI2_I_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

`AUDI2_I_TO_UDINT` is a composite function block that maps the bidirectional adapter AUDI2 onto plain event and UDINT data ports. It belongs to the conversion family analogous to AR2/AB2/AE2.

Interface Structure

Event Inputs

- **REQ** (Request to Adapter): Sends the data `OUT` through the adapter (associated with `OUT`)

Event Outputs

- **CNF** (Confirmation from Adapter): Triggered when the adapter delivers an event on its incoming side (associated with `IN`)

Data Inputs

- **OUT** (UDINT): Data sent to the adapter

Data Outputs

- **IN** (UDINT): Data received from the adapter

Adapters

- **AUDI2_IN** (Socket): Adapter of type `adapter::types::bidirectional::AUDI2`

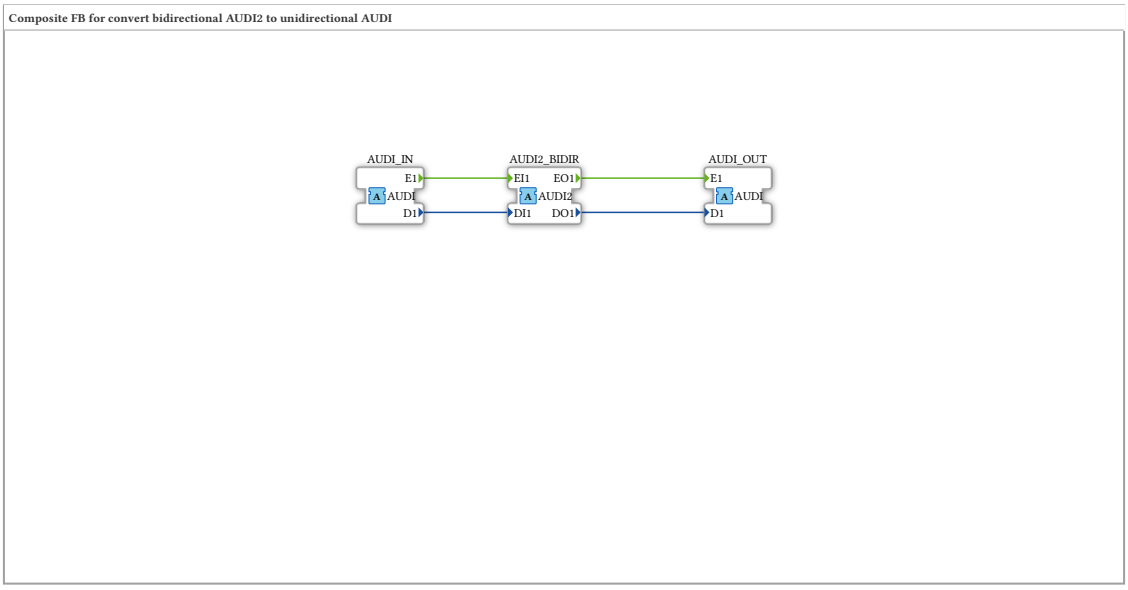
Functionality

The block consists of wiring only, without any logic of its own:

- `REQ` ⟶ `AUDI2_IN.EI1` and `OUT` ⟶ `AUDI2_IN.DI1`: The request event stream together with its data is published onto the outgoing side of the adapter.
- `AUDI2_IN.EO1` ⟶ `CNF` and `AUDI2_IN.DO1` ⟶ `IN`: Whatever is reported on the incoming side of the adapter appears as event `CNF` with the data `IN`.

Technical Details

- Stateless composite block without algorithms
- Every destination variable has exactly one writer
- The adapter data is passed through unchanged, no value conversion takes place

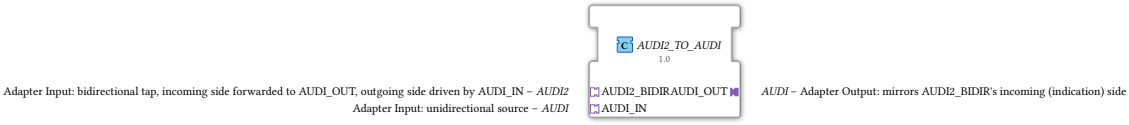


Application Scenarios

- Connecting classic event/data ports to a bidirectional AUDI2 adapter
- Integrating blocks with UDINT ports into adapter-based networks

Conclusion

`AUDI2_I_TO_UDINT` maps the bidirectional AUDI2 adapter onto the ports `REQ`/`OUT` and `CNF`/`IN` without any logic.



AUDI2_TO_AUDI

• — ○ • — ○ • — ○ •

Introduction

The AUDI2_TO_AUDI function block is the mirror image of AUDI_TO_AUDI2: here the bidirectional AUDI2 tap sits as a socket on the left (input) side, complemented by a second unidirectional AUDI socket and a unidirectional AUDI plug.

Interface Structure

Event Inputs

The function block has no direct event inputs — communication happens exclusively through the adapters.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AUDI2_BIDIR** (Socket): bidirectional tap whose incoming side is forwarded to `AUDI_OUT` and whose outgoing side is fed by `AUDI_IN`, of type `adapter::types::bidirectional::AUDI2`
- **AUDI_IN** (Socket): unidirectional UDINT source, of type `adapter::types::unidirectional::AUDI`
- **AUDI_OUT** (Plug): mirrors the incoming (indication) side of `AUDI2_BIDIR` as a unidirectional signal, of type `adapter::types::unidirectional::AUDI`

Functionality

The block operates in two directions at once: whatever the socket `AUDI2_BIDIR` receives on its indication side (`EO1`/`DO1` — i.e. whatever a bidirectional peer attached to AUDI2_BIDIR reports) is output unchanged as a standalone unidirectional signal via the plug `AUDI_OUT`. Conversely, whatever arrives at the socket `AUDI_IN` (`E1`/`D1`) is published onto the request side of `AUDI2_BIDIR` (`EI1`/`DI1`) — so AUDI2_BIDIR forwards the same signal to the attached bidirectional peer.

Technical Details

- Three adapters instead of two: the direction received from the tap and the separately injected direction are deliberately kept apart rather than mixed
- Pure wiring, no logic or state, every destination variable has exactly one writer
- `AUDI_OUT` only reflects what is reported via `AUDI2_BIDIR` by an attached bidirectional peer — without such a peer, `AUDI_OUT` stays idle

State Overview

The block is stateless:

- AUDI2_BIDIR.EO1 ⟶ AUDI_OUT.E1, AUDI2_BIDIR.DO1 ⟶ AUDI_OUT.D1
- AUDI_IN.E1 ⟶ AUDI2_BIDIR.EI1, AUDI_IN.D1 ⟶ AUDI2_BIDIR.DI1

Application Scenarios

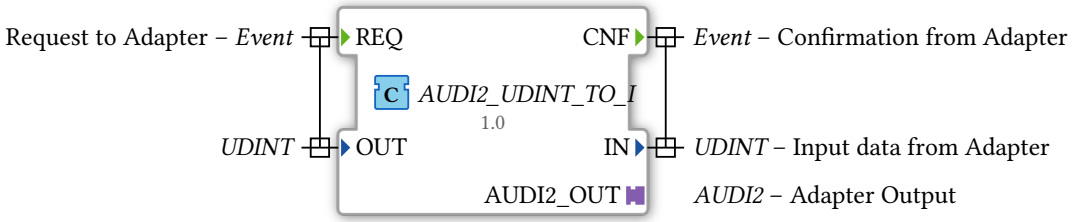
- Reading the status of a bidirectional AUDI2 peer as a plain unidirectional AUDI signal, combined with injecting a separate unidirectional command signal
- Systems where a bidirectional peer needs to be monitored without converting the rest of the control logic to AUDI2
- Bridging a bidirectional AUDI2 zone and a unidirectional AUDI zone

⚖️ Comparison with Similar Blocks

AUDI_TO_AUDI2 is the mirror image of this block — there, `AUDI2_BIDIR` sits as a plug on the right side.

Conclusion

AUDI2_TO_AUDI is not a simple converter but a tap point: it makes the state of a bidirectional AUDI2 peer visible as a standalone unidirectional AUDI signal while simultaneously injecting a separate unidirectional signal into the bidirectional side.



AUDI2_UDINT_TO_I

• – ○ • – ○ • – ○ •

Introduction

`AUDI2_UDINT_TO_I` is a composite function block that mediates between classic event/data connections of type `UDINT` and a **bidirectional** `AUDI2` adapter. On `REQ`, the input `OUT` is written onto the outgoing side of the adapter plug `AUDI2_OUT`; the value reported via the adapter's backward direction appears at output `IN` and is acknowledged with `CNF`.

Interface Structure

Event Inputs

- **REQ**: Request to the adapter. Associated data: `OUT`

Event Outputs

- **CNF**: Confirmation from the adapter. Associated data: `IN`

Data Inputs

- **OUT** (`UDINT`): Data sent to the adapter

Data Outputs

- **IN** (`UDINT`): Data received from the adapter

Adapters

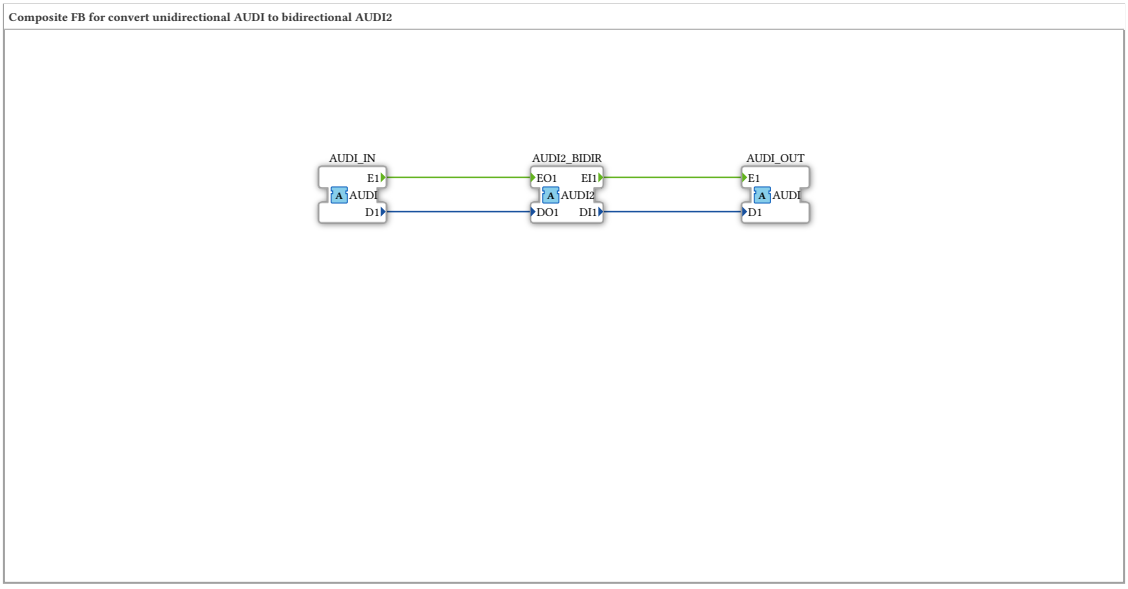
- **AUDI2_OUT** (plug): Bidirectional adapter of type `adapter::types::bidirectional::AUDI2` (adapter output)

How it works

1. `REQ` is forwarded to `AUDI2_OUT.EO1`, `OUT` to `AUDI2_OUT.DO1`.
2. `AUDI2_OUT.EI1` is forwarded to `CNF`, `AUDI2_OUT.DI1` to `IN`.

Technical Details

- Pure event/data connections (`FBNetwork`), no logic of its own and no internal state
- Part of the conversion family (analogous to `AR2`/`AB2`/`AE2`)

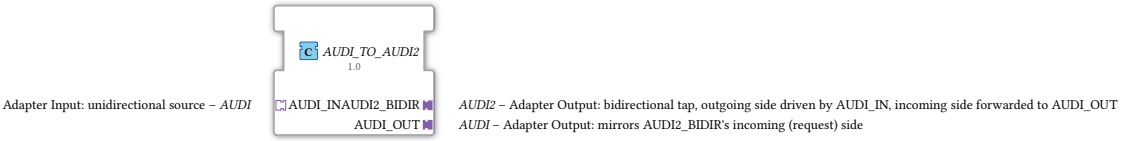


Application Scenarios

- Connecting `UDINT` values from classic function block networks to a bidirectional `AUDI2` adapter

Summary

`AUDI2_UDINT_TO_I` maps `UDINT` event/data connections 1:1 onto the two directions of an `AUDI2` adapter.



AUDI_TO_AUDI2

• — ○ • — ○ • — ○ •

Introduction

The `AUDI_TO_AUDI2` function block inserts a bidirectional `AUDI2` tap into a unidirectional `AUDI` chain (UDINT). It uses **three** adapters: an incoming unidirectional AUDI signal is published onto the bidirectional AUDI2 interface, and whatever AUDI2 returns on its request side is output again as a standalone unidirectional AUDI signal.

Interface Structure

Event Inputs

The function block has no direct event inputs.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AUDI_IN** (socket): unidirectional UDINT source, type `adapter::types::unidirectional::AUDI`
- **AUDI2_BIDIR** (plug): bidirectional tap whose outgoing side is fed by `AUDI_IN` and whose incoming side is forwarded to `AUDI_OUT`, type `adapter::types::bidirectional::AUDI2`
- **AUDI_OUT** (plug): mirrors the incoming (request) side of `AUDI2_BIDIR` as a unidirectional signal, type `adapter::types::unidirectional::AUDI`

Functionality

The block operates in two directions at once: whatever arrives at the socket `AUDI_IN` (`E1`/`D1`) is published directly onto the outgoing side of `AUDI2_BIDIR` (`EO1`/`DO1`). Conversely, whatever `AUDI2_BIDIR` receives on its request side (`EI1`/`DI1`) is output unchanged as a standalone unidirectional signal via the plug `AUDI_OUT`. `AUDI2_BIDIR` thus acts as a tap point that does not break the unidirectional chain but extends it with a bidirectional observation/injection point.

Technical Details

- Three adapters instead of two: the incoming signal direction and the direction coming back from the tap are deliberately kept separate
- Pure wiring, no logic or state, every destination variable has exactly one writer
- `AUDI_OUT` only reflects what comes back via `AUDI2_BIDIR` from an attached bidirectional peer; without such a peer, `AUDI_OUT` stays idle

State Overview

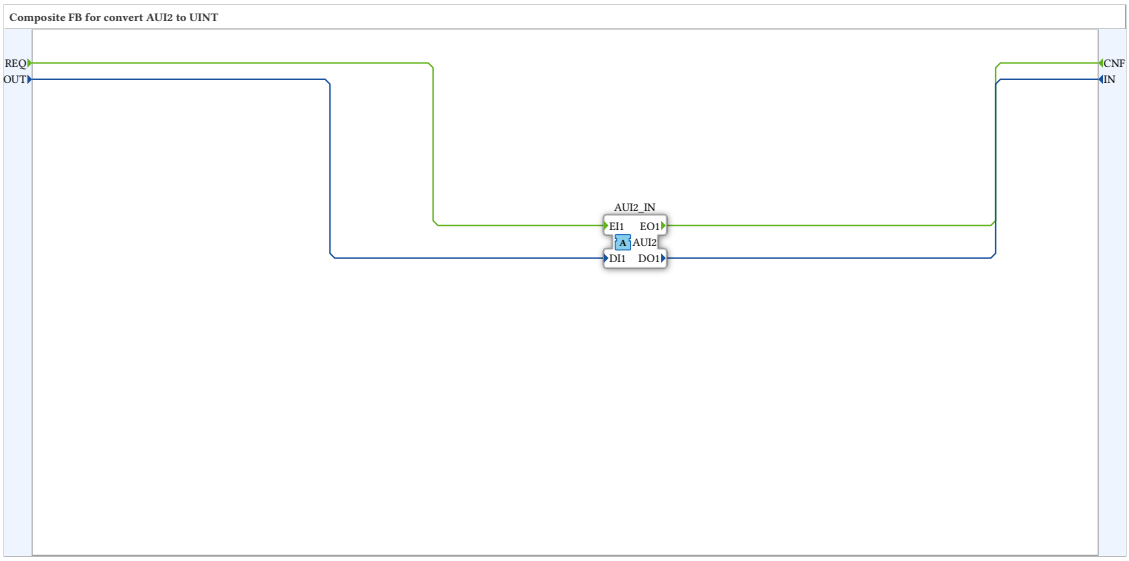
The block is stateless:

- AUDI_IN.E1 ⟶ AUDI2_BIDIR.EO1, AUDI_IN.D1 ⟶ AUDI2_BIDIR.DO1
- AUDI2_BIDIR.EI1 ⟶ AUDI_OUT.E1, AUDI2_BIDIR.DI1 ⟶ AUDI_OUT.D1

Application Scenarios

- Retrofitting a bidirectional diagnostic or control point into an existing unidirectional AUDI signal chain without breaking it
- Bridging a unidirectional AUDI zone and a bidirectional AUDI2 zone

⚖️ Comparison with Similar Blocks

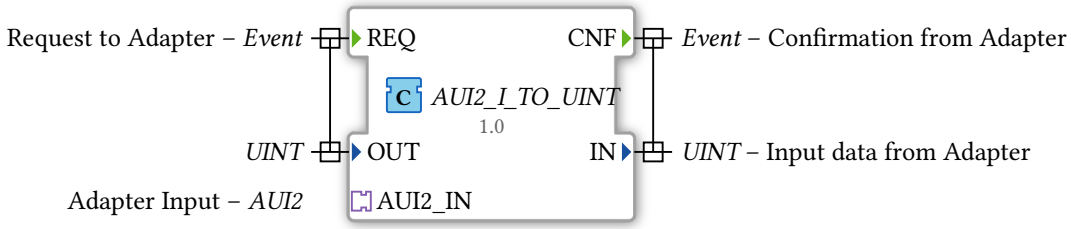


The counterpart in the opposite direction is the block `AUDI2_TO_AUDI` (there, `AUDI2_BIDIR` is a socket on the left side). The blocks of this conversion family exist analogously for the adapters `AR`/`AR2`, `AB`/`AB2` and `AE`/`AE2`.

Conclusion

`AUDI_TO_AUDI2` is not a simple converter but a tap point: it makes a unidirectional AUDI signal visible at a bidirectional AUDI2 point without breaking the original signal chain, while forwarding the request signal received there as a standalone AUDI signal.

UINT



AUI2_I_TO_UINT

• – ○ • – ○ • – ○ •

Introduction

`AUI2_I_TO_UINT` is a composite FB that mediates between a `UINT` data pair (`OUT`/`IN`) and the bidirectional adapter `AUI2`. In contrast to the plug variant `AUI2_UINT_TO_R` it has an adapter **socket** (input). It completes the conversion family analogously to `AR2`/`AB2`/`AE2`.

Interface Structure

Event Inputs

- `REQ`: Request to the adapter. Associated data: `OUT`.

Event Outputs

- `CNF`: Confirmation from the adapter. Associated data: `IN`.

Data Inputs

- `OUT` (`UINT`): Value sent to the adapter.

Data Outputs

- `IN` (`UINT`): Value received from the adapter.

Adapters

Direction	Name	Adapter type	Comment
Socket (input)	`AUI2_IN`	`adapter::types::bidirectional::AUI2`	Adapter input.

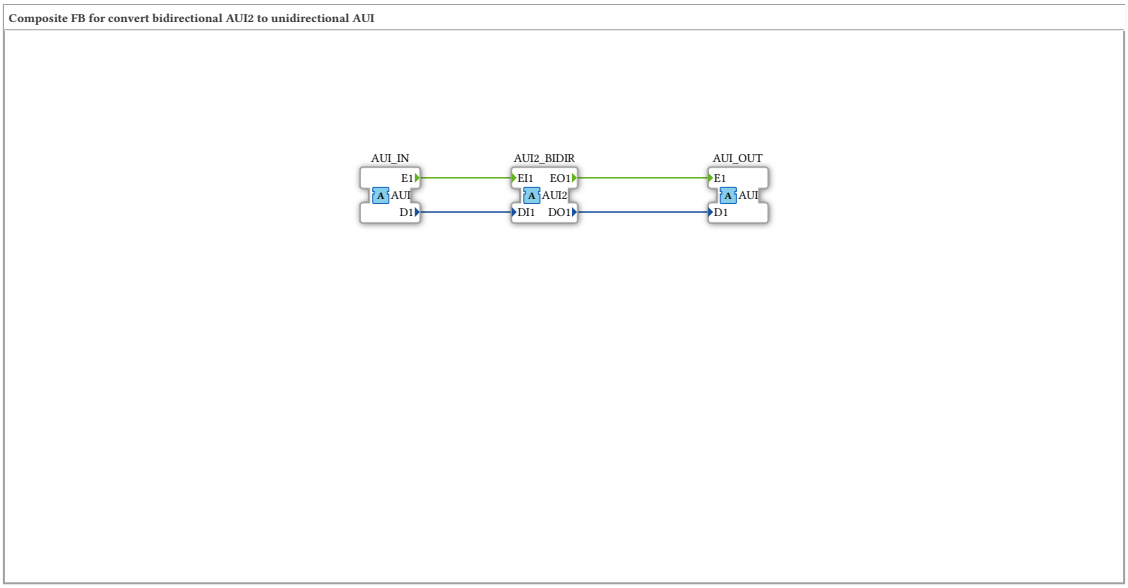
Functionality

The block contains no internal FBs, only connections:

- `REQ` ⟶ `AUI2_IN.EI1` and `OUT` ⟶ `AUI2_IN.DI1`: a `REQ` event sends the value `OUT` through the adapter.
- `AUI2_IN.EO1` ⟶ `CNF` and `AUI2_IN.DO1` ⟶ `IN`: an event coming from the adapter is output as `CNF`, and the received value appears at `IN`.

Technical Details

- Pure pass-through without logic and without internal state.
- The data type is `UINT` (unsigned 16-bit integer).
- The naming `OUT`/`IN` is chosen from the adapter's point of view: `OUT` goes out to the adapter, `IN` comes in from the adapter.

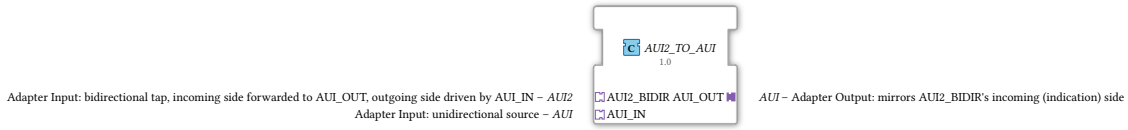


Application Scenarios

- Output a `UINT` value to a bidirectional `AUI2` adapter and at the same time read its backward channel as a data output, when the adapter is present as a socket.

Summary

`AUI2_I_TO_UINT` connects events and `UINT` data 1:1 with the bidirectional adapter `AUI2` (socket variant).



AUI2_TO_AUI

• — ○ • — ○ • — ○ •

Introduction

`AUI2_TO_AUI` is a composite function block that converts a **bidirectional** `AUI2` adapter into a **unidirectional** `AUI` adapter. The incoming side (`EO1`/`DO1`) of the bidirectional adapter is output as a plain unidirectional signal via `AUI_OUT`; via `AUI_IN` a value is written onto the outgoing side (`EI1`/`DI1`) of the bidirectional adapter.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

- **AUI2_BIDIR** (socket): Bidirectional adapter of type `adapter::types::bidirectional::AUI2` - the incoming side is forwarded to `AUI_OUT`, the outgoing side is driven by `AUI_IN`
- **AUI_IN** (socket): Unidirectional adapter of type `adapter::types::unidirectional::AUI` - unidirectional source
- **AUI_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::AUI` - mirrors the incoming (indication) side of `AUI2_BIDIR`

How it works

1. `AUI2_BIDIR.EO1` is forwarded to `AUI_OUT.E1` and `AUI2_BIDIR.DO1` to `AUI_OUT.D1`.
2. `AUI_IN.E1` is forwarded to `AUI2_BIDIR.EI1` and `AUI_IN.D1` to `AUI2_BIDIR.DI1`.

Technical Details

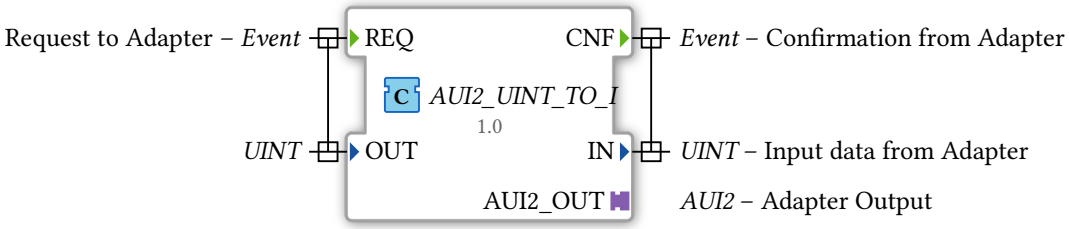
- Pure event/data connections (`FBNetwork`), no logic of its own and no internal state
- Part of the conversion family (analogous to `AR2`/`AB2`/`AE2`)

Application Scenarios

- Connecting a unidirectional `AUI` consumer or producer to a bidirectional `AUI2` adapter

Summary

`AUI2_TO_AUI` separates the two directions of a bidirectional `AUI2` adapter into a unidirectional output (`AUI_OUT`) and a unidirectional input (`AUI_IN`).



AUI2_UINT_TO_I

• – ○ • – ○ • – ○ •

Introduction

`AUI2_UINT_TO_I` is a composite function block that maps the plain event and `UINT` data ports `REQ`/`OUT` and `CNF`/`IN` onto the bidirectional adapter `AUI2` (as a plug). It belongs to the conversion family analogous to AR2/AB2/AE2.

Interface Structure

Event Inputs

- **REQ** (request to adapter): sends the data `OUT` through the adapter (associated with `OUT`)

Event Outputs

- **CNF** (confirmation from adapter): fires when the adapter delivers an event on its incoming side (associated with `IN`)

Data Inputs

- **OUT** (UINT): data that is sent to the adapter

Data Outputs

- **IN** (UINT): data received from the adapter

Adapters

- **AUI2_OUT** (plug): adapter of type `adapter::types::bidirectional::AUI2`

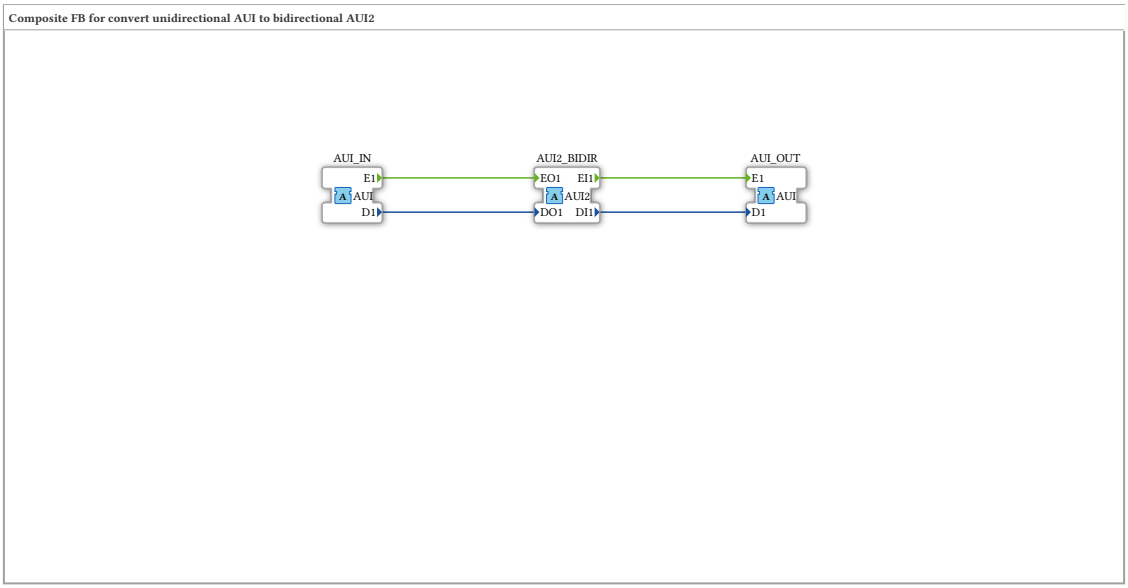
Functionality

The block consists of wiring only, without any logic of its own:

- `REQ` ⟶ `AUI2_OUT.EO1` and `OUT` ⟶ `AUI2_OUT.DO1`: the request event stream together with its data is published onto the outgoing side of the adapter.
- `AUI2_OUT.EI1` ⟶ `CNF` and `AUI2_OUT.DI1` ⟶ `IN`: whatever is reported on the incoming side of the adapter appears as the event `CNF` with the data `IN`.

Technical Details

- Stateless composite block without algorithms
- Every destination variable has exactly one writer
- The adapter data is passed through unchanged; no value conversion takes place
- The adapter is used as a plug here, so the block sits at the start of an AUI2 connection

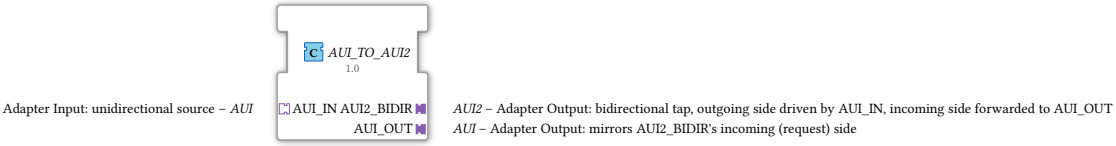


Application Scenarios

- Connecting classic event/data ports to a bidirectional AUI2 adapter
- Integrating blocks with `UINT` ports into adapter-based networks

Conclusion

`AUI2_UINT_TO_I` maps the ports `REQ`/`OUT` and `CNF`/`IN` onto the bidirectional AUI2 adapter without any logic.



AUI_TO_AUI2

• – ○ • – ○ • – ○ •

Introduction

The `AUI_TO_AUI2` function block inserts a bidirectional `AUI2` tap into a unidirectional `AUI` chain (UINT). It uses **three** adapters: an incoming unidirectional AUI signal is published onto the bidirectional AUI2 interface, and whatever AUI2 returns on its request side is output again as a standalone unidirectional AUI signal.

Interface Structure

Event Inputs

The function block has no direct event inputs.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **AUI_IN** (socket): unidirectional UINT source, type `adapter::types::unidirectional::AUI`
- **AUI2_BIDIR** (plug): bidirectional tap whose outgoing side is fed by `AUI_IN` and whose incoming side is forwarded to `AUI_OUT`, type `adapter::types::bidirectional::AUI2`
- **AUI_OUT** (plug): mirrors the incoming (request) side of `AUI2_BIDIR` as a unidirectional signal, type `adapter::types::unidirectional::AUI`

Functionality

The block operates in two directions at once: whatever arrives at the socket `AUI_IN` (`E1`/`D1`) is published directly onto the outgoing side of `AUI2_BIDIR` (`EO1`/`DO1`). Conversely, whatever `AUI2_BIDIR` receives on its request side (`EI1`/`DI1`) is output unchanged as a standalone unidirectional signal via the plug `AUI_OUT`.

AUI2_BIDIR thus acts as a tap point that does not break the unidirectional chain but extends it with a bidirectional observation/injection point.

Technical Details

- Three adapters instead of two: the incoming signal direction and the direction coming back from the tap are deliberately kept separate
- Pure wiring, no logic or state, every destination variable has exactly one writer
- AUI_OUT only reflects what comes back via AUI2_BIDIR from an attached bidirectional peer; without such a peer, AUI_OUT stays idle

State Overview

The block is stateless:

- AUI_IN.E1 ⟶ AUI2_BIDIR.EO1, AUI_IN.D1 ⟶ AUI2_BIDIR.DO1
- AUI2_BIDIR.EI1 ⟶ AUI_OUT.E1, AUI2_BIDIR.DI1 ⟶ AUI_OUT.D1

Application Scenarios

- Retrofitting a bidirectional diagnostic or control point into an existing unidirectional AUI signal chain without breaking it
- Bridging a unidirectional AUI zone and a bidirectional AUI2 zone

⚖️ Comparison with Similar Blocks

The counterpart in the opposite direction is the block AUI2_TO_AUI (there, AUI2_BIDIR is a socket on the left side). The blocks of this conversion family exist analogously for the adapters AR/AR2, AB/AB2 and AE/AE2.

Conclusion

AUI_TO_AUI2 is not a simple converter but a tap point: it makes a unidirectional AUI signal visible at a bidirectional AUI2 point without breaking the original signal chain, while forwarding the request signal received there as a standalone AUI signal.

Numeric vs. bitwise: the FORTE conversion trap

• – ◦ • – ◦ • – ◦ •

Introduction

Every block in this folder (AB_TO_AR, AD_TO_ADI, AI_TO_AR, etc.) as well as the underlying standard function blocks iec61131::conversion::F_X_TO_Y (part of the 4diac IDE standard library, not vendored in this repository) convert a value from one IEC 61131 data type to another. For some of these combinations that is a **real numeric value conversion** for others it is a **pure bit-reinterpretation**, where the numeric value is deliberately ignored and the raw bit pattern is copied instead. Not knowing the difference easily produces a silent, hard-to-find bug — see AD_TO_AR_TODO.md in the source repository for the concrete case that triggered this page.

The four type categories

IEC 61131-3 distinguishes four relevant categories:

Category	Types	Meaning
ANY_BIT	BOOL, BYTE, WORD, DWORD, LWORD	pure bit patterns with no numeric semantics of their own
ANY_INT (signed)	SINT, INT, DINT, LINT	signed integers
ANY_INT (unsigned)	USINT, UINT, UDINT, ULINT	unsigned integers
ANY_REAL	REAL, LREAL	IEEE754 floating-point numbers

The adapter prefixes in this folder correspond to: AB=BYTE, AW=WORD, AD=DWORD, AL=LWORD, AX=BOOL, AS=SINT, AI=INT, ADI=DINT, ALI=LINT, AUS=USINT, AUI=UINT, AUDI=UDINT, AULI=ULINT, AR=REAL, ALR=LREAL.

The conversion matrix

Verified against the FORTE core (`core/include/forte/datatypes/forte_any.h`, `CIEC_ANY::cast<U,T>`, and `forte_real.cpp/forte_lreal.cpp`, `CIEC_REAL::castRealData`) — the same logic behind every `F_X_TO_Y` block and every adapter wrapper in this folder:

Source ⊠ Destination	→ ANY_BIT	→ ANY_INT	→ ANY_REAL
ANY_BIT (except BOOL)	bit copy (structural, no numeric meaning)	bit-reinterpretation — **value-preserving** if the destination is same-or-wider width; truncates otherwise	⚠ **bit-reinterpretation — NOT a numeric value!** IEEE754 misinterpretation
BOOL	parity/LSB test	numeric (0/1)	numeric (0.0/1.0) — special case, see below
ANY_INT	stores the bit pattern (expected behavior for a bit-string destination)	numeric (sign-/zero-extension is safe, narrowing may truncate)	**numeric** (correct cast)
ANY_REAL	bit extraction (intentional, e.g. serialization via `F_REAL_TO_DWORD`)	numeric (rounding, `llrint`)	numeric (widen/narrow precision)

The one genuine trap is therefore the **ANY_BIT (except BOOL) → ANY_REAL** cell: using `BYTE`/`WORD`/`DWORD`/`LWORD` as the source of a conversion to `REAL`/`LREAL`. In this library that concretely affects two blocks:

- `AD_TO_AR` (DWORD→REAL) — safe replacement: `AD_TO_AR_NUM`
- `AL_TO_ALR` (LWORD→LREAL) — safe replacement: `AL_TO_AULI` + `AULI_TO_ALR`

(There are no `AB_TO_AR`/`AB_TO_ALR`/`AW_TO_AR`/`AW_TO_ALR` pairs in this library — only width-matched bit↔real combinations were offered as adapters.)

Why is BOOL→REAL safe even though BOOL belongs to ANY_BIT? FORTE treats BOOL as an explicit special case when casting to REAL (`case e_BOOL: setTFLOAT(...)` instead of the generic bit-string copy) — the one exception in the matrix.

Why is ANY_BIT→ANY_REAL implemented this way at all?

It's not arbitrary: for bit-string destinations (`ANY_BIT→ANY_BIT`) and for the reverse direction `ANY_REAL→ANY_BIT`, bit-reinterpretation is exactly the intended, documented behavior — e.g. to pack a REAL's IEEE754 bit pattern into a DWORD for transport (`F_REAL_TO_DWORD`) and later unpack it again with `AD_TO_AR`. The pitfall is **confusion**: the same mechanism gets used by mistake when a raw counter or analog value (not a serialized bit pattern) is actually meant to become that numeric value in REAL.

Practical rule of thumb

- **Does the value come from an `F_REAL_TO_X`/`F_X_TO_REAL` round trip, or from fieldbus/protocol deserialization where bit patterns are explicitly transported?** → Bit-reinterpretation is correct (`AD_TO_AR`, `AL_TO_ALR`).
- **Is the value a raw counter, analog, or other integer value meant to carry the same numeric value in REAL?** → Use the numeric variant (`AD_TO_AR_NUM`, or in general: chain through the matching `ANY_INT` intermediate type, e.g. `AD_TO_AUDI` → `AUDI_TO_AR`).
- **Every other cell of the matrix** is either unambiguously numeric or unambiguously structural (a bit operation) — without the hidden misinterpretation risk of the ANY_BIT→ANY_REAL cell. Every block in this folder carries a short note about this in its "Technical Details" section.

Also affects the standard conversion blocks

The adapter blocks documented here (`AD_TO_AR` etc.) are thin wrappers around the standard 4diac function blocks `iec61131::conversion::F_X_TO_Y` (e.g. `F_DWORD_TO_REAL`). These standard blocks are part of the 4diac IDE distribution itself (not vendored in this repository) and are subject to exactly the same matrix

— `F_DWORD_TO_REAL`, `F_WORD_TO_REAL`, `F_BYTE_TO_LREAL` etc. are likewise bit-reinterpretations, while `F_DINT_TO_REAL`, `F_UDINT_TO_REAL` etc. are numerically correct.

Numeric vs. Bitwise: The Conversion Trap in FORTE

• – ◦ • – ◦ • – ◦ •

Introduction

All the building blocks in this folder (`AB_TO_AR`, `AD_TO_ADI`, `AI_TO_AR`, etc.) and the underlying standard function blocks `iec61131::conversion::F_X_TO_Y` (part of the 4diac IDE standard library, not vendored in this repository) convert a value from one IEC 61131 data type to another. For some of these combinations, this is a **true numeric value conversion** for others, it is a **pure bit reinterpretation**, where the numeric value is deliberately ignored and the raw bit pattern is used instead. Those who don't know the difference can easily create a silent, hard-to-find bug—see `AD_TO_AR_TODO.md` in the source repository for the specific case that triggered this page.

The Four Type Categories

IEC 61131-3 distinguishes four relevant categories:

Category	Types	Meaning
ANY_BIT	`BOOL`, `BYTE`, `WORD`, `DWORD`, `LWORD`	pure bit patterns without their own numerical semantics
ANY_INT (signed)	`SINT`, `INT`, `DINT`, `LINT`	Signed Integers
ANY_INT (Unsigned)	`USINT`, `UINT`, `UDINT`, `ULINT`	Unsigned Integers
ANY_REAL	`REAL`, `LREAL`	IEEE 754 Floating-Point Numbers

The adapter prefixes in this folder correspond to: `AB`=BYTE, `AW`=WORD, `AD`=DWORD, `AL`=LWORD, `AX`=BOOL, `AS`=SINT, `AI`=INT, `ADI`=DINT, `ALI`=LINT, `AUS`=USINT, `AUI`=UINT, `AUDI`=UDINT, `AULI`=ULINT, `AR`=REAL, `ALR`=LREAL.

The Conversion Matrix

Verified in the FORTE core (`core/include/forte/datatypes/forte_any.h`, `CIEC_ANY::cast<U,T>`, as well as `forte_real.cpp`/`forte_lreal.cpp`, `CIEC_REAL::castRealData`) — the same logic behind every `F_X_TO_Y` block and every adapter wrapper in this folder:

Source < Destination	→ BOOL	→ ANY_BIT (except BOOL)	→ ANY_INT	→ ANY_REAL
ANY_BIT (except BOOL)	LSB test	Bit-pattern transfer (structural, no numeric value)	Bit reinterpretation — a **wider** target preserves the numeric value (zero extension); a **same-width** target keeps the bit pattern but a signed target can change the numeric value (e.g. `0xFF` as `BYTE` becomes `-1` as `SINT`, not `255`); a **narrower** target truncates the high bits	⚠️ **Bit reinterpretation — NO numeric value!** IEEE 754 misinterpretation

BOOL	Identity	Numeric `0`/`1`	numeric (0/1)	numeric (0.0/1.0) — special case, see below
ANY_INT	Boolean conversion (`!= 0`)	Bit-pattern transfer (expected behavior for a bit string target)	numeric (sign expansion/zero expansion safe, narrowing can truncate)	**numeric** (correct cast)
ANY_REAL	Boolean conversion (`!= 0.0`)	Bit extraction (intentional, e.g., serialization via `F_REAL_TO_DWORD`)	numeric (rounding, `llrint`)	numeric (rounding up/down precision)

The most conspicuous pitfall is the cell **ANY_BIT (except BOOL) → ANY_REAL** (highlighted in red): `BYTE`/`WORD`/`DWORD`/`LWORD` as the source of a conversion to `REAL`/`LREAL`. In this library, this specifically affects two building blocks:

A further pitfall, already noted in the matrix above, affects `ANY_BIT` (except BOOL) ⟶ `ANY_INT` at the same bit width: the bit pattern is preserved, but a signed target can change the numeric value (e.g. `0xFF` as `BYTE` becomes `-1` as `SINT`). Unlike `ANY_BIT`⟶`ANY_REAL`, the resulting value stays within a plausible numeric range instead of being turned into nonsense by an IEEE 754 misinterpretation, so the error is usually caught faster while debugging.

- `AD_TO_AR` (DWORD⟶REAL) — safe replacement: `AD_TO_AR_NUM`
- `AL_TO_ALR` (LWORD⟶LREAL) — safe replacement: `AL_TO_AULI` + `AULI_TO_ALR`

(There are no `AB_TO_AR`/`AB_TO_ALR`/`AW_TO_AR`/`AW_TO_ALR` pairs in this library — only width-matched bit↔real combinations were offered as adapters.)

Why is BOOL⟶REAL safe even though BOOL belongs to ANY_BIT? FORTE treats BOOL as an explicit special case when casting to REAL (`case e_BOOL: setTFLOAT(...)` instead of the generic bit string copy) — the only exception in the matrix.

Why is ANY_BIT⟶ANY_REAL implemented this way at all?

Not arbitrarily: For bit string destinations (`ANY_BIT`⟶`ANY_BIT`) and for the return path `ANY_REAL`⟶`ANY_BIT`, bit reinterpretation is precisely the desired, documented behavior — e.g., For example, to pack the IEEE 754 bit pattern of a REAL into a DWORD for transmission (`F_REAL_TO_DWORD`) and later unpack it again using `AD_TO_AR`. The problem is the **risk of confusion**: the same mechanism is incorrectly used when a raw counter or analog value (not a serialized bit pattern) is actually intended to be numerically transferred to REAL.

Practical Rule of Thumb

- **Does the value come from a `F_REAL_TO_X`/`F_X_TO_REAL` round trip or a fieldbus/protocol deserialization where bit patterns are explicitly transmitted?** ⟶ Bit reinterpretation is correct (`AD_TO_AR`, `AL_TO_ALR`).
- **Is the value a raw counter, analog, or other integer value that should be represented as the same numeric value in REAL?** ⟶ Use the numeric variant (`AD_TO_AR_NUM`, or more generally: a two-stage conversion via the appropriate intermediate type `ANY_INT`, e.g., `AD_TO_AUDI` ⟶ `AUDI_TO_AR`).
- **All other cells in the matrix** are either uniquely numeric or uniquely structural (bit operation) — without the hidden risk of misinterpretation inherent in the ANY_BIT⟶ANY_REAL cell. Each component in this folder includes a brief note about this in its "Technical Specifications" section.

Also applies to the standard conversion blocks

The adapter blocks documented here (`AD_TO_AR` etc.) are thin wrappers around the standard 4diac function blocks `iec61131::conversion::F_X_TO_Y` (e.g., `F_DWORD_TO_REAL`).These standard building blocks are part of the 4diac IDE distribution itself (not vendored in this repository) and are subject to the exact same matrix—`F_DWORD_TO_REAL`, `F_WORD_TO_REAL`, `F_BYTE_TO_LREAL`, etc., are bit reinterpretations, while `F_DINT_TO_REAL`, `F_UDINT_TO_REAL`, etc., are numerically correct.

AB_TO_AD

BYTE Adapter Input – *AB*

AD – DWORD Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AB_TO_AD** is a composite function block (FB) that converts a BYTE adapter (type `AB`) into a DWORD adapter (type `AD`). It serves as an interface converter in unidirectional communication and enables the easy connection of components based on different data word widths.

Interface Structure

Event Inputs

- **AB_IN.E1** – Event input from the BYTE adapter. It is forwarded directly to the DWORD adapter.

Event Outputs

- **AD_OUT.E1** – Event output to the DWORD adapter. Corresponds to the forwarded event of **AB_IN.E1**.

Data Inputs

- **AB_IN.D1** – Data input from the BYTE adapter (1 byte data width). Passed directly to the DWORD adapter.

Data Outputs

- **AD_OUT.D1** – Data output to the DWORD adapter (4 bytes data width). Contains the same value as the input **AB_IN.D1**, but in DWORD (Double Word) format.

Adapters

- **AB_IN** (Socket) – Unidirectional BYTE adapter (type `AB`) that serves as an input.
- **AD_OUT** (Plug) – Unidirectional DWORD adapter (type `AD`) that serves as an output.

Functionality

This function block connects the interfaces of a BYTE adapter (input) to those of a DWORD adapter (output). Every incoming event (**E1**) is forwarded to the output without delay or processing. Similarly, the incoming data value (**D1**) is passed to the output unchanged, but as a 4-byte DWORD. The function block has no logic of its own; it functions solely as a passthrough between the two adapter types.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- **Unidirectionality:** The function block supports only one direction of data flow, from the BYTE adapter to the DWORD adapter. Reverse data transfer is not supported.
- **Data Width Adjustment:** The incoming BYTE value (1 byte) is embedded within a DWORD value (4 bytes). The least significant byte of the DWORD corresponds to the incoming BYTE; the more significant bytes are set to zero (or remain unchanged, depending on the implementation of the target adapter).
- **Simple Coupling:** The FB is a pure connection block in the FBNetwork and does not require its own state machine or algorithms.

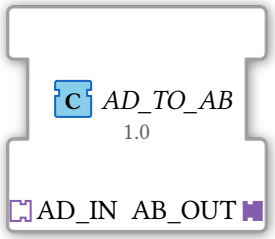
State Overview

The block has no state logic of its own, as it functions solely as a connection between the adapters. Its behavior is event-driven: Every event at the input is immediately passed on to the output.

Application Scenarios

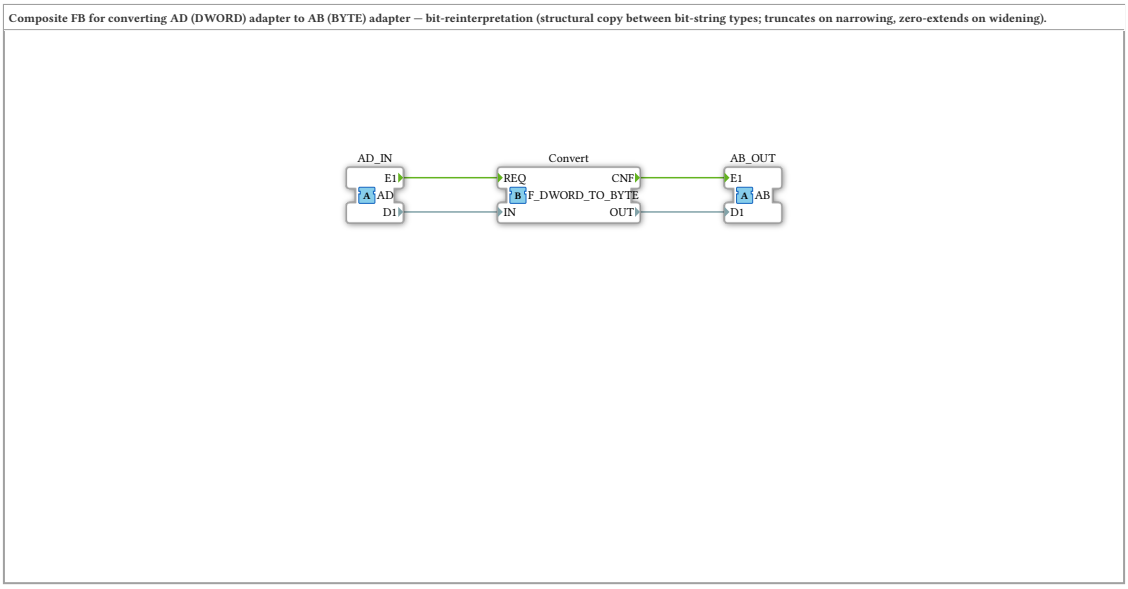
- **System Integration:** If a subsystem uses BYTE adapters, but a subsequent subsystem expects DWORD adapters, `AB_TO_AD` can be used as an intermediary converter.
- **Data Aggregation:** Several such blocks can be used to combine individual bytes into a DWORD if the source adapters each only supply one byte.
- **Protocol Adaptation:** In fieldbus or sensor connections where the data width varies between components, the block serves as a simple adaptation layer.

Comparison with Similar Modules



Analog converter modules exist for other data widths, e.g., `AB_TO_WORD` (BYTE to WORD) or `WORD_TO_DWORD`. This module specializes in the combination `AB` ⟶ `AD` and is therefore ideal for directly replacing or coupling corresponding adapters. Unlike more complex converters with data manipulation or buffers, it operates without delay and without additional logic.

Conclusion



AB_TO_AD` is a lean, clearly structured converter module that enables the unidirectional conversion of a BYTE adapter to a DWORD adapter. Its simple pass-through makes it ideal for the rapid integration of different interfaces into IEC 61499-based control systems without introducing additional functional complexity.

AD_TO_AB

DWORD Adapter Input – *AD*

AB – BYTE Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The **AD_TO_AB** function block is a composite module for the unidirectional conversion of a 32-bit DWORD adapter (AD) to an 8-bit BYTE adapter (AB). It serves as a bridge between components designed for different data widths and encapsulates the necessary type conversion according to IEC 61131-3.

Interface Structure

Event Inputs

The module has no directly visible event inputs. Event control is handled via the **AD_IN** adapter.

Event Outputs

The module has no directly visible event outputs. Event feedback is provided via the **AB_OUT** adapter.

Data Inputs

This function block has no directly visible data inputs. The DWORD value is provided via the **AD_IN** adapter.

Data Outputs

This function block has no directly visible data outputs. The BYTE value is output via the **AB_OUT** adapter.

Adapters

Adapter	Type	Direction	Description
AD_IN	`adapter::types::unidirectional::AD`	Socket (Input)	Accepts a DWORD (32-bit) and an associated event (here `E1`).
AB_OUT	`adapter::types::unidirectional::AB`	Plug (Output)	Outputs a converted byte (8-bit) and an acknowledgment event (here `E1`).

Both adapters are unidirectional. The exact signature of the adapters (number of event and data channels) corresponds to the types defined in the 4diac library.

Functionality

The function block operates purely event-driven and encapsulates the conversion using the internal base function block **F_DWORD_TO_BYTE** from the IEC 61131-1 library.

1. An incoming event at **AD_IN.E1** triggers the call to the internal conversion function block via its input `REQ`.
2. The value from **AD_IN.D1** (DWORD) is forwarded to the converter's data input `IN`.
3. After the conversion is complete, the converter signals the readiness of the result with `CNF`.
4. This event is passed to **AB_OUT.E1**, and the converted BYTE value (from `OUT`) is output to **AB_OUT.D1**.

The conversion is performed according to IEC 61131-3: The least significant 8 bits of the incoming DWORD are interpreted as a BYTE.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- The module is implemented as a composite, meaning it does not contain its own state machine but delegates all logic to the internal base module.
- Neither buffering nor error handling is implemented; data transfer occurs directly synchronously with the event.
- This module is designed for use in systems that require a clear separation between adapters for different data widths.

State Overview

Since this is a pure composite module without its own state machine, there is no explicit state machine. Its behavior is entirely determined by the internal **F_DWORD_TO_BYTE** module, which has a simple wait state (IDLE) and a processing state.

Application Scenarios

- **Connecting Sensors/Actuators**: A sensor delivers 32-bit raw data via an AD adapter, which, after conversion to an 8-bit value, is passed on to a downstream BYTE adapter.
- **Protocol Conversion**: In a communication chain, a DWORD interface is mapped to a BYTE interface, e.g., when integrating older fieldbus devices.
- **Data Width Reduction**: Targeted extraction of the least significant byte from a DWORD for subsequent processing steps.

Comparison with Similar Function Blocks

Function Block	Conversion	Direction	Adapter Type
AD_TO_AB	DWORD ⟶ BYTE	Unidirectional	AD ↔ AB
AD_TO_AW	DWORD ⟶ WORD	Unidirectional	AD ↔ AW
AW_TO_AB	WORD ⟶ BYTE	Unidirectional	AW ↔ AB

The **AD_TO_AB** function differs in its specific target data width and the use of the corresponding adapters. It is specifically designed for systems that use standard unidirectional adapters.

Conclusion

The composite block **AD_TO_AB** offers a simple, event-driven way to convert a DWORD adapter to a BYTE adapter. It cleanly encapsulates the type conversion and can be integrated into existing 4diac networks without its own state logic. Reusing the standardized **F_DWORD_TO_BYTE** block guarantees correct behavior according to IEC 61131-3.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AB_TO_ADI

BYTE Adapter Input – *AB* *ADI* – DINT Adapter Output

• – ◦ • – ◦ • – ◦ • –

Introduction

The function block **AB_TO_ADI** is a composite function block (FB) that converts an incoming BYTE value from an **AB** adapter into a DINT value and outputs it via an **ADI** adapter. It serves as a simple, unidirectional conversion interface between these two adapter types.

Interface Structure

Event Inputs

None – event control is handled exclusively via the incoming adapter (`AB_IN`).

Event Outputs

None – events are only passed on via the outgoing adapter (`ADI_OUT`).

Data Inputs

None – the data is provided via the `AB_IN` adapter.

Data Outputs

None – the converted data is output via the `ADI_OUT` adapter.

Adapters

Type	Name	Direction	Comment
Socket	`AB_IN`	Input	BYTE adapter (input)
Plug	`ADI_OUT`	Output	DINT adapter (output)

Functionality

The function block (FB) internally contains a single conversion block, `F_BYTE_TO_DINT` (from the IEC 61131 library). The incoming event `E1` from adapter `AB_IN` triggers the conversion of the data value `D1` (BYTE). The resulting DINT value is forwarded via `OUT` to the data output `D1` of adapter `ADI_OUT`. Upon completion of the conversion, the output adapter's event `E1` is triggered.

The control is purely data flow-driven: Each event at the input adapter causes a one-time conversion and forwarding.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Composite Block** – No dedicated state logic; instead, it uses the internal function block `F_BYTE_TO_DINT`.
- **Adapter-Based** – The interfaces are defined as adapters, enabling high reusability and interchangeability with other function blocks.
- **License** – The function block is released under the **Eclipse Public License 2.0**.
- **Package** – The function block is organized in the package `adapter::conversion::unidirectional`.

State Overview

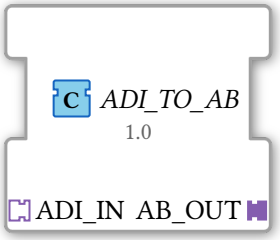
The function block does not have its own state machine. Its functionality is derived solely from the internal circuitry of the conversion block. Processing is strictly event-driven and combinatorial.

Application Scenarios

- Conversion of BYTE-based sensor data (e.g., digital status values) into integer DINT values for further processing by control logic.
- Connecting components using the **AB** adapter to systems that expect the **ADI** adapter.
- Use in adapter-based communication architectures where a uniform data representation is required.

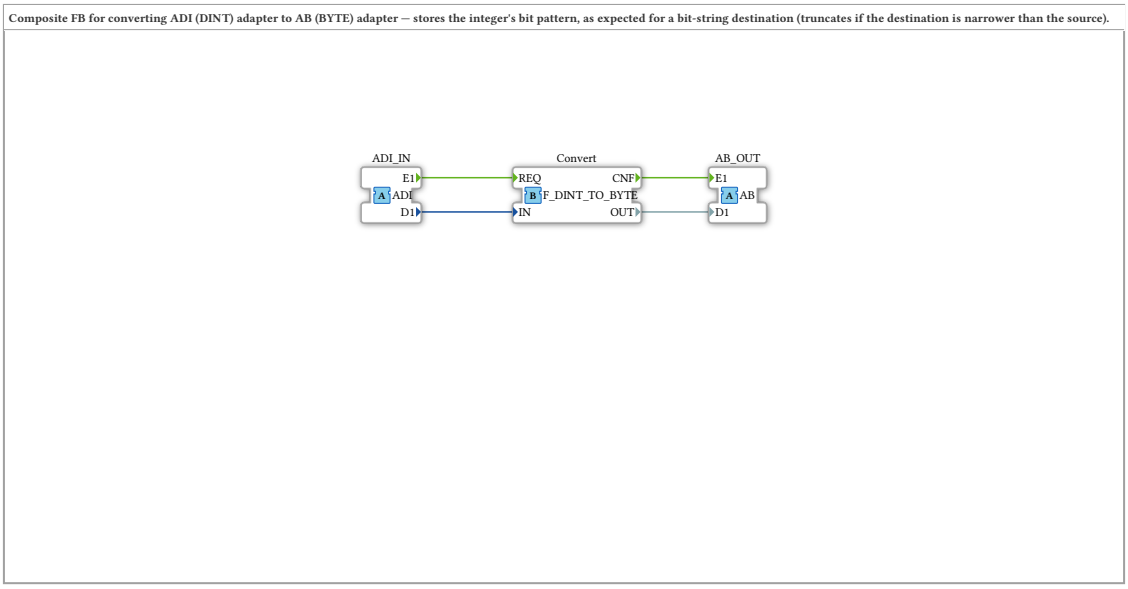
Comparison with similar modules

- **AB_TO_AI** – Converts BYTE to INT (16-bit integer).
- **AB_TO_AREAL** – Converts BYTE to REAL.
- **AB_TO_ADI** – Specifically for BYTE to DINT (32-bit integer).



All these modules follow the same principle: Input and output are defined as unidirectional adapters that internally use a standard conversion function.

Conclusion



The FB `AB_TO_ADI` represents a minimalist and reliable solution for converting BYTE to DINT data. Its adapter interfaces enable seamless integration into modular control systems without requiring reimplementation of the underlying conversion logic. It is particularly suitable for applications that value a clear separation of communication protocols and data formats.

ADI_TO_AB

DINT Adapter Input – *ADI*

AB – BYTE Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The function block `ADI_TO_AB` serves as a composite module for converting a 32-bit integer value (DINT) into a byte value (BYTE). It encapsulates the conversion between two unidirectional adapters: the **ADI adapter** (input) and the **AB adapter** (output). The module is used to transfer data from a DINT adapter to a BYTE adapter without requiring the user to implement the actual conversion logic.

Interface Structure

Event Inputs

The module does not have direct event inputs. Event reception is handled via the **ADI_IN socket adapter**:

Adapter Port	Type	Description
ADI_IN.E1	Event	Starts the conversion at the input.

Event Outputs

Event output is also handled exclusively via the **AB_OUT plug adapter**:

Adapter Port	Type	Description
AB_OUT.E1	Event	Signals that the value has been converted and is ready at the output.

Data Inputs

The data is provided via the ADI_IN adapter:

Adapter Port	Type	Description
ADI_IN.D1	DINT	32-bit integer input value.

Data Outputs

The converted data is output via the AB_OUT adapter:

Adapter Port	Type	Description
AB_OUT.D1	BYTE	8-bit byte output value.

Adapters

Name	Direction	Adapter Type	Description

ADI_IN	Socket	`adapter::types::unidirectional::ADI`	DINT adapter as input.
AB_OUT	Plug	`adapter::types::unidirectional::AB`	BYTE adapter as output.

Functionality

Internally, the function block uses the predefined IEC 61131-3 function block `F_DINT_TO_BYTE` to perform the actual data type conversion. The event and data flows are as follows:

1. An event at **ADI_IN.E1** triggers the conversion.
2. The data value from **ADI_IN.D1** is forwarded to the input `IN` of the internal `F_DINT_TO_BYTE` function block.
3. After the conversion is complete, the internal function block generates the event **CNF**.
4. This event is output as **AB_OUT.E1**.
5. Simultaneously, the converted value is available at the output `OUT` of the internal function block and is output via **AB_OUT.D1**.

All the logic is encapsulated in a composite function block, so the user only needs to connect the adapters.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Function Block**: The function block consists of an internal network and does not have its own state machine (ECC). It performs the conversion strictly event-driven.
- **Use of IEC 61131-3 standard function blocks**: Conversion is performed using the standardized function block `F_DINT_TO_BYTE`, ensuring portability and compliance with industry standards.
- **Adapter-based input/output**: All data and events are routed via adapters – not individual ports. This simplifies integration with similar adapter interfaces in the 4diac environment.

State Overview

Since this is a composite function block without its own state machine, there are no explicit states. The function block reacts to the incoming event, converts the value, and outputs the result. After outputting the result, it is immediately ready for another conversion.

Application Scenarios

- **Data Protocol Adaptation**: When a sensor or controller delivers DINT values, but the connected device or communication channel expects BYTE values.
- **Adapter Mediation**: In a modular architecture that allows the exchange of adapters with different data types without having to rewrite the connection logic each time.
- **Interface Coupling**: Between components that use unidirectional adapters, e.g., in a pipeline structure.

Comparison with Similar Components

There are numerous conversion components for direct data type conversions (e.g., `F_DINT_TO_INT`, `F_DINT_TO_WORD`). The `ADI_TO_AB` differs in that it uses complete adapters instead of individual data and event ports. This improves encapsulation and increases reusability. A similar concept exists for other data type pairs (e.g., `ADI_TO_AC` for DINT to CHAR) that follow the same design logic.

Conclusion

The function block `ADI_TO_AB` offers a cleanly encapsulated, adapter-based conversion of DINT to BYTE values. It uses standard IEC function blocks and event-driven control, allowing for seamless integration into 4diac projects. Its adapter interfaces make it particularly suitable for modular and reusable control applications.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AB_TO_AI

• – ○ • – ○ • – ○ •

Introduction

The **AB_TO_AI** is a composite function block for converting an **AB adapter (BYTE)** to an **AI adapter (INT)**. It enables the seamless integration of BYTE-based adapter interfaces into systems that expect INT values. Internally, the block uses the IEC 61131 conversion block `F_BYTE_TO_INT`.

Interface Structure

Event Inputs

The function block does not have direct event inputs. The event is provided via the connected adapter **AB_IN** (socket):

- **AB_IN.E1** – Event that triggers the conversion of an incoming BYTE value.

Event Outputs

The FB has no direct event outputs. The output event is sent via the connected adapter **AI_OUT** (Plug):

- **AI_OUT.E1** – Event indicating that the converted INT value is present at the output.

Data Inputs

The FB has no direct data inputs. The input value is provided via the adapter **AB_IN** (Socket):

- **AB_IN.D1** – BYTE value (0...255) to be converted into an INT value.

Data Outputs

The FB has no direct data outputs. The output value is provided via the adapter **AI_OUT** (Plug):

- **AI_OUT.D1** – INT value representing the converted BYTE.

Adapters

Name	Type	Direction	Description
AB_IN	`adapter::types::unidirectional::AB`	Socket (Input)	BYTE adapter that provides the value to be converted and the start event.
AI_OUT	`adapter::types::unidirectional::AI`	Plug (Output)	INT adapter that provides the converted value and the confirmation event.

Functionality

1. An incoming event on **AB_IN.E1** triggers the processing.
2. The BYTE value provided by **AB_IN.D1** is passed to the internal block `F_BYTE_TO_INT`.
3. `F_BYTE_TO_INT` performs the type conversion and provides the INT value at its output `OUT`.
4. After successful conversion, the event **AI_OUT.E1** is sent, and the INT value is available at **AI_OUT.D1**.

The conversion is performed without loss of value range: BYTE (0…255) is directly mapped to INT.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Composite Function Block:** The logic is implemented entirely through an internal network consisting of a single conversion block.
- **Reusable:** The block can be integrated into projects that require unidirectional adapter conversion.
- **License:** The block and its associated materials are licensed under the **Eclipse Public License 2.0**.
- **Package:** `adapter::conversion::unidirectional`

State Overview

The function block (FB) does not have its own internal state machine. Its behavior is determined solely by the triggering events and the embedded block `F_BYTE_TO_INT`. There are no persistent states.

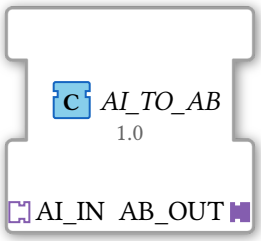
Application Scenarios

- **Sensor Connection:** A sensor delivers data as BYTE via an AB adapter; downstream processing expects INT values via an AI adapter.
- **Protocol Adaptation:** In heterogeneous communication paths, BYTE-encoded information must be converted into an INT-based data model.
- **Adapter Mediation:** As an intermediary between two system components that use different adapter types.

Comparison with Similar Function Blocks

Direct conversion blocks like `F_BYTE_TO_INT` (IEC 61131) often exist, but these do not offer adapter event control. The **AB_TO_AI** encapsulates this conversion in a complete adapter-to-adapter transition with event propagation. Similar blocks for other data types (e.g., WORD to DINT) could be built according to the same pattern.

Conclusion



The **AB_TO_AI** is a useful and simple function block that bridges the gap between BYTE- and INT-based adapter interfaces. It facilitates the integration of components with different data type interfaces in the 4diac IDE and follows proven design patterns of the IEC 61499 standard. Thanks to its composite structure, it is easily extensible and can serve as a template for similar adapter conversions.

AI_TO_AB

INT Adapter Input – *AI*

AB – BYTE Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The composite function block `AI_TO_AB` converts an **INT** value, provided via a unidirectional **AI** adapter, into a **BYTE** value and forwards it via a unidirectional **AB** adapter. The actual conversion is performed by the internally used function block `F_INT_TO_BYTE`. This function block is part of an adapter conversion library and enables the seamless integration of components with different data types in IEC 61499 systems.

Interface Structure

Event Inputs

No standalone event inputs. Event-driven communication is handled via the AI_IN adapter (see Adapters).

Event Outputs

No standalone event outputs. Event-driven output is handled via the AB_OUT adapter (see Adapters).

Data Inputs

No standalone data inputs. The INT value to be converted is provided via the AI_IN adapter.

Data Outputs

No standalone data outputs. The converted BYTE value is output via the AB_OUT adapter.

Adapters

Direction	Name	Type	Description
Socket (Input)	`AI_IN`	`adapter::types::unidirectional::AI`	Provides the INT input value (D1) and the triggering event (E1).

Plug (Output)	AB_OUT	adapter::types::unidirectional::AB	Outputs the converted BYTE value (D1) and the associated event (E1).

Functionality

The FB AI_TO_AB operates as a pure data converter based on event control:

1. An event **E1** is received at the **AI_IN** adapter.
2. This event triggers the internal FB Convert of type F_INT_TO_BYTE via its **REQ** input.
3. Simultaneously, the INT data value from AI_IN.D1 is forwarded to the **IN** input of Convert.
4. After the conversion is complete, Convert generates an acknowledgment event (**CNF**).
5. This event is sent to **AB_OUT.E1**, and the converted BYTE value (Convert.OUT) is passed to **AB_OUT.D1**.

Thus, every incoming INT value is synchronously converted into a BYTE value via an event and made available through the output adapter.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite FB:** The function block encapsulates the logic in a network consisting of a single conversion function block. It is not itself an elementary function block but utilizes the reuse of F_INT_TO_BYTE.
- **Adapter-Based Interface:** Events and data are transmitted exclusively via unidirectional adapters, resulting in loose coupling between source and target components.
- **Type Conversion:** The actual conversion of INT -> BYTE follows the IEC 61131-3 convention (e.g., value range <0,255>; an overflow occurs if the range is exceeded). This depends on the implementation of the F_INT_TO_BYTE function block used.
- **No Internal State Machine:** The function block is purely combinatorial with event-driven execution.

State Overview

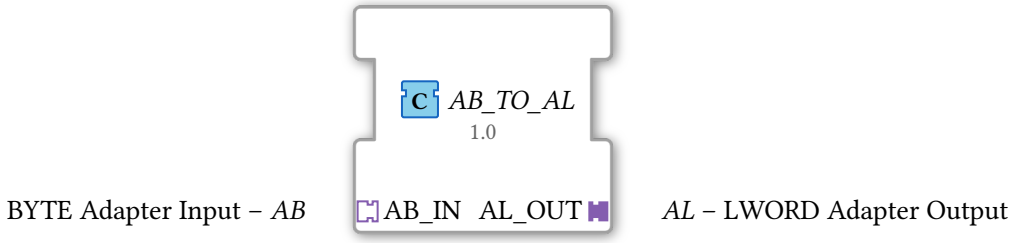
Since it is a composite function block, AI_TO_AB does not have its own state machine. The internal function block F_INT_TO_BYTE may have a simple state machine (IDLE, EXECUTING), depending on the implementation, but this is not visible within the scope of this function block. The data and event flows are deterministic and are controlled by the interaction of the connections.

Application Scenarios

- **Sensor Connection:** A sensor delivers INT values that must be processed as BYTE by a control unit (e.g., for simple I/O cards).
- **Data Format Conversion:** in heterogeneous IEC 61499 systems to connect components with different adapter types.
- **Adapter Translation:** in libraries designed for unidirectional communication, e.g., when using fieldbus protocols that expect BYTE-oriented data.

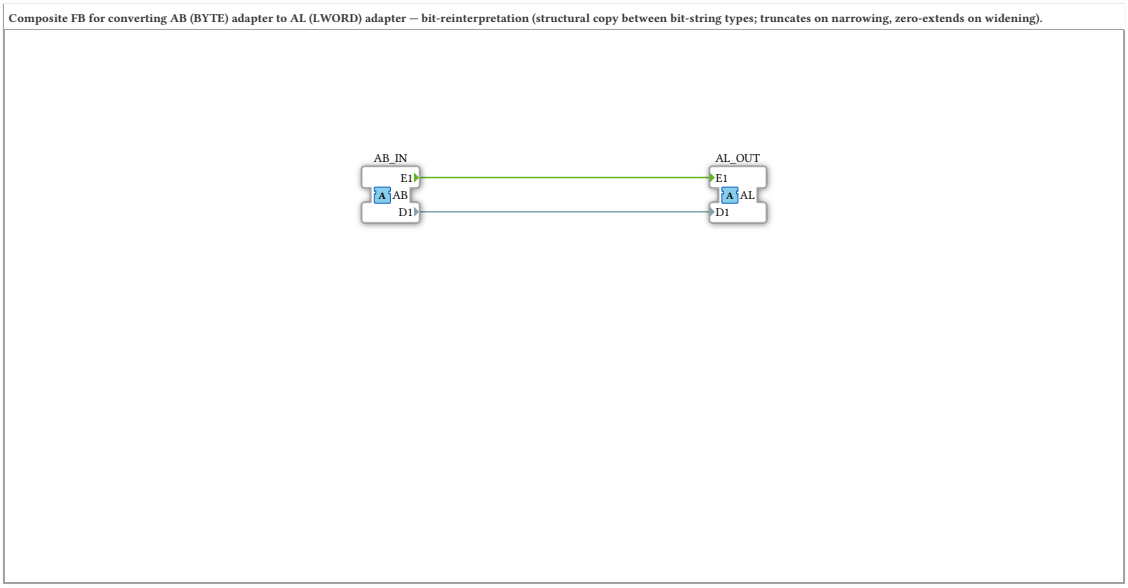
Comparison with Similar Components

- **Direct Converters (e.g., F_INT_TO_BYTE):** These operate at the data port level and require explicit event control. AI_TO_AB encapsulates this in an adapter-based interface.
- **Additional Adapter Converters:** Possible modules include AI_TO_AW (INT to WORD) or AB_TO_AI (BYTE to INT). AI_TO_AB is specifically designed for combining the two unidirectional adapters AI and AB.
- **Composite Converters vs. Elementary Converters:** Composite function blocks offer a higher level of abstraction and reusability, while elementary function blocks allow more control over the internal logic.



Conclusion

The composite function block AI_TO_AB provides an efficient, adapter-based solution for converting INT to BYTE values. It simplifies the integration of components with different data types into IEC 61499 applications by encapsulating the conversion logic in a standardized, reusable interface. Event-driven execution and the use of an established conversion block ensure reliable and deterministic data processing.



Numeric Index (unidirectional)

AB_TO_AL

BYTE Adapter Input – *AB* — *AL* – LWORD Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block `AB_TO_AL` is a composite block for converting a unidirectional BYTE adapter (type `AB`) into a unidirectional LWORD adapter (type `AL`). It is used to convert data from an 8-bit data format to a 64-bit data format, thereby transferring the event control of the source adapter to the target adapter.

Interface Structure

Event Inputs

The block does not have direct event inputs. Incoming events are received indirectly via the socket adapter `AB_IN`. The adapter `AB` provides an internal event input (`E1`) that is connected to the event output of the target adapter.

Event Outputs

This function block does not have direct event outputs. The outgoing event flow is indirect via the plug adapter `AL_OUT`. The adapter `AL` provides an internal event output (`E1`) that is activated by the internal connection.

Data Inputs

Name	Data Type	Description
`AB_IN.D1`	BYTE	8-bit input value (via the socket adapter)

Data Outputs

Name	Data Type	Description
AL_OUT.D1	LWORD	64-bit output value (via the plug adapter)

Adapters

Name	Direction	Adapter Type	Description
AB_IN	Socket	adapter::types::unidirectional::AB	Input adapter, returns BYTE data and an event
AL_OUT	Plug	adapter::types::unidirectional::AL	Output adapter, expects LWORD data and passes on an event

Functionality

The component is implemented as a pure wiring (composite) circuit. Internally, the following connections are established:

- Event: AB_IN.E1 ⟶ AL_OUT.E1
- Data: AB_IN.D1 ⟶ AL_OUT.D1

As soon as an event arrives at the socket adapter AB_IN, the corresponding BYTE value (D1) is passed to the data output AL_OUT.D1, and simultaneously the event is forwarded to AL_OUT.E1. An implicit type conversion from BYTE (8 bits) to LWORD (64 bits) takes place – the upper 56 bits are padded with zeros. The component has no internal state logic or delay.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- **Pure Composite Block**: No algorithm, no state machine – functionality is derived solely from the internal wiring.
- **Unidirectional Adapters**: Data flow is only possible from AB_IN to AL_OUT; there is no reverse direction.
- **Automatic Type Conversion**: The 4diac IDE implicitly performs the conversion from BYTE to LWORD (big-endian extension with zeros).
- **No Parameters or Configuration**: The block requires no additional settings.

State Overview

As a composite block without its own state machine, there is no defined state. Its behavior is entirely determined by the incoming events and data of the socket adapter.

Application Scenarios

- **Interface Adaptation**: A sensor delivers BYTE data via an AB adapter, but the downstream system expects LWORD data via an AL adapter.
- **Data Preparation**: Simplified integration of 8-bit devices into 64-bit control architectures.
- **Protocol Conversion**: When events and data are encapsulated via adapters, AB_TO_AL can serve as a universal conversion stage.

Comparison with Similar Components

Other adapter conversion components exist, such as WORD_TO_DWORD, ARRAY_TO_STRUCT, or specific type converters. However, AB_TO_AL is distinguished by its complete encapsulation within adapters – both events and data are converted together. This simplifies the exchange of complete interfaces without the need to model separate data and event connections.

Conclusion

AB_TO_AL` is a simple yet useful composite building block for converting a BYTE adapter to an LWORD adapter. It reduces the modeling effort for type conversions in adapter-based networks and ensures that

events are passed on synchronously with the data. Due to its clearly defined interface, it is particularly well-suited for modular and reusable automation solutions.

AL_TO_AB

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AL_TO_AB** is a composite function block that enables unidirectional conversion from an LWORD adapter (AL) to a BYTE adapter (AB). It is used to convert data from an LWORD-based adapter to the format of a BYTE adapter, with the conversion being performed internally by the IEC 61131-3 block `F_LWORD_TO_BYTE`.

Interface Structure

Adapter (Input)

Name	Type	Description
AL_IN	`adapter::types::unidirectional::AL`	LWORD adapter socket. This adapter receives the LWORD data to be converted. By default, the adapter provides an event output `E1` and a data output `D1` (data type LWORD).

Adapter (Output)

Name	Type	Description
AB_OUT	`adapter::types::unidirectional::AB`	BYTE adapter plug. This adapter outputs the converted BYTE data. The adapter has an event input `E1` and a data input `D1` (data type BYTE).

Note: The function block (FB) has no separate event or data inputs/outputs; all communication takes place via the two adapter interfaces.

Functionality

1. An event (at the adapter's event output `E1`) is received via socket `AL_IN`, which simultaneously provides an LWORD value via data output `D1`.
2. This event internally triggers the function block `F_LWORD_TO_BYTE` (type: `iec61131::conversion::F_LWORD_TO_BYTE`), which converts the LWORD value into a BYTE value.
3. After successful conversion, `F_LWORD_TO_BYTE` signals completion via its event output `CNF`, which forwards the event to plug `AB_OUT`.
4. Simultaneously, the converted BYTE value is transferred via the converter's data output `OUT` to the data input `D1` of `AB_OUT`.
5. The connected receiver on plug `AB_OUT` thus receives the event and the converted data value.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- **Integration of IEC 61131-3**: The conversion uses the standardized function block `F_LWORD_TO_BYTE` from the IEC 61131-3 library. This ensures that the conversion logic is standards-compliant and portable.
- **Composite Structure**: The function block consists exclusively of an internal network, has no independent state (ECC), and therefore operates in an event-driven manner without delay.
- **Unidirectional Adapters**: The unidirectional adapters `AL` and `AB` are used, which define a clear direction for data and event flows.
- **Package Structure**: The function block is organized in the package `adapter::conversion::unidirectional`, which facilitates reuse in modular projects.

State Overview

The function block does not have its own state machine. The entire process control is managed via the event chain of the internal network. Therefore, status monitoring is not required.

Application Scenarios

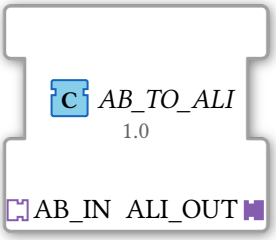
- **Protocol Adaptation**: When an adapter in a distributed system that delivers LWORD data needs to be replaced by an adapter that only processes BYTE data.
- **System Integration**: Coupling components that use different adapter formats (e.g., AL and AB adapters) without modifying the original components.
- **Data Reduction**: Targeted conversion of 64-bit LWORD to 8-bit BYTE when the higher bytes are not needed or a narrower interface is required.

Comparison with Similar Components

Component	Function	Difference
`LWORD_TO_BYTE`	Pure data type conversion without adapters	No adapter interface; direct data and event ports
AB_TO_AL`	Reverse conversion (BYTE → LWORD)	Opposite direction; also composite with adapters
WORD_TO_BYTE`	Conversion from WORD (16-bit) to BYTE	Different data type; similar structure, but different adapter types

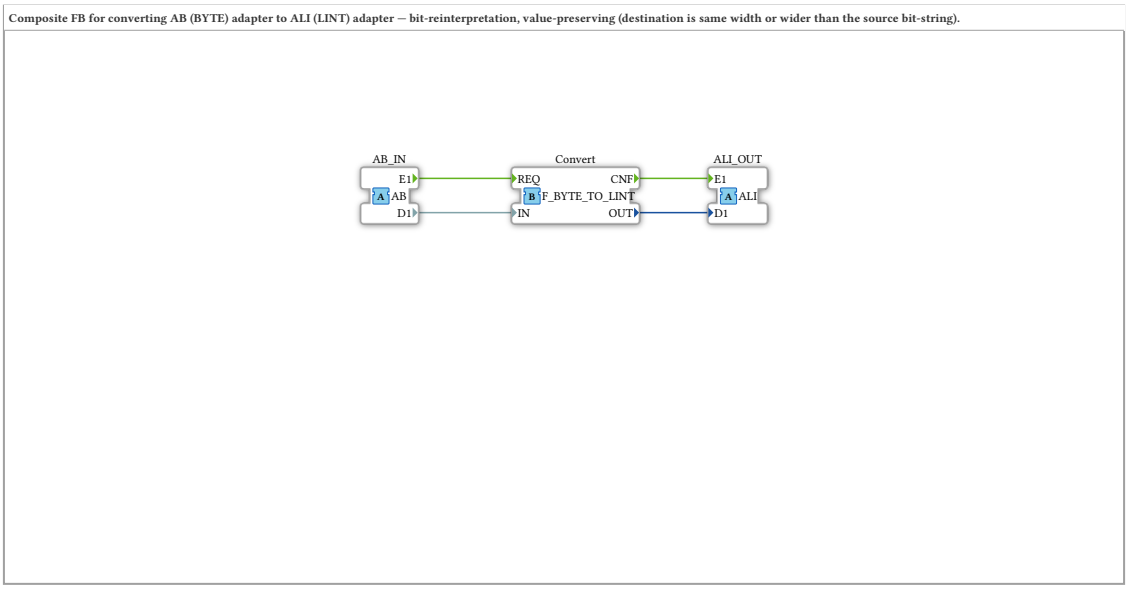
The **AL_TO_AB** is specifically designed for use with the unidirectional adapters `AL` and `AB` and offers clean, reusable encapsulation.

Conclusion



The `AL_TO_AB` function block provides a simple yet effective solution for converting an LWORD adapter signal into a BYTE adapter signal. By using a standardized IEC 61131-3 converter and a consistent adapter interface, it is easily integrated into existing systems and promotes a modular, maintainable design.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AB_TO_ALI

BYTE Adapter Input – *AB*

ALI – LINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block `AB_TO_ALI` is a composite function block that performs conversion from a BYTE adapter (`AB`) to a LINT adapter (`ALI`). It enables seamless integration between interfaces based on different data types and provides data transfer via standardized adapters.

Interface Structure

Event Inputs

The function block has no direct event inputs. Events are received via the socket adapter `AB_IN`.

Event Outputs

The function block has no direct event outputs. Events are output via the plug adapter `ALI_OUT`.

Data Inputs

No direct data inputs for the function block. Data is received via the socket adapter `AB_IN`.

Data Outputs

No direct data outputs for the function block. Data is output via the plug adapter `ALI_OUT`.

Adapters

- **Socket `AB_IN`** (Type: `adapter::types::unidirectional::AB`)

Receives a BYTE signal (via data port `D1`) and an event (via event port `E1`).

- **Plug `ALI_OUT`** (Type: `adapter::types::unidirectional::ALI`)

Sends a LINT signal (via data port `D1`) and an event (via event port `E1`).

Functionality

The function block operates as a pure data conversion loop:

1. An incoming event at socket `AB_IN` (port `E1`) triggers the internal conversion module `F_BYTE_TO_LINT`.
2. The BYTE value (`D1`), also present at the socket, is passed to the input `IN` of the converter.
3. The converter transforms the BYTE value into a LINT value and makes it available at its output `OUT`.
4. The converter's acknowledgment event (`CNF`) is forwarded to the plug `ALI_OUT` (port `E1`), and the converted LINT value is output on the plug's data port `D1`.

Technical Features

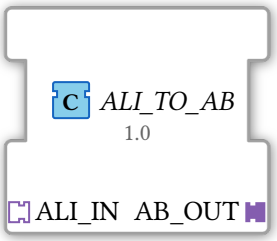
- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- This is a **composite function block** that internally uses the standard function block `iec61131::conversion::F_BYTE_TO_LINT`.
- The conversion is **event-driven** – any change at the input triggers processing.
- The function block is designed for unidirectional adapters and does not support reverse conversion.
- The adapter type information (`AB` and `ALI`) is defined as unidirectional interfaces and each contains one event port and one data port.

State Overview

The function block does not have its own state machine. The conversion is **stateless** – with each incoming event, the current value is immediately converted and output. There is no delay, buffering, or internal state.

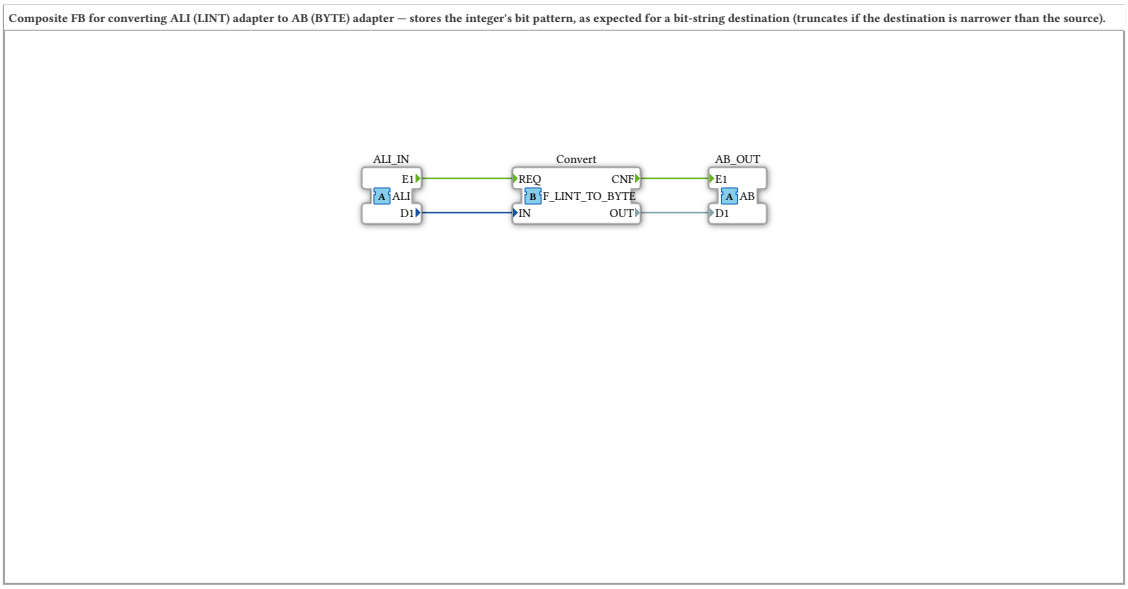
Application Scenarios

- **Integration of fieldbus systems** or sensors that deliver BYTE data into a control environment that expects LINT values (e.g., for further processing in counters or long integer operations).
- **Adapter conversion** in modular function block networks where the interfaces use different data types (e.g., in agricultural or automation technology).
- **Bridging** between older BYTE-based modules and modern LINT-based components.



Comparison with Similar Function Blocks

- `AB_TO_ALI` is specifically for converting **BYTE** to **LINT**. Analogous function blocks exist for other data type combinations (e.g., `WORD_TO_DINT`, `BYTE_TO_INT`).
- Unlike generic converters or scaling blocks, this function block is optimized for a fixed type conversion and requires no parameterization.
- The use of adapters instead of direct input/output ports enables greater reusability and a clean separation of interfaces.



Conclusion

The `AB_TO_ALI` function block offers a simple and reliable way to convert BYTE data to LINT data via an adapter. By using standard conversion modules and a clear event-driven architecture, it is ideally suited for modular automation systems that require consistent data conversion between different adapter types.

ALI_TO_AB

LINT Adapter Input – *ALI* *AB* – BYTE Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **ALI_TO_AB** function block is a composite function block (FB) according to IEC 61499-2, used to convert a LINT value (64-bit integer) into a BYTE value (8-bit). The conversion is performed via two unidirectional adapter interfaces: The ALI_receiver (socket) receives a LINT value, and the AB_sender (plug) transmits the converted BYTE value. Internally, the conversion block `F_LINT_TO_BYTE` from the IEC 61131 library is used.

Interface Structure

Event Inputs

The FB has no direct event inputs. Events are received exclusively via the **ALI_IN** adapter (socket).

Event	Description
E1 (via ALI_IN)	Signal to trigger the conversion.

Event Outputs

The FB has no direct event outputs. Events are sent exclusively via the **AB_OUT** adapter (plug).

Event	Description
E1 (via AB_OUT)	Acknowledgement after successful conversion.

Data Inputs

The FB has no direct data inputs. Data is provided exclusively via the **ALI_IN** adapter (socket).

Data	Type	Description

D1 (via ALI_IN)	LINT	64-bit integer to be converted.

Data Outputs

The FB has no direct data outputs. Data is output exclusively via the **AB_OUT** adapter (plug).

Data	Type	Description
D1 (via AB_OUT)	BYTE	8-bit converted value.

Adapters

Adapter	Direction	Type	Description
ALI_IN	Socket (Input)	`adapter::types::unidirectional::ALI`	Receives the LINT value and an associated event.
AB_OUT	Plug (Output)	`adapter::types::unidirectional::AB`	Outputs the converted BYTE value and an acknowledgment event.

Functionality

1. The function block waits for an event at the **ALI_IN** adapter (E1).
2. As soon as the event arrives, the data value D1 (LINT) is passed to the internal conversion block `F_LINT_TO_BYTE` and converted into a BYTE value.
3. After the conversion is complete, the BYTE value is output via the **AB_OUT** adapter (D1) and the acknowledgment event (E1) is sent.

The conversion from LINT (64 bits) to BYTE (8 bits) is performed by truncating the 8 least significant bits. Higher-order bits are lost in the process.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Type Conversion with Loss of Value:** Since LINT is 64 bits wide, but BYTE is only 8 bits, only the lower 8 bits of the LINT value are retained. A value range of 0 to 255 is correctly represented; larger numbers are reduced modulo 256.
- **Pure Adapter Interface:** The component has no direct inputs/outputs, but communicates exclusively via two unidirectional adapters. This enables loose coupling in adapter-based architectures.
- **Standard Compliance:** The function block (FB) is based on the IEC 61131 block `F_LINT_TO_BYTE` and can therefore be used in environments that support this library.

State Overview

As a composite block, **ALI_TO_AB** does not have its own internal state machine. The states of the included `F_LINT_TO_BYTE` (e.g., IDLE, BUSY) are not visible to the user. The FB therefore behaves like a combinational or event-driven function without an explicit state mask.

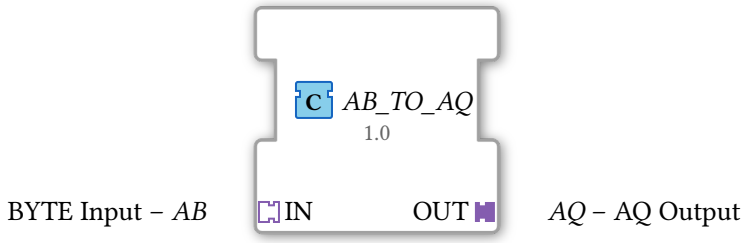
Application Scenarios

- **Adapter-Based Data Conversion:** In systems connected via adapters with ALI and AB interfaces, ALI_TO_AB can be used as a bridge between a LINT-supplying module and a BYTE-receiving module.
- **Data Width Reduction:** This function block is suitable when a 64-bit value (e.g., a counter reading) needs to be mapped to an 8-bit signal (e.g., a simple status byte).
- **Protocol Conversion:** In heterogeneous control systems using different adapter types, ALI_TO_AB enables simple type conversion.

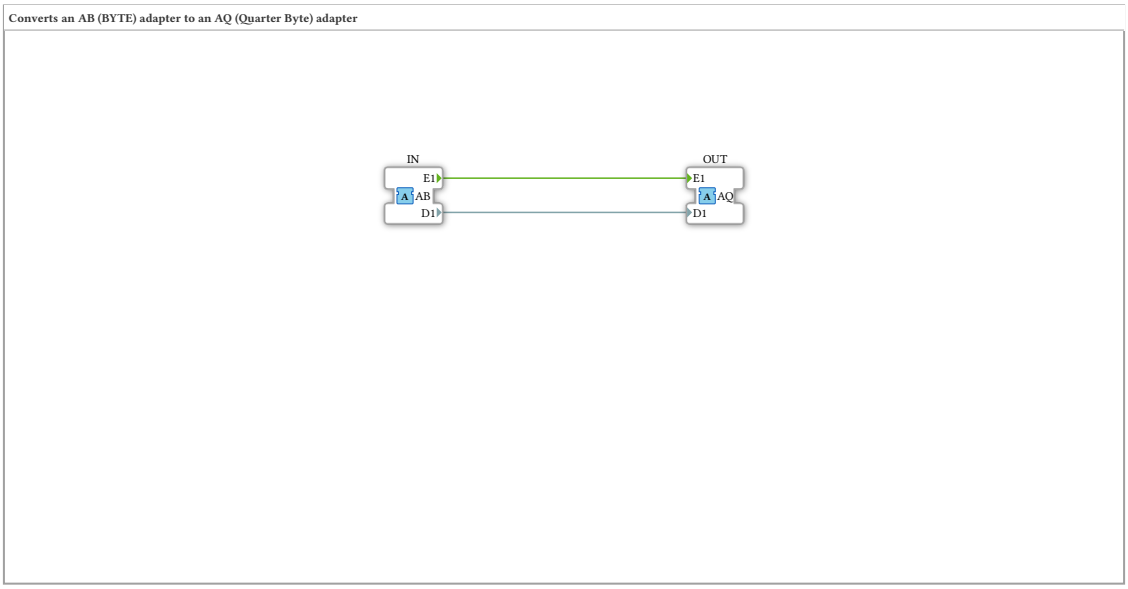
Comparison with Similar Function Blocks

- **ALI_TO_Ax (LINT to ANY):** A more general converter that converts LINT to any other data type. ALI_TO_AB is specialized for BYTE and is therefore simpler and more direct.
- **F_LINT_TO_BYTE:** The underlying IEC 61131 function block. ALI_TO_AB encapsulates this in an adapter-based interface, allowing its use in environments that only support adapter communication.

- **Direct Adapter Connection:** Without conversion, an ALI adapter could not be directly connected to an AB adapter. ALI_TO_AB closes this gap.



Conclusion



ALI_TO_AB is a simple yet useful conversion block for adapter-based communication. It enables the conversion of a LINT value to a BYTE value using a standardized IEC 61131 block. Its complete encapsulation within two unidirectional adapters allows for seamless integration into adapter networks without requiring the user to implement the internal type conversion. The loss of value due to the reduced data width should be considered when using this feature.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AB_TO_AQ

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_TO_AQ** converts a unidirectional adapter of type **AB (BYTE)** to an adapter of type **AQ (Quarter Byte)**. It directly passes an event and a data value from the input interface to the output interface, implicitly reducing the data width from 8 bits to 2 bits.

Interface Structure

Event Inputs

- **IN.E1** (via adapter IN): Event input of the BYTE adapter.

Event Outputs

- **OUT.E1** (via adapter OUT): Event output of the Quarter Byte adapter.

Data Inputs

- **IN.D1** (via adapter IN): Data input of the BYTE adapter (1 byte).

Data Outputs

- **OUT.D1** (via adapter OUT): Data output of the quarter-byte adapter (1 quarter byte).

Adapters

Adapter	Direction	Type	Description
IN	Socket	`adapter::types::unidirectional::AB`	BYTE input adapter (8 bits)
OUT	Plug	`adapter::types::unidirectional::AQ`	Quarter-byte output adapter (2 bits)

Functionality

This function block forwards an incoming event (E1) and the associated data (D1) directly from the IN adapter to the OUT adapter. No internal processing or state changes occur; the data is simply passed through. The conversion from an 8-bit to a 2-bit format is determined by the different adapter types – typically, the least significant bits (LSB) of the BYTE value are converted to the quarter byte, unless otherwise specified.

Technical Features

- Pure pass-through block without its own state logic (no ECC).
- Event and data paths are directly connected: `IN.E1 → OUT.E1` and `IN.D1 → OUT.D1`.
- Data reduction from 8 bits to 2 bits is achieved solely through type conversion; explicit conversion (e.g., truncation or rounding) is not implemented in the function block itself.
- The block is designed as a unidirectional adapter converter and does not support bidirectional communication.

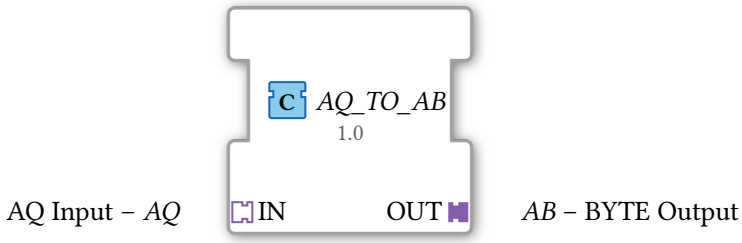
State Overview

There is no state machine. The function block (FB) operates purely combinatorially: Every event at the input is immediately forwarded as an event at the output, accompanied by the current data value.

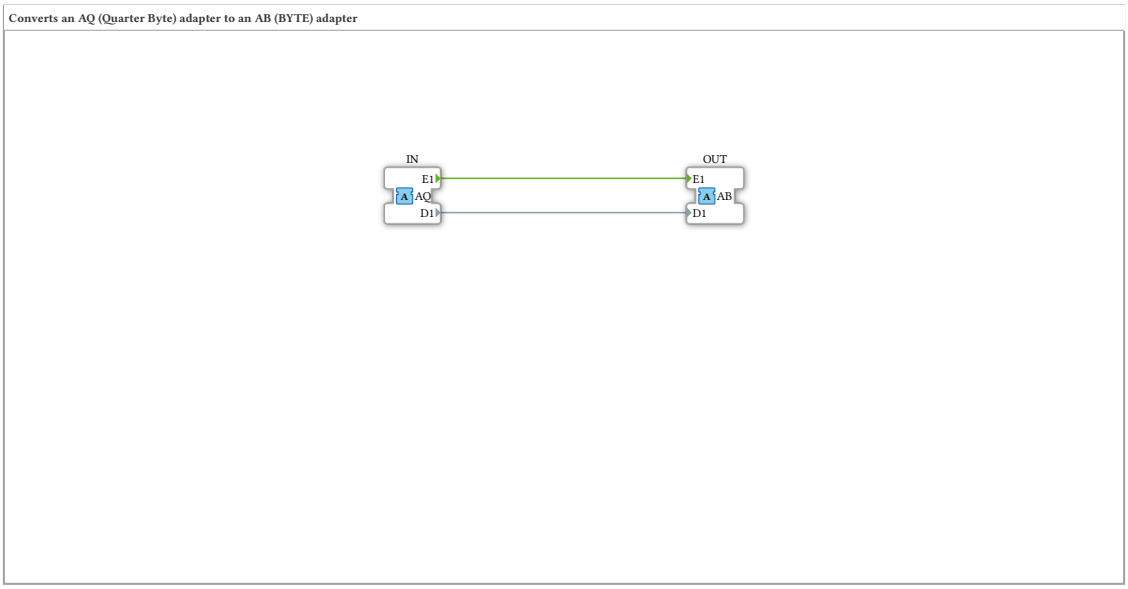
Application Scenarios

- Connecting a byte-oriented interface to logic that processes only two-bit wide data (e.g., status bits or switching signals).
- Reducing the data width in an adapter cascade when the original byte information can be compressed to the lower two bits.
- Test and simulation environments where different adapter formats need to be interconnected.

Comparison with Similar Function Blocks



- **AB_TO_AQ** is similar to other unidirectional adapter converters such as `AB_TO_AB` (identical types) or `AQ_TO_AB` (extension to one byte). The difference lies in the data width and the type of implicit conversion.



AB_TO_AQ Unlike converters with explicit algorithms (e.g., scaling or bit masking), this function block offers no configuration options – the conversion is fixed.

Conclusion

The **AB_TO_AQ** function block is a simple yet useful adapter converter that establishes a direct electrical and logical connection between two different unidirectional adapter types. It is ideally suited for situations where byte information needs to be reduced to the two most important bits and passed on without generating additional processing overhead.

AQ_TO_AB

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AQ_TO_AB` converts an AQ adapter (Quarter Byte) to an AB adapter (BYTE). It enables the seamless connection of components using different adapter interfaces by passing the signals through unchanged. The block is implemented as a pure “pass-through” function block that does not manipulate any data.

Interface Structure

Event Inputs

The function block has no explicit top-level event inputs. Events are transmitted via the adapter interfaces.

Event Outputs

The function block has no explicit top-level event outputs. Events are transmitted via the adapter interfaces.

Data Inputs

The FB has no explicit top-level data inputs. Data transmission occurs via the adapter interfaces.

Data Outputs

The FB has no explicit top-level data outputs. Data transmission occurs via the adapter interfaces.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AQ`	IN	Input (Socket)	AQ adapter as input interface for quarter-byte data

`adapter::types::unidirectional::AB`	OUT	Output (Plug)	AB adapter as output interface for byte data

Functionality

The function block internally connects the event and data channels of the input adapter `IN` directly to the corresponding channels of the output adapter `OUT`. Specifically, the following connections are established:

- Event connection: `IN.E1` ⟶ `OUT.E1`
- Data connection: `IN.D1` ⟶ `OUT.D1`

Thus, all incoming events and data from the AQ adapter are passed on to the AB adapter unchanged. The function block itself does not process or convert the user data – it functions solely as an interface adapter.

Technical Features

- **Unidirectional Data Flow:** The function block supports only one direction (AQ ⟶ AB).
- **No State Change:** Since no logic or memory is present, this is a purely combinational function block.
- **Simple Loop-Through:** The implementation is limited to two direct connections in the FBNetwork.
- **Adapter Conversion:** The function block allows the integration of AQ-compatible components into a system that expects AB adapters without requiring any modifications to the connected function blocks.

State Overview

The function block does not have a state machine. Its behavior is deterministic: Every incoming event immediately triggers the corresponding output event, and every incoming data value is forwarded to the output without delay.

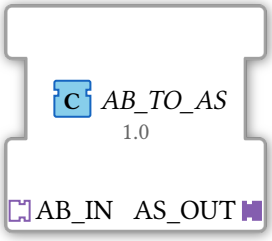
Application Scenarios

- **System Integration:** Connecting a sensor module with an AQ interface to a controller that uses AB adapters.
- **Protocol Implementation:** Use in libraries to make different adapter types compatible.
- **Test Environments:** Use as a simple adapter in test setups to adapt interfaces.

Comparison with Similar Function Blocks

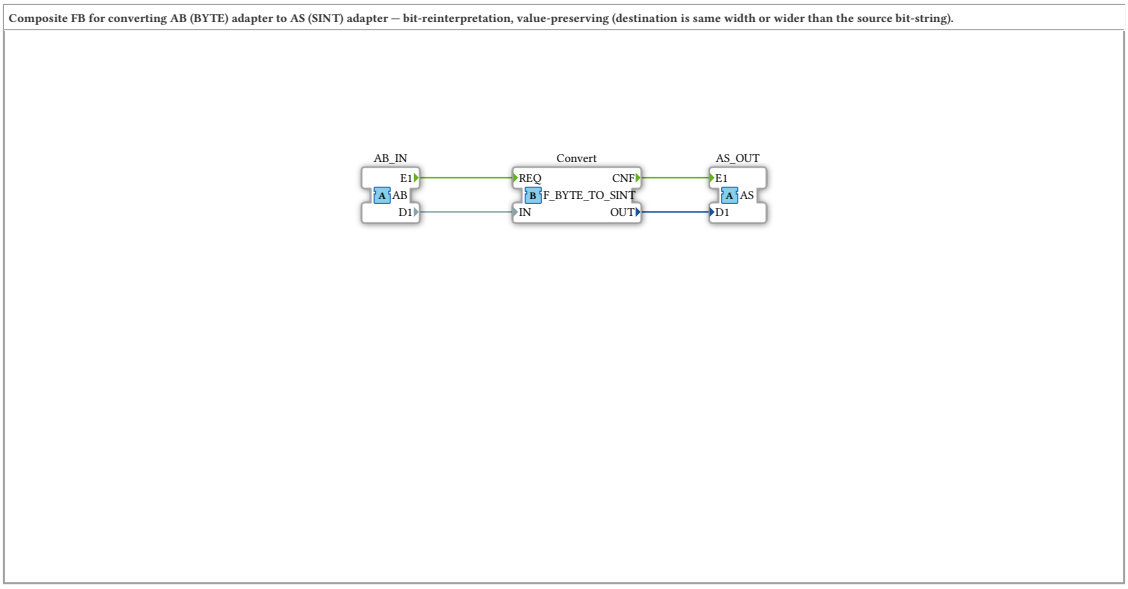
- **AB_TO_AQ:** Performs the reverse conversion (AB ⟶ AQ).
- **AQ_TO_BYTE_EXT:** A hypothetical function block that additionally performs data conversions (e.g., scaling, formatting), while `AQ_TO_AB` only changes the interface.
- **Generic Adapter Wrappers:** Other platforms often offer generic conversion blocks, but these require more complex configuration. `AQ_TO_AB` is specialized and therefore very lightweight.

Conclusion



The function block `AQ_TO_AB` offers a lean and efficient solution for adapter conversion from AQ to AB. Its simple pass-through structure makes it reliable, resource-efficient, and ideal for situations where only the interface type needs to be changed without affecting the signals. It is particularly suitable for modular systems with different adapter standards.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AB_TO_AS

BYTE Adapter Input – *AB*

AS – SINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AB_TO_AS** is a composite function block (FB) that converts a unidirectional AB adapter (BYTE) into a unidirectional AS adapter (SINT). It serves as a conversion bridge between two different data types in an IEC 61499-based control application.

Interface Structure

The FB does not have its own top-level event or data ports. All communication takes place via two adapter interfaces:

Event Inputs

- **E1** (via **AB_IN**, socket, type `adapter::types::unidirectional::AB`)

This event is received by the connected source adapter and triggers the conversion of a BYTE value to a SINT value.

Event Outputs

- **E1** (via **AS_OUT**, Plug, Type `adapter::types::unidirectional::AS`)

This event is sent to the target adapter after successful conversion to signal the new SINT value.

Data Inputs

- **D1** (BYTE, via **AB_IN** adapter)

Contains the BYTE value to be converted. It is sampled at the input via the **E1** event.

Data Outputs

- **D1** (SINT, via **AS_OUT** adapter)

Provides the converted SINT value. It becomes valid at the output after the conversion is complete with the **E1** event.

Adapters

Adapter	Direction	Type	Description
AB_IN	Socket (Input)	`adapter::types::unidirectional::AB`	Receives BYTE data and a trigger event from the source system.

AS_OUT	Plug (Output)	`adapter::types::unidirectional::AS`	Provides the converted SINT data with an acknowledgment event to the target system.

Functionality

The **AB_TO_AS** function block internally contains a single function module of type `iec61131::conversion::F_BYTE_TO_SINT`. This module performs the actual data type conversion from BYTE to SINT.

1. An incoming event **AB_IN.E1** triggers the **F_BYTE_TO_SINT** function block via its **REQ** input.
2. Simultaneously, the data value from **AB_IN.D1** (BYTE) is placed on the **IN** input of the converter.
3. After processing, the converter signals its **CNF** event, which is forwarded to the adapter output **AS_OUT.E1**.
4. The converted SINT value is transferred from the **OUT** output of the converter to **AS_OUT.D1**.

This implements an asynchronous, event-driven translation of a BYTE value into a SINT value.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Composite FB**: The logic is completely encapsulated within the internal FB network structure. This facilitates maintenance and reuse.
- **License**: This module is provided under the **Eclipse Public License 2.0** (SPDX license identifier: EPL-2.0).
- **Version**: 1.0, released 2026.
- **Dependencies**: The internal converter module `F_BYTE_TO_SINT` from the library `iec61131::conversion` is required.

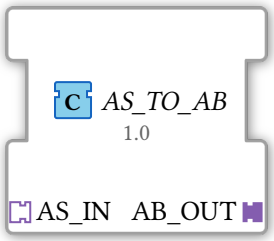
State Overview

The **AB_TO_AS** module does not have its own state machine. Processing is purely data-flow and event-driven via the embedded **F_BYTE_TO_SINT** module. Therefore, there are no explicit states, only the implicit processes: *Waiting for input event*, *Conversion active*, and *Output event sent*.

Application Scenarios

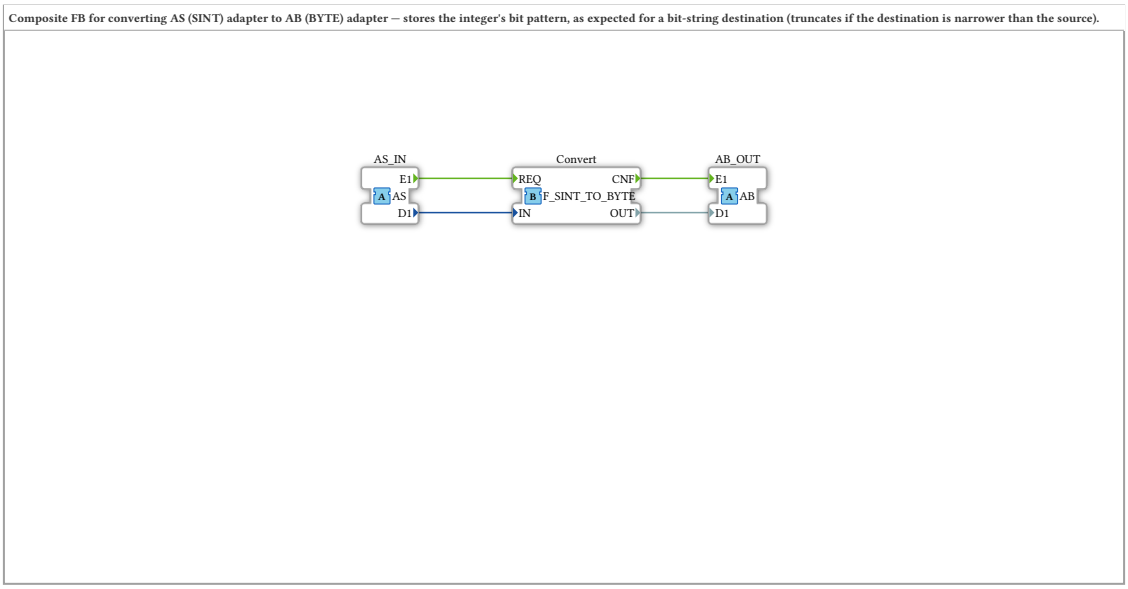
- **System Integration**: Connecting two subsystems that use different adapter data types (BYTE vs. SINT).
- **Data Format Conversion**: When an existing control algorithm expects SINT values, but the source only provides BYTE adapters.
- **Protocol Adaptation**: In heterogeneous automation environments where function blocks from different manufacturers or libraries need to be combined.

Comparison with Similar Function Blocks



- **F_BYTE_TO_SINT** (Direct Function Block): Offers the same conversion logic, but without adapter encapsulation. Requires manual wiring of event and data lines.
- **AB_TO_INT** or **AB_TO_USINT**: Similar adapter converters for other target data types. **AB_TO_AS** is specifically designed for SINT.
- **Custom Implementation**: The composite design allows for easy extension, e.g., by adding plausibility checks or scaling, without changing the basic functionality.

Company Implementation



Conclusion

The **AB_TO_AS** is a specialized yet simple composite function block that offers a clean and reusable solution for adapter-based data type conversion from BYTE to SINT. By utilizing a standardized converter block and clear event control, it integrates seamlessly into IEC 61499 networks. Its licensing under EPL 2.0 promotes open use and further development.

AS_TO_AB

SINT Adapter Input – *AS* *AB* – BYTE Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AS_TO_AB** is a composite function block that converts an AS adapter (SINT) into an AB adapter (BYTE). It serves as a bridge between different adapter types and enables data type conversion within an adapter-based communication chain. The block internally uses the IEC 61131 function **F_SINT_TO_BYTE** and is implemented as a pure data converter without state logic.

Interface Structure

Since the function block does not have direct event or data ports, inputs and outputs are provided via the following adapters:

Event Inputs

Port	Description
`AS_IN.E1`	Starts the conversion of a SINT value.

Event Outputs

Port	Description
`AB_OUT.E1`	Signals the completion of the conversion.

Data Inputs

Port	Data Type	Description
`AS_IN.D1`	SINT	The value to be converted (Signed Short Integer).

Data Outputs

Port	Data Type	Description
AB_OUT.D1	BYTE	The converted value (byte).

Adapter

Label	Type	Direction	Comment
AS_IN	adapter::types::unidirectional::AS	Socket (Input)	SINT Adapter Input
AB_OUT	adapter::types::unidirectional::AB	Plug (Output)	BYTE Adapter Output

Functionality

1. An incoming event on AS_IN.E1 triggers processing.
2. The current value of AS_IN.D1 (SINT) is read.
3. The internal instance F_SINT_TO_BYTE performs the conversion to a BYTE value.
4. After successful conversion, an event is output on AB_OUT.E1, and the calculated BYTE value is made available on AB_OUT.D1.

The conversion strictly adheres to IEC 61131 semantics: The SINT value is mapped bitwise to the BYTE data type, without any sign or range considerations (since SINT comprises 8 bits, identical to BYTE).

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite FB**: The function block encapsulates the conversion logic and provides it as an adapter converter.
- **Unidirectional Adapters**: Both the input and output adapters are unidirectional – data flows in only one direction.
- **No Internal State**: The FB behaves like a pure function; each activation produces the correct result regardless of the previous state.
- **Dependency**: The function block imports the IEC 61131 function F_SINT_TO_BYTE, which must be available in the target environment.

State Overview

The FB has **no state diagram** – it is event-driven and performs a one-time conversion immediately upon each activation.

The internal element F_SINT_TO_BYTE is also stateless.

Application Scenarios

- **Adapter Coupling**: If a sensor or actuator provides an AS adapter (SINT), but the downstream system expects an AB adapter (BYTE), this function block (FB) is used as an intermediary.
- **Protocol Conversion**: In PLC or automation systems, different data types often need to be converted between adapters – specifically SINT ↔ BYTE.
- **Modularization**: The FB allows conversion logic to be encapsulated in reusable adapter blocks, instead of having to implement it anew in each application FB.

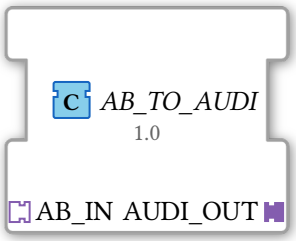
Comparison with Similar Function Blocks

- **AS_TO_WORD / AS_TO_INT**: Convert SINT to WORD or INT; AS_TO_AB specializes in BYTE.
- **Direct use of F_SINT_TO_BYTE**: The composite function block offers the advantage that the conversion is performed via adapter ports, eliminating the need for manual wiring of event and data flows.
- **Other adapter converters**: If similar adapter converters exist in the library (e.g., AB_TO_AS), this function block complements the unidirectional conversion in the opposite direction.

Conclusion

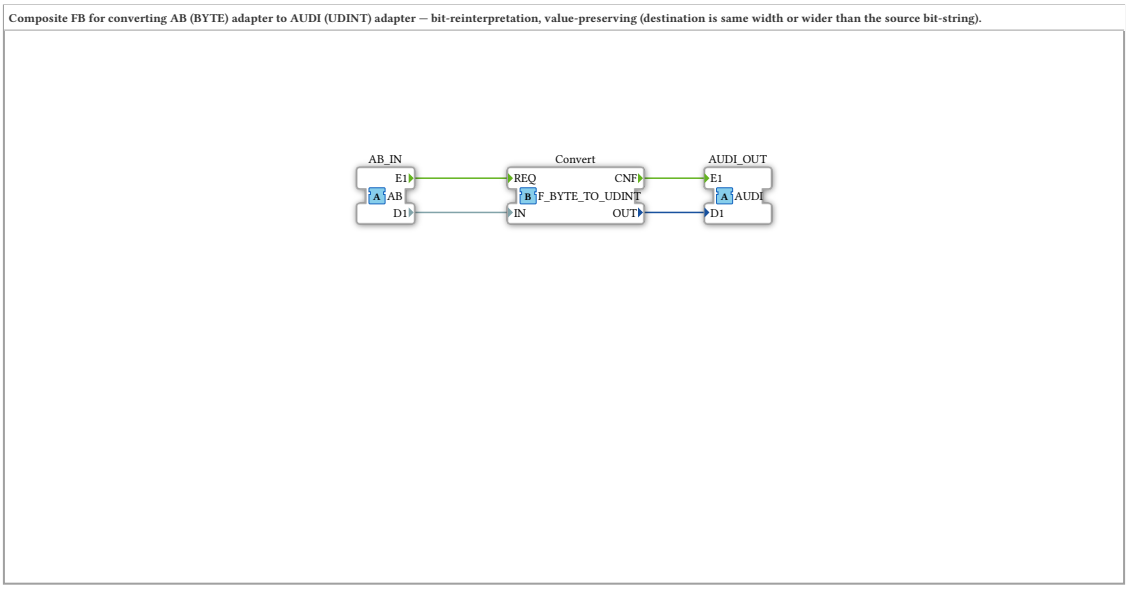
The **AS_TO_AB** function block is a simple yet useful converter for adapter-based architectures.

It allows the seamless integration of SINT and BYTE-communicating components without requiring the user to program the underlying conversion themselves.



Thanks to its composite structure, the logic remains clear and maintainable – ideal for use in industrial control systems according to IEC 61499.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AB_TO_AUDI

BYTE Adapter Input – *AB*

AUDI – UDINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AB_TO_AUDI** is a composite function block (FB) that converts an AB adapter (data type BYTE) into an AUDI adapter (data type UDINT). It serves as an interface between different data formats in an IEC 61499-based automation environment.

Interface Structure

The function block has no direct event or data input/output at the top level. Communication occurs exclusively via two adapters:

Event Inputs

- None (events are provided via the socket adapter `AB_IN`)

Event Outputs

- None (events are output via the plug adapter `AUDI_OUT`)

Data Inputs

- None (data is provided via the socket adapter `AB_IN`)

Data Outputs

- None (data is output via the plug adapter `AUDI_OUT`)

Adapter

- **`AB_IN`** (Socket) – Type: `adapter::types::unidirectional::AB`

Accepts a BYTE signal. The adapter provides an event `E1` and a data value `D1` (BYTE).

- **`AUDI_OUT`** (Plug) – Type: `adapter::types::unidirectional::AUDI`

Outputs the converted UDINT signal. The adapter expects an event `E1` and a data value `D1` (UDINT).

Functionality

The module internally uses a predefined conversion module `F_BYTE_TO_UDINT` from the IEC 61131 library. The process:

1. An event `E1` is received via socket `AB_IN`, triggering the start of the conversion.
2. Simultaneously, the corresponding BYTE data value from `AB_IN.D1` is forwarded to the converter `F_BYTE_TO_UDINT.IN`.
3. The converter calculates the UDINT value and outputs it at its output `OUT`.
4. The converter's acknowledgment event `CNF` is sent to the plug `AUDI_OUT.E1`.
5. The converted UDINT value is passed to the connected component via `AUDI_OUT.D1`.

This enables unidirectional BYTE-to-UDINT conversion with event-driven control.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Unidirectional Adapters**: Both the input and output adapters are unidirectional – data flows in only one direction (BYTE → UDINT).
- **Synchronous Operation**: The conversion is strictly event-driven: Each incoming event `E1` triggers exactly one conversion and one outgoing event.
- **Standard Conversion**: The internal function block `F_BYTE_TO_UDINT` is an established IEC 61131 function block, ensuring that the conversion is standards-compliant and portable.

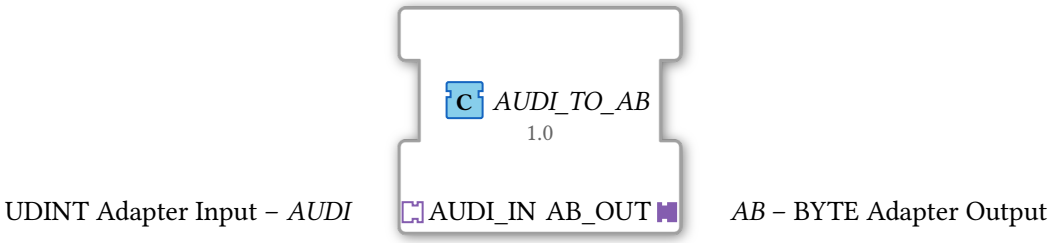
State Overview

Since this is a purely composite component without its own state machine, the state logic results from the interaction of the internal connections:

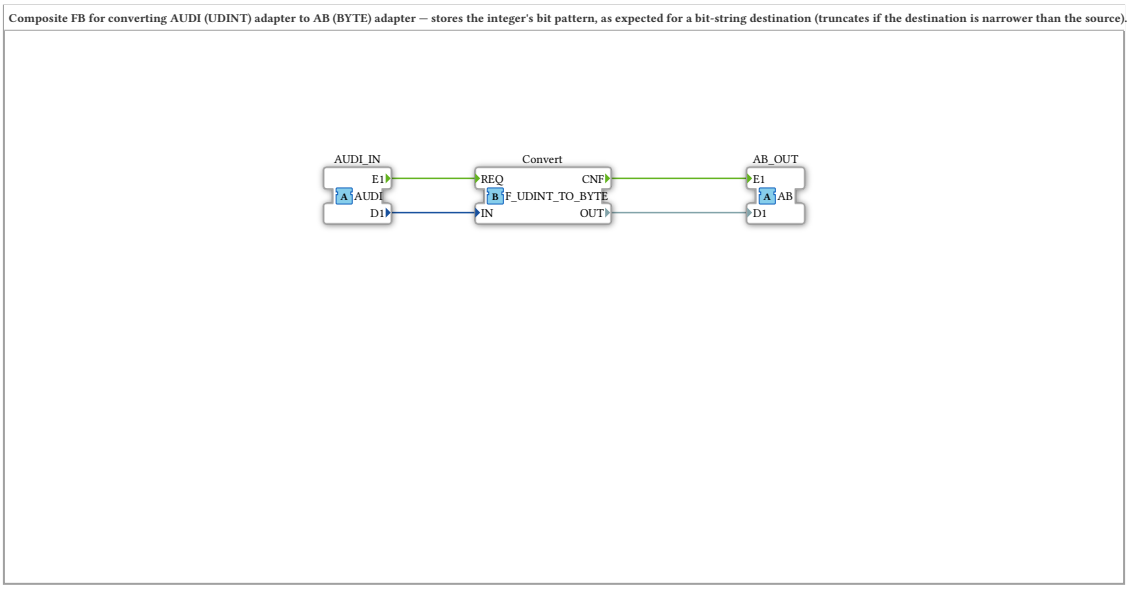
- **Ready**: After initialization, wait for event `AB_IN.E1`.
- **Conversion Active**: After receiving `AB_IN.E1`, while the internal converter is working.
- **Output Ready**: After confirmation by `Convert.CNF`, until event `AUDI_OUT.E1` and the associated data value are transmitted.

Application Scenarios

- **Protocol Adaptation**: When a sensor or actuator with a BYTE interface is to be connected to a control unit that expects UDINT (e.g., for counts, frequencies, or time values).
- **Data Preparation in Automation Networks**: Used in PLC or distributed systems to harmonize different data widths.
- **Adapter Bridge**: As an intermediary between predefined adapter types in an IEC 61499 application.



Comparison with Similar Function Blocks



- **AB_TO_DINT**: Converts BYTE to DINT (signed) – here, the conversion is to UDINT (unsigned).
- **Direct Converters** such as `F_BYTE_TO_UDINT`: These are simple function blocks without an adapter interface. `AB_TO_AUDI` encapsulates this function block in an adapter structure and integrates event control.

Conclusion

The function block `AB_TO_AUDI` provides a compact and reusable solution for converting BYTE data via an AB adapter to UDINT data via an AUDI adapter. The use of standardized conversion and adapters ensures high compatibility and clear interfaces in IEC 61499 systems.

AUDI_TO_AB

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUDI_TO_AB** function block is a composite function block (FB) that converts a UDINT interface (AUDI, 32-bit unsigned integer) into a BYTE interface (AB, 8-bit). It encapsulates the conversion logic and provides two unidirectional adapters: a socket for the AUDI input and a plug for the AB output. This function block is typically used to enable data communication between systems that use different data types via adapters.

Interface Structure

Event Inputs

Name	Type	Description
`AUDI_IN.E1`	Event (via adapter)	Trigger for data conversion – an incoming event starts the conversion of the current UDINT value to a BYTE value.

Event Outputs

Name	Type	Description
`AB_OUT.E1`	Event (via adapter)	Conversion confirmation – after successful conversion, an event is output that signals the new BYTE value to the downstream system.

Data Inputs

Name	Type	Description

AUDI_IN.D1	UDINT (32-bit)	The 32-bit unsigned integer value to be converted, provided via the AUDI adapter.

Data Outputs

Name	Type	Description
AB_OUT.D1	BYTE (8-bit)	The converted 8-bit value, output via the AB adapter.

Adapters

Name	Type	Direction	Description
AUDI_IN	adapter::types::unidirectional::AUDI	Socket (Input)	Unidirectional adapter that provides events and data of type UDINT.
AB_OUT	adapter::types::unidirectional::AB	Plug (Output)	Unidirectional adapter that outputs events and data of type BYTE.

Functionality

1. An external system sends an event via the adapter AUDI_IN (E1).
2. This event triggers the internal conversion block F_UDINT_TO_BYTE (from the IEC 61131 library) via its REQ input.
3. Simultaneously, the current data value from AUDI_IN.D1 is transferred to the IN input of the conversion module.
4. The conversion module converts the UDINT value into a BYTE value and stores the result at its OUT output.
5. After the conversion is complete, F_UDINT_TO_BYTE sends an acknowledgment event (CNF), which is forwarded to the AB_OUT adapter (E1).
6. Simultaneously, the converted BYTE value is output to AB_OUT.D1 and is available to the receiving system. ...`` The entire processing is event-driven and without intermediate storage – each incoming event generates exactly one outgoing event.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Structure**: The function block is implemented as a network of sub-functions. It uses the predefined conversion function block F_UDINT_TO_BYTE from the IEC 61131 library, ensuring standardized and testable conversion.
- **Unidirectional Adapters**: Both the input and output adapters are unidirectional. This reduces coupling and enables easy integration into data flows that only require one direction.
- **No State Storage**: The function block is purely combinatorial (no internal states). It reacts to each incoming event immediately and outputs the result without delay.
- **Compatibility**: Complies with the IEC 61499-2 standard and can be used in environments that support unidirectional adapters (AUDI/AB).

State Overview

This function block does not have an explicit state machine. It operates event-driven according to the principle "input event → conversion → output event". There are no queues or delays – processing is atomic and occurs within a single cycle.

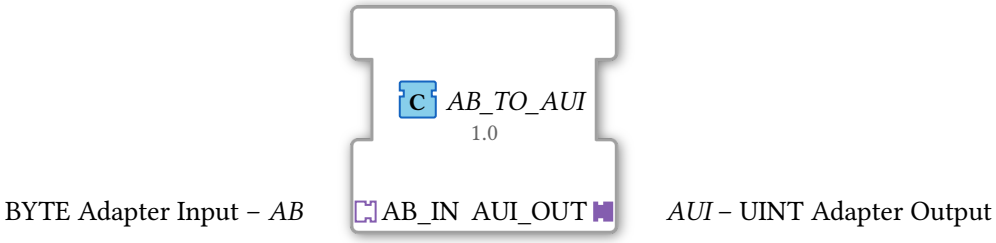
Application Scenarios

- **Data Adaptation in Adapter-Based Systems**: If a component or protocol delivers a UDINT value via an AUDI adapter, but the downstream function block expects a BYTE value via an AB adapter, this function block can be used for seamless coupling.

- **Transition from 32-bit to 8-bit interfaces**: For example, in sensor-actuator communication, where a sensor provides 32-bit raw data, but the actuator only processes 8-bit commands.
- **Test and simulation environments**: Allows easy replacement of adapters without having to change the entire data path logic.

Comparison with similar function blocks

Function block	Description	Difference to AUDI_TO_AB
`F_UDINT_TO_BYTE`	Direct conversion function without adapters	Expects standard event and data interfaces; AUDI_TO_AB encapsulates the conversion in adapter signatures.
`UDINT_TO_BYTE` (Composite with standard ports)	Similar logic, but with a SOCKET/PLUG interface	May use different adapter types or bidirectional interfaces; AUDI_TO_AB is specialized for unidirectional adapters.



Conclusion

The **AUDI_TO_AB** function block offers a clean, reusable solution for type conversion between UDINT and BYTE values using unidirectional adapters. Its compact composite structure, based on a standardized IEC conversion function, makes it reliable and easy to integrate. Its event-driven architecture without state storage makes it particularly suitable for time-critical data flows in automation technology.

AB_TO_AUI

BYTE Adapter Input – *AB* — *AUI* – UINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AB_TO_AUI** serves as an adapter converter between an AB adapter (BYTE-based) and an AUI adapter (UINT-based). It performs a unidirectional conversion from BYTE to UINT data type. The block is implemented as a composite FB and internally uses the IEC 61131-3 conversion function `F_BYTE_TO_UINT`. It is specifically designed for connecting sensors or actuators that deliver their data in BYTE format but must be processed in a UINT-based environment.

Interface Structure

Event Inputs

The FB does not have direct event inputs at the top level. Event control is handled via the connected adapters.

Event Outputs

The FB has no direct event outputs at the top level. Events are passed on via the connected adapters.

Data Inputs

The FB has no direct data inputs at the top level. Data is received via the connected AB adapter.

Data Outputs

The FB has no direct data outputs at the top level. Data is output via the connected AUI adapter.

Adapters

Direction	Name	Adapter Type	Description
Socket	AB_IN	`adapter::types::unidirectional::AB`	Input adapter for BYTE data (source adapter)
Plug	AUI_OUT	`adapter::types::unidirectional::AUI`	Output adapter for UINT data (destination adapter)

Note: Adapters of type `AB` and `AUI` each have an event input (`E1`), an event output (`E1`), a data input (`D1` of type BYTE or UINT), and a data output (`D1` of type BYTE or UINT). See the corresponding adapter definitions for complete details.

Functionality

The module functions as a pure converter: As soon as an event occurs at socket `AB_IN` (typically via the adapter's event input), it is forwarded to the internal function block `F_BYTE_TO_UINT`. Simultaneously, the BYTE value provided by the adapter (via the AB adapter's data input `D1`) is passed to the conversion function block. The conversion function block converts the BYTE value into an equivalent UINT value. After successful conversion, an event is triggered via the event output of the internal function block, which is then passed to plug `AUI_OUT`. The converted UINT value is transferred via the conversion function block's data output to the AUI adapter's data input.

The following diagram shows the internal wiring:

- Event connection: `AB_IN.E1` ⟶ `Convert.REQ` ⟶ `Convert.CNF` ⟶ `AUI_OUT.E1`
- Data connection: `AB_IN.D1` ⟶ `Convert.IN` ⟶ `Convert.OUT` ⟶ `AUI_OUT.D1`

The entire process is strictly sequential and event-driven.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Unidirectional Operation:** The function block only supports data flow from AB (BYTE) to AUI (UINT). Reverse conversion is not possible with this function block.
- **Use of IEC 61131-3 Conversion:** The conversion is performed using the standardized function block `F_BYTE_TO_UINT` from the IEC 61131 library. This ensures reliable and portable conversion.
- **Adapter-Based Interface:** The function block is intentionally designed as an adapter converter and not as a standalone function block with direct inputs/outputs. This allows for easy integration into existing adapter-based communication structures.

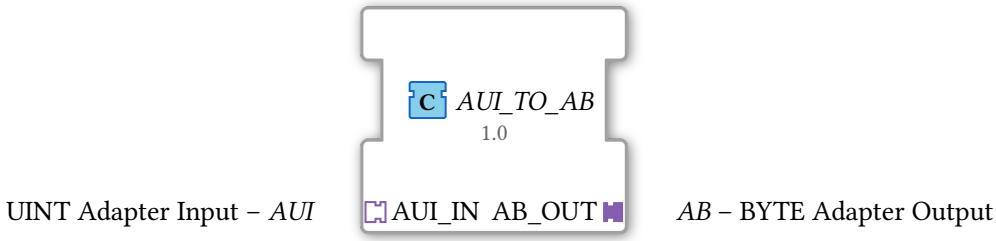
- **No State Storage:** The function block is stateless, meaning it does not store intermediate values. Each conversion process is independent of previous ones.

State Overview

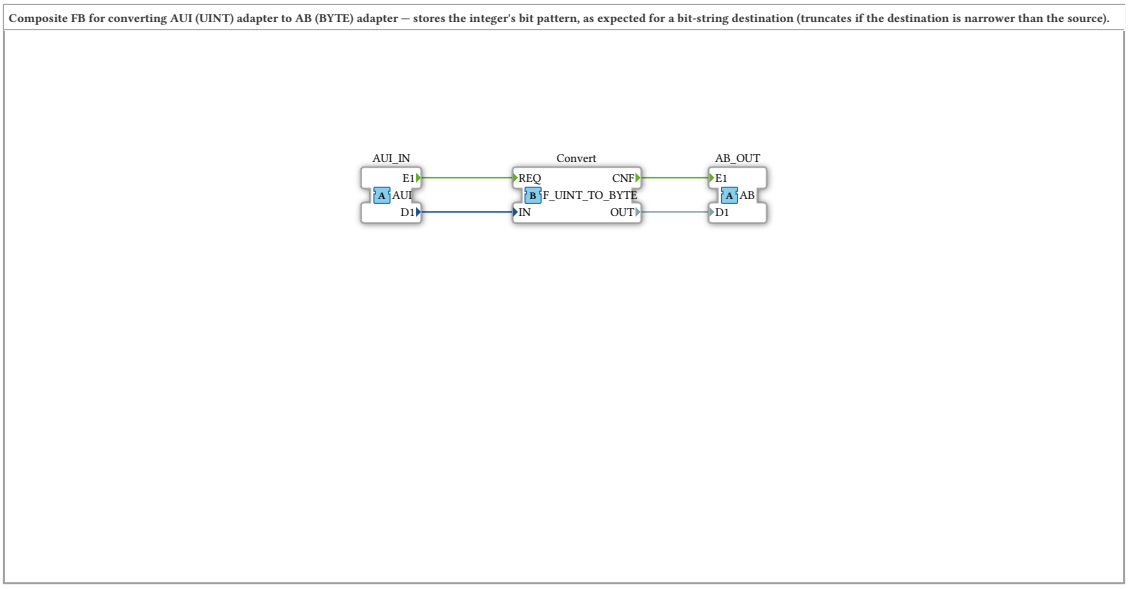
The function block does not have its own state machines. Its behavior is determined by the internal function block `F_BYTE_TO_UINT` (a simple function block without states) and event chaining. Therefore, the function block is always ready to perform a conversion as soon as an event arrives at the input adapter.

Application Scenarios

- **Sensor Connection:** A sensor delivers measured values in BYTE format (e.g., via an AB adapter), while the control system processes only UINT values. The AB_TO_AUI function block converts the values accordingly.
- **Protocol Adaptation:** In heterogeneous fieldbus systems, the function block can be used as a simple data type converter between different adapter types.
- **Testing and Simulation:** During development, this function block can be used to convert BYTE data from a test environment into UINT data for the target application.



Comparison with Similar Function Blocks



Other adapter converters exist, such as `AB_TO_UDINT`, `BYTE_TO_WORD`, or direct converters like `F_BYTE_TO_SINT`. The `AB_TO_AUI` focuses specifically on adapter conversion while preserving the adapter structure. Unlike pure function blocks, it retains the adapter interfaces, thus enabling easy encapsulation in adapter-based architectures. Other blocks, such as the `F_BYTE_TO_UINT`, operate at the signal level and require separate interfaces.

Conclusion

The `AB_TO_AUI` is a compact and specialized composite function block for the unidirectional conversion of BYTE to UINT data using standardized adapter interfaces. It allows for seamless integration into adapter-based systems and reduces the effort required for manual data conversion. Thanks to the use of the IEC 61131-3 conversion block, its functionality is reliable and portable. This block is particularly suitable for applications that rely on loose coupling between data sources and sinks.

AUI_TO_AB

No image available

• – ○ • – ○ • – ○ •

Introduction

The **AUI_TO_AB** function block is a composite block that converts an AUI interface (UINT) to an AB interface (BYTE). It encapsulates the conversion using the internal IEC 61131 block `F_UINT_TO_BYTE` and provides a uniform, unidirectional data flow via adapters. This block was developed for use in automation systems that need to transfer different data types between adapters.

Interface Structure

Event Inputs

Name	Description	Data Type
`AUI_IN.E1`	Event via the AUI adapter (socket) that triggers the conversion.	Event

Event Outputs

Name	Description	Data Type
`AB_OUT.E1`	Event via the AB adapter (plug) that is sent after successful conversion.	Event

Data Inputs

Name	Description	Data Type
`AUI_IN.D1`	UINT value that is received and converted via the AUI adapter.	UINT

Data Outputs

Name	Description	Data Type
`AB_OUT.D1`	Converted BYTE value output via the AB adapter.	BYTE

Adapters

Type	Name	Direction	Comment
`adapter::types::unidirectional::AUI`	`AUI_IN`	Socket	UINT adapter input

adapter::types::unidirectional::AB	AB_OUT	Plug	BYTE Adapter Output

Functionality

This component functions as a pure signal converter:

1. An incoming event at **AUI_IN.E1** is forwarded to the internal function block `Convert` (type `F_UINT_TO_BYTE`).
2. Simultaneously, the data value **AUI_IN.D1** is passed to the input `Convert.IN`.
3. The converter transforms the UINT value into a BYTE value (data truncation to the least significant byte).
4. Upon completion, the event **AB_OUT.E1** is triggered, and the converted value is made available via **AB_OUT.D1**.

Internally, the mapping logic is implemented by a single IEC 61131 component, resulting in minimal latency and deterministic operation.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Structure**: The function block is implemented as a composite, meaning it contains an internal network with a single function block. This facilitates reuse and encapsulation.
- **Adapter Concept**: Input and output are handled exclusively via typed adapters (`AUI` and `AB`). This enables loose coupling and easy exchange of communication protocols within the application.
- **License**: The function block is licensed under the Eclipse Public License 2.0 (EPL-2.0). The source code is open and can be freely modified.
- **Dependency**: It requires the IEC 61131 function block `F_UINT_TO_BYTE`, which must be included in the package `iec61131::conversion`.

State Overview

Since the function block does not have an internal state machine (composite without its own ECC), its state is determined solely by the internal function block `F_UINT_TO_BYTE`. This block operates in an event-driven manner and does not have a persistent state. After each event, the function block returns to its idle state.

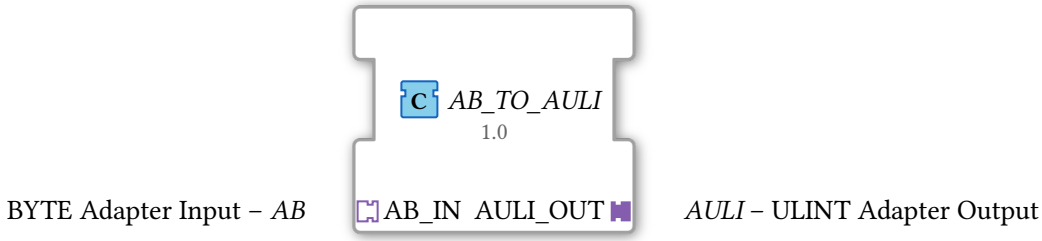
Application Scenarios

- **Data Conversion**: When a sensor delivers data in UINT format via an AUI adapter, but the downstream system expects a BYTE value via an AB adapter.
- **System Integration**: As an intermediary between different adapter types in heterogeneous automation networks.
- **Protocol Conversion**: In scenarios where existing libraries only support certain adapter types and type conversion is required.

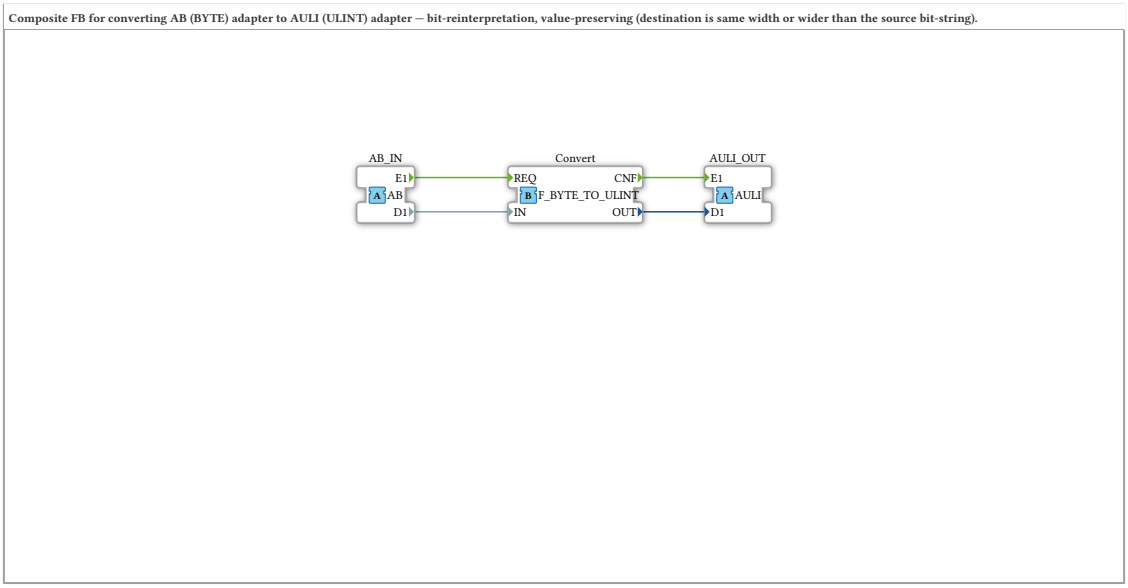
Comparison with Similar Function Blocks

- **Direct `F_UINT_TO_BYTE`**: This IEC function block is also used internally, but operates without an adapter – it requires direct data and event ports. `AUI_TO_AB` encapsulates this interface in adapter form.
- **Other Adapter Converters**: Similar function blocks exist, such as `AB_TO_AUI` or `ADI_TO_AB`, for other type combinations. They follow the same pattern and are interchangeable.

The key advantage of `AUI_TO_AB` is its complete integration into adapter-based architectures – without the application needing to know the internal conversion logic.



Conclusion



The **AUI_TO_AB** function block is a simple yet useful composite function block for type conversion between two unidirectional adapters. Its clear structure and the use of a standardized converter make it reliable and easy to understand. It represents an elegant solution for all applications requiring clean adapter separation.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AB_TO_AULI

• – ○ • – ○ • – ○ •

Introduction

The function block **AB_TO_AULI** is a composite function block (FB) that converts a unidirectional adapter of type `AB` (BYTE) into a unidirectional adapter of type `AULI` (ULINT). It serves as a converter between different data types in adapter communication according to IEC 61499-2. The FB internally uses the standardized conversion block `F_BYTE_TO_ULINT` from the IEC 61131 library.

Interface Structure

Event Inputs

- **AB_IN.E1** – Event input of the AB adapter socket. Triggered by the incoming adapter protocol, this starts the conversion.

Event Outputs

- **AULI_OUT.E1** – Event output of the AULI adapter plug. Signals the completion of the conversion to the downstream adapter path.

Data Inputs

- **AB_IN.D1** (Data type: BYTE) – Receives the value to be converted via the AB adapter.

Data Outputs

- **AULI_OUT.D1** (Data type: ULINT) – Provides the converted ULINT value via the AULI adapter.

Adapters

- **Socket “AB_IN”** – Type: `adapter::types::unidirectional::AB`

Unidirectional input adapter for the BYTE data type.

- **Plug "AULI_OUT"** – Type: `adapter::types::unidirectional::AULI`

Unidirectional output adapter for the ULINT data type.

Functionality

The function block (FB) waits for an event at the input adapter `AB_IN`. As soon as the event arrives, the BYTE value at `AB_IN.D1` is forwarded to the internal conversion block `F_BYTE_TO_ULINT` and converted into a ULINT value. After the conversion is complete, the resulting value is output to `AULI_OUT.D1`, and the completion event is sent to `AULI_OUT.E1`. The entire process is event-driven and does not use state machines.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- The function block does not implement any states or algorithms of its own – it is simply a standard conversion FB interconnect.
- The conversion is performed according to the rules of IEC 61131-3: The BYTE value is interpreted as an 8-bit representation of a ULINT and converted into an unsigned 64-bit integer.
- The adapters are based on a unidirectional communication pattern, meaning that data and events flow only in one direction (from the socket to the plug).
- The function block (FB) is not stateful; each request is processed independently.

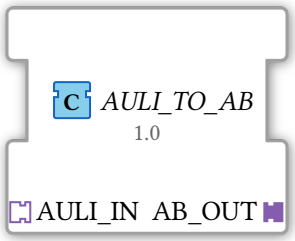
State Overview

The function block does not have its own state machine. Execution follows a simple event-driven sequence:

1. Wait for an input event (`AB_IN.E1`).
2. Convert the data value.
3. Output the result and trigger the output event (`AULI_OUT.E1`).

Application Scenarios

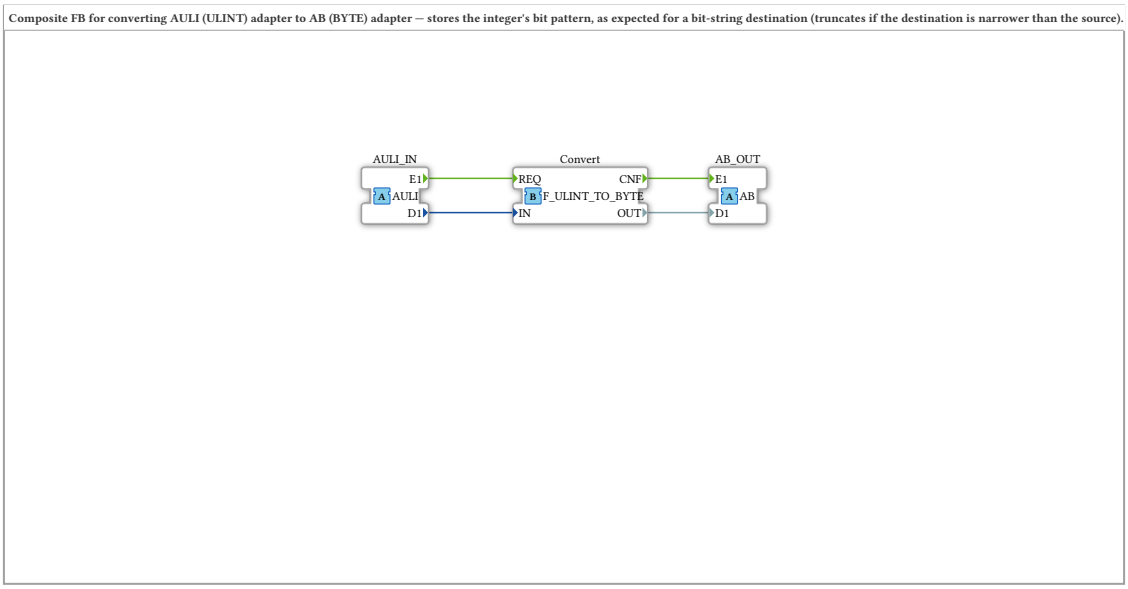
- **Connecting BYTE-based sensors** to a controller that uses ULINT as a uniform data type for longer measured values.
- **Data format conversion** in adapter chains when a protocol communicates at the BYTE level, but the application expects a ULINT value.
- **Test and debugging setups** where a BYTE test adapter needs to be converted to a ULINT interface.



Comparison with Similar Function Blocks

- **Direct conversion without adapters** (e.g., `F_BYTE_TO_ULINT`): These function blocks operate at the data level, not the adapter level. The `AB_TO_AULI` encapsulates the conversion, including the adapter interfaces.
- **Adapter converters for other data types** (e.g., `AB_TO_AUDINT`): These are structurally similar but differ in the target data type and, if applicable, in the conversion function used.
- **Bidirectional adapter converters**: If required, two unidirectional converters (e.g., `AB_TO_AULI` and `AULI_TO_AB`) would need to be combined.

Conclusion



The function block `AB_TO_AULI` provides a simple, standards-compliant way to convert a BYTE adapter to a ULINT adapter. By using an established IEC 61131 conversion block, the conversion is reliable and easily traceable. The block is ideal for adapter-based communication chains that require a data type change at the adapter level.

AULI_TO_AB

ULINT Adapter Input – *AULI*

AB – BYTE Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block `AULI_TO_AB` is a composite function block that converts an AULI adapter (ULINT data type) into an AB adapter (BYTE data type). It enables the seamless connection of components using different adapter interfaces by converting the incoming data and providing it as a compatible output.

Interface Structure

The function block has no direct event or data inputs/outputs. All input and output is handled via adapters.

Event Inputs

None (events are received via the AULI adapter).

Event Outputs

None (events are sent via the AB adapter).

Data Inputs

None (data is received via the AULI adapter).

Data Outputs

None (data is sent via the AB adapter).

Adapters

Name	Type	Direction	Comment
`AULI_IN`	`adapter::types::unidirectional::AULI`	Socket (Input Adapter)	ULINT adapter that provides the values to be converted and the trigger event

AB_OUT	adapter::types::unidirectional::AB	Plug (Output Adapter)	BYTE adapter that provides the converted values and the confirmation event

Functionality

The component internally uses the IEC 61131 component F_ULINT_TO_BYTE for ULINT to BYTE conversion. The process is as follows:

1. **Input**: An event (E1) is received at socket AULI_IN, triggering the conversion. Simultaneously, the data value (D1) is present as a ULINT.
2. **Processing**: The event and data are forwarded to the internal component F_ULINT_TO_BYTE (event REQ, data IN). This component performs the type conversion.
3. **Output**: After successful conversion, the internal block signals an event (CNF) and delivers the result (OUT) as a BYTE. Both are transferred to the plug AB_OUT (event E1, data D1).

The entire process occurs synchronously within one execution cycle of the composite block.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Block**: The logic is implemented entirely through the internal network of predefined blocks – there is no separate ECC (Execution Control Chart).
- **License and Copyright**: The block is licensed under the Eclipse Public License 2.0 (EPL-2.0) and is subject to third-party copyright.
- **Dependencies**: It requires the IEC 61131 function block F_ULINT_TO_BYTE from the library iec61131::conversion.
- **Package Structure**: The function block belongs to the package adapter::conversion::unidirectional.

State Overview

Since the function block does not have its own ECC, there are no explicit states. The internal flow is strictly defined by the event chain AULI_IN.E1 → Convert.REQ → Convert.CNF → AB_OUT.E1.

Application Scenarios

- Integration of a ULINT-providing sensor (e.g., a high-resolution distance sensor) into a control system based on BYTE adapter interfaces.
- Retrofitting existing systems where components with different adapter types (ULINT vs. BYTE) need to be integrated.
- Prototype development where ULINT values are temporarily processed via a BYTE channel (e.g., simulation or testing).

Comparison with similar function blocks

Analog conversion function blocks exist for other data types (e.g., AULI_TO_xx or xx_TO_AB). The AULI_TO_AB is specifically optimized for converting ULINT to BYTE and utilizes the corresponding adapter types. Unlike generic function blocks, it avoids the manual wiring of individual events and data and offers an encapsulated, adapter-based interface.

Conclusion

The AULI_TO_AB is a compact, reliable composite function block for converting between two common adapter types in the 4diac IDE. It reduces wiring effort and simplifies the integration of heterogeneous components. By using the standardized IEC 61131 conversion block, the conversion remains type-safe and efficient.

AB_TO_AUS

BYTE Adapter Input – *AB*

AUS – USINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AB_TO_AUS** is a composite block that performs a unidirectional conversion of data from the **AB adapter** (BYTE) to the **AUS adapter** (USINT). It encapsulates the necessary type conversion and event passing, thus enabling the seamless integration of components based on different data types.

Interface Structure

Event Inputs

The function block does not have separate event inputs at the top level. The triggering event is provided via the socket adapter **AB_IN** (available there as `E1`).

Event Outputs

There are no direct event outputs at the composite function block level. The resulting event is output via the plug adapter **AUS_OUT** (there as `E1`).

Data Inputs

No data inputs are defined at the top level. The input data (BYTE) is received via the socket adapter **AB_IN** (there as `D1`).

Data Outputs

There are no direct data outputs. The converted data (USINT) is provided via the plug adapter **AUS_OUT** (there as `D1`).

Adapters

Type	Name	Direction	Description
Socket	**AB_IN**	Input	Unidirectional adapter of type `adapter::types::unidirectional::AB`. Returns a BYTE (`D1`) and an event (`E1`).
Plug	**OFF_OUT**	Output	Unidirectional adapter of type `adapter::types::unidirectional::AUS`. Provides a USINT (`D1`) and an event (`E1`).

Functionality

1. An event at `AB_IN.E1` triggers processing.
2. The value of `AB_IN.D1` (BYTE) is passed to the internal converter **F_BYTE_TO_USINT**.
3. The converter transforms the BYTE into a USINT value. 4. The result is output to `AUS_OUT.D1` (USINT).
4. Simultaneously, an event is generated on `AUS_OUT.E1` to signal the subsequent processing.

The entire conversion is event-driven and performed in a single step.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Unidirectional Adapter Coupling**: The function block connects two unidirectional adapters (ON → OFF) and ensures that the data flow direction is clearly defined.
- **Reusable IEC Conversion**: Internally, the standardized function block `iec61131::conversion::F_BYTE_TO_USINT` is used.
- **Composite Architecture**: The conversion logic is encapsulated and can be easily integrated into other projects or replaced by alternative converters.
- **No Internal State**: The function block does not have its own state machine; it forwards events and data directly.

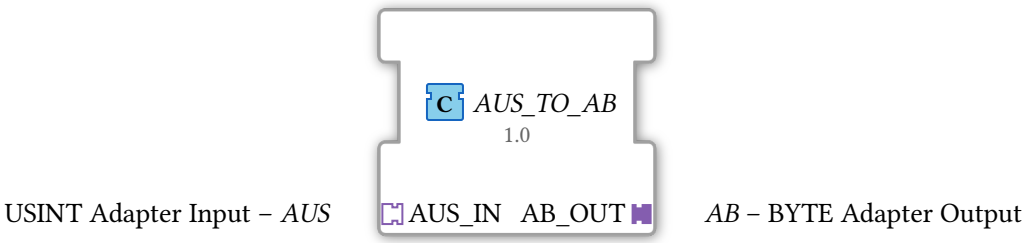
State Overview

The **AB_TO_AUS** function block does not have its own state machine. Its operation is based on a purely event-driven data conversion. The internal converter `F_BYTE_TO_USINT` also operates without state storage.

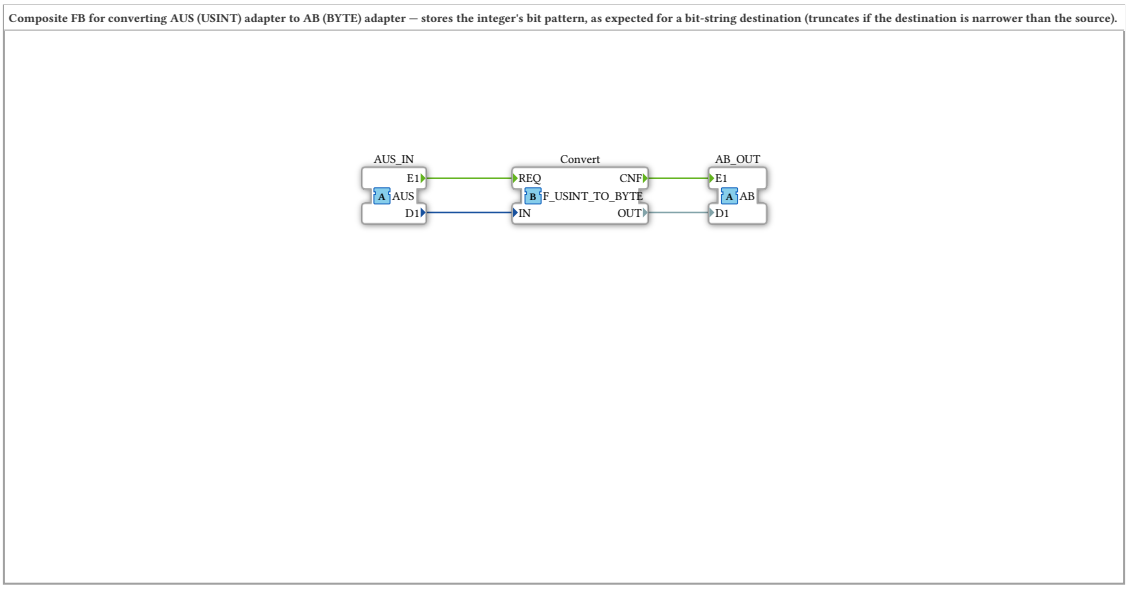
Application Scenarios

- **System Integration**: Connecting a device that provides measured values as BYTE via the AB adapter to a controller that expects USINT data via the AUS adapter.
- **Protocol Conversion**: Converting BYTE-encoded commands to USINT-encoded values for further processing in libraries that exclusively support USINT.
- **Modular Reuse**: Encapsulating the conversion as a standalone function block to improve clarity in large automation projects.

Comparison with Similar Function Blocks



Function Block	Description
F_BYTE_TO_USINT	Simple IEC converter without adapter connection. Must be manually wired with event and data connections.
AB_TO_AUS	Composite function block that encapsulates the entire adapter conversion, including event forwarding, thus providing a clean, abstracted interface.
AUS_TO_AB (hypothetical)	Reverse conversion from USINT to BYTE – mirrored functionality for the opposite direction.



The **AB_TO_AUS** function block stands out due to its ease of use and direct adapter compatibility.

Conclusion

The **AB_TO_AUS** function block offers an elegant and standardized way to convert BYTE data from an AB adapter to USINT data for an AUS adapter. Encapsulating the conversion logic in a composite block promotes reusability and simplifies system integration. It is particularly suitable for modular automation solutions based on IEC 61499.

OFF_TO_AB

• – ○ • – ○ • – ○ •

Introduction

The **OFF_TO_AB** is a composite function block for converting a unidirectional **OFF adapter** (USINT data type) to an **AB adapter** (BYTE data type). It serves as a bridge between different adapter interfaces in automation systems and enables the seamless integration of components based on different data types. Internally, the block uses the standard conversion block *F_USINT_TO_BYTE* from the IEC 61131 library.

Interface Structure

Event Inputs

The block does not have its own event input ports. Events are received via the **OFF_IN** adapter (socket):

- **OFF_IN.E1** – Trigger for data conversion and forwarding to the output.

Event Outputs

Events are output via the **AB_OUT** adapter (plug):

- **AB_OUT.E1** – Confirmation that the converted value is present at the output.

Data Inputs

Data is provided via the **AUS_IN** adapter:

- **AUS_IN.D1** (USINT) – The 8-bit unsigned integer value to be converted.

Data Outputs

Data is passed through the **AB_OUT** adapter:

- **AB_OUT.D1** (BYTE) – The converted byte value.

Adapters

Name	Type	Direction	Description
AUS_IN	adapter::types::unidirectional::AUS	Socket	Input adapter for USINT data and events.
AB_OUT	adapter::types::unidirectional::AB	Plug	Output adapter for BYTE data and events.

Functionality

The **AUS_TO_AB** is implemented as a pure composite function block without its own logic. It connects the AUS_IN and AB_OUT adapters via the internal function block **F_USINT_TO_BYTE**:

1. An incoming event on **AUS_IN.E1** triggers the conversion function block **Convert** (`F_USINT_TO_BYTE`) via its **REQ** input.
2. Simultaneously, the data value from **AUS_IN.D1** is passed to the **Convert.IN** input.
3. After the conversion (USINT ⟶ BYTE) is complete, **Convert** acknowledges with an event on **CNF**.
4. This event is forwarded directly to **AB_OUT.E1**.
5. The converted byte value from **Convert.OUT** is passed to **AB_OUT.D1**.

This ensures synchronized, event-driven data transfer.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite FB**: Does not contain its own state machine; all logic is implemented by the internal FB `F_USINT_TO_BYTE`.
- **Unidirectional Adapters**: Both the incoming and outgoing adapters are unidirectional – data flows occur exclusively in one direction.
- **Standard Compliance**: The block is based on IEC 61499-2 and uses the IEC 61131 conversion function `F_USINT_TO_BYTE`. This makes it immediately usable in compatible runtime environments (e.g., 4diac-FORTE).
- **License**: Released under the Eclipse Public License 2.0 (EPL-2.0). Copyright © 2026 HR Agrartechnik GmbH.

State Overview

Since this is a composite function block without its own ECC (Execution Control Chart), there is no explicit state machine. Its behavior is purely event-driven and determined by the internal interconnection of the individual function blocks. After startup, the system is always ready – an incoming event is processed immediately.

Application Scenarios

- **System integration** in agricultural technology or other automation environments where an **OFF adapter** (USINT) needs to be connected to an **AB adapter** (BYTE).
- **Retrofitting older components** that provide a BYTE output with modern USINT-based sensors or actuators.
- **Prototyping and test setups** where rapid switching between different adapter types is required.
- **Data processing** in communication nodes that standardize different adapter protocols.

Comparison with Similar Function Blocks

- **F_USINT_TO_BYTE** – a direct function block for pure data type conversion, but without adapter integration. **AUS_TO_AB** adds the adapter and event logic.
- **BYTE_TO_USINT** – inverse conversion (BYTE ⟶ USINT) if the reverse adapter direction is required (not included with this function block).

- **Generic Adapter Converters** – more complex blocks that convert multiple data types simultaneously. **AUS_TO_AB** is optimized for the specific use case and is therefore more compact.

Conclusion

The **AUS_TO_AB** is a useful and lightweight function block for converting an **AUS adapter (USINT)** to an **AB adapter (BYTE)**. Its composite structure minimizes implementation effort, while the use of a standardized conversion block ensures reliability. This module is particularly suitable for the rapid integration of heterogeneous adapter interfaces into IEC 61499-based control systems.

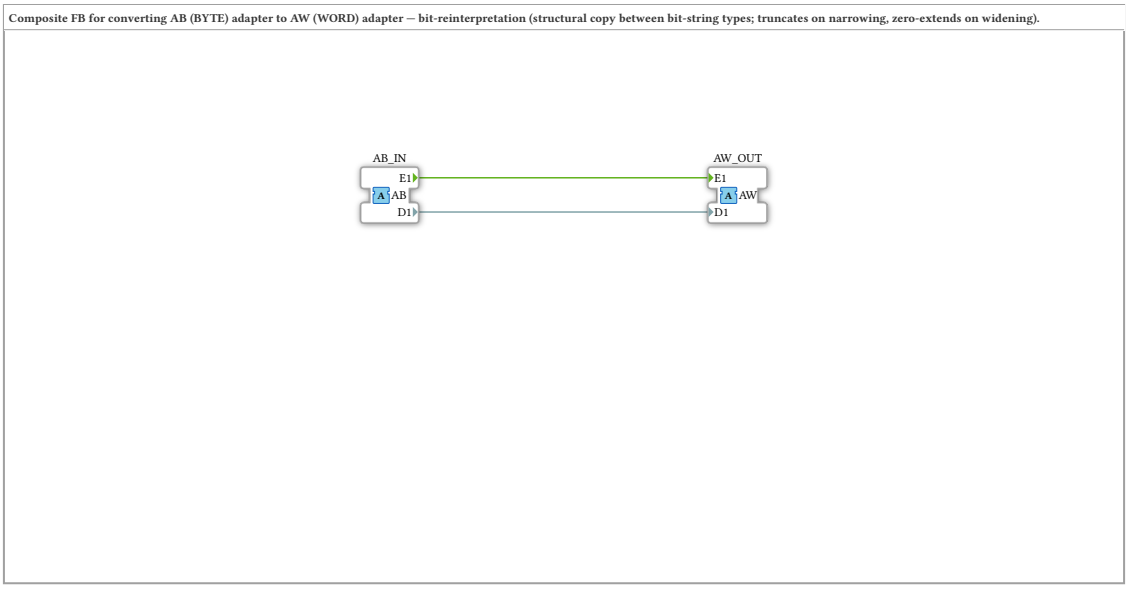
Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AB_TO_AW

BYTE Adapter Input – *AB*

AW – WORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_TO_AW** is a composite block that performs a unidirectional conversion from an AB adapter (BYTE-based) to an AW adapter (WORD-based). It serves as an interface converter when a system component delivers data in BYTE format, but the downstream component expects a WORD format.

Interface Structure

The block does not have any classic event or data inputs/outputs at the top level, but uses only adapter interfaces.

Event Inputs

- No direct event inputs are available. Events are received via the **AB_IN** adapter.

Event Outputs

- No direct event outputs are available. Events are sent via the **AW_OUT** adapter.

Data Inputs

- No direct data inputs are available. Data is received via the **AB_IN** adapter.

Data Outputs

- No direct data outputs are available. Data is sent via the **AW_OUT** adapter.

Adapters

Direction	Name	Type	Comment
Input (Socket)	**AB_IN**	`adapter::types::unidirectional::AB`	BYTE adapter input, provides a BYTE date and an event
Output (Plug)	**AW_OUT**	`adapter::types::unidirectional::AW`	WORD adapter output, provides a WORD date and an event

Functionality

This function block forwards the incoming signals from the **AB_IN** adapter directly to the **AW_OUT** adapter:

- The **E1** event of the **AB_IN** is linked to the **E1** event of the **AW_OUT**.
- The **D1** (BYTE) data of the **AB_IN** is linked to the **D1** (WORD) data of the **AW_OUT**.

Since this is a simple pass-through, no data conversion in the sense of a value change occurs; the BYTE data is interpreted as WORD data (implicit type conversion via the data connection). The actual conversion (e.g., extending the value range) depends on the implementation of the underlying adapters.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- The function block is implemented as a **composite function block**, meaning its behavior is entirely defined by the internal network (FBNetwork).
- The conversion is unidirectional: only from the AB adapter to the AW adapter.
- The connection is established at the event and data level without intermediate storage or synchronization.
- The function block is part of the package structure `adapter::conversion::unidirectional`.

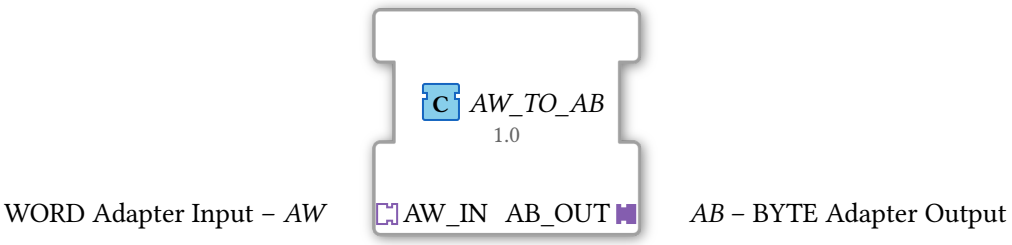
State Overview

The function block does **not have its own state machine**. Its behavior is purely combinatorial: Every incoming event is immediately forwarded to the output, as is the data.

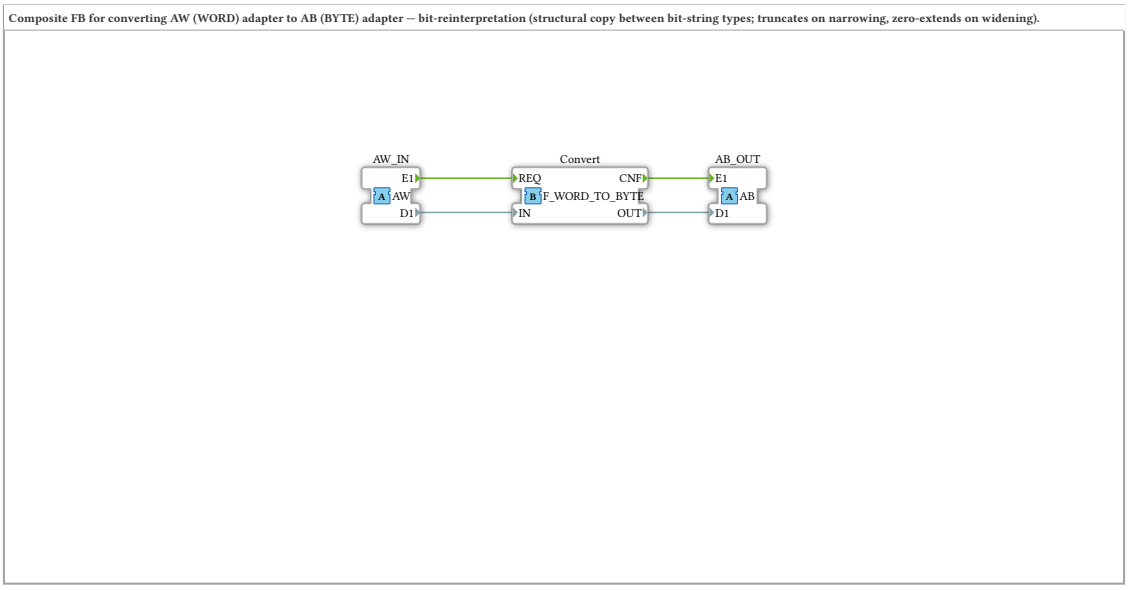
Application Scenarios

- **Connecting Sensors/Actuators**: A module provides a BYTE value (e.g., via an AB adapter), but downstream logic expects WORD format.
- **Protocol Adaptation**: In heterogeneous systems where different adapter types interact.
- **System Integration**: When an existing BYTE-based sequence control needs to be integrated into a WORD-based environment.

Comparison with Similar Components



- **WORD_TO_BYTE**: An analogous component may exist for the reverse direction (WORD ⟶ BYTE).
- **Direct Adapter Connection**: Without this component, the programmer would have to manually link the event and data in the network; **AB_TO_AW** encapsulates this connection and increases reusability.



- **Type Converter**: Pure data converters (e.g., `BYTE_TO_WORD`) often operate without event forwarding; here, the event is also passed through.

Conclusion

The **AB_TO_AW** is a simple but useful interface component for the unidirectional conversion of a BYTE adapter to a WORD adapter. By encapsulating the connection logic, clarity in the application network is improved and the reuse of standardized conversion patterns is promoted.

AW_TO_AB

• – ○ • – ○ • – ○ •

Introduction

The function block `AW_TO_AB` is a composite block that converts a unidirectional WORD adapter (`AW`) into a unidirectional BYTE adapter (`AB`). It serves as an interface converter between components based on different data types. The conversion is performed by the integrated standard function block `F_WORD_TO_BYTE`.

Interface Structure

Event Inputs

The block does not have its own event inputs. Instead, the trigger signal is provided via the adapter input `AW_IN` (event `E1`).

Event Outputs

The function block does not have its own event outputs. The result is signaled via the adapter output `AB_OUT` (event `E1`).

Data Inputs

The function block does not have its own data inputs. The WORD value to be converted is provided via the adapter input `AW_IN` (data `D1`).

Data Outputs

The function block does not have its own data outputs. The converted BYTE result is output via the adapter output `AB_OUT` (data `D1`).

Adapter

Name	Direction	Type	Description
`AW_IN`	Socket (Input)	`adapter::types::unidirectional::AW`	WORD adapter with one event `E1` and one data value `D1` (WORD)
`AB_OUT`	Plug (Output)	`adapter::types::unidirectional::AB`	BYTE adapter with one event `E1` and one data value `D1` (BYTE)

Functionality

This function block performs a simple data conversion from WORD (16 bits) to BYTE (8 bits). The process is as follows:

1. An event at the adapter input `AW_IN.E1` triggers the internal function block `F_WORD_TO_BYTE`.
2. The data value `AW_IN.D1` (WORD) is passed as an input to `F_WORD_TO_BYTE.IN`.
3. After the conversion, the result is forwarded via `F_WORD_TO_BYTE.OUT` to the adapter output `AB_OUT.D1`.
4. The output `AB_OUT.E1` is activated to signal completion.

The conversion according to IEC 61131-3 returns the least significant byte (low byte) of the WORD value by default.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- **Unidirectional Adapter**: The module operates in only one data flow direction – from the socket to the plug.
- **Integrated Conversion**: The actual conversion is performed by the established module `F_WORD_TO_BYTE`, so no custom logic needs to be implemented.
- **Data Loss**: Since a WORD (16 bits) is mapped to a BYTE (8 bits), the upper 8 bits are lost. This must be taken into account in the application.
- **Package Structure**: The function block is located in package `adapter::conversion::unidirectional` and uses the import `iec61131::conversion::F_WORD_TO_BYTE`.

State Overview

The composite function block does not have its own state machine. Its operation is purely event-driven:

- **Idle**: Waiting for an event at socket `AW_IN`.
- **Conversion Active**: After receiving an event, the internal function block `F_WORD_TO_BYTE` is executed (combinatorial logic without wait cycles).
- **Output**: Once the conversion is complete, the event is output to plug `AB_OUT`, along with the new data value.

Application Scenarios

- **Protocol Adaptation**: When a sensor provides a WORD value, but the actuator only supports BYTE-capable adapters.
- **Interface Reduction**: In hierarchical control systems where byte sizes are used for performance or memory reasons.
- **Adapter Bridge**: As an intermediary in a 4diac IDE application to connect components with incompatible adapter types.

Comparison with Similar Blocks

- **`F_WORD_TO_BYTE`**: A pure data conversion block without adapter integration. `AW_TO_AB` encapsulates this block and provides a standardized adapter interface.
- **`AW_TO_AW` (identical type)**: Not useful; this block is specifically designed for type conversion.

- **Manual Conversion**: Without this component, the developer would have to manually insert `F_WORD_TO_BYTE` into the network and wire the adapter connections themselves – this composite component simplifies this process.

Conclusion

AW_TO_ABis `a simple yet useful composite component for converting a WORD adapter to a BYTE adapter. It reduces the wiring effort in 4diac applications and ensures consistent conversion by reusing the standard componentF_WORD_TO_BYTE`. Users should be aware of the potential data loss due to the reduced bit width.

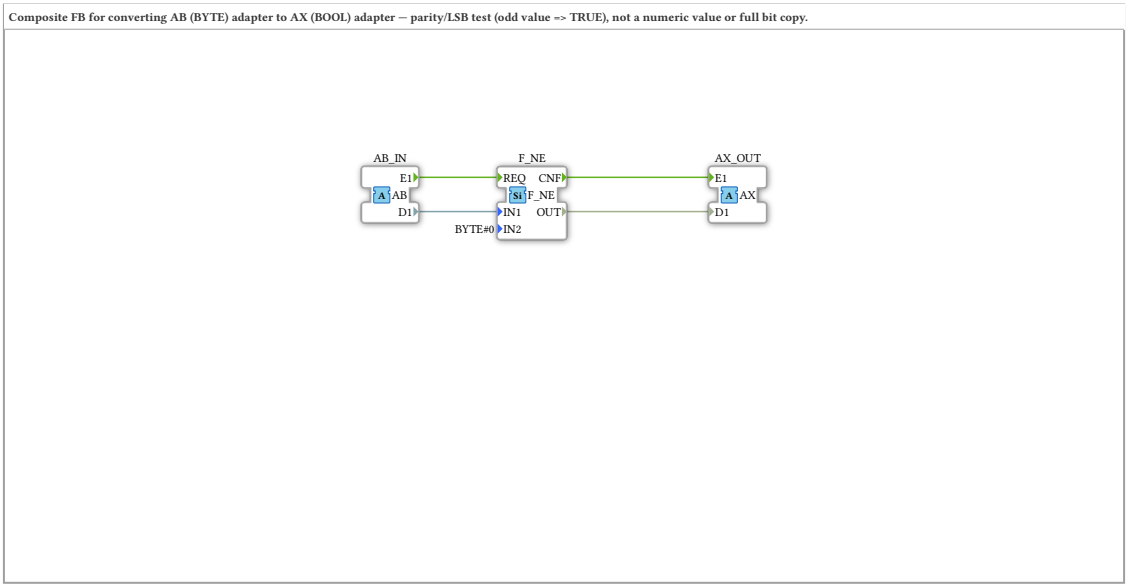
Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AB_TO_AX

BYTE Adapter Input – *AB*

AX – BOOL Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_TO_AX** is a composite function block (FB) for converting a BYTE signal (via the AB adapter) into a BOOL signal (via the AX adapter). It serves as a converter between two different adapter types of the unidirectional adapter family.

Interface Structure

Adapter (Input)

- **AB_IN** (Type: `adapter::types::unidirectional::AB`):

Accepts a BYTE value and an associated event. The adapter provides the data via the internal channels D1 (BYTE) and E1 (event).

Adapter (Output)

- **AX_OUT** (Type: `adapter::types::unidirectional::AX`):

Outputs a BOOL value and a triggering event. The adapter provides the result via D1 (BOOL) and E1 (event).

Functionality

The function block internally uses a `F_NE` comparison block (not equal to). The incoming BYTE signal (AB_IN.D1) is compared to the constant value `BYTE#0`.

- If the BYTE value is not equal to 0, the comparison returns `TRUE`.
- If the BYTE value is equal to 0, the comparison returns `FALSE`.

The process is started by the event `AB_IN.E1`. This triggers the `F_NE` function block. After the comparison is complete, the event `AX_OUT.E1` is triggered, and the result (BOOL) is output via `AX_OUT.D1`.

Technical Features

- **Parity/LSB test** (odd value => TRUE), not a numeric value or full bit copy.
- The function block is implemented as a composite, meaning its functionality results from the interconnection of standard function blocks (here, `F_NE`).
- It is designed for use in the 4diac IDE with the IEC 61499-2 specification.
- The adapters `AB` and `AX` are unidirectional, ensuring a clear separation of data and event flows.
- The internal comparison is binary: Each non-zero BYTE value is interpreted as `TRUE`.

State Overview

The function block does not have its own state machine. All processing is event-driven via internal connections. The `F_NE` function block operates deterministically without intermediate states.

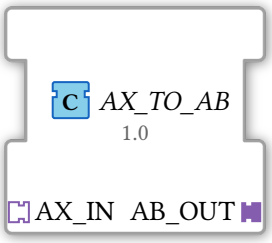
Application Scenarios

- **Signal Conversion**: A digital sensor provides a byte value (e.g., counter reading or status). AB_TO_AX converts this into a Boolean signal, which, for example, triggers an alarm as soon as the value is not zero.
- **Adapter Bridge**: An AB adapter is used in a control component, but the downstream logic expects an AX adapter. The function block acts as a simple translator.
- **Threshold Replacement**: Replaces an explicit comparison block with a compact adapter converter.

Comparison with Similar Function Blocks

Other converter function blocks, such as `BOOL_TO_BYTE` or `BYTE_TO_BOOL`, exist as simple data converters, but usually operate at the data level without an adapter. AB_TO_AX integrates the adapter interface, thus enabling seamless integration into adapter-based architectures. Unlike a general comparison function block (`F_NE`), this function block encapsulates the specific conversion logic and offers a clean interface.

Conclusion



The **AB_TO_AX** function block provides a clean and simple method for converting a BYTE signal from an AB adapter into a BOOL signal for an AX adapter. By using the standard comparison `Ungleich Null`, it is particularly suitable for binary threshold decisions and simplifies reuse in adapter-oriented control projects.

AX_TO_AB

BOOL Adapter Input – *AX*

AB – BYTE Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The composite function block `AX_TO_AB` converts a BOOL adapter signal of type `AX` into a BYTE adapter signal of type `AB`. It encapsulates the type conversion and event passing in a reusable unit.

Interface Structure

Event Inputs

Name	Description
`E1` (from `AX_IN`)	Event input received via the BOOL adapter and passed on unchanged to the output.

Event Outputs

Name	Description
`E1` (from `AB_OUT`)	Event output that provides the event passed through from the input.

Data Inputs

Name	Data Type	Description
`D1` (from `AX_IN`)	`BOOL`	The Boolean signal to be converted (TRUE or FALSE).

Data Outputs

Name	Data Type	Description
`D1` (from `AB_OUT`)	`BYTE`	The converted signal: `TRUE` becomes `1`, `FALSE` becomes `0`.

Adapter

Type	Direction	Identifier	Comment
adapter::types::unidirectional::AX	Socket (Input)	AX_IN	BOOL adapter that provides the input data and events.
adapter::types::unidirectional::AB	Plug (Output)	AB_OUT	BYTE adapter that outputs the converted data and events.

Functionality

Internally, the function block consists only of connections that route the event and data from the socket `AX_IN` to the plug `AB_OUT`.

- The event `E1` is passed on without delay or modification.
- The data value `D1` is converted from type `BOOL` to type `BYTE`. The Boolean value `TRUE` is converted to the byte `1`, and `FALSE` is converted to the byte `0`. This conversion is performed implicitly by the 4diac runtime environment.

Since this is a composite function block, all internal connections are defined at design time; there is no dynamic logic or state machines.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- **Composite Type**: The function block is a pure network function block without its own algorithms. Conversion is achieved by connecting two different adapter types.
- **Type Conversion**: The conversion from `BOOL` to `BYTE` is standards-compliant and uses the implicit cast function of the 4diac IDE. This eliminates the need for a separate conversion function block.
- **Versioning**: The function block is version `1.0` dated February 17, 2026, and is intended for use in the package `adapter::conversion::unidirectional`.

State Overview

The function block has no internal states – it operates purely combinatorially. The output values are a direct function of the input values at any given time.

Application Scenarios

- **Connecting Sensors/Actuators**: If a device or controller operates as a BOOL signal, but the target system expects a BYTE adapter format, `AX_TO_AB` can be used as an intermediary.
- **Adapter Bridges**: In heterogeneous automation networks where different adapter protocols are used, the function block (FB) allows for a simple and type-safe connection.
- **Testing and Simulation**: The FB can be used as a simple converter in test environments to translate signals between different logic layers.

Comparison with Similar Function Blocks

Special conversion FBs exist, such as `BOOL_TO_BYTE` or `BYTE_TO_BOOL`, but these are usually implemented as basic function blocks (FBs) with an algorithm. In contrast, `AX_TO_AB` is a composite function block at the adapter level and encapsulates all communication (events and data). It is useful when entire adapter interfaces need to be implemented, not just individual data points.

Conclusion

The composite function block `AX_TO_AB` offers a compact and elegant solution for converting a BOOL adapter to a BYTE adapter. Through implicit type conversion and direct event forwarding, it reduces manual adjustments and increases reusability in modular automation projects.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ADI_TO_AI

• – ○ • – ○ • – ○ •

Introduction

The function block **ADI_TO_AI** is a composite FB that converts a DINT adapter (ADI) into an INT adapter (AI). It serves as a unidirectional conversion interface between two adapter types and internally uses the block `F_DINT_TO_INT` for type conversion of the data values.

Interface Structure

Event Inputs

The FB does not have separate event inputs. Event-driven processing is handled via the **Socket ADI_IN**:

- **ADI_IN.E1** – Event to request the conversion (internally forwarded to `Convert.REQ`).

Event Outputs

The FB has no separate event outputs. Result feedback is provided via the **AI_OUT** plug:

- **AI_OUT.E1** – Event triggered after successful conversion (corresponds to `Convert.CNF`).

Data Inputs

The FB has no separate data inputs. Input data is provided via the **ADI_IN** socket:

- **ADI_IN.D1** – DINT value (32-bit integer) to be converted to an INT value.

Data Outputs

The FB has no separate data outputs. Result data is output via the **AI_OUT** plug:

- **AI_OUT.D1** – INT value (16-bit integer), the result of the conversion.

Adapter

- **Socket**: `ADI_IN` (Type `adapter::types::unidirectional::ADI`) – DINT adapter input.
- **Plug**: `AI_OUT` (Type `adapter::types::unidirectional::AI`) – INT adapter output.

Functionality

This function block connects the adapter interfaces directly to an internal instance of the conversion function block `F_DINT_TO_INT`:

1. An event at `ADI_IN.E1` triggers `Convert.REQ`.
2. The value of `ADI_IN.D1` is passed to `Convert.IN`.
3. The conversion `DINT → INT` is performed.
4. Upon completion, `Convert.CNF` signals the event to `AI_OUT.E1`, and the converted value from `Convert.OUT` is forwarded to `AI_OUT.D1`.

Technical Features

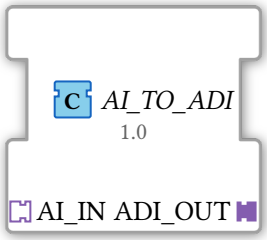
- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **No Dedicated State Machine**: The function block is a pure composite (network) without ECC. Its behavior is determined solely by the internal connection and the conversion block used.
- **Type Conversion**: The conversion from DINT to INT is performed according to IEC 61131-3 (overflow on value range exceeding is not handled; INT range: −32768 … 32767).
- **Package**: The function block (FB) is organized in the package `adapter::conversion::unidirectional`.

State Overview

The FB does not have an explicit state machine. Its behavior is purely data flow-driven: Each incoming event results in exactly one conversion and one output.

Application Scenarios

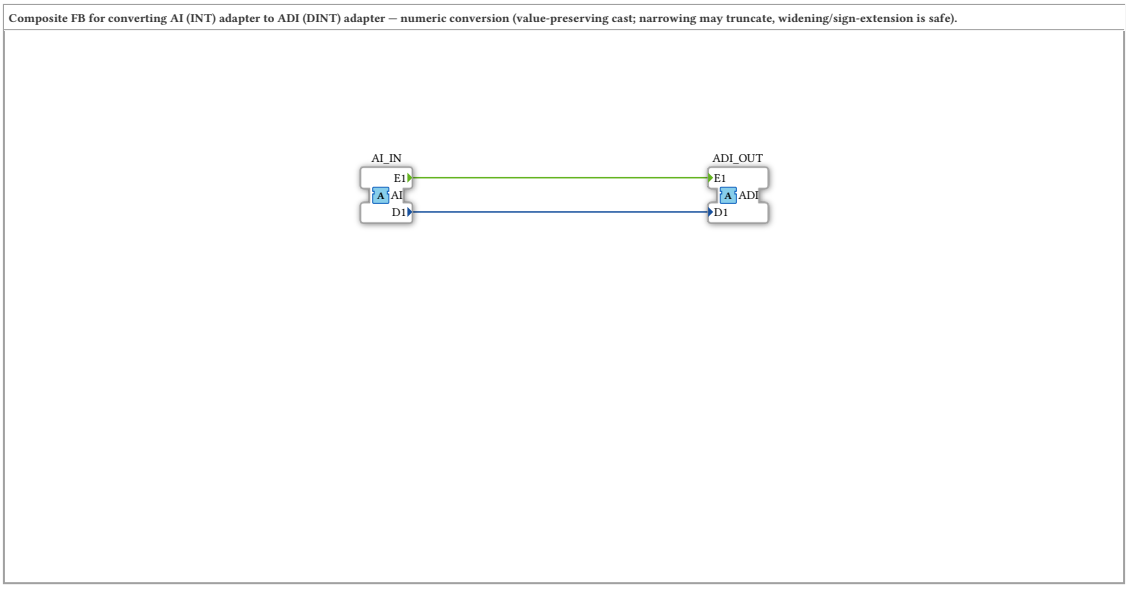
- **Integration of DINT-based components** into an environment that only supports INT adapters (e.g., older controllers or standardized interfaces).
- **Type adaptation** in heterogeneous automation systems that use different data widths.



Comparison with Similar Function Blocks

- **AI_TO_ADI**: The reverse conversion (INT ⟶ DINT). While `ADI_TO_AI` reduces the value range (potential data loss), `AI_TO_ADI` extends the value range without information loss.
- **Direct Adapter Coupling**: Without conversion, the adapter types would have to match exactly. `ADI_TO_AI` enables communication between incompatible types.

Conclusion



The `ADI_TO_AI` module is a simple yet useful converter that bridges the gap between DINT and INT adapter interfaces. Its composite structure makes it easy to understand and maintain. Using the standardized `F_DINT_TO_INT` ensures correct conversion.

AI_TO_ADI

INT Adapter Input – *AI*

ADI – DINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The AI_TO_ADI function block is a composite function block that converts an AI adapter (integer values, type INT) into an ADI adapter (double integer values, type DINT). It serves as a bridge between components that use different adapter interfaces.

Interface Structure

Event Inputs

The function block does not have its own event inputs. The event is provided via the incoming adapter AI_IN:

- **AI_IN.E1** (Event): Trigger for forwarding the data value and the event to the output.

Event Outputs

The function block does not have its own event outputs. The event is output via the outgoing adapter ADI_OUT:

- **ADI_OUT.E1** (Event): Triggered after successful data transmission.

Data Inputs

The function block (FB) does not have its own data inputs. The data is provided via the incoming adapter AI_IN:

- **AI_IN.D1** (INT): The integer value to be converted.

Data Outputs

The function block (FB) does not have its own data outputs. The data is output via the outgoing adapter ADI_OUT:

- **ADI_OUT.D1** (DINT): The converted double-integer value.

Adapters

Name	Direction	Type	Description
AI_IN	Socket	adapter::types::unidirectional::AI	Input adapter for integer values (INT)
ADI_OUT	Plug	adapter::types::unidirectional::ADI	Output adapter for double integer values (DINT)

Functionality

This function block operates as a simple forwarder: As soon as the event `E1` is present at the incoming adapter `AI_IN`, the current value of `AI_IN.D1` is read and passed unchanged to `ADI_OUT.D1`. Subsequently, the event `E1` is triggered at the outgoing adapter `ADI_OUT`. The type conversion from `INT` to `DINT` is performed automatically via the adapter binding; no explicit conversion logic is required.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Implicit Type Conversion:** The function block (FB) performs the conversion from 16-bit integer (INT) to 32-bit double integer (DINT) without data loss, as the target data type is larger.
- **Composite Implementation:** The function block is implemented as a composite FB, meaning it contains an internal network that directly connects the two adapters. It can be used in control projects like a primitive FB.
- **Unidirectional Communication:** Both adapters are designed to be unidirectional – data flows only from input to output.
- **No Latency or Buffering:** Data forwarding is event-driven and occurs without any additional delay.
- **No Latency or Buffering:**

State Overview

The AI_TO_ADI has no internal state machine (ECC). It behaves passively and immediately forwards every incoming event and its associated data. There are no internal states, wait times, or value storage.

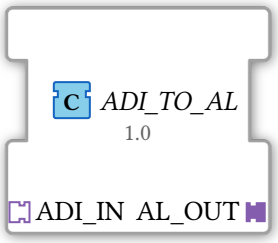
Application Scenarios

- **Adapter Bridge:** If a sensor module provides an AI adapter (INT), but a subsequent processing module expects an ADI adapter (DINT), the AI_TO_ADI can be used as an intermediary.
- **System Integration:** In heterogeneous automation systems where different data types are used for adapter interfaces, this function block enables easy adaptation without modifying the original components.
- **Prototyping:** Rapid coupling of function blocks from different libraries based on different adapter types.

Comparison with Similar Function Blocks

Function Block	Type Conversion	Interface	Use Case
AI_TO_ADI	INT -> DINT	Adapter (Socket/Plug)	Bridge between adapter-based components
INT_TO_DINT	INT -> DINT	Direct inputs/outputs (e.g., DI1, DO1)	Simple data conversion without adapters
CONV_ANY_TO_ANY	Generic	Flexible inputs/outputs	Universal conversion (often more complex)

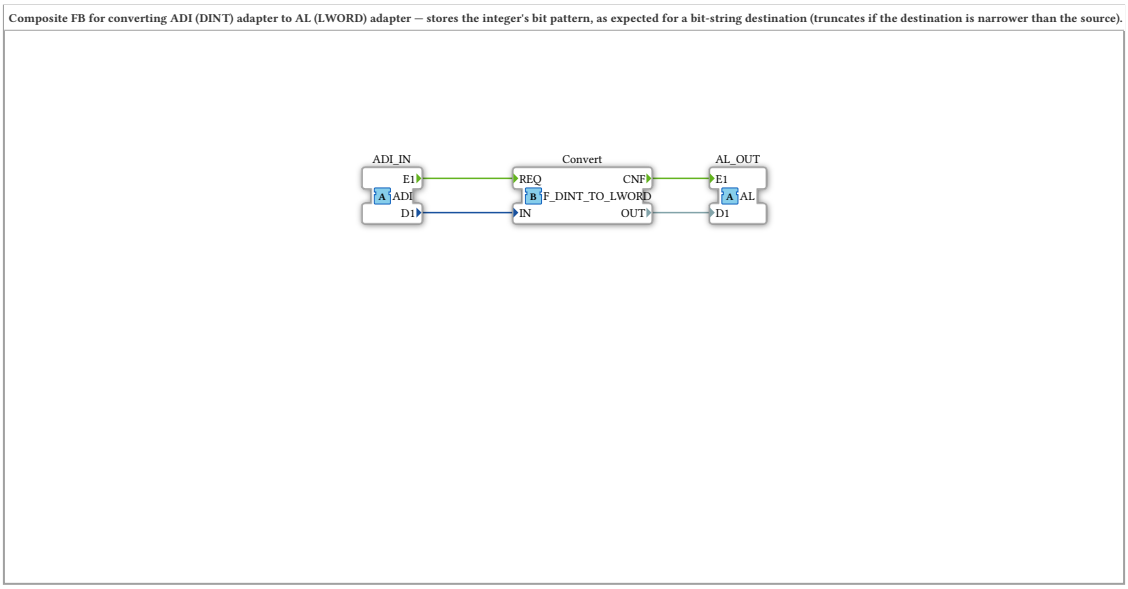
While function blocks like `INT_TO_DINT` offer direct data conversion with their own inputs and outputs, AI_TO_ADI seamlessly integrates the conversion into an adapter-based architecture, thus facilitating the reuse of existing adapter definitions.



Conclusion

The AI_TO_ADI is a simple yet valuable function block for converting integer to double-integer adapter interfaces. Its composite structure and implicit type conversion allow it to be integrated into adapter-based control systems without additional programming logic, simplifying the integration of components with different data widths.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

ADI_TO_AL

DINT Adapter Input – *ADI*

AL – LWORD Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block `ADI_TO_AL` serves as a composite block for converting an ADI adapter (DINT) to an AL adapter (LWORD). It encapsulates a type conversion from a 32-bit integer value to a 64-bit word and provides the connection via unidirectional adapters. The block is ideal for systems where different data type representations between components need to be bridged.

Interface Structure

The block has no direct event or data inputs/outputs. All communication takes place via two adapter interfaces:

Event Inputs

- **No direct event inputs**

The event is received via the ADI adapter `ADI_IN.E1`.

Event Outputs

- **No direct event outputs**

The outgoing event is sent via the AL adapter `AL_OUT.E1`.

Data Inputs

- **No direct data inputs**

The input data is provided via the ADI adapter `ADI_IN.D1` (data type: DINT).

Data Outputs

- **No direct data outputs**

The output data is provided via the AL adapter `AL_OUT.D1` (data type: LWORD).

Adapter

Name	Type	Direction	Comment
ADI_IN	adapter::types::unidirectional::ADI	Socket (Input)	Returns a DINT value and controls processing via event E1.
AL_OUT	adapter::types::unidirectional::AL	Plug (Output)	Outputs the converted LWORD value and acknowledges it via event E1.

Functionality

The function block implements a simple type conversion chain:

1. An event received via the ADI adapter ADI_IN (E1) starts the conversion.
2. The internal function block F_DINT_TO_LWORD converts the incoming DINT value (ADI_IN.D1) into an LWORD value.
3. After successful conversion, the result is output as an LWORD via the AL adapter (AL_OUT.D1), and an event (E1) is sent.

Communication between the adapters and the conversion function block is asynchronous, using event and data connections within the composite block's network.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Unidirectional Adapters** – The block uses exclusively unidirectional adapters (socket for input, plug for output), which define a clear data flow direction.
- **Internal Conversion** – The actual type conversion is handled by the standard block F_DINT_TO_LWORD from the IEC 61131 library, eliminating the need for a custom implementation.
- **License** – The block is licensed under the Eclipse Public License 2.0 (EPL-2.0) and can be freely used, modified, and distributed.
- **No States** – The composite block has no state logic of its own; all control is achieved through event chaining.

State Overview

The block does not have its own state machine. Its behavior is purely reactive: An incoming event at the ADI adapter is immediately reflected in the output of the AL adapter. Internal delays are undefined.

Application Scenarios

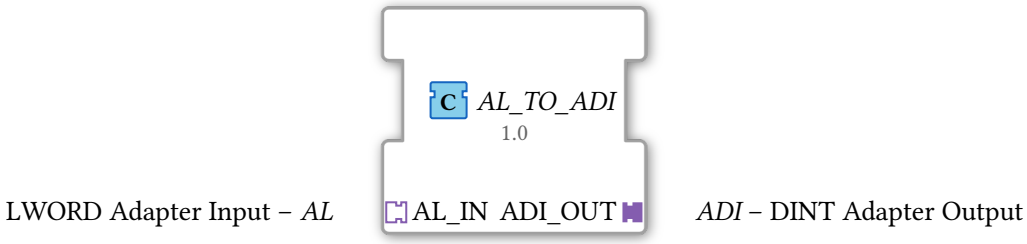
- **Data Bridge Between Different Bus Systems** – When a sensor or controller delivers a DINT value, but a subsequent component expects an LWORD value (e.g., with 64-bit actuators or fieldbus interfaces).
- **Middleware Adaptation** – Use in heterogeneous automation systems to harmonize adapter types without modifying the original components.
- **Test and Simulation Environments** – Easy conversion of data types for debugging or backup connections.

Comparison with Similar Function Blocks

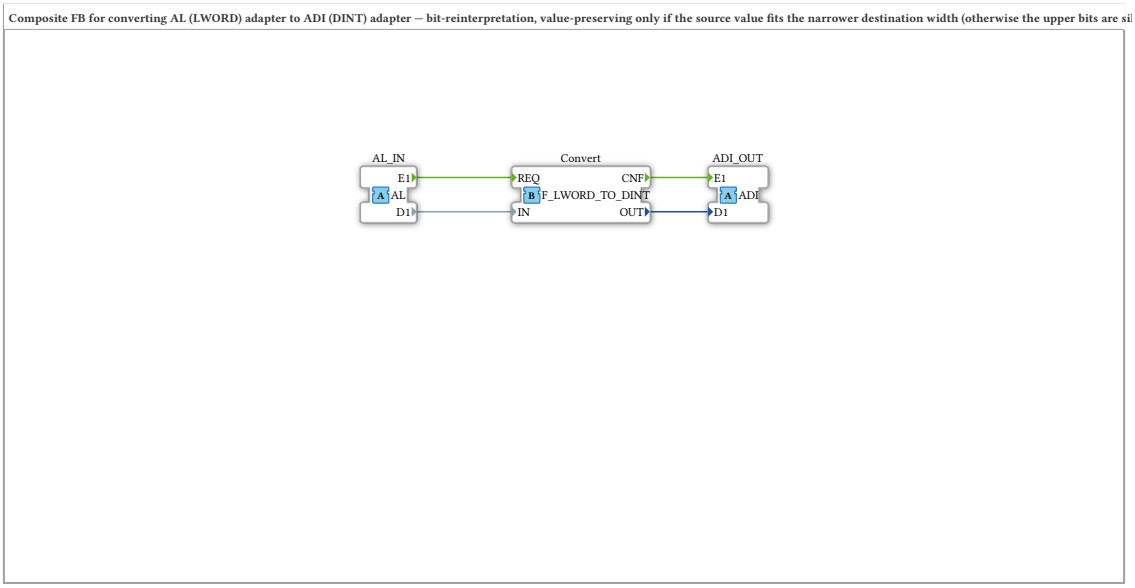
- **Single Conversion Function Blocks** – Function blocks like DINT_TO_LWORD (direct conversion without an adapter) offer a more compact interface but require their own event and data lines.

Middleware Adaptation – Use in heterogeneous automation systems to harmonize adapter types without modifying the original components. - **Universal Adapter Converters** – Generic converters exist that can convert any data type via adapters. ADI_TO_AL is specifically optimized for the DINT→LWORD combination and is therefore easier to understand and maintain.

- **Bidirectional Adapters** – Unlike bidirectional variants, this module is limited to one data flow direction, which reduces the potential for errors.



Conclusion



The `ADI_TO_AL` module offers a clean, streamlined solution for converting DINT to LWORD using unidirectional adapters. It can be easily integrated into existing 4diac projects, requires no custom state modeling, and benefits from the reusability of the internal standard conversion module. This makes it ideal for all applications where fast and reliable data conversion between different adapter types is required.

AL_TO_ADI

• – ○ • – ○ • – ○ •

The composite function block `AL_TO_ADI` serves to standardize the conversion of a unidirectional LWORD adapter (`AL`) into a unidirectional DINT adapter (`ADI`). It enables the seamless integration of components that work with different data types in a 4diac adapter landscape.

Since the function block is implemented as a composite, it does not have its own event or data interfaces outside of the adapters. All inputs and outputs are handled via the integrated adapters.

No dedicated event inputs. The event triggering the conversion is received via socket `AL_IN` (specifically via event `E1`).

No dedicated event outputs. The confirmation event after the conversion is complete is sent via plug `ADI_OUT` (specifically via event `E1`).

No dedicated data inputs. The LWORD value to be converted is provided via socket `AL_IN` (specifically via date `D1`).

No dedicated data outputs. The converted DINT value is output via plug `ADI_OUT` (specifically, via the date `D1`).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- **AL_IN (Socket)**

Type: `adapter::types::unidirectional::AL`
Includes a unidirectional LWORD adapter. Provides the trigger event (`E1`) and the LWORD input value (`D1`).

- **ADI_OUT (Plug)**

Type: `adapter::types::unidirectional::ADI`
Provides a unidirectional DINT adapter. Returns the confirmation event (`E1`) and the converted DINT output value (`D1`).

Functionality

The FB is a composite function block that internally uses the IEC 61131 standard function `F_LWORD_TO_DINT`. The process is as follows:

1. An event at socket `AL_IN.E1` activates the internal converter (`Convert.REQ`).
2. The converter reads the LWORD value from `AL_IN.D1`, converts it to a DINT, and places the result at `Convert.OUT`.
3. After successful conversion, an event from `Convert.CNF` is forwarded to the plug `ADI_OUT.E1`.
4. Simultaneously, the converted DINT value from `Convert.OUT` is transferred to `ADI_OUT.D1`.

This ensures a complete and timely conversion from an LWORD adapter to a DINT adapter.

- The function block uses the IEC 61131-3 function `F_LWORD_TO_DINT` – a standardized and reliable type conversion.
- This is a purely **unidirectional** conversion: Data and events flow only from the socket (`AL_IN`) to the plug (`ADI_OUT`).
- The function block (FB) is modeled as a composite, which allows for a clear separation of conversion logic and adapter interfaces and promotes reuse.
- When converting from LWORD (64-bit) to DINT (32-bit), values outside the DINT range can lead to overflows or limits – this is defined by the IEC function.

The FB does not have its own state machine (ECC) because it is implemented as a composite without sequential logic. Its functionality is implemented purely through event-driven chaining of the internal elements. A one-time conversion pass occurs with each incoming event at `AL_IN`.

- **Sensor Connection:** A sensor provides LWORD data (e.g., a time signal or a large counter variable) that must be further processed as DINT in a controller.
- **Library Extension:** Deployment as part of a collection of unidirectional type converter adapters for various IEC 61131-3 data types.

Similar converter adapters exist in 4diac, for example, for `AL_TO_UDINT`, `BYTE_TO_DINT`, or `LWORD_TO_REAL`. The `AL_TO_ADI` is specifically designed for the LWORD ⟶ DINT combination. Unlike simple function blocks that only convert data, it offers full adapter coupling with event control. Compared to bidirectional adapters, it is fixed to the data flow direction from AL to ADI. Potential data loss due to the reduction in bit width (64 ⟶ 32 bits) must be considered during the selection process.

The Composite Function Block `AL_TO_ADI` provides a clean and standardized solution for converting a unidirectional LWORD adapter to a DINT adapter. By utilizing the IEC 61131 function and embedding it within the 4diac adapter concept, it significantly simplifies the integration of heterogeneous system

components. It is easy to maintain, reusable, and follows established design patterns in industrial automation.

ADI_TO_ALI

DINT Adapter Input – *ADI*

ALI – LINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **ADI_TO_ALI** function block is a composite block that converts a unidirectional ADI adapter (DINT data type) into a unidirectional ALI adapter (LINT data type). It adapts the data width from 32 bits to 64 bits, thus enabling the seamless integration of components of different integer types in automation systems according to IEC 61499-2. The block is available under the Eclipse Public License 2.0.

Interface Structure

Event Inputs
None

Event Outputs
None

Data Inputs
None

Data Outputs
None

Adapters
- **ADI_IN** (Socket) – Type: `adapter::types::unidirectional::ADI`

Accepts a DINT value (32-bit) and its associated event.

- **ALI_OUT** (Plug) – Type: `adapter::types::unidirectional::ALI`

Outputs the converted LINT value (64-bit) and the forwarded event.

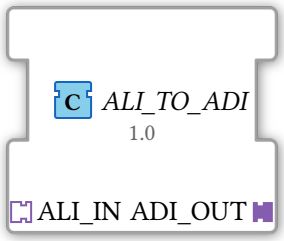
Functionality
This function block implements direct passthrough:

- The event `E1` from the ADI_IN socket is passed to the ALI_OUT plug without delay.
- Simultaneously, the data value `D1` (DINT) is transmitted; this involves an implicit type conversion from 32-bit integer (DINT) to 64-bit integer (LINT).
- No intermediate storage or processing logic takes place – every incoming event-data combination is immediately forwarded to the output side.

Technical Features
- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **No internal state** – The function block is entirely combinatorial and has no memory.
- **Automatic type conversion** via the data connection; the value range of DINT is fully covered by LINT, so no information loss occurs.
- **Adapter-based communication** according to IEC 61499-2 enables loose coupling and reusability.
- The function block is implemented as a composite, meaning its behavior is defined solely by the internal function block network (one event and one data connection).

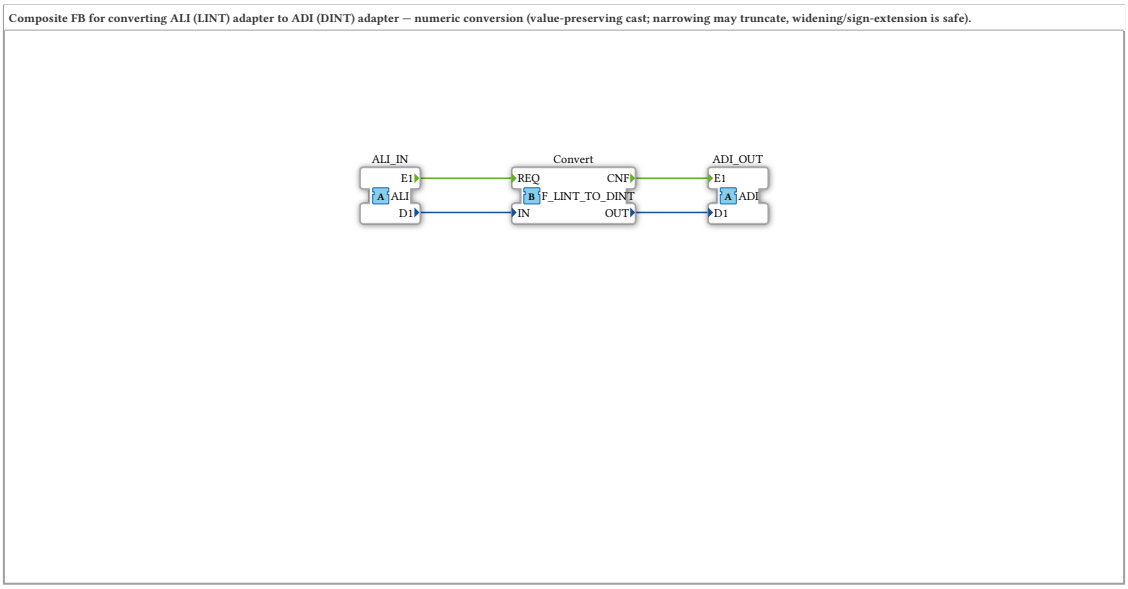
State Overview
This function block does not have a state machine. Its functionality is limited to the direct forwarding of adapter signals.

Application Scenarios
- **System migration** from 32-bit to 64-bit data processing, e.g., during the modernization of controllers.
- **Integration of older components** that provide DINT values into new modules that require LINT interfaces.
- **Adapter bridge** in heterogeneous networks to adapt different integer types between function blocks.



Comparison with Similar Function Blocks
Simple type converters (e.g., `DINT_TO_LINT`) usually operate at the data level without event forwarding. The `ADI_TO_ALI` block, on the other hand, encapsulates events and data in an adapter interface and is therefore particularly suitable for modular, event-driven architectures. Compared to manual conversion over the network, it reduces complexity and increases system readability.

Conclusion



ADI_TO_ALI` is a minimal yet effective block for adapting the data width between DINT and LINT adapters. Its simple pass-through logic and automatic type conversion make it a useful tool for bridging integer types in IEC 61499 systems. Compliance with the standard and licensing under EPL 2.0 ensure open usability and interoperability.

ALI_TO_ADI

LINT Adapter Input – *ALI*

ADI – DINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

This composite function block converts an **ALI** adapter type (LINT, 64-bit integer) to an **ADI** adapter type (DINT, 32-bit integer). It enables seamless integration of components using different adapter formats by encapsulating data conversion and synchronizing it via event control.

Interface Structure

Event Inputs

No direct event inputs are available. Control is handled via the incoming adapter **ALI_IN**.

Event Outputs

No direct event outputs are available. Output is clocked via the outgoing adapter **ADI_OUT**.

Data Inputs

No direct data inputs are available. The input data is provided via the **ALI_IN** adapter (of type ALI).

Data Outputs

No direct data outputs are available. The converted data is output via the **ADI_OUT** adapter (of type ADI).

Adapters

Name	Type	Direction	Description
ALI_IN	`adapter::types::unidirectional::ALI`	Socket (Input)	Returns the LINT value and an associated event (E1).
ADI_OUT	`adapter::types::unidirectional::ADI`	Plug (Output)	Outputs the converted DINT value and an acknowledgment event (E1).

Functionality

The component contains the instance `Convert` of type `iec61131::conversion::F_LINT_TO_DINT`.
The event and data connections are configured as follows:

- The event `ALI_IN.E1` triggers the conversion via `Convert.REQ`.
- The data value `ALI_IN.D1` is passed to `Convert.IN`.
- After successful conversion, `Convert.CNF` signals the event `ADI_OUT.E1`.
- The result value `Convert.OUT` is forwarded to `ADI_OUT.D1`.

Thus, with each event at the input adapter, the LINT value is converted to a DINT value and synchronously provided via the output adapter.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block**: The function block encapsulates the conversion in a reusable adapter-to-adapter converter.
- **Data Type Conversion**: A 64-bit to 32-bit integer conversion takes place. Values outside the DINT range (-2^{31} … $2^{31}-1$) result in an overflow or a limit (depending on the implementation).
- **Event Synchronization**: The conversion is strictly timed through the event chain; a new value is only processed after a previous event.

State Overview

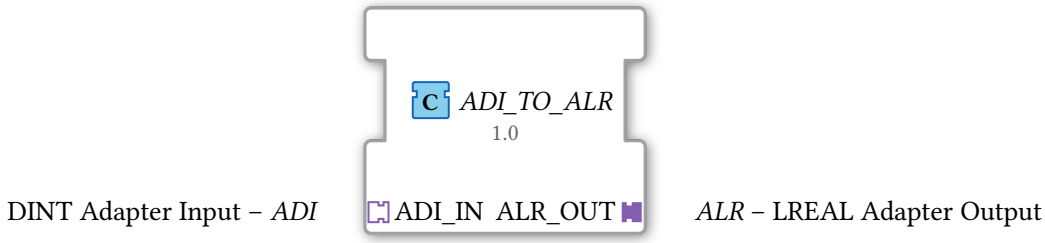
The block does not have its own state machine (ECC). Its entire logic is implemented by the internal function block `F_LINT_TO_DINT`, which operates as a simple conversion block without state behavior.

Application Scenarios

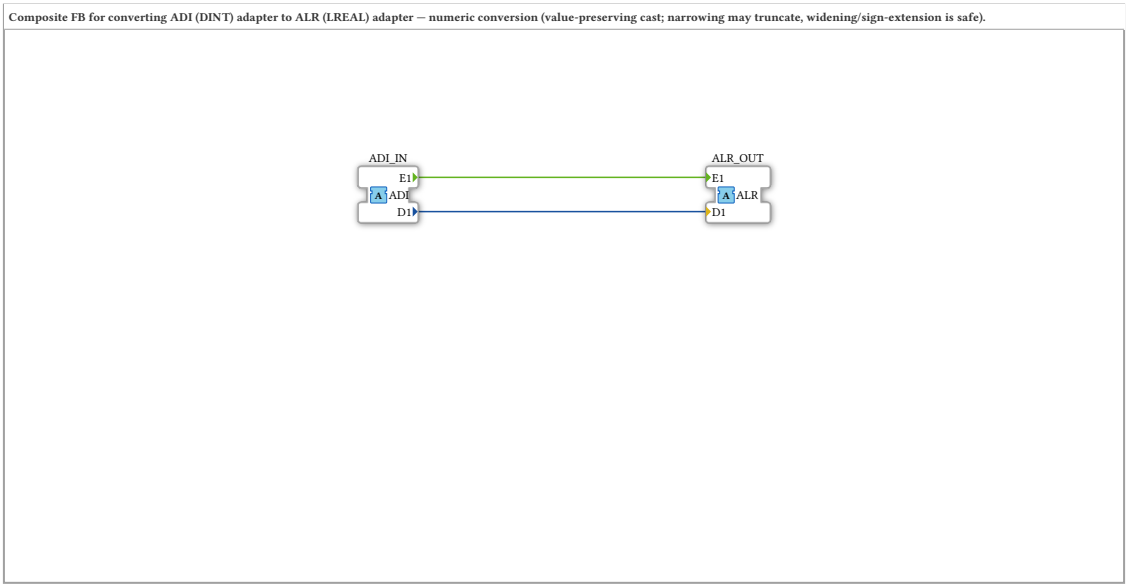
- Connecting a component that provides a 64-bit counter or timestamp (LINT) to a system that only supports 32-bit DINT adapters.
- Migrating legacy systems with 32-bit arithmetic to newer 64-bit sensors without changing the entire adapter landscape.
- Intermediate layer in a hierarchy where different integer widths meet.

Comparison with Similar Blocks

Separate conversion blocks such as `F_LINT_TO_DINT` exist for direct data conversions. The `ALI_TO_ADI` function block stands out because it fully integrates the conversion into the adapter interface. Instead of multiple discrete function blocks and manual adapter wiring, all the logic is combined in a reusable composite block that automatically handles the event and data streams.



Conclusion



The `ALI_TO_ADI` function block offers a clean, encapsulated solution for converting LINT to DINT adapters. By using a composite block, it reduces application complexity and ensures standardized, event-driven conversion between different integer widths in the IEC 61499 environment.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ADI_TO_ALR

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ADI_TO_ALR** is a composite function block (FB) that converts an ADI adapter (data type DINT) into an ALR adapter (data type LREAL). It serves as a unidirectional converter between two standardized adapter interfaces and enables the seamless integration of integer values into systems that require floating-point numbers.

Interface Structure

Event Inputs

- No dedicated event inputs are available.

Event forwarding is handled via the **ADI_IN** adapter (see Adapter section).

Event Outputs

- No dedicated event outputs are available.

The event is output via the **ALR_OUT** adapter (see Adapter section).

Data Inputs

- No dedicated data inputs are available.

The value to be converted is provided via the **ADI_IN** adapter (see Adapter section).

Data Outputs

- No dedicated data outputs are available.

The converted value is output via the **ALR_OUT** adapter (see Adapter section).

Adapters

Name	Type	Direction	Description
ADI_IN	`adapter::types::unidirectional::ADI`	Socket	Input: DINT value and event
ALR_OUT	`adapter::types::unidirectional::ALR`	Plug	Output: LREAL Value and Event

Note: The adapters each imply an event and a data signal (`E1` and `D1`).

Functionality

The module performs direct internal routing:

- **Event:** The incoming event `ADI_IN.E1` is transmitted to the output `ALR_OUT.E1` without delay.
- **Data:** The integer value `ADI_IN.D1` (data type DINT) is converted to the LREAL data type without scaling or conversion and output as `ALR_OUT.D1`. Type conversion is performed implicitly by the runtime environment of the IEC 61499 system.

No further processing (filtering, limiting, delaying) takes place.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block:** The conversion is implemented via a simple wire-through in the FB network – no state machine, no proprietary algorithms.
- **Implicit Type Conversion:** DINT → LREAL is a lossless conversion (LREAL offers 64-bit accuracy).
- **Unidirectional:** Data flows exclusively from the socket to the plug.
- **Reusability:** Encapsulated as an adapter converter, the block can be used in any system that relies on the corresponding adapter interfaces.

State Overview

The block has **no state machine**. It is purely combinatorial (event-driven) and executes the pass-through immediately upon receiving an event.

Application Scenarios

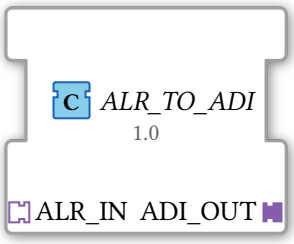
- **Counter Values as Floating-Point Numbers:** An integer counter (e.g., quantities, pulses) is to be processed as an LREAL value in a controller.
- **Interface Adaptation:** System components that already work with ADI adapters can be seamlessly connected to components that expect ALR adapters.
- **Prototypical Development:** Simple conversion without additional logic to quickly link different adapter protocols.

Comparison with Similar Function Blocks

Function Block	Type Conversion	Event Behavior
ADI_TO_ALR	DINT → LREAL	Direct Pass-Through without Delay
`INT_TO_REAL` (4diac)	INT → REAL	Standalone function block with its own event interface
Individual converters	Any number of	Often with state machines or parameterization

This function block is characterized by its **simple, adapter-oriented structure**, which enables direct coupling in adapter networks without having to define separate data and event channels.

Conclusion



ADI_TO_ALR is a minimal yet useful converter for the unidirectional transfer of DINT values to the LREAL format. It is robust, fast, and requires no configuration. Thanks to its composite structure, it can be easily integrated into existing applications based on adapter interfaces.

ALR_TO_ADI

LREAL Adapter Input – *ALR*

ADI – DINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **ALR_TO_ADI** function block is a composite block that enables conversion between two different adapter types. It translates an **ALR adapter** (which provides LREAL data) into an **ADI adapter** (which provides DINT data). It is used in environments based on the IEC 61499 standard to standardize communication between components with different data type interfaces.

Interface Structure

The function block does not have any independent event or data inputs/outputs at the top level. All communication takes place via the two adapter interfaces.

Event Inputs

The function block does not have direct event inputs. Events are received via the **ALR_IN** socket.

Event Outputs

The FB has no direct event outputs. Events are sent via the **ADI_OUT** plug.

Data Inputs

The FB has no direct data inputs. Data is received via the **ALR_IN** socket.

Data Outputs

The FB has no direct data outputs. Data is sent via the **ADI_OUT** plug.

Adapters

Adapter	Direction	Type	Description
ALR_IN	Socket	adapter::types::unidirectional::ALR	Returns an event (E1) and a data value (D1) of type LREAL.
ADI_OUT	Plug	adapter::types::unidirectional::ADI	Expects an event (E1) and outputs a data value (D1) of type DINT.

Functionality

The function block is implemented as a composite and internally contains a single conversion function block: `iec61131::conversion::F_LREAL_TO_DINT`. The connection is as follows:

1. **Event Forwarding**: An event (E1) arriving at socket **ALR_IN** is directly forwarded to the `REQ` input of the conversion function block.
2. **Data Transfer**: The data value **D1** of the **ALR_IN** adapter is transferred to the `IN` input of the conversion function block.
3. **Conversion**: The function block `F_LREAL_TO_DINT` converts the LREAL value into a DINT value.
4. **Feedback**: The confirmation event (CNF) of the conversion function block triggers the event **E1** at the **ADI_OUT** plug.
5. **Data Output**: The converted DINT value from the output `OUT` of the conversion function block is transferred to the data output **D1** of the **ADI_OUT** adapter.

This results in a synchronized, event-driven conversion: Each input pulse generates an output pulse with the converted data value.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block**: The implementation uses an internal standard function block from the IEC 61131 library, which promotes maintainability and reusability.
- **Unidirectionality**: The adapters are declared as unidirectional, meaning data flows in only one direction (ALR → ADI).
- **Package Structure**: The function block is organized in the package `adapter::conversion::unidirectional`, which allows for clear integration into a library.
- **No State Storage**: The conversion is purely combinatorial with event-driven triggering – no internal state is stored.

State Overview

Since the function block does not have its own state diagram, the state logic is limited to that of the internal conversion function block. There are essentially two phases:

- **Waiting**: The function block waits for an event at the ALR_IN socket.
- **Converting**: After receiving the event, the conversion is performed, and the result is output at the ADI_OUT socket.

There are no delays or error handling – the conversion is instantaneous and always produces a valid DINT value (in case of overflow or invalid values, the conversion function block behaves according to IEC 61131).

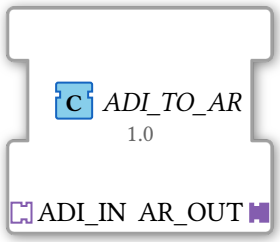
Application Scenarios

- **System Integration**: One system component provides data as LREAL (e.g., floating-point measurements), while another requires integer DINT values (e.g., for counter registers or index calculations).
- **Adapter Adaptation**: If one component only supports ALR adapters, but another component expects ADI adapters, this function block can act as an intermediary.
- **Protocol Conversion**: In standalone subsystems connected via adapters, this function block enables clean type conversion without changing the original adapter definition.
-

Comparison with Similar Function Blocks

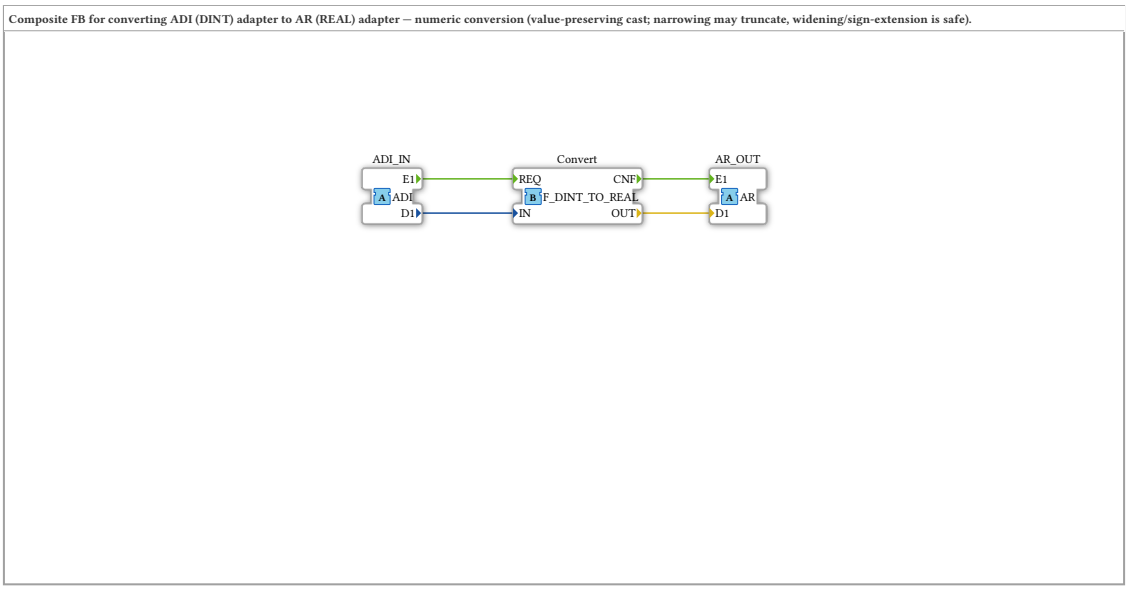
- **F_LREAL_TO_DINT (Direct Function Block)**: This function block performs the conversion itself but requires its own event and data interfaces and no adapters. `ALR_TO_ADI` encapsulates this function block to make it compatible with adapter-based connections.
- **ALR_TO_DINT (Hypothetical)**: A direct function block with its own input/output interface (event + data) would not use any adapters. This function block is specifically designed for use in an adapter framework.
- **Reverse Conversion (ADI_TO_ALR)**: A function block for the reverse direction (DINT ⟶ LREAL) likely exists, based on the same conversion principle.

Conclusion



The composite function block `ALR_TO_ADI` offers an elegant solution for mediating between adapter types with different data types. By reusing a standardized conversion block, the implementation remains lean and reliable. The function block is particularly suitable for modular, adapter-based systems where type conflicts between components need to be resolved.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ADI_TO_AR

DINT Adapter Input – *ADI*

AR – REAL Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **ADI_TO_AR** function block is a composite module that converts a DINT adapter (ADI) into a REAL adapter (AR). It acts as an intermediary between components that communicate via unidirectional adapters, performing a data type conversion from integer (DINT) to floating-point number (REAL).

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **ADI_IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **AR_OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input data value is provided via the **ADI_IN** adapter (data point D1 of type DINT).

Data Outputs

- No directly visible data outputs. The output data value is provided via the **AR_OUT** adapter (data point D1 of type REAL).

Adapters

Adapter	Role	Type	Description
ADI_IN	Socket	adapter::types::unidirectional::ADI	Unidirectional DINT adapter as input interface.
AR_OUT	Plug	adapter::types::unidirectional::AR	Unidirectional REAL adapter as output interface.

Functionality

The function block internally contains a single function block, `F_DINT_TO_REAL`, from the IEC 61131-3 standard library. The sequence control is purely event-driven:

1. An event at the input adapter **ADI_IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **ADI_IN.D1** (DINT) is passed to the input **IN** of the converter.
3. Upon completion of the conversion, the output **CNF** of the converter signals an event.
4. This event is forwarded to the output adapter **AR_OUT.E1**.
5. Simultaneously, the converted REAL value (output **OUT**) is passed to the data point **AR_OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Type Conversion according to IEC 61131-3**: The internal function block `F_DINT_TO_REAL` guarantees standards-compliant conversion of 32-bit integers to floating-point numbers (single precision).
- **Unidirectional Adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported, which simplifies implementation and clearly defines the data flow.
- **Composite Structure**: The function block consists of a network that is completely encapsulated within the function block itself. It is therefore particularly well-suited for modular, reusable interfaces.
- **No States**: There is no state machine – the functionality is purely combinatorial with an event-driven trigger.

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

Step	Action
1	Wait for event at **ADI_IN.E1**
2	Convert the data value from DINT to REAL

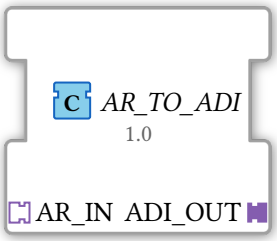
3	Output the converted value to **AR_OUT.D1** and event to **AR_OUT.E1**
4	Return to step 1

Application Scenarios

- **Sensor Integration**: A sensor provides integer measurements (e.g., speed, counter reading) via an ADI adapter. This function block is used as a converter for downstream control or visualization systems that expect REAL values.
- **Interface Adaptation**: In heterogeneous control systems where different components use different data types, this function block enables seamless integration without modifying existing adapter definitions.
- **Type-safe data processing**: Explicit conversion avoids runtime errors that can occur with implicit type conversions in IEC 61499.

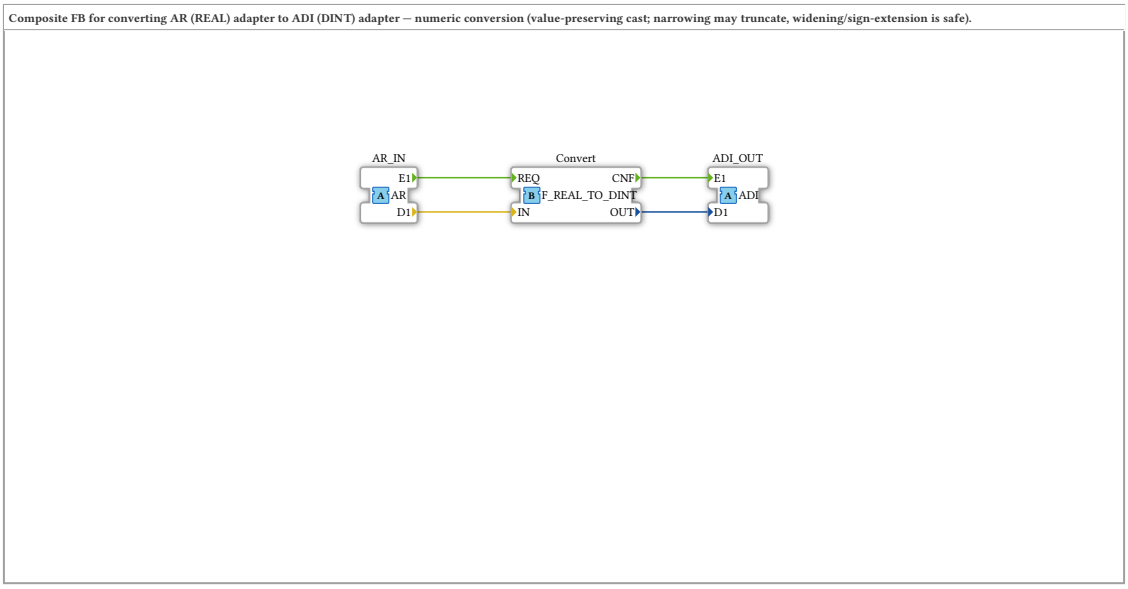
Comparison with similar function blocks

- **F_DINT_TO_REAL**: A direct call to this standard function block would serve the same purpose, but requires manual configuration of event and data connections. The adapter-based approach simplifies reuse and improves network readability.
- **ADI_TO_AR** in contrast to other conversion function blocks (e.g., REAL_TO_DINT): This function block is specifically designed for unidirectional adapter communication and does not offer any other conversion directions.
- **Composite function blocks without adapters**: Other implementations use direct data and event ports, which limits flexibility when replacing components. The adapter interface allows for simple plug-and-play in predefined architectures.



F_DINT_TO_REAL: ** ...

Conclusion



The **ADI_TO_AR** function block represents an elegant and standards-compliant solution for converting DINT values to REAL values, fully embedded in the adapter-based communication structure of IEC 61499. By encapsulating the conversion process in a reusable composite component, it supports the development of modular, type-safe, and well-documented automation systems.

AR_TO_ADI

REAL Adapter Input – *AR*

ADI – DINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The function block **AR_TO_ADI** is a composite block that converts a REAL adapter (AR) into a DINT adapter (ADI). It is used to mediate between interfaces with different data types, with the conversion occurring in an event-driven manner.

Interface Structure

The block's interface consists exclusively of adapters that bundle both events and data. There are no separate inputs or outputs.

Event Inputs

- **AR_IN.E1** – Event input via the AR adapter

Triggers the conversion of the incoming REAL value.

Event Outputs

- **ADI_OUT.E1** – Event output via the ADI adapter

Activated after successful conversion.

Data Inputs

- **AR_IN.D1** (Data type REAL) – The floating-point value to be converted.

Data Outputs

- **ADI_OUT.D1** (Data type DINT) – The converted integer value.

Adapters

Adapter	Name	Direction	Description
AR	AR_IN	Socket (Input)	Unidirectional REAL adapter that provides the input signal.
ADI	ADI_OUT	Plug (Output)	Unidirectional DINT adapter that forwards the converted signal.

Functionality

The function block is implemented as a composite function block. It contains an instance of the IEC 61131 standard function block `F_REAL_TO_DINT`.

As soon as an event arrives at the event input **AR_IN.E1**, the REAL value present at **AR_IN.D1** is passed to the internal converter. After the conversion is complete, the result is forwarded to **ADI_OUT.D1** and the event **ADI_OUT.E1** is triggered.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- The function block uses the data type converter `F_REAL_TO_DINT` from the IEC 61131 library.
- It is a composite function block that does not have its own state logic; instead, the functionality is implemented through the internal function block.
- The interface is purely adapter-based, allowing for easy integration into existing adapter networks.

State Overview

Since the FB does not contain a state machine, the following simple sequence applies:

1. **Waiting** – The FB is ready to receive an event on **AR_IN.E1**.
2. **Conversion** – As soon as an event arrives, the REAL value is converted to DINT.
3. **Output** – After the conversion is complete, the result is output and the output event is sent. The FB then returns to the wait state.

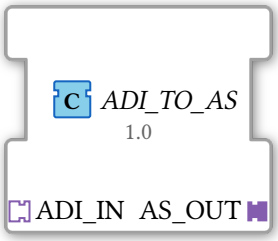
Application Scenarios

- Adapting a sensor that delivers REAL values to a controller that expects DINT values.
- Bridging the gap between two adapter-based components with different data types in an IEC 61499 system.
- Use in data preprocessing chains where floating-point numbers need to be converted to integers.

Comparison with similar function blocks

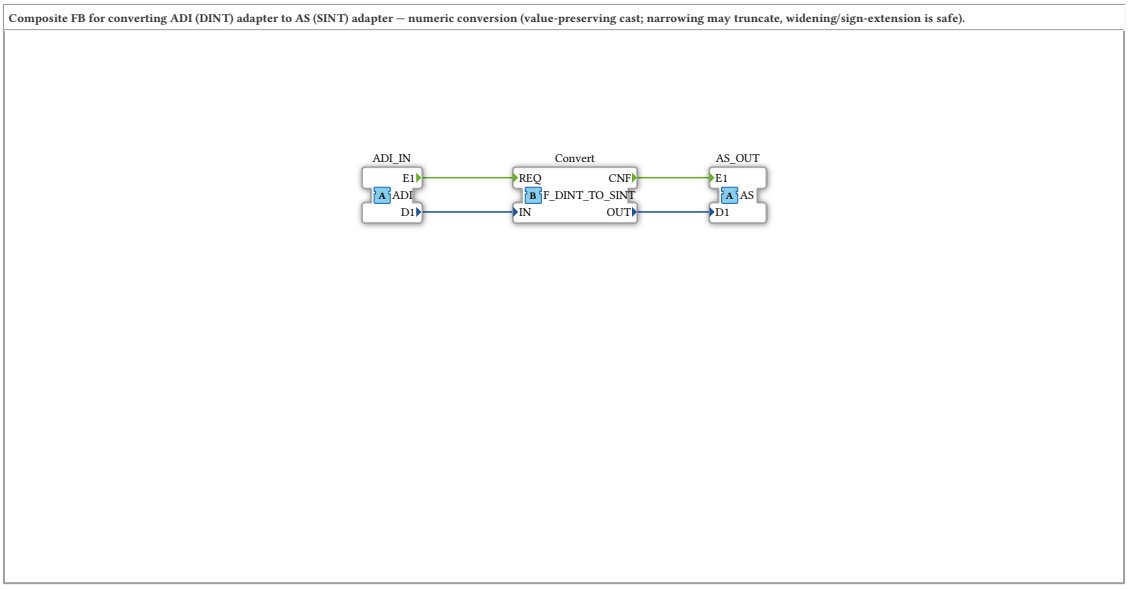
- **`F_REAL_TO_DINT`** – This function block performs the actual conversion but expects separate event and data connections. **AR_TO_ADI** encapsulates this functionality in an adapter-based interface, thus simplifying integration into adapter networks.
- **Other adapter converters** – Similar function blocks exist for other data type combinations (e.g., AR_TO_AINT, ADI_TO_AR). They all follow the same pattern: using an internal conversion function block embedded in a uniform adapter shell.

Conclusion



AR_TO_ADI is a compact, reusable composite function block that enables clean conversion from REAL to DINT adapters. Thanks to its simple, event-driven structure and the use of standardized conversion modules, it is ideally suited for adapter-based designs in industrial control systems.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ADI_TO_AS

DINT Adapter Input – *ADI*

AS – SINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The composite function block **ADI_TO_AS** is used to convert a **DINT adapter signal** (type `ADI`) into a **SINT adapter signal** (type `AS`). It is used when data and event exchange is required via unidirectional adapters and a data type conversion from DINT (32-bit signed integer) to SINT (8-bit signed integer) is necessary.

Interface Structure

Event Inputs

No separate event inputs – event control is handled via the integrated **ADI-IN adapter** (socket).

Event Outputs

No separate event outputs – event forwarding is handled via the integrated **AS-OUT adapter** (plug).

Data Inputs

No separate data inputs – the data value is provided via the **ADI-IN adapter**.

Data Outputs

No separate data outputs – the converted value is output via the **AS-OUT adapter**.

Adapters

Adapter	Direction	Type	Comment
ADI_IN	Socket (Input)	`adapter::types::unidirectional::ADI`	DINT Adapter Input
AS_OUT	Plug (Output)	`adapter::types::unidirectional::AS`	SINT Adapter Output

The **ADI-IN Adapter** provides an event interface `E1` and a data interface `D1` (type DINT). The **AS-OUT Adapter** provides `E1` and `D1` (type SINT).

Functionality

Inside the composite module, a single function block `Convert` of type `iec61131::conversion::F_DINT_TO_SINT` is used. The signal connections are as follows:

1. An incoming event at the **ADI-IN adapter** (`E1`) triggers the **Convert FB** via its event input `REQ`.
2. Simultaneously, the DINT value is transferred from the adapter's data port `ADI_IN.D1` to the **Convert input** `IN`.
3. After the conversion is complete, **Convert** generates an event at its output `CNF`.
4. This event is forwarded directly to the **AS-OUT adapter** (`E1`).

5. The converted SINT value is available at the **Convert output** `OUT` and is transferred to the adapter data port `AS_OUT.D1`.

This enables complete, event-driven conversion from DINT to SINT via the adapter interfaces.

Technical Details

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **License and Origin:** This module is subject to the **Eclipse Public License 2.0** and is from **HR Agrartechnik GmbH** (Version 1.0, Author: Franz Höpfinger, Date: 2026-02-17).
- **Dependency:** It uses the library module `iec61131::conversion::F_DINT_TO_SINT` from the IEC 61131 conversion package.
- **Composite Structure:** No separate states or algorithms are defined – all logic is executed by the internal network.
- **Packet Assignment:** The function block is organized in the package `adapter::conversion::unidirectional`.

State Overview

As a composite function block, **ADI_TO_AS** does not have its own state machine. Its behavior results solely from the execution of the embedded function block `F_DINT_TO_SINT` and the hard-wired connections.

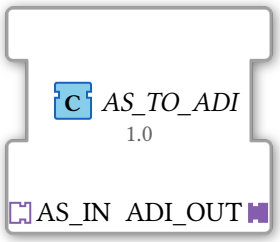
Application Scenarios

- **Adapter Type Conversion:** When a component (e.g., a sensor or actuator) communicates via a unidirectional DINT adapter, but the target system expects a SINT adapter.
- **Data Range Reduction:** Applications where a 32-bit value needs to be converted to an 8-bit value, e.g.,... B. for controlling simple peripherals with limited resolution.
- **Interface adaptation:** Integration into a toolchain based on 4diac's unidirectional adapter concept, requiring a clean separation of event and data flows.

Comparison with similar modules

Other adapter conversion modules exist, such as `ADI_TO_AI` (DINT → INT) or `ADI_TO_ADI` (identical passthrough). The **ADI_TO_AS** module differs in its specific target type conversion to SINT. All share a uniform adapter interface and event-driven processing via an integrated conversion module.

Conclusion



The **ADI_TO_AS** is a compact, pre-built composite module that reliably and easily converts a DINT adapter signal to a SINT adapter signal. It is ideal for all applications requiring clean type conversion within the 4diac adapter concept, without the need to manually implement separate conversion logic. Thanks to its EPL 2.0 license, it can be freely used and adapted in your own projects.

AS_TO_ADI

SINT Adapter Input – *AS* *ADI* – DINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The **AS_TO_ADI** function block converts a SINT adapter (AS) into a DINT adapter (ADI). It is a composite function block that establishes a unidirectional, type-converting connection between the two different data adapters.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapter

Type	Direction	Name	Description
Socket	Input	AS_IN	Adapter type `AS` (SINT, 8-bit signed integer) – receives the SINT signal.
Plug	Output	ADI_OUT	Adapter type `ADI` (DINT, 32-bit signed integer) – outputs the converted DINT signal.

Functionality

The module internally links the event and data lines of the two adapters directly:

- The incoming event `E1` of socket `AS_IN` is transferred unchanged to the output plug `ADI_OUT` at its event `E1`.
- The data value `D1` from the SINT adapter (`AS_IN.D1`) is forwarded to data port `D1` of the DINT adapter (`ADI_OUT.D1`).

Since the data types are different (SINT ⟶ DINT), implicit value preservation occurs: The SINT value (value range −128 … 127) is copied into a signed 32-bit value (sign extension). The function block itself does not execute its own conversion logic but relies on the type conversion defined by the adapter interfaces.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Function Block**: The function block does not have its own behavior model (ECC) but only an internal function block network that connects the adapters.
- **Type Conversion**: The conversion from SINT to DINT is handled system-wide by the runtime environment (type compatibility for data connections).
- **Package**: The function block is located in the package `adapter::conversion::unidirectional`.
- **Fully Predefined**: The internal wiring is fixed; the adapters must each have an event port and a data port (`E1`, `D1`).

State Overview

Since this is a composite function block without its own state machine, there are no states or steps. The function block operates purely data-flow synchronously – every incoming event immediately triggers the forwarding.

Application Scenarios

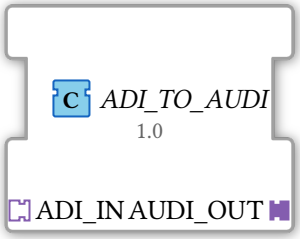
- **Sensor Connection**: A SINT adapter (e.g., from an 8-bit sensor) is to be connected to a controller that expects a DINT adapter as its interface.
- **System Integration**: In systems where different accuracy levels (8-bit vs. 32-bit) are used, this function block enables simple, standardized conversion.
- **Protocol Adaptation**: As part of an adapter cascade to switch from a simple data interface standard to a more powerful one.

Comparison with Similar Function Blocks

- **AS_TO_UDI** – Converts SINT to UINT (unsigned 16-bit integer), different value range interpretation.
- **ADI_TO_AS** – Backward conversion from DINT to SINT (with potential overflow risks).
- **DIRECT_LINK** – Pure passthrough without type conversion, usable only with identical adapter types.

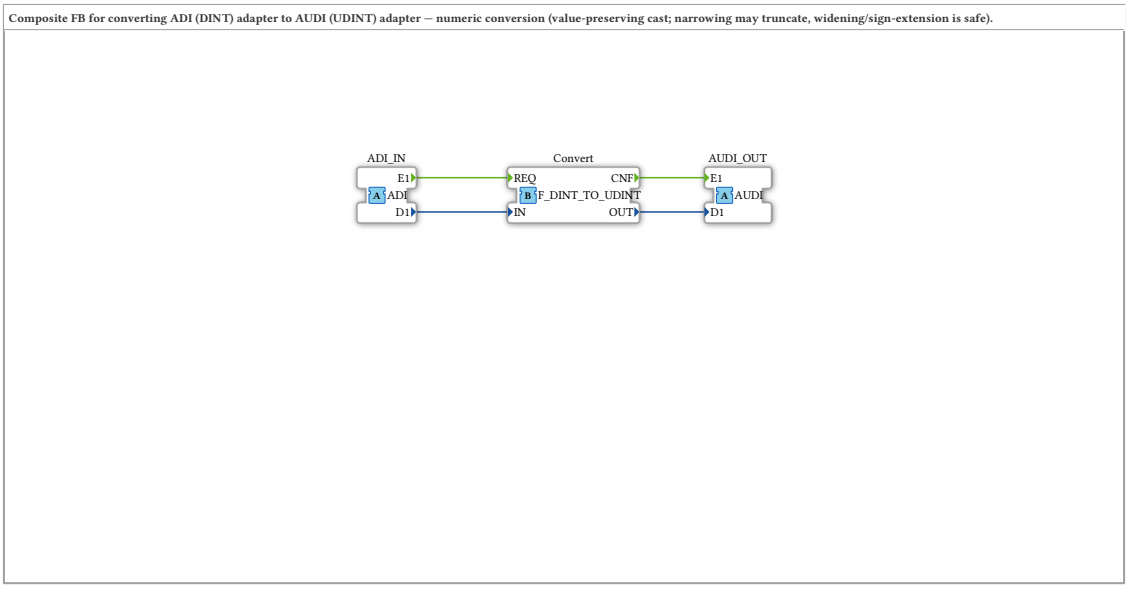
Unlike universal converters (e.g., using `MATH` function blocks), `AS_TO_ADI` offers a specialized, compact solution without additional parameterization.

Conclusion



The **AS_TO_ADI** function block enables fast and reliable type conversion between SINT and DINT adapters. Its simple, composite-based structure makes it ideal for standardized adapter conversions in automation technology where unidirectional 8-bit to 32-bit conversion is required.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ADI_TO_AUDI

DINT Adapter Input – *ADI*

AUDI – UDINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block ADI_TO_AUDI converts an ADI (DINT) adapter to an AUDI (UDINT) adapter. It is a composite function block (FB) that uses an internal conversion block to convert the data types from signed 32-bit integer (DINT) to unsigned 32-bit integer (UDINT). The block enables the seamless integration of components that use different adapter types.

Interface Structure

Event Inputs

The function block does not have direct event inputs. Events are provided via the incoming adapter **ADI_IN**. The ADI adapter defines an event output E1, which is connected to the event input REQ of the internal conversion block.

Label	Data Type	Description
(via ADI_IN.E1)	EVENT	Trigger for Conversion

Event Outputs

This function block does not have direct event outputs. Events are passed on via the outgoing adapter **AUDI_OUT**. The internal conversion function block signals completion via CNF, which is connected to the event input E1 of the AUDI adapter.

Name	Data Type	Description
(via AUDI_OUT.E1)	EVENT	Confirmation of Completed Conversion

Data Inputs

This function block has no direct data inputs. The DINT value to be converted is provided via the incoming adapter **ADI_IN** (output D1).

Name	Data Type	Description
(via ADI_IN.D1)	DINT	The value in DINT format to be converted to UDINT

Data Outputs

This function block has no direct data outputs. The converted UDINT value is output via the outgoing adapter **AUDI_OUT** (input D1).

Name	Data Type	Description
(via AUDI_OUT.D1)	UDINT	The result of the conversion as UDINT

Adapters

The function block provides two adapter interfaces:

Name	Direction	Type	Description
ADI_IN	Socket	adi (unidirectional)	Input adapter – provides DINT data and a trigger event
AUDI_OUT	Plug	audi (unidirectional)	Output adapter – outputs converted UDINT data and an acknowledgment event

The adapters are unidirectional, meaning they transmit data and events in only one direction.

Functionality

The function block operates as a pure wrapper (composite) and contains a single internal function block of type `iec61131::conversion::F_DINT_TO_UDINT`. As soon as an event arrives at input adapter E1 on the ADI_IN input, the internal function block is triggered via its REQ input. This block reads the DINT value present at ADI_IN.D1, converts it to a UDINT value, and outputs the result to its output OUT. Simultaneously, it generates an acknowledgment event at CNF, which is forwarded via the output adapter AUDI_OUT.E1. The converted value is then available at AUDI_OUT.D1.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- The function block is implemented as a composite function block and does not contain any logic of its own. All functionality is provided by the internal conversion block.
- The adapters are of type "unidirectional," meaning that data and event flows are directed.
- The function block is part of the adapter conversion library and facilitates the connection of components with different adapter data types.
- The data type conversion from DINT to UDINT is typed; An overflow for negative values must be considered (e.g., –1 becomes 4294967295).

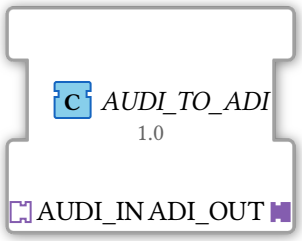
State Overview

The function block does not have its own state machine. Its behavior results solely from the interaction of the internal block `F_DINT_TO_UDINT` and the event connections. The internal block has simple state logic: In its idle state, it waits for a REQ event, then performs the conversion and sends CNF. There are no other states.

Application Scenarios

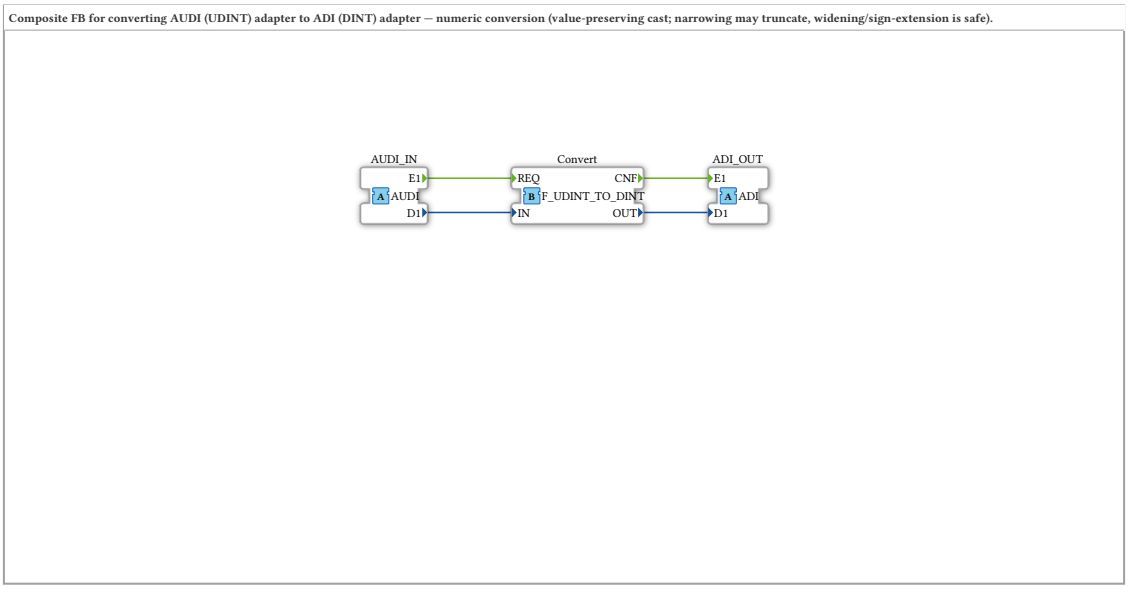
- **Adapter Replacement**: When an application needs to replace a DINT-based adapter (ADI) with a UDINT-based adapter (AUDI) without changing the surrounding logic.
- **System Integration**: Connecting components that use different integer types (e.g., a sensor provides DINT, an actuator expects UDINT).
- **Protocol Adaptation**: In heterogeneous control systems where adapter types are not directly compatible.

Comparison with Similar Function Blocks



- **ADI_TO_AUDI** (this function block): Converts DINT adapters to UDINT adapters.
- **AUDI_TO_ADI**: A hypothetical counterpart that would convert UDINT to DINT (does not exist in the given XML, but is conceivable).
- **Direct Conversion with F_DINT_TO_UDINT**: Instead of using the adapter, the conversion function block could be used directly, but the adapter structure would then have to be manually recreated. ADI_TO_AUDI encapsulates this adaptation and provides a clean interface.

Conclusion



The ADI_TO_AUDI function block provides a simple and effective solution for converting DINT to UDINT adapters. As a composite function block, it utilizes a proven standard conversion block and offers a clear, unidirectional interface via its adapters. It is particularly well-suited for system integration and adapter adaptation in IEC 61499-based automation solutions.

AUDI_TO_ADI

UDINT Adapter Input – *AUDI*

ADI – DINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AUDI_TO_ADI** function block is a composite block that converts a unidirectional AUDI adapter (UDINT) into an ADI adapter (DINT). It serves as a bridge between components that use different data types via adapter interfaces. The conversion is performed by the inner block `iec61131::conversion::F_UDINT_TO_DINT`.

Interface Structure

Event Inputs

Name	Type	Comment
AUDI_IN.E1	EVENT	Event input via the AUDI adapter; triggers the conversion

Event Outputs

Name	Type	Comment
ADI_OUT.E1	EVENT	Event output via the ADI adapter; signals completion of conversion

Data Inputs

Name	Type	Comment
AUDI_IN.D1	UDINT	Unsigned 32-bit value converted to a signed DINT

Data Outputs

Name	Type	Comment
ADI_OUT.D1	DINT	Converted signed 32-bit value

Adapter

Name	Type	Direction	Comment
AUDI_IN	adapter::types::unidirectional::AUDI	Socket (Input)	UDINT Adapter Interface
ADI_OUT	adapter::types::unidirectional::ADI	Plug (Output)	DINT Adapter Interface

Functionality

The function block receives a UDINT value via socket `AUDI_IN` along with an event at input `E1`. This event triggers the conversion of the incoming UDINT value to a DINT value. The conversion is performed internally by the function block `F_UDINT_TO_DINT`. After successful conversion, the converted DINT value is provided via the plug `ADI_OUT`, and an event is sent at the output `E1`.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- The block is a composite function block and does not contain its own algorithm – all logic is delegated to the embedded `F_UDINT_TO_DINT`.
- The conversion follows the IEC 61131-3 definition of `UDINT_TO_DINT`, meaning that values outside the DINT range (−2147483648 … 2147483647) are clamped to the nearest valid value.
- Event forwarding is strictly causal: the output event is only activated after the conversion is complete.

State Overview

The function block has no internal states of its own. Its behavior is purely reactive:

An input event is always followed by an output event – provided the data is valid. A dedicated state machine does not exist.

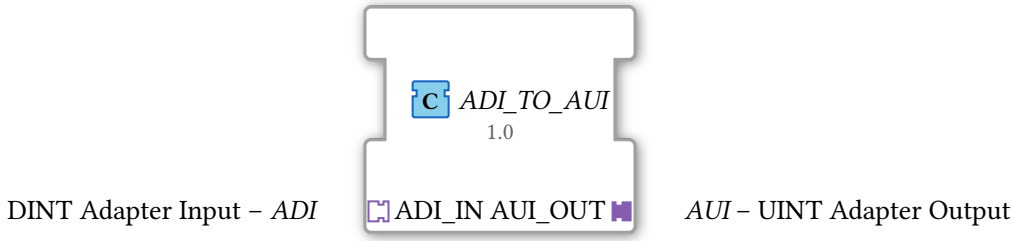
Application Scenarios

- Connecting a UDINT-providing sensor (e.g., counter or position value) to an actuator that expects a DINT adapter.
- Integrating PLC components that use different adapter data types without requiring the user to manually program the conversion.
- A unified adapter interface in a control architecture that works partly with signed and partly with unsigned values.

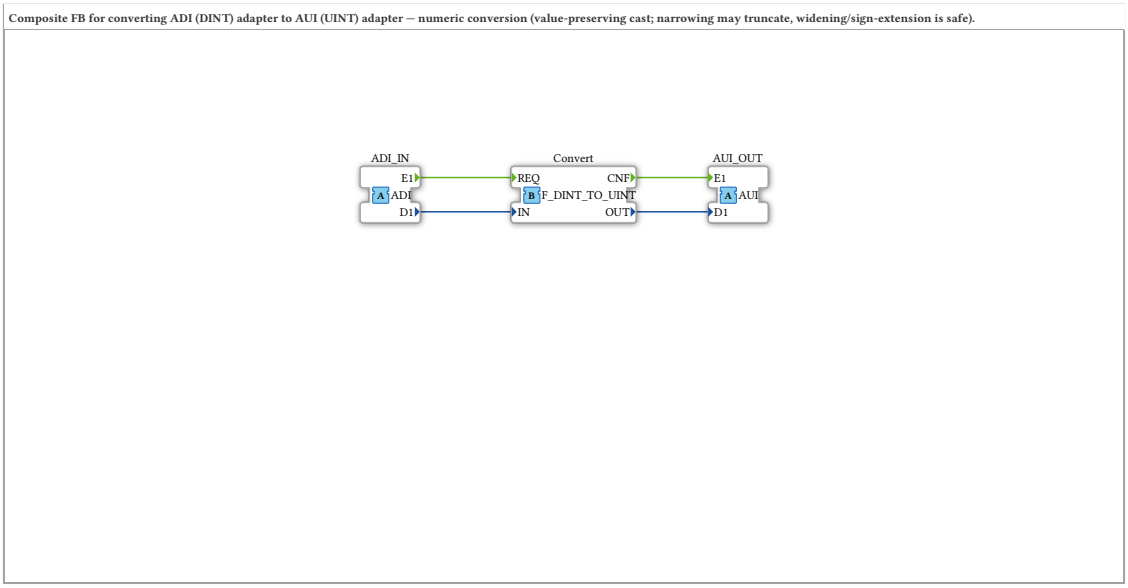
Comparison with Similar Function Blocks

- **DINT_TO_AUDI**: Performs the reverse conversion (DINT → UDINT).
- **F_UDINT_TO_DINT**: Direct use of the conversion function block without adapter encapsulation.

This function block encapsulates the data type conversion in an adapter context, thus simplifying the interconnection of components that rely on adapter interfaces.



Conclusion



AUDI_TO_ADI offers a clean, compact solution for converting UDINT adapter data to DINT adapter data. The use of a standardized conversion function block ensures reliable and easily traceable functionality. The composite approach reduces complexity in the higher-level system and facilitates the reusability of the adapter logic.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ADI_TO_AUI

• – ○ • – ○ • – ○ •

Introduction

The **ADI_TO_AUI** function block is a composite function block that implements interface conversion between the ADI adapter (DINT, 32-bit integer) and the AUI adapter (UINT, 16-bit integer). It enables the unidirectional transfer of a value from a DINT adapter to a UINT adapter using a standardized IEC 61131 conversion block.

Interface Structure

Event Inputs

None – event control is handled exclusively via the adapters.

Event Outputs

None.

Data Inputs

None – all data is provided via the socket adapter.

Data Outputs

None – all data is output via the plug adapter.

Adapters

Type	Name	Direction	Description

Socket	ADI_IN	Input	ADI adapter (DINT) – provides the value to be converted and an event
Plug	AUI_OUT	Output	AUI adapter (UINT) – provides the converted value and the associated event

Functionality

The function block does not have its own input/output events or top-level data points. All control and data transmission is handled via the two adapters:

1. **Event Forwarding**:

The event E1 received at socket ADI_IN is forwarded directly to the internal block F_DINT_TO_UINT (type: iec61131::conversion) to trigger a conversion.

1. **Data Path**:

The DINT value provided via ADI_IN.D1 is passed to input IN of F_DINT_TO_UINT. After successful conversion, the result (UINT) is available at output OUT and is assigned to the data output D1 of the plug adapter AUI_OUT.

1. **Feedback**:

The internal function block signals the end of the conversion with the event CNF. This event is transferred to the output event E1 of the plug adapter AUI_OUT – synchronously with the provided data value.

Thus, the function block implements a **unidirectional, event-driven** transfer of a DINT value to a UINT value via the adapter interfaces.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Function Block**: The function block fully encapsulates the conversion logic and offers a clean, reusable interface.
- **Core Function Block Used**: iec61131::conversion::F_DINT_TO_UINT – a standardized IEC 61131 function for converting DINT to UINT (value range adjustment: DINT to UINT is considered without a sign; negative values are converted accordingly).
- **Adapter Types**: The adapters ADI and AUI are defined as unidirectional adapters (adapter::types::unidirectional). They each provide an event pair (E1/E1) and a data point (D1 in the corresponding data type).
- **Package Structure**: The function block is organized in the package adapter::conversion::unidirectional.
- **License**: The function block is subject to the Eclipse Public License 2.0 (EPL-2.0). Copyright belongs to HR Agrartechnik GmbH.

State Overview

As a composite function block, **ADI_TO_AUI** does not have its own internal state machine. The state is determined exclusively by the embedded function block F_DINT_TO_UINT, which performs the conversion after receiving the REQ event and completes with CNF. The function block is therefore **stateless** in the sense of a pure function block (no stored states outside the core function block).

Application Scenarios

- **Interface adaptation** between system components that use different data types for analog or digital values (e.g., sensors with DINT output and actuators with UINT input).
- **Data consolidation** in heterogeneous IEC 61499 networks where adapters of different data types interact.
- **Prototypes and Migration**: Easy integration of function blocks that originally work with DINT into an environment that expects UINT – without manual conversion at each connection step.

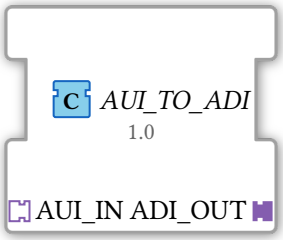
Comparison with Similar Function Blocks

Directly comparable adapter conversion blocks exist for other data types (e.g., BOOL_TO_UINT, INT_TO_DINT). The difference with **ADI_TO_AUI** lies in the specific combination of adapter interfaces

(ADI ↔ AUI). Unlike simple conversion function blocks (`F_DINT_TO_UINT`), this composite function block encapsulates both the adapter connection and the event and data synchronization in a reusable module.

An alternative design could use a generic conversion block with configurable adapter types; however, the dedicated solution offers clearer documentation and easier handling within the 4diac IDE.

Conclusion



The **ADI_TO_AUI** function block provides a clean, maintainable, and standardized way to convert DINT data via an ADI adapter to a UINT signal via an AUI adapter. By using an IEC 61131 core block, the conversion is standards-compliant and reliable. The composite approach increases reusability and simplifies engineering in distributed automation systems.

AUI_TO_ADI

UINT Adapter Input – *AUI*

ADI – DINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The AUI_TO_ADI function block is a composite module that converts a unidirectional AUI adapter (data type UINT) into a unidirectional ADI adapter (data type DINT). It serves as a standardized interface between components that use different data types for analog input or output values.

Interface Structure

Event Inputs

None. Event control is handled via the connected AUI adapter (socket AUI_IN).

Event Outputs

None. Event output is handled via the ADI adapter (plug ADI_OUT).

Data Inputs

None. Data input is handled via the connected AUI adapter.

Data Outputs

None. Data output is handled via the ADI adapter.

Adapter

Name	Direction	Type	Description
AUI_IN	Socket (Input)	`adapter::types::unidirectional::AUI`	UINT adapter for receiving input data and events.
ADI_OUT	Plug (Output)	`adapter::types::unidirectional::ADI`	DINT adapter for sending the converted data and events.

Functionality

The function block receives an event and a UINT value via the AUI_IN socket. This event triggers the internal conversion block `F_UINT_TO_DINT`, which converts the value from type UINT to type DINT. After successful conversion, an event is output via the ADI_OUT plug, along with the converted DINT value. The conversion is performed according to the IEC 61131 standard and is lossless, as the entire value range of UINT (0…65535) can be mapped to DINT.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- The function block (FB) is implemented as a **composite block**, meaning its functionality is based on an integrated IEC 61131 block (`F_UINT_TO_DINT`).
- Communication occurs exclusively via **unidirectional adapters** – no separate event or data inputs/outputs are required at the top level.
- The internal converter operates **event-driven**: Every incoming event at the AUI_IN adapter triggers a conversion.

State Overview

The FB does not have its own state machine. The state logic is fully implemented by the internal function block `F_UINT_TO_DINT`, which performs a one-time conversion for each REQ event and acknowledges it with CNF.

Application Scenarios

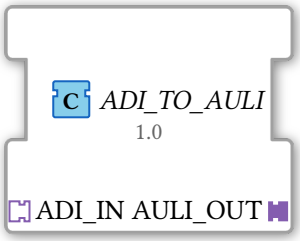
- **Interface Adaptation**: A sensor provides measured values via a UINT-based AUI adapter, but the downstream logic requires DINT values (e.g., for arithmetic operations or visualization).
- **System Integration**: In heterogeneous automation systems where different components use different adapter types, the function block can be used as an intermediary layer.
- **Migration**: Existing systems with UINT data paths are to be gradually converted to DINT.

Comparison with Similar Function Blocks

- **F_UINT_TO_DINT**: Direct IEC 61131 converter, but without adapter encapsulation. Requires separate event and data lines.
- **AUI_TO_ABOOL**: Analog converter for binary outputs (UINT ⟶ BOOL), not for numeric types.
- **ATO_TO_ADI**: Converts ATO adapters (DWORD) to ADI, different data width.

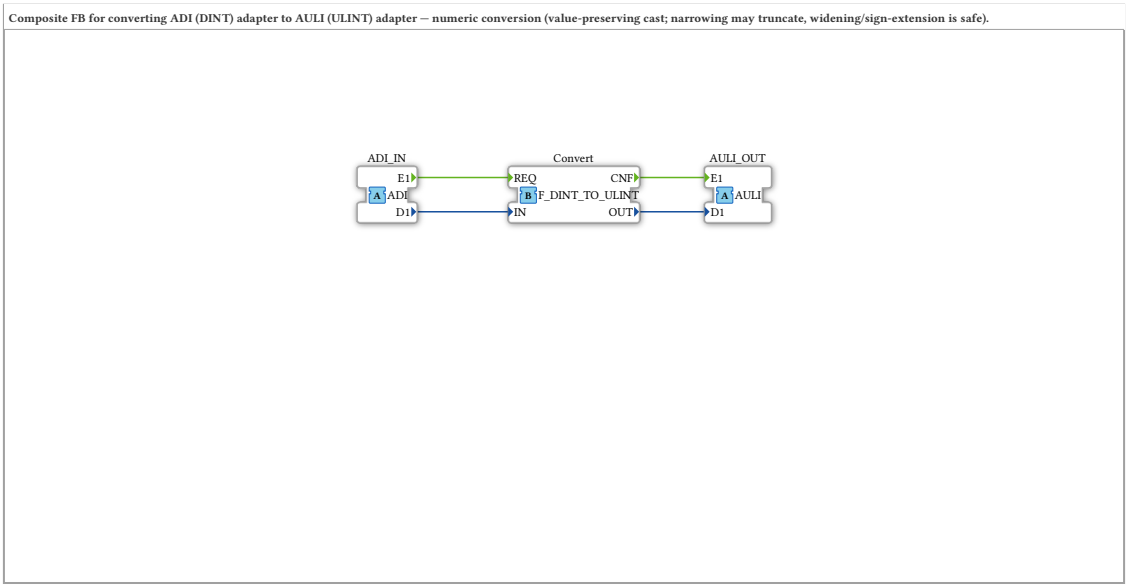
This function block stands out due to its complete adapter integration and unidirectional design, which facilitates its use in adapter-based architectures.

Conclusion



The `AUI_TO_ADI` function block offers a clean, encapsulated solution for type conversion from UINT to DINT via standardized adapters. It reduces wiring effort and increases reusability in modular automation solutions. The use of a proven IEC 61131 function block ensures the correctness of the conversion.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

ADI_TO_AULI

DINT Adapter Input – *ADI*

AULI – ULINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **ADI_TO_AULI** function block is a composite function block (FB) according to IEC 61499. It converts a DINT value (signed 32-bit integer) received via an ADI adapter (input interface) into a ULINT value (unsigned 64-bit integer) output via an AULI adapter (output interface). Internally, the standardized conversion block `F_DINT_TO_ULINT` from the IEC 61131 library is used. This function block simplifies the integration of adapters and type conversion in automation solutions.

Interface Structure

Event Inputs

Name	Type	Description
ADI_IN.E1	Event (implicit)	Trigger for conversion; provided by the ADI adapter.

Event Outputs

Name	Type	Description
AULI_OUT.E1	Event (implicit)	Signals completion of conversion; passed to the AULI adapter.

Data Inputs

Name	Type	Description
ADI_IN.D1	DINT	Input value to be converted to ULINT.

Data Outputs

Name	Type	Description
AULI_OUT.D1	ULINT	Converted output value (unsigned).

Adapter

Name	Type (Interface)	Direction	Description
ADI_IN	ADI (Socket)	Input	Receives the DINT value via a unidirectional ADI adapter.
AULI_OUT	AULI (Plug)	Output	Provides the converted ULINT value via a unidirectional AULI adapter.

Functionality

The function block waits for an event at the input adapter `ADI_IN.E1`. As soon as this event arrives, the current data value `ADI_IN.D1` (type DINT) is passed to the internal conversion function block `F_DINT_TO_ULINT`. After successful conversion, the result (type ULINT) is forwarded to the output `AULI_OUT.D1`, and an event is triggered at the output `AULI_OUT.E1`. The entire logic is purely combinational – there are no delays or states other than the signal processing of the internal module.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Adapter-Based Interface:** The module uses only adapter plugs and sockets for input and output. This allows for clean encapsulation and reuse in modular control architectures.
- **Unidirectional Adapters:** Both the ADI and AULI adapters are declared as unidirectional and transmit only in one direction (input or output).
- **Internal Conversion:** The function block `F_DINT_TO_ULINT`, responsible for the actual conversion, is taken from the package `iec61131::conversion` and provides a standardized, sequence-invariant function.
- **Namespace:** The composite function block belongs to the package `adapter::conversion::unidirectional`, which clearly indicates its role as an adapter wrapper.

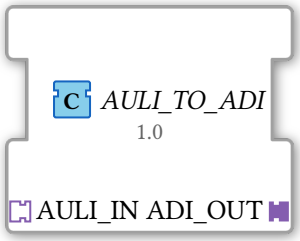
State Overview

As a composite function block, `ADI_TO_AULI` does not have its own state machine. Its behavior is entirely determined by the internal linking of event and data flows between the socket `ADI_IN`, the conversion function block, and the plug `AULI_OUT`. The state logic of the internal function block `F_DINT_TO_ULINT` is transparent to its operation.

Application Scenarios

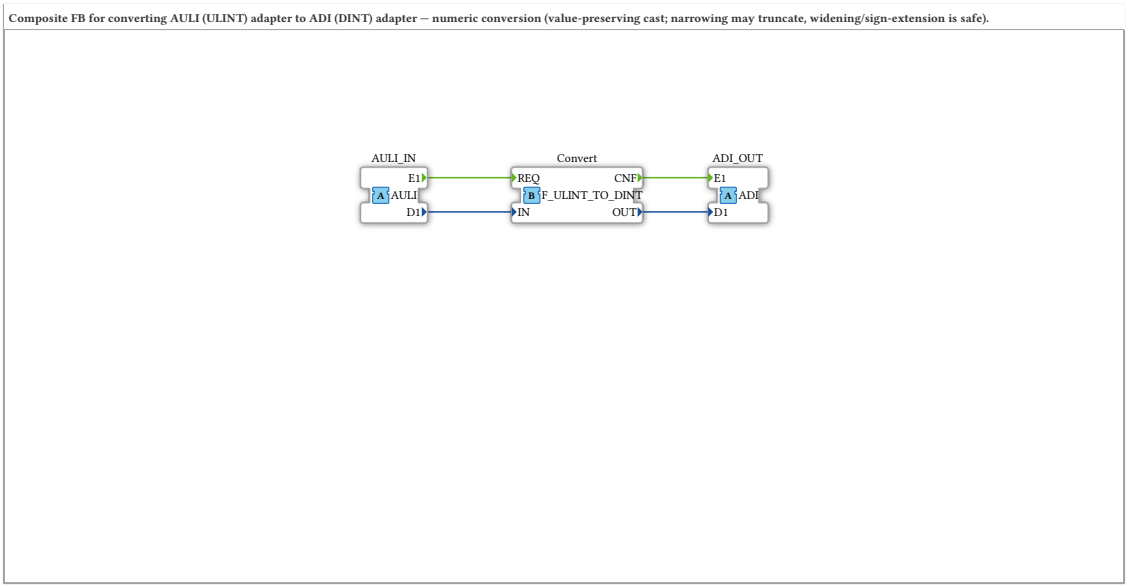
- **Transition between control systems:** When a system with DINT signals (e.g., PLC data) needs to communicate with another system that expects ULINT values (e.g., visualization or long-term archiving with 64-bit timestamps).
- **Adapter bridge:** In a modular automation environment where adapters for different data types are defined, this function block serves as a simple "translation link" between ADI and AULI interfaces.
- **Prototypes or migration:** Rapid integration of components with different integer representations without application-specific conversion logic.

Comparison with similar function blocks



- **Separate `F_DINT_TO_ULINT`:** The internal function block used here is directly responsible for the pure type conversion but requires separate event and data connections. `ADI_TO_AULI` encapsulates these connections and the adapter interface in a single block.
- **Other Adapter Wrappers:** Similar composite blocks exist for other type conversions (e.g., `ADI_TO_AUDI`, `ASI_TO_AULI`), which are structured according to the same pattern. They differ only in the data types involved.
- **Direct Type Conversion Without Adapters:** Some systems offer conversion functions as pure function blocks without an adapter layer. The present block is specifically designed for use with adapters.

Conclusion



The `ADI_TO_AULI` block is a compact, adapter-based wrapper for converting DINT to ULINT values. By cleanly separating adapter and conversion logic, it increases the reusability and readability of control programs. It is particularly suitable for modular automation solutions that rely on unidirectional adapters and require standardized type conversion.

AULI_TO_ADI

ULINT Adapter Input – *AULI*

ADI – DINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AULI_TO_ADI** function block is a composite module for converting an **AULI** adapter (unsigned 64-bit value) into an **ADI** adapter (signed 32-bit value). It enables simple conversion between two unidirectional adapter interfaces and internally utilizes an IEC 61131 type conversion function.

Interface Structure

The module has no event or data inputs/outputs of its own. All communication takes place exclusively via the two adapters.

Event Inputs

None (exclusively via adapters).

Event Outputs

None (exclusively via adapters).

Data Inputs

None (exclusively via adapter).

Data Outputs

None (exclusively via adapter).

Adapters

Type	Name	Direction	Description
adapter::types::unidirectional::AULI	AULI_IN	Socket / Input	Receives a ULINT value via event and data channels (E1, D1)
adapter::types::unidirectional::ADI	ADI_OUT	Plug / Output	Provides the converted DINT value via event and data channels (E1, D1)

Functionality

The module operates as a pure cascade:

1. An event at socket `AULI_IN.E1` triggers the data transfer from `AULI_IN.D1` (ULINT).
2. This event is transferred to the input `REQ` of the internal conversion module `F_ULINT_TO_DINT` (IEC 61131 type conversion).
3. The converter transforms the ULINT value into a DINT value and places it at its output `OUT`.
4. After the conversion is complete, the converter signals the event with `CNF`, which triggers the plug `ADI_OUT.E1` and simultaneously makes the converted value available on `ADI_OUT.D1`.
5. The connected receiver thus receives a DINT value that corresponds to the original ULINT value – insofar as it can be represented (DINT value range: -2^{31} … $2^{31}-1$).

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Adapter-based**: The function block does not implement direct input/output variables, but uses only adapter sockets and plugs for loose coupling.
- **Type conversion**: The conversion is performed using the IEC 61131 standard function block `F_ULINT_TO_DINT`. ULINT values outside the DINT range can lead to overflows or unexpected results.
- **Compact Structure**: Since there is no state logic or branching, the function block operates deterministically and without delay beyond the pure conversion time.
- **Package**: The function block is packaged in `adapter::conversion::unidirectional`.

State Overview

The function block has no internal state machine. It behaves like a pure functional mapping: An input event is immediately followed by an output event with the converted value.

Application Scenarios

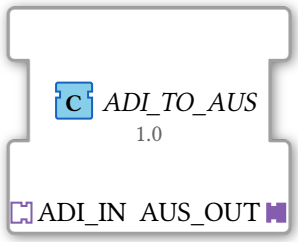
- **Interface Adaptation**: When a sensor or controller provides a ULINT adapter, but the downstream system expects a DINT adapter.
- **Data Reduction**: Reducing the bit width from 64 to 32 bits in cases where a 32-bit resolution is sufficient.
- **Adapter Cascades**: Used as a link in a seamless conversion chain between different data adapter types.

Comparison with Similar Function Blocks

- **AULI_TO_UDI**: Converts ULINT to UDINT (unsigned 32-bit) – the value range remains positive, and overflows only occur with values > $2^{32}-1$.

- **DIRECT_CONVERT**: A generic function block with direct data input and output that does not use adapters – AULI_TO_ADI, on the other hand, offers loose coupling and standardized adapter interfaces.
- **Manual Conversion**: Without this function block, the conversion would have to be implemented in the application function block itself – AULI_TO_ADI encapsulates this task and promotes reusability.

Conclusion



AULI_TO_ADI is a specialized, adapter-based conversion module that efficiently and in a standardized manner handles the conversion of ULINT to DINT data via unidirectional adapters. By utilizing an IEC 61131-compliant conversion function block, the conversion is reliable, and the simple adapter interface allows for flexible integration into existing systems. This module is particularly well-suited for loosely coupled architectures where data formats need to be adapted without burdening the application logic with type conversion.

ADI_TO_AUS

DINT Adapter Input – *ADI*

AUS – USINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The ADI_TO_AUS function block acts as an adapter converter from a DINT adapter (ADI) to a USINT adapter (AUS). It converts a DINT value to a USINT value and enables the seamless integration of components with different data types in the 4diac IDE.

Interface Structure

Event Inputs

- **E1** (via ADI_IN): This event triggers the conversion.

Event Outputs

- **E1** (via AUS_OUT): Signals the completion of the conversion and the availability of the output value.

Data Inputs

- **D1** (via ADI_IN): The DINT value to be converted.

Data Outputs

- **D1** (via AUS_OUT): USINT value, the result of the conversion.

Adapters

- **ADI_IN**: Socket (input) of type `adapter::types::unidirectional::ADI`. Provides DINT data and events.
- **AUS_OUT**: Plug (output) of type `adapter::types::unidirectional::AUS`. Receives USINT data and events for further processing.

Functionality

The function block is implemented as a composite FB. Upon an event at event input E1 (via ADI_IN), the corresponding DINT value is read from data input D1 and passed to the internal conversion block `F_DINT_TO_USINT`. This function block converts the value according to the IEC 61131 standard (e.g., by limiting it to the USINT range 0–255 or by type conversion). The result is output via data output D1, and an event at output E1 (via AUS_OUT) signals the availability of the new value.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- The function block uses an IEC 61131-compliant conversion block for type conversion from DINT to USINT.
- It is a composite function block (nested block) that maps the logic in a network of a single Convert function block.
- Communication takes place exclusively via adapter interfaces, which enables modular encapsulation.
- During conversion, values outside the USINT range (0–255) can be truncated or limited to the maximum or minimum value (depending on the conversion block used).

State Overview

Since the function block does not have its own state machine, its behavior is purely event-driven: It reacts to every incoming event with an immediate conversion and output. There are no internal states or delays.

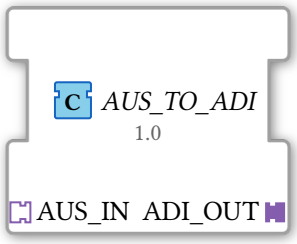
Application Scenarios

- Connecting a sensor that delivers DINT values to a controller that expects USINT.
- Integrating adapter-based components with different data types into a 4diac application.
- Migrating existing systems where data formats need to be adapted.

Comparison with Similar Function Blocks

- A direct conversion function block like `F_DINT_TO_USINT` performs the same conversion but operates on standard inputs/outputs. The ADI_TO_AUS encapsulates the logic in adapter interfaces and is therefore specifically designed for adapter-based communication paths.
- This function block differs from other adapter converters due to the specific type combination DINT↔USINT.

Conclusion



The ADI_TO_AUS is a practical building block for the seamless integration of DINT and USINT adapters in the 4diac IDE. Its simple, event-driven functionality and encapsulation as a composite function block make it flexible and easily maintainable. It is particularly suitable for projects that require a clear separation between adapter interfaces and conversion logic.

AUS_TO_ADI

USINT Adapter Input – *AUS*

ADI – DINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block AUS_TO_ADI is a composite function block that performs a unidirectional adapter conversion from `AUS` (data of type `USINT`) to `ADI` (data of type `DINT`). It encapsulates an IEC 61131 conversion block, thus enabling a clean separation of adapter types in the 4diac IDE.

Interface Structure

Event Inputs

No separate event inputs are available. Event control is handled via the socket adapter `AUS_IN` (see section **Adapters**).

Event Outputs

No separate event outputs are available. Event forwarding is handled via the plug adapter `ADI_OUT` (see section **Adapters**).

Data Inputs

No separate data inputs are available. Data is provided via the socket adapter `AUS_IN`.

Data Outputs

No separate data outputs are available. The converted data is output via the plug adapter `ADI_OUT`.

Adapters

Name	Direction	Type	Description
AUS_IN	Socket (Input)	adapter::types::unidirectional::AUS	Unidirectional adapter input that provides a USINT value (and an associated event).
ADI_OUT	Plug (Output)	adapter::types::unidirectional::ADI	Unidirectional adapter output that outputs the converted DINT value (and an associated event).

Functionality

The module operates in an event-driven manner:

1. An incoming event at socket AUS_IN.E1 triggers the internal conversion module Convert (type F_USINT_TO_DINT).
2. The conversion module reads the data value AUS_IN.D1 (USINT) and converts it into a DINT value.
3. After the conversion is complete, an event is generated at output Convert.CNF.
4. This event is forwarded to the plug adapter ADI_OUT.E1, and the converted value is output via ADI_OUT.D1.

All logic is represented as data flow within the internal function block network – no state machine logic is used within the composite block.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- The block uses the IEC 61131 block F_USINT_TO_DINT (type conversion of unsigned 8-bit to signed 32-bit integer).
- It is a pure **composite block** – its behavior is entirely defined by the internal function block network.
- The adapters are designed to be **unidirectional**: data flows only from the socket to the plug.
- By encapsulating the conversion in a separate block, different adapter types can be interconnected without requiring the surrounding application to convert the types.

State Overview

The block does not have its own state machine. Its behavior is controlled directly by the internal conversion block and the event connections. Error handling (e.g., range exceeding during conversion) is not explicitly implemented and would need to be added either in the calling context or by extending the function block.

Application Scenarios

- **Adapter Bridge**: Exchange of data between components that use different adapter types (e.g., sensors with USINT values and controllers that expect DINT values).
- **Data Integration**: Integration of function blocks from IEC 61131 libraries into a 4diac application based on adapters.
- **Type Conversion**: Fast conversion of data types at the adapter level without having to change the logic of the connected function blocks.

Comparison with Similar Modules

- Unlike directly using the conversion module F_USINT_TO_DINT, AUS_TO_ADI offers an adapter-oriented interface. This makes the conversion completely transparent for the user, who only works with the adapters.
- Similar adapter conversions may exist for other data types (e.g., BOOL_TO_ADI, INT_TO_ADI). This module is specifically designed for converting USINT to DINT.

Conclusion

The AUS_TO_ADI composite block offers a simple and clean way to convert a AUS adapter (USINT-based) into a ADI adapter (DINT-based). Thanks to the internal use of the IEC 61131 conversion block, the con-

version is standards-compliant and reusable. The block is particularly suitable for modular applications where different adapter types need to be harmonized.

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

ADI_TO_AW

DINT Adapter Input – *ADI*

AW – WORD Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **ADI_TO_AW** is a composite module that converts a DINT value into a WORD value. It acts as a unidirectional converter between an **ADI** adapter (DINT input) and an **AW** adapter (WORD output). The function block encapsulates the conversion logic and provides a standardized interface for data exchange at the adapter level.

Interface Structure

The function block has no direct event or data inputs/outputs. All communication takes place via adapters:

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::ADI`	`ADI_IN`	Socket (Input)	DINT adapter providing the value to be converted

adapter::types::unidirectional::AW	AW_OUT	Plug (Output)	WORD adapter outputting the converted value

The internal event and data connections of the composite function block result from the adapter interfaces used:

Event Inputs (via ADI_IN)

Event	Description
E1	Trigger for converting the DINT value

Event Outputs (via AW_OUT)

Event	Description
E1	Confirmation of successful conversion and output of the WORD value

Data Inputs (via ADI_IN)

Identifier	Type	Description
D1	DINT	The integer value to be converted

Data Outputs (via AW_OUT)

Identifier	Type	Description
D1	WORD	The converted bit pattern value (16 bits)

Functionality

The function block operates in an event-driven manner:

1. An incoming event at ADI_IN.E1 is internally forwarded to the conversion block F_DINT_TO_WORD (via its REQ input).
2. Simultaneously, the data value from ADI_IN.D1 is transferred as DINT to the IN input of the conversion function.
3. The function block F_DINT_TO_WORD converts the DINT value to a WORD value (according to IEC 61131-3).
4. After the conversion is complete, the converter's output event (CNF) is sent.
5. This event is forwarded to AW_OUT.E1, and the converted WORD value (from OUT) is passed to AW_OUT.D1.

Thus, the entire conversion occurs in a strict event/data flow without any additional states.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Adapter-Based Encapsulation:** The function block (FB) uses adapters exclusively for input and output, enabling modular and reusable integration in 4diac projects.
- **Unidirectional Conversion:** Data conversion only occurs from socket to plug; reverse conversion is not supported.
- **Use of IEC 61131 Libraries:** The core function F_DINT_TO_WORD is derived from the iec61131::conversion package, ensuring standards-compliant and high-performance conversion.
- **No Internal States:** The FB does not have an internal state diagram; its logic is determined solely by the behavior of the contained block.

State Overview

Since this is a purely structured composite FB without its own Execution Control Chart (ECC), there is no explicit state model. The behavior is purely data stream-driven and corresponds to that of the internal conversion block (IDLE → REQ → CNF → IDLE).

Application Scenarios

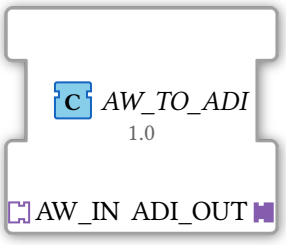
- **PLC Coupling:** Connecting a DINT-based sensor (e.g., encoder) to a subsystem that expects WORD values.
- **Data Format Conversion in Adapter Chains:** Use in a 4diac application where different adapter types need to be harmonized.
- **Interface Standardization:** Implementing a standardized WORD interface for downstream logic blocks, while the source is in DINT format.

Comparison with Similar Blocks

Block	Function	Difference
`F_DINT_TO_WORD`	Direct DINT to Word conversion	No adapter encapsulation; must be manually integrated into a network
ADI_TO_AW`	Adapter-based encapsulation of the same conversion	Provides ready-to-use adapter interfaces; simplifies reuse
WORD_TO_DINT`	Reverse conversion	Other direction; requires a custom adapter type

The `ADI_TO_AW` is specifically optimized for environments where adapters are required as standardized interfaces.

Conclusion



The function block `ADI_TO_AW` provides a reusable, adapter-based solution for converting `DINT` to `WORD`. It cleanly encapsulates the conversion logic and enables easy integration into 4diac architectures based on the adapter concept. The use of standard libraries ensures reliability and adherence to specifications. This component is particularly suitable for scenarios where different data formats need to be connected via adapter bridges.

AW_TO_ADI

WORD Adapter Input – *AW*

ADI – DINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The **AW_TO_ADI** function block is a composite block that converts a unidirectional WORD adapter (AW) into a unidirectional DINT adapter (ADI). It enables the seamless integration of components that work with WORD data into systems that expect DINT values. Internally, the block uses the standard conversion block `F_WORD_TO_DINT` from the IEC 61131 library.

Interface Structure

Event Inputs

- **No Direct Event Inputs**

The block does not have any standalone event inputs. The triggering event is provided via the socket adapter `AW_IN`.

Event Outputs

- **No Direct Event Outputs**

This function block has no independent event outputs. The result event is passed on via the plug adapter `ADI_OUT`.

Data Inputs

- **No Direct Data Inputs**

The WORD value to be converted is received via the socket adapter `AW_IN`.

Data Outputs

- **No Direct Data Outputs**

The converted DINT value is output via the plug adapter `ADI_OUT`.

Adapters

Name	Type	Direction	Description
`AW_IN`	`adapter::types::unidirectional::AW`	Socket (Input)	WORD adapter as input. Returns the trigger event (E1) and the WORD data value (D1).

ADI_OUT	adapter::types::unidirectional::ADI	Plug (Output)	DINT adapter as output. Returns the acknowledgment event (E1) and the converted DINT value (D1).

Functionality

1. An incoming event at socket AW_IN.E1 triggers the internal function block F_WORD_TO_DINT via its event input REQ.
2. Simultaneously, the WORD data value from AW_IN.D1 is transferred to the data input IN of F_WORD_TO_DINT.
3. After the conversion is complete, F_WORD_TO_DINT generates an acknowledgment event at CNF.
4. This event is forwarded to plug ADI_OUT.E1, while the converted DINT value is transferred from F_WORD_TO_DINT.OUT to ADI_OUT.D1.

The entire process is thus synchronous: A pulse at the WORD adapter results in a pulse at the DINT adapter with the converted value.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Pure Coupling:** The block contains no logic of its own, but simply connects the adapter interfaces to an existing conversion block.
- **Use of IEC 61131 Standard Blocks:** The actual conversion is performed by F_WORD_TO_DINT, which provides a defined and standardized conversion.
- **Unidirectional Adapters:** Both AW_IN and ADI_OUT are designed as unidirectional adapters, meaning they only transport events and data in one direction.
- **No Internal States:** As a composite device, AW_TO_ADI has no internal states of its own – its behavior is entirely determined by the interconnection of its constituent elements.

State Overview

Since this is a composite device without its own state machine, there is no separate state overview. The runtime behavior is determined by the embedded F_WORD_TO_DINT, which performs a processing step after an input event and outputs the result.

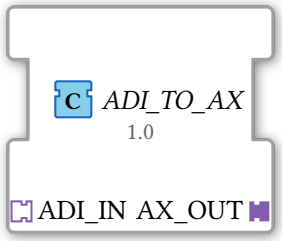
Application Scenarios

- **Agricultural Technology:** Connecting sensors or actuators that deliver WORD data (e.g., via field-buses with 16-bit values) to controllers that require DINT.
- **Migration of Legacy Systems:** Replacing WORD-based interfaces with modern DINT components without redesigning the entire architecture.
- **Adapter Encapsulation:** Integrating libraries or modules designed for different data types using a single adapter converter.

Comparison with Similar Components

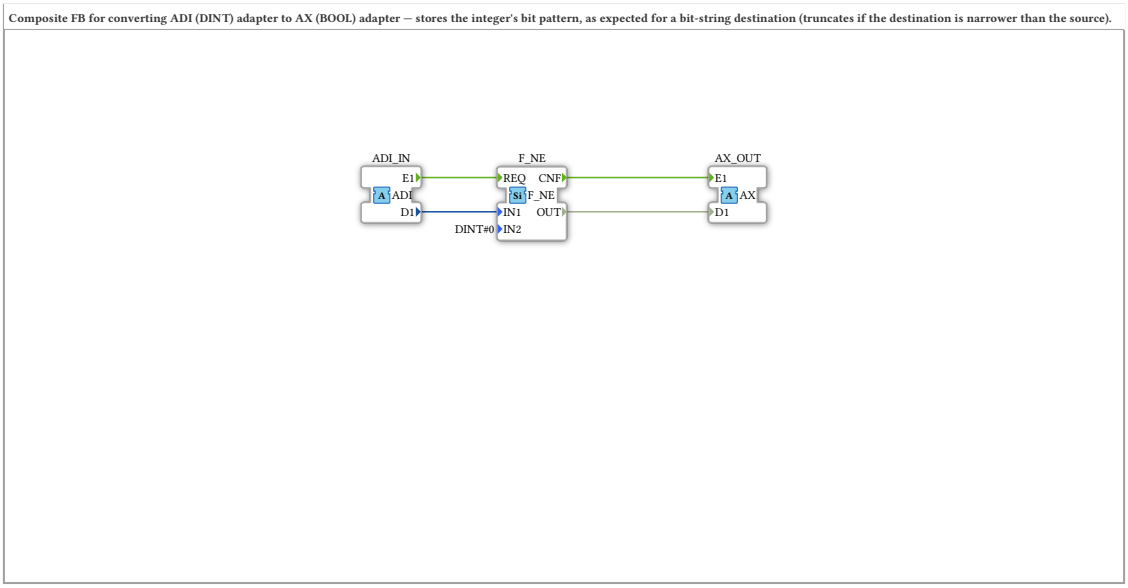
- **Direct Conversion:** Unlike a simple F_WORD_TO_DINT, AW_TO_ADI offers an adapter-based interface that enables loose coupling between components.
- **Bidirectional Converters:** There are modules that combine both forward and reverse conversion (e.g., WORD ↔ DINT) in a single module. This module is intentionally designed to be unidirectional.
- **Type Conversion via Flexible Adapters:** Other adapter converters use generic or polymorphic interfaces; this module is specifically designed for WORD-to-DINT conversion.

Conclusion



The AW_TO_ADI is a simple yet effective composite module for converting a WORD adapter to a DINT adapter. By using a standardized conversion module and clear adapter interfaces, it is particularly well-suited for use in modular automation solutions where data type conversions between components are required. Its structure is transparent, easy to understand, and allows for rapid integration into existing projects.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

ADI_TO_AX

DINT Adapter Input – *ADI*

AX – BOOL Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **ADI_TO_AX** function block is a composite module that performs a simple signal conversion between two adapter types. It converts a DINT value (type: *adapter::types::unidirectional::ADI*) received via the **ADI_IN** socket into a BOOL value and outputs it via the **AX_OUT** plug (type: *adapter::types::unidirectional::AX*). The conversion is performed by comparing the received DINT value with the constant value 0. If the value is not equal to 0, the BOOL output is set to TRUE; if they are equal, it is set to FALSE. This module is particularly suitable for connecting digital signal sources encoded as integers to Boolean interfaces.

Interface Structure

Event Inputs

Name	Description
(No explicit event inputs)*	The function block (FB) uses only the events connected via the ADI_IN adapter. In fact, the event `E1` of the ADI_IN adapter is internally forwarded to the function block `F_NE`.

Event Outputs

Name	Description
(No explicit event outputs)*	The output is via the AX_OUT adapter; the event `E1` of the AX_OUT adapter is sent after successful processing of the `F_NE` call.

Data Inputs

Name	Type	Description
(via ADI_IN adapter)	`DINT`	The DINT value (e.g., measured value or status code) connected via the adapter socket is received as input `D1` of the ADI_IN adapter.

Data Outputs

Name	Type	Description
(via AX_OUT adapter)	`BOOL`	The output value is provided as `D1` of the AX_OUT adapter. TRUE if the received DINT value is not 0; otherwise FALSE.

Adapter

Adapter	Name	Direction	Type	Description
Socket	ADI_IN	Input	`adapter::types::unidirectional::ADI`	Receives a DINT value (with associated event).
Plug	AX_OUT	Output	`adapter::types::unidirectional::AX`	Passes on the resulting BOOL value (with associated event).

Functionality

Internally, the function block consists of a single function block **F_NE** of type `iec61131::comparison::F_NE`. This implements the IEC 61131 function "Not Equal" (NE). Behavior:

1. An incoming event **E1** from the ADI_IN adapter is forwarded to the **REQ** input of **F_NE**.
2. The data value **D1** of the ADI_IN adapter is applied to the **IN1** input of the **F_NE**. The second comparison value, **IN2**, is fixed to the value `DINT#0`.
3. The **F_NE** compares `IN1 != IN2`. The result (BOOL) is output at the **OUT** output.
4. After processing is complete, **F_NE.CNF** signals completion. This event is sent to the **E1** input of the AX_OUT adapter, which then passes the output value (also the **OUT** signal) to **D1** of the AX_OUT adapter.

Thus, the function block implements a simple threshold logic: Any non-zero DINT value is interpreted as logically "true". The function block operates strictly event-driven – each incoming event triggers exactly one comparison and output action.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Adapter Coupling:** The function block is designed as a composite block that connects two unidirectional adapters. It can therefore be seamlessly integrated into an adapter-based communication architecture.
- **No Internal States:** Since the function block has no internal state variables or timers, its behavior is purely combinatorial and deterministic.
- **Direct Impedance:** The function block used, `F_NE` from the IEC 61131 library, is high-performance and does not require dynamic memory management.
- **Type Safety:** The constant `DINT#0` is explicitly declared as a DINT, so no implicit type conversions occur.
- **License Notice:** This function block is subject to the Eclipse Public License 2.0 (EPL-2.0), Copyright 2026 HR Agrartechnik GmbH.

State Overview

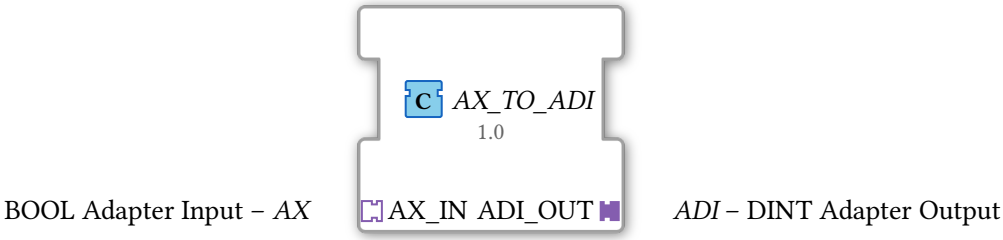
This function block has no states of its own, as it is entirely based on the internal functional block **F_NE**. Therefore, its behavior requires no delays or storage. The sequence is as follows:

- **Waiting for Event:** Inactive until an event arrives via the ADI_IN adapter.
- **Processing:** Upon receiving an event, the comparison is performed; the output is updated immediately. After the comparison, the output event is sent.

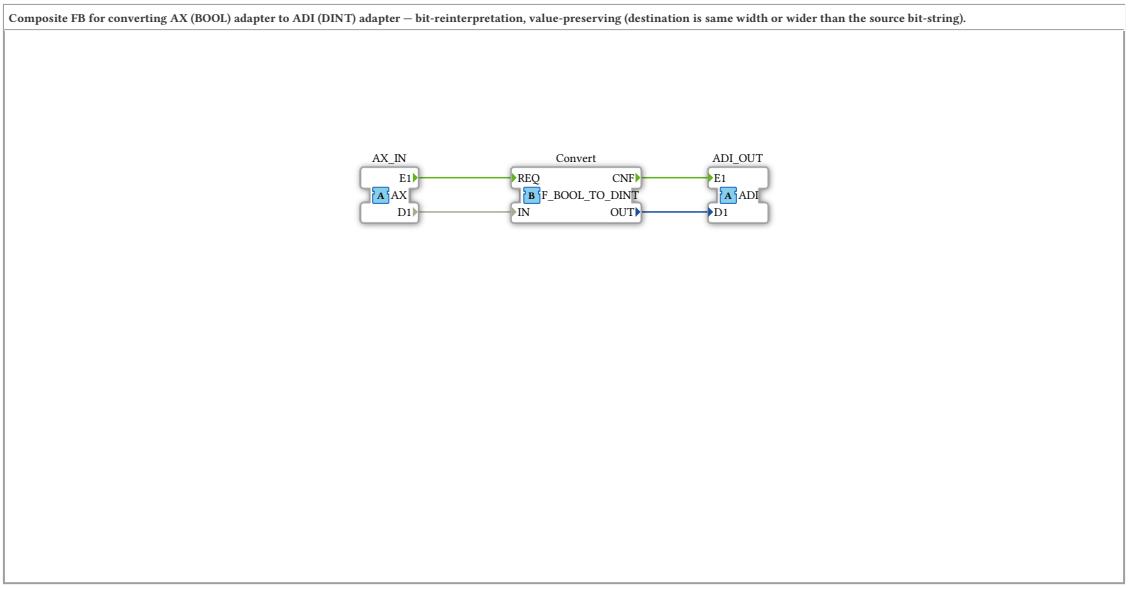
Application Scenarios

- **Digitization of Analog Values:** In automation, DINT values (e.g., counter readings, error codes) are often interpreted as Boolean signals. This function block is suitable for converting non-zero conditions into binary signals.
- **Adapter Bridging:** If a component only provides an ADI adapter, but the downstream logic only accepts AX adapters, this function block can be used as a lossless converter.
- **Simple Switching Thresholds:** With minimal effort, it's possible to determine whether a value deviates from zero – useful, for example, for monitoring counting pulses or limit violations.

Comparison with Similar Function Blocks



Function Block	Type	Function
ADI_TO_AX (this function block)	Composite	DINT ≠ 0 ⟶ BOOL
`BOOL_TO_DINT` (Standard Library)	Function	Direct conversion from BOOL to DINT (e.g., TRUE ⟶ 1)
`F_NE` (IEC 61131)	Function	General Non-Equal Comparison of Arbitrary Data Types
Custom Adapter Converter	–	Can be easily extended with other comparison functions (F_EQ, F_GT, etc.)



Compared to a pure BOOL-to-DINT conversion, **ADI_TO_AX** offers the advantage that the DINT value is retained exactly (e.g., 42 ⟶ TRUE), whereas a Boolean conversion can only distinguish between TRUE/FALSE and 1/0.

Conclusion

The **ADI_TO_AX** function block is a lean and robust adapter converter for unidirectional interfaces. It utilizes the proven IEC 61131 comparison block `F_NE` and thus implements a simple yet useful logic: "Any non-zero value is true." The function block is particularly suitable for use in modular automation systems where different adapter standards need to be coordinated. Thanks to its composite structure, it can be easily integrated into existing networks and expanded as needed.

AX_TO_ADI

• — ○ • — ○ • — ○ •

Introduction

The **AX_TO_ADI** function block is a composite function block (FB) that converts an AX adapter with a Boolean interface (BOOL) into an ADI adapter with an integer interface (DINT). It serves as a converter between unidirectional adapters and enables the seamless integration of binary signals into systems that use integer-based adapters.

Interface Structure

Since it is a composite FB, all inputs and outputs are implemented via the included adapters. The following list shows the logical interfaces.

Event Inputs

The function block does not have direct event inputs. Event control is handled via the **AX_IN** adapter:

- **E1** (BOOT): Event input of the AX adapter that triggers the data conversion.

Event Outputs

This function block does not have direct event outputs. Event forwarding is handled via the **ADI_OUT** adapter:

- **E1** (CNF): Event output of the ADI adapter, signals completion of the conversion.

Data Inputs

This function block does not have direct data inputs. Data is acquired via the **AX_IN** adapter:

- **D1** (BOOL): Boolean input value that is converted to a DINT value.

Data Outputs

This function block does not have direct data outputs. Data output is handled via the **ADI_OUT** adapter:

- **D1** (DINT): Converted integer output value (0 for FALSE, 1 for TRUE).

Adapter

- **AX_IN** (Socket): Receives an AX adapter (type: `adapter::types::unidirectional::AX`) with a Boolean data and event key.
- **ADI_OUT** (Plug): Provides an ADI adapter (type: `adapter::types::unidirectional::ADI`) with a DINT data and event key.

Functionality

The function block internally uses the IEC 61131-3 converter `F_BOOL_TO_DINT`. As soon as an event arrives at **AX_IN.E1**, the current value of **AX_IN.D1** is read and passed to the converter. The converter sets the value 0 for FALSE and the value 1 for TRUE. After the conversion is complete, the result is passed to **ADI_OUT.D1** and an event is simultaneously sent to **ADI_OUT.E1**.

The event chain is thus fully looped:
AX_IN.E1→ `Conversion` →ADI_OUT.E1`.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Pure Data Conversion:** The function block does not perform any state logic or time delay – every event activation at the input immediately generates an output.
- **Use of IEC 61131 Libraries:** The conversion is based on the standardized function block `F_BOOL_TO_DINT` from the IEC 61131 conversion library.
- **Unidirectional Adapters:** Both AX and ADI are unidirectional adapters, meaning they only support one direction (input or output). This simplifies data flow control.
- **Composite Function Block without its own state:** As a composite function block, it has no internal state machine; all logic is implemented by the embedded function block.

State Overview

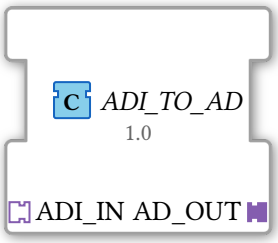
As a composite function block, **AX_TO_ADI** does not have its own state machine. Its behavior is determined solely by the embedded `F_BOOL_TO_DINT`, which has no state-dependent logic. The output is always a direct function of the input at the time of event activation.

Application Scenarios

- **Binary Signal Conversion:** When a sensor or switch provides a Boolean signal via an AX adapter that needs to be further processed in a system with ADI adapters (DINT).
- **Gateway Function:** Connection between subsystems using different adapter types without changing the underlying logic.
- **Testing and Simulation:** Generation of a defined DINT value from a Boolean input for testing purposes.

Comparison with Similar Function Blocks

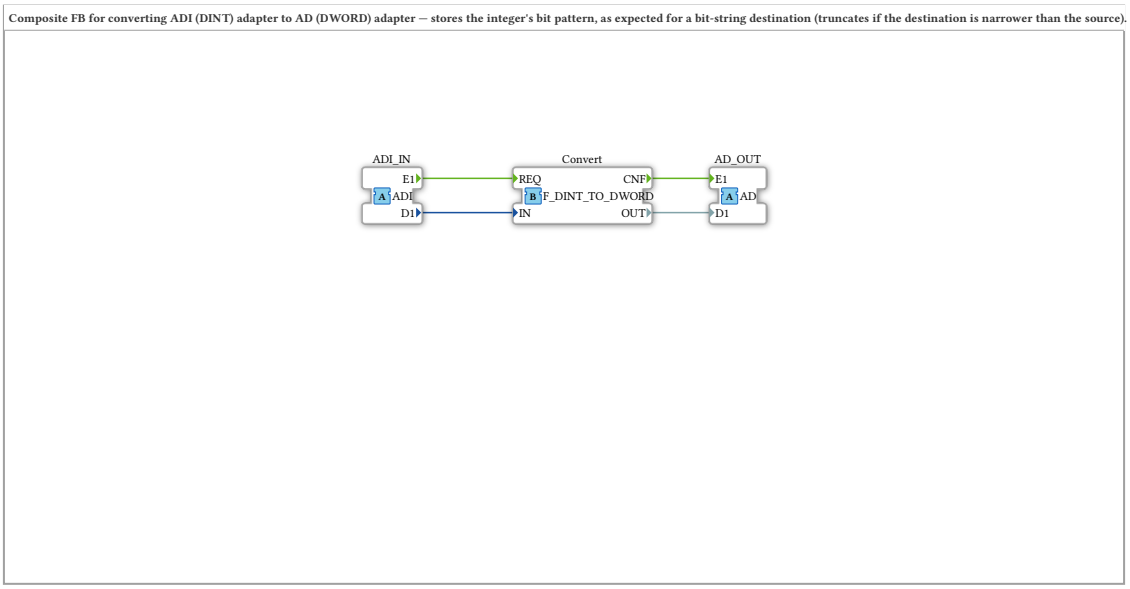
- **AX_TO_ADI (this function block):** Converts BOOL to DINT via adapters.
- **ADI_TO_AX (hypothetical):** Would convert DINT to BOOL, e.g., by comparison with zero or a threshold.
- **Direct Command F_BOOL_TO_DINT:** This function block is an encapsulated version specifically designed for use with unidirectional adapters. Unlike the basic function block, the adapter interfaces are already integrated.



Conclusion

AX_TO_ADI is a simple yet useful converter function block that converts Boolean adapter signals into integer-based adapter signals. It enhances interoperability between different components of a system and enables a clean separation of data and event flows. Due to its low complexity, it can be deployed quickly and easily integrated into larger composite function block chains.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ADI_TO_AD

DINT Adapter Input – *ADI*

AD – DWORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **ADI_TO_AD** function block is a composite block that performs interface conversion from an **ADI** adapter (DINT-based) to an **AD** adapter (DWORD-based). It functions as a unidirectional converter and enables seamless integration of components with different data adapter types in the 4diac IDE.

Interface Structure

Event Inputs

The function block does not have its own dedicated event inputs at the interface level. Event control is handled exclusively via the connected **ADI_IN** socket adapter:

- **ADI_IN.E1** – Event that triggers the data conversion.

Event Outputs

There are no separate event outputs at this level either. The output is provided via the **AD_OUT** plug adapter:

- **AD_OUT.E1** – Event triggered after successful conversion.

Data Inputs

- **ADI_IN.D1** – Input of the DINT value to be converted (source adapter).

Data Outputs

- **AD_OUT.D1** – Output of the converted DWORD value (destination adapter).

Adapters

- **ADI_IN** (Socket) – of type `adapter::types::unidirectional::ADI` (DINT data).
- **AD_OUT** (Plug) – of type `adapter::types::unidirectional::AD` (DWORD data).

Both adapters are unidirectional (one event channel and one data channel each).

Functionality

The function block contains an internal block `F_DINT_TO_DWORD` from the IEC 61131 library, which performs the actual type conversion. The sequence of operations is as follows:

1. An incoming event at **ADI_IN.E1** triggers the **Convert.REQ** input of the internal converter.
2. The converter converts the DINT value received at **ADI_IN.D1** into a DWORD value.
3. After the conversion is complete, **Convert.CNF** signals successful completion and fires the event at **AD_OUT.E1**, while simultaneously outputting the converted value to **AD_OUT.D1**.

This enables transparent, event-driven conversion between the adapter types.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Type Conversion**: The actual conversion is performed using the standardized IEC 61131 function block `F_DINT_TO_DWORD`, which ensures bit-perfect transfer of the integer value to the DWORD space (no logical interpretation, only type conversion).
- **Unidirectionality**: The function block is strictly unidirectional and expects exactly one input and one output adapter. Reverse conversion is not supported.
- **Package Structure**: The function block is organized in the package `adapter::conversion::unidirectional` and imports the corresponding IEC library.

State Overview

As a composite function block, **ADI_TO_AD** has no explicit states of its own. Its behavior is entirely determined by the internal converter:

- **Idle**: Waits for an event at the ADI_IN.

Idle }: Waits for an event at the ADI_IN. - **Conversion active: When `Convert.REQ` is set.

- **Completion**: After `Convert.CNF`, the result is provided at the output.

Application Scenarios

- **Interface adaptation**: When a component provides a DINT adapter, but a downstream module expects a DWORD adapter (e.g., when integrating controllers with different data widths).
- **System modernization**: Older DINT-based sensors or actuators (via ADI) are to be connected to new DWORD-enabled bus systems (via AD).
- **Prototypical development**: Rapid switching between adapter variants without changing the application logic.

Comparison with Similar Function Blocks

- **Direct Converter Function Blocks**: Unlike pure type converters (such as `F_DINT_TO_DWORD`), **ADI_TO_AD** operates at the adapter level and integrates event control and interface adaptation into a single function block.
- **Bidirectional Adapters**: Function blocks also exist that offer conversion in both directions (e.g., ADI_TO_AD and AD_TO_ADI combined). This function block is specialized for one direction and is therefore more streamlined.
- **Manual Wiring**: Without this function block, the adapters would have to be wired manually internally, and the event signals routed separately – the composite function block encapsulates this complexity.

Conclusion

The **ADI_TO_AD** function block is a useful and clearly structured composite function block for easy adaptation between DINT- and DWORD-based adapters. It reduces manual wiring effort, utilizes proven IEC conversion logic, and integrates seamlessly into unidirectional data flows. Ideal for developers who need to switch quickly and cleanly between adapter types without delving deeply into internal signal processing.

AD_TO_ADI

DWORD Adapter Input – *AD*

ADI – DINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **AD_TO_ADI** function block is a composite module for converting a DWORD adapter (AD) to a DINT adapter (ADI). It enables the seamless integration of components with different data types into an IEC 61499 application without requiring the user to implement the conversion logic themselves.

Interface Structure

Event Inputs

No direct event inputs. Event control is handled via the socket adapter `AD_IN`.

Event Outputs

No direct event outputs. Event output is handled via the plug adapter `ADI_OUT`.

Data Inputs

No direct data inputs. Data is transferred via the socket adapter `AD_IN`.

Data Outputs

No direct data outputs. Data is transferred via the plug adapter `ADI_OUT`.

Adapters

Name	Type	Direction	Comment

AD_IN	adapter::types::unidirectional::AD	Socket (Input)	DWORD Adapter Input – returns a DWORD date and an event
ADI_OUT	adapter::types::unidirectional::ADI	Plug (Output)	DINT Adapter Output – Returns a Converted DINT Data and an Event

Functionality

This function block encapsulates a call to the IEC 61131-3 conversion function `F_DWORD_TO_DINT`. The process is as follows:

1. An event at socket `AD_IN.E1` triggers the conversion function block `Convert` (event `REQ`).
2. Simultaneously, the DWORD data `AD_IN.D1` is passed to input `Convert.IN`.
3. The conversion function block converts the value into a DINT and signals completion via the event `CNF`.
4. This event is forwarded to plug `ADI_OUT.E1`, and the converted DINT value (`Convert.OUT`) is placed in `ADI_OUT.D1`.

As a result, from the application's perspective, the composite function block behaves like a direct adapter converter without any side effects.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **IEC 61131-3 Compatibility** – The conversion is performed via the standardized library function `F_DWORD_TO_DINT`, which is available for common PLC systems.
- **Unidirectional Adapters** – Both the input and output adapters are unidirectional; feedback or reverse-direction data is not supported.
- **No State Information** – The composite itself has no internal state variables; each conversion is atomic and time-independent.
- **Autonomy** – The function block can be used in a network configuration without manually integrating other function blocks.

State Overview

The composite function block does not have its own state machine. Its behavior results purely from the sequential processing of its internal connections:

- **Waiting for Event** – No activity occurs as long as no event is present at `AD_IN.E1`.
- **Conversion** – After an event is received, the result is converted once and output.
- **Completion** – The function block is immediately ready for the next event.

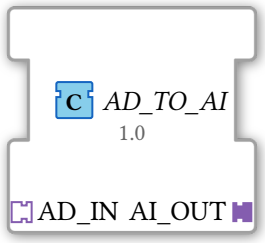
Application Scenarios

- **Gateway between systems with different data widths** – e.g., connecting a DWORD sensor value to DINT-based control logic.
- **Adapter Bridge in IEC 61499 Architectures** – When components need to communicate via standardized unidirectional adapters (AD/ADI).
- **Encapsulation of plausibility checks** – the DWORD value can be validated in upstream logic before conversion to the DINT format.

Comparison with similar function blocks

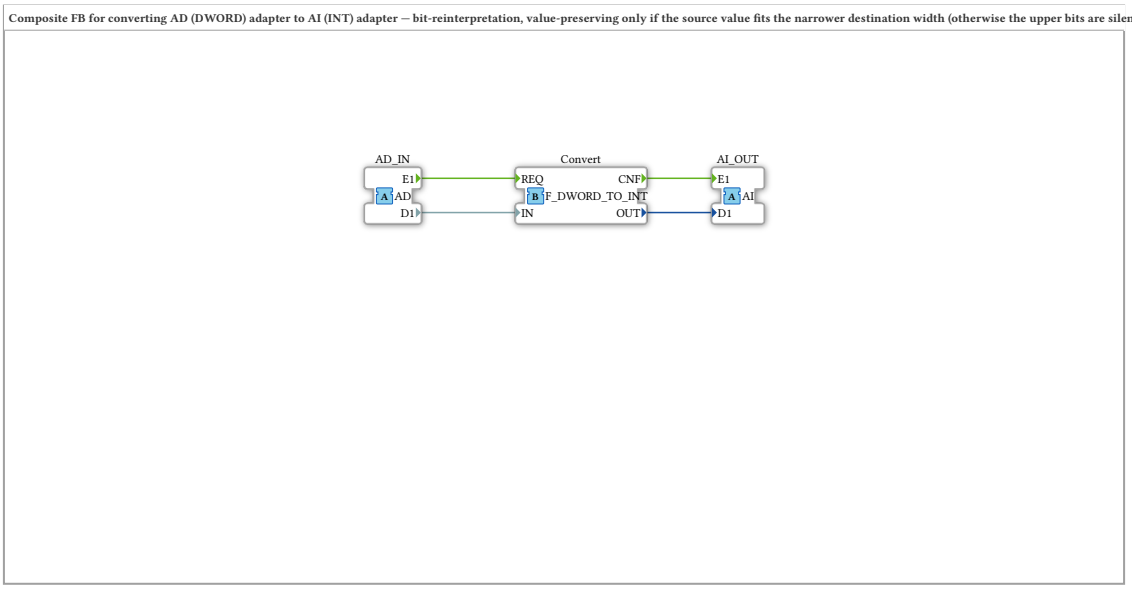
- **AD_TO_ADI** specializes in converting DWORD to DINT and follows a strict unidirectional adapter profile.
- Similar function blocks such as `AD_TO_AI` (DWORD to INT) or `ADI_TO_AD` (reverse conversion) exist for other data types but share the same design pattern.
- Unlike a generic conversion function block (e.g., `F_DWORD_TO_DINT` alone), the composite function block offers direct adapter integration, eliminating the need for users to create manual adapter interfaces.

Conclusion



The composite function block **AD_TO_ADI** provides a simple, robust, and standards-compliant solution for converting DWORD to DINT adapter data. It reduces configuration effort within IEC 61499 networks and increases the reusability of function blocks from different sources. Thanks to its purely functional implementation without state issues, it is particularly suitable for time-critical and safety-related applications.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AD_TO_AI

DWORD Adapter Input – *AD*

AI – INT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AD_TO_AI** acts as a converter between two different adapter interfaces: It converts an **AD adapter (DWORD)** into an **AI adapter (INT)**. The block is implemented as a composite function block and internally uses the IEC 61131-3 function `F_DWORD_TO_INT` to perform the actual type conversion. The goal is to facilitate the integration of components based on different data types while ensuring event-driven data transfer within the 4diac IDE.

Interface Structure

Event Inputs

The function block does not have direct event inputs at the top level. Event control is handled via the connected adapters:

- **AD_IN.E1** (Socket adapter event) – triggers the conversion.

Event Outputs

These are also provided exclusively via the adapters:

- **AI_OUT.E1** (Plug adapter event) – signals the completion of the converted data.

Data Inputs

- **AD_IN.D1** (DWORD) – The original data value supplied by the AD adapter.

Data Outputs

- **AI_OUT.D1** (INT) – The converted value output via the AI adapter.

Adapters

Adapter Type	Direction	Type	Description
Socket	Input	`adapter::types::unidirectional::AD`	Receives a DWORD value (via event E1 and data D1).
Plug	Output	`adapter::types::unidirectional::AI`	Provides the converted INT value (event E1, data D1).

Functionality

The function block operates in an event-driven manner:

1. An event at socket **AD_IN.E1** triggers the internal instance `Convert` (type `F_DWORD_TO_INT`) via its event input **REQ**.
2. Simultaneously, the data value **AD_IN.D1** (DWORD) is passed to the data input **IN** of `Convert`.
3. The function `F_DWORD_TO_INT` performs the type conversion from DWORD to INT.
4. After the calculation is complete, `Convert` sends an event at its output **CNF**, which is connected to the plug event **AI_OUT.E1**.
5. In parallel, the converted INT value is forwarded from the output **OUT** of `Convert` to the data output **AI_OUT.D1**.

Thus, after each incoming event at the socket, a converted data value is automatically made available on the plug.

Technical Features

- **Bit-reinterpretation**, value-preserving only if the source value fits the narrower destination width (otherwise the upper bits are silently dropped).
- **Composition:** The FB is a pure composite function block – it contains no internal logic but delegates the conversion to the standard function block `F_DWORD_TO_INT` from the IEC 61131 library.
- **Data Types:** DWORD is a 32-bit value, while INT is a 16-bit signed integer. Data loss can occur during conversion if the DWORD value is outside the INT range (−32768 … 32767) or does not fit within this range. The user must take this into account when using the function block.
- **Adapter Coupling:** The connection between the socket and the plug is established exclusively via the internal event and data flows. The adapters themselves are of type `unidirectional`, i.e., They only transfer data in one direction.
- **Package Structure:** The function block is provided in package `adapter::conversion::unidirectional` and imports the conversion function from `iec61131::conversion`.

State Overview

Since this is a composite function block without its own state machine, there are no explicit states. The function block behaves like a transparent converter:

- **Idle:** Waits for an event at the socket.
- **Processing:** After receiving an event, the conversion is started; no other events are active during this phase.
- **Done:** After the conversion, the output event is displayed; the function block returns to the idle state.

The internal function block `F_DWORD_TO_INT` has its own system-defined state logic, which is not visible due to its encapsulation within the composite function block.

Application Scenarios

- **Integration of Different Adapter Types:** A sensor delivers data as DWORD via an AD adapter, but downstream logic expects INT values via an AI adapter. The function block handles the type conversion seamlessly.
- **Heterogeneous System Architectures:** In systems where different components use different data types, `AD_TO_AI` enables simple and standardized connectivity.
- **Prototyping and Migration:** When switching from DWORD-based data processing to INT-based components, the function block can be used as a temporary or permanent converter.

Comparison with Similar Function Blocks

Other converter function blocks exist, such as `AD_TO_AI`, `AI_TO_AD`, `INT_TO_DWORD`, etc. This function block focuses specifically on the adapter level and operates entirely event-driven. Unlike simple data conversion function blocks (e.g., `F_DWORD_TO_INT`), it offers a pre-built adapter interface that enables direct coupling to adapter-oriented architectures without requiring the manual drawing of additional connections.

Other similar composite function blocks differ primarily in the direction (e.g., `AI_TO_AD` for reverse conversion) or in the data types used.

Conclusion

The composite function block **AD_TO_AI** is a useful tool for type conversion between DWORD and INT adapters. It encapsulates the conversion logic in a clean, event-driven interface, thus facilitating reusability and integration into existing 4diac projects. Its simple structure and the use of a proven standard function block make it reliable and easy to understand. However, users should always keep the limitations of the INT data type in mind to avoid unintentional data loss.

AI_TO_AD

INT Adapter Input – *AI*

AD – DWORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The composite function block **AI_TO_AD** converts an INT-based adapter interface (AI) to a DWORD-based adapter interface (AD). It encapsulates the type conversion from `INT` to `DWORD`, thus enabling the seamless integration of different adapter types into control applications. The block is unidirectional and event-driven.

Interface Structure

Event Inputs

The block does not have direct event inputs. Event-driven triggering occurs via the adapter **AI_IN** (socket).

- **E1 (via AI_IN)**: Trigger event for converting the incoming INTEGER value.

Event Outputs

This function block has no direct event outputs. Conversion confirmation is provided via the **AD_OUT** adapter (plug).

- **E1 (via AD_OUT)**: Confirmation event after successful conversion.

Data Inputs

This function block has no direct data inputs. The INTEGER value to be converted is provided via the **AI_IN** adapter.

- **D1 (via AI_IN)**: Input value of type `INT`.

Data Outputs

This function block has no direct data outputs. The converted DWORD value is output via the **AD_OUT** adapter.

- **D1 (via AD_OUT)**: Output value of type `DWORD`.

Adapters

- **AI_IN** (Socket) – Input adapter type `adapter::types::unidirectional::AI`. It provides an INTEGER input (D1) and a trigger event (E1).
- **AD_OUT** (Plug) – Output adapter type `adapter::types::unidirectional::AD`. It provides a DWORD output (D1) and an acknowledgement event (E1).

Functionality

The function block is implemented as a composite. Internally, the IEC 61131-compliant function block **F_INT_TO_DWORD** is used.

Process:

1. An event at the input adapter **AI_IN.E1** triggers the data transfer.
2. The value of **AI_IN.D1** (INT) is forwarded to input `IN` of `F_INT_TO_DWORD`.
3. The internal function block performs the type conversion `INT → DWORD`.
4. The result is present at output `OUT` of `F_INT_TO_DWORD` and is passed to **AD_OUT.D1**.
5. Simultaneously, the event **AD_OUT.E1** is triggered to signal processing in the subsequent network.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Function Block**: The functionality is implemented by an embedded function block, so no separate state machine (ECC) is required.
- **Unidirectional**: Data flows exclusively from the input to the output adapter; feedback is not provided.
- **Type Conversion**: The function block uses the standardized IEC 61131 function block `F_INT_TO_DWORD`, ensuring compatibility with many automation systems.

- **Adapter Encapsulation**: The conversion logic is fully embedded in the adapter interfaces, simplifying reuse in different contexts.

State Overview

The function block does not have its own state machine. Internal processing is entirely controlled by the embedded function block `F_INT_TO_DWORD`, which implements simple event-driven data processing without states. Error behavior and timeouts are not defined.

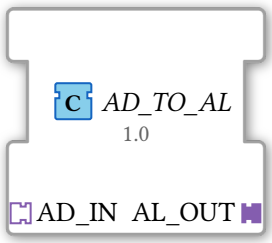
Application Scenarios

- **Adapter Bridge**: When a system component provides an INTEGER adapter (AI), but the target component expects a DWORD adapter (AD).
- **Data Word Generation**: Conversion of analog values (e.g., 16-bit measured values) into a 32-bit data word for data transmission or storage.
- **Library Independence**: Encapsulation of the conversion function, so application developers do not need to directly access IEC 61131 function blocks.

Comparison with Similar Function Blocks

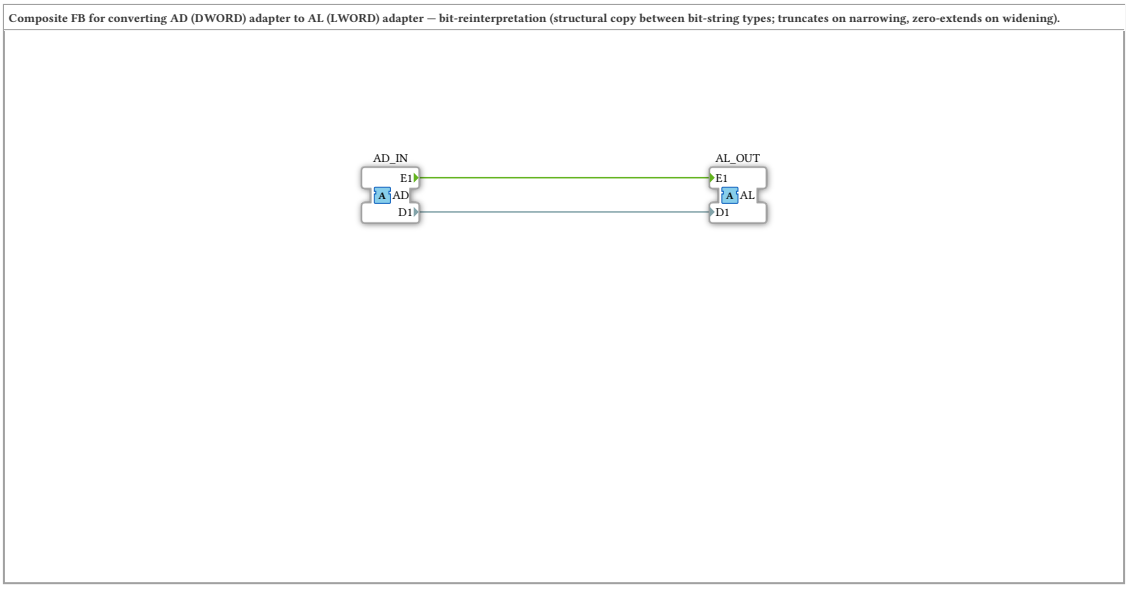
- **F_INT_TO_DWORD**: The direct IEC 61131 function provides pure type conversion without adapter embedding. `AI_TO_AD` adds the adapter interfaces, thus facilitating integration into adapter-based architectures.
- **DWORD_TO_INT (inverse)**: A corresponding function block for reverse conversion would be conceivable, but is not part of this implementation.
- **Custom Adapter Wrappers**: Other function blocks could provide similar conversions for other data types (e.g., `REAL_TO_DWORD`).

Conclusion



AI_TO_AD is a compact, adapter-oriented conversion function block that seamlessly integrates the conversion of INTEGER to DWORD values into existing control networks. By using standardized IEC 61131 function blocks and clearly defining interfaces via adapters, it is particularly well-suited for modular, reusable automation solutions.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AD_TO_AL

DWORD Adapter Input – *AD*

AL – LWORD Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AD_TO_AL** function block is a composite function block that performs a unidirectional conversion of an AD adapter (DWORD) to an AL adapter (LWORD). It serves as a bridge between subsystems that use different adapter types but require the same logical connection. The function block passes event and data signals through one-to-one, thus enabling the seamless integration of heterogeneous components.

Interface Structure

The function block has only adapter interfaces; separate event or data inputs/outputs are not available.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Type	Direction	Name	Comment
Socket (Input)	Input	`AD_IN`	DWORD adapter input of type `adapter::types::unidirectional::AD`
Plug (Output)	Output	`AL_OUT`	LWORD adapter output of type `adapter::types::unidirectional::AL`

Functionality

This function block is a simple forwarding block. Within the composite function block, the adapter channels are directly connected:

- **Event Connection:** `AD_IN.E1` ⟶ `AL_OUT.E1` Every incoming event at the AD adapter is passed unchanged to the AL adapter.

- **Data Connection:** `AD_IN.D1` ⟶ `AL_OUT.D1` The incoming data value (DWORD) is passed to the output as an LWORD without transformation.

Type conversion occurs implicitly through the coupling of the adapters; no explicit data type conversion takes place. The runtime environment ensures that the values are handled according to the adapter definition.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- **Composite Function Block:** The function block contains no internal logic (no state machine, no algorithms) and consists exclusively of internal connections.
- **Unidirectionality:** The adapters are designed to be unidirectional (only one data direction and one event direction).
- **Package Structure:** The function block (FB) is located in the package `adapter::conversion::unidirectional`.
- **Type Conversion:** AD (DWORD) and AL (LWORD) are defined as independent adapter types; the FB enables their interconnection without manual coding.
- **Metadata:** This function block originates from *HR Agrartechnik GmbH*, version 1.0, created on February 17, 2026.

State Overview

The function block does not have an internal state machine. Its state is identical to the state of the connected adapters. Passing through occurs without delay or logic.

Application Scenarios

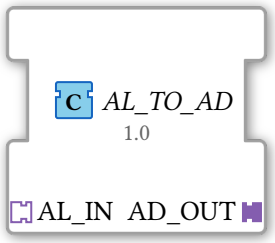
- **System Integration:** Connecting components that use different adapter protocols (e.g., a controller with a DWORD interface and a bus coupler with an LWORD interface).
- **Test Environments:** Easy injection of test data by replacing adapters.
- **Modularization:** Separation of interface definition and data flow logic in large IEC 61499 projects.

Comparison with Similar Blocks

- `AL_TO_AD`: Performs the reverse conversion (LWORD ⟶ DWORD).
- Direct adapter conversion blocks (e.g., `BYTE_TO_WORD`) generally do not replace adapters but convert elementary data types.
- Other "composite" blocks in the `adapter::conversion` package offer similar forwarding for other adapter types (e.g., `AI_TO_AO`, `DI_TO_DO`).

Unlike function blocks with their own logic, `AD_TO_AL` is limited to simple pass-through, ensuring maximum transparency and the lowest possible latency.

Conclusion



The `AD_TO_AL` function block is a lean yet valuable tool for adapter conversion in the 4diac IDE. It reduces manual wiring effort and increases the reusability of components that rely on different adapter standards. Thanks to its simple structure, it is robust, performant, and easy to understand – ideal for typical work with unidirectional adapter flows.

AL_TO_AD

LWORD Adapter Input – *AL*

AD – DWORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **AL_TO_AD** function block is a composite function block that converts a unidirectional LWORD adapter (AL) into a unidirectional DWORD adapter (AD). It enables data conversion between two different adapter types within the 4diac IDE, based on the IEC 61499 standard.

Interface Structure

Event Inputs

- None (the FB has no dedicated event inputs; event control is handled via the AL_IN socket)

Event Outputs

- None (the FB has no dedicated event outputs; event forwarding is handled via the AD_OUT plug)

Data Inputs

- None (data is provided exclusively via the AL_IN socket)

Data Outputs

- None (data is output exclusively via the AD_OUT plug)

Adapter

Type	Name	Direction	Description
Socket	AL_IN	Input	Unidirectional LWORD adapter with one event input (`E1`) and one data input (`D1` of type `LWORD`)
Plug	AD_OUT	Output	Unidirectional DWORD adapter with one event output (`E1`) and one data output (`D1` of type `DWORD`)

Functionality

The function block receives an LWORD data word (`D1`) along with an event (`E1`) via the **AL_IN** socket. The event iterates through the internal function block **F_LWORD_TO_DWORD**, which performs the conversion according to the IEC 61131 standard. After successful conversion, the result is output as a DWORD (`AD_OUT.D1`) via the plug, accompanied by an event (`AD_OUT.E1`).

The event then passes through the internal function block **F_LWORD_TO_DWORD**, which performs the conversion according to the IEC 61131 standard. The internal network structure consists of:

- A **F_LWORD_TO_DWORD** block (from the library `iec61131::conversion`)
- Event connection: `AL_IN.E1` ⟶ `Convert.REQ` / `Convert.CNF` ⟶ `AD_OUT.E1`
- Data connection: `AL_IN.D1` ⟶ `Convert.IN` / `Convert.OUT` ⟶ `AD_OUT.D1`

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- **Standard Compliance**: The conversion is performed using the IEC 61131-compliant FB `F_LWORD_TO_DWORD`, which enables lossless conversion from 64-bit to 32-bit (low-order 32-bit) support.
- **Unidirectional Adapters**: Both the input and output adapters are unidirectional, reducing complexity and ensuring a clearly defined data flow direction.
- **Event-driven Communication**: Conversion is triggered by an event at the input adapter; the result is also passed on in an event-driven manner.
- **Embedded in Composite Function Blocks**: By encapsulating the function block as a composite block, the function block can be easily integrated into larger networks.

State Overview

The **AL_TO_AD** function block does not have its own state machine, as it is implemented as a composite function block. The state logic is fully implemented by the internal **F_LWORD_TO_DWORD** function block:

1. **Wait** – No event is present at the input.
2. **Convert** – After receiving an event, the conversion of the LWORD data is performed (one clock cycle).
3. **Output** – The DWORD result and an acknowledgment event are provided at the output adapter.

Application Scenarios

- **System Integration** – When a component (e.g., a PLC) provides LWORD data, but a downstream module expects DWORD data.
- **Adapter Bridge** – In heterogeneous networks where devices use different data types for the same physical value.
- **Data Preparation** – Preprocessing of 64-bit values that are to be further processed on a 32-bit basis (e.g., for measured values or counters).

Comparison with Similar Function Blocks

- **WORD_TO_DWORD** – Converts 16-bit words to 32-bit double words, but on simple data types, not on adapters.
- **Direct Adapter Coupling** – Without conversion, both systems would have to use the same adapter type (either AL or AD), which is often not the case.
- **F_LWORD_TO_DWORD (Isolated)** – This function block operates only at the data layer; the adapter connection must be established separately. **AL_TO_AD** simplifies handling by encapsulating the adapter logic and conversion.

Conclusion

The **AL_TO_AD** function block provides a lean and standards-compliant solution for converting LWORD to DWORD adapter data. Combining adapter and conversion logic in a single composite function block increases reusability and simplifies network creation. It is particularly well-suited for integrating various IEC 61499 components and contributes to the modularity of industrial automation solutions.

AD_TO_ALI

• – ○ • – ○ • – ○ •

The **AD_TO_ALI** is a composite function block for the unidirectional conversion of a DWORD value (via an AD adapter) to a LINT value (via an ALI adapter). The conversion is performed using the integrated standard function block `F_DWORD_TO_LINT`. The block enables simple and standardized integration of components that exchange different data types via adapter interfaces. No separate event inputs are available. Event control is handled via the **AD_IN** adapter (event *E1*).

No separate event outputs are available. Output events are provided via the **ALI_OUT** adapter (event *E1*).

No separate data inputs are available. The input data (DWORD) is obtained via the **AD_IN** adapter (Data *D1*).

No separate data outputs are available. The output data (LINT) is output via the **ALI_OUT** adapter (Data *D1*).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

Adapter	Type	Direction	Description
AD_IN	`adapter::types::unidirectional::AD`	Socket	Receives a DWORD value (*D1*) and an input event (*E1*).
ALI_OUT	`adapter::types::unidirectional::ALI`	Plug	Sends the converted LINT value (*D1*) and an output event (*E1*).

Functionality

The function block waits for an event at the **AD_IN** adapter (event *E1*). As soon as this event arrives, the currently incoming DWORD value (Data *D1*) is read from the adapter and passed to the internal function block **Convert** (type `F_DWORD_TO_LINT`). This block performs the data type conversion. After successful conversion, the resulting LINT value is passed to the **ALI_OUT** adapter (Data *D1*), and an event (*E1*) is triggered for confirmation.

- **Pure Composite Logic**: The function block does not contain its own state machine but implements the conversion exclusively through the interconnection of the embedded function block `F_DWORD_TO_LINT`.
- **Standard Compliance**: The conversion function used complies with IEC 61131-3 (type conversion `DWORD_TO_LINT`).
- **Synchronization**: Events and data are forwarded from input to output within a single execution cycle (E1 → REQ → CNF → E1).

As a composite function block, **AD_TO_ALI** does not have its own state machine. Its behavior is determined solely by its internal interconnection and the states of the function block `F_DWORD_TO_LINT`. A graphical state overview is not provided.

- **Industrial Automation**: Conversion of DWORD-based sensor data (e.g., counter readings) into LINT values for further processing in systems with 64-bit integers.
- **Data Integration**: Connecting components that use different adapter protocols via a standardized conversion interface.

Analog conversion function blocks such as `AD_TO_ALI` exist for other data types (e.g., `AD_TO_ALI` for DWORD→LINT, `AI_TO_ALI` for INT→LINT). This function block specifically covers the conversion from **DWORD** to **LINT** and is optimized for this combination. It does not replace the general `F_DWORD_TO_LINT` function, but rather encapsulates it in an adapter-based interface.

The **AD_TO_ALI** offers a clean, reusable solution for converting DWORD adapters to LINT adapters. Thanks to its composite structure, the logic remains transparent and easily integrated into existing 4diac projects. It is particularly suitable for scenarios requiring a uniform adapter interface but needing to combine different data types.

ALI_TO_AD

LINT Adapter Input – *ALI* *AD* – DWORD Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block `ALI_TO_AD` is a composite block for converting a LINT adapter interface (ALI) to a DWORD adapter interface (AD). It serves as a unidirectional translator between two different data types within an adapter-based communication structure.

Interface Structure

The block has no independent event or data inputs/outputs. All communication takes place exclusively via predefined adapters.

Event Inputs

None. Event control is handled via the incoming socket adapter `ALI_IN`.

Event Outputs

None. The output events are provided via the outgoing plug adapter `AD_OUT`.

Data Inputs

None. Input data is transmitted via the socket adapter `ALI_IN`.

Data Outputs

None. Output data is transmitted via the plug adapter `AD_OUT`.

Adapters

Direction	Name	Type	Description
Socket	ALI_IN	`adapter::types::unidirectional::ALI`	Input adapter of type LINT
Plug	AD_OUT	`adapter::types::unidirectional::AD`	Output Adapter of Type DWORD

Functionality

Inside the function block, a single instance of the function block `iec61131::conversion::F_LINT_TO_DWORD` is used. The event and data connections are wired as follows:

1. An event from socket `ALI_IN.E1` triggers the input `REQ` of the converter.
2. The converter reads the LINT value from input `ALI_IN.D1` and converts it to a DWORD value.
3. After successful conversion, the converter generates the confirmation event `CNF`, which is forwarded to plug `AD_OUT.E1`.
4. Simultaneously, the converted DWORD value is transferred from output `Convert.OUT` to data output `AD_OUT.D1`.

The entire conversion process is event-driven: An incoming event triggers the conversion, and the result is acknowledged with an output event.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- The module is fully implemented as a composite and requires no dedicated runtime logic.
- The internal converter `F_LINT_TO_DWORD` is an IEC 61131-3 module that performs a bit-perfect conversion of a 64-bit integer value (LINT) to a 32-bit double-word value (DWORD).
- The adapters are defined as unidirectional, meaning that data flows exclusively from the input to the output adapter.
- This function block is designed for use in automation systems that utilize adapter interfaces according to the IEC 61499 standard.

State Overview

The function block does not have its own explicit state machine. Its behavior is entirely determined by event propagation and the internal logic of the converter block. From the user's perspective, it behaves like a transparent data conversion that is executed once for each incoming event.

Application Scenarios

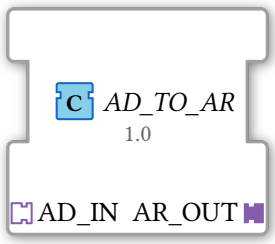
- **Integration of Heterogeneous Field Devices** – When a device or subnetwork provides data in LINT format (e.g., as a counter value or timestamp), but the target system expects DWORD values.
- **Adapter Bridge Between Subsystems** – In a distributed control system according to IEC 61499, `ALI_TO_AD` can be used to connect two subsystems with different adapter definitions.
- **Data Format Adaptation in Migration Projects** – When modernizing systems where older components still provide LINT adapters, but newer components require DWORD adapters.

Comparison with Similar Components

- **`INT_TO_DWORD`** – Converts a 16-bit integer value to DWORD, but is not offered at the adapter level.
- **`DWORD_TO_LINT`** – Reverses the conversion described here and converts DWORD back to LINT.
- **Custom Combination Components** – Instead of a hardwired adapter converter, the conversion could also be performed manually using a `F_LINT_TO_DWORD` and separate adapters. The composite component offers a compact and reusable solution.

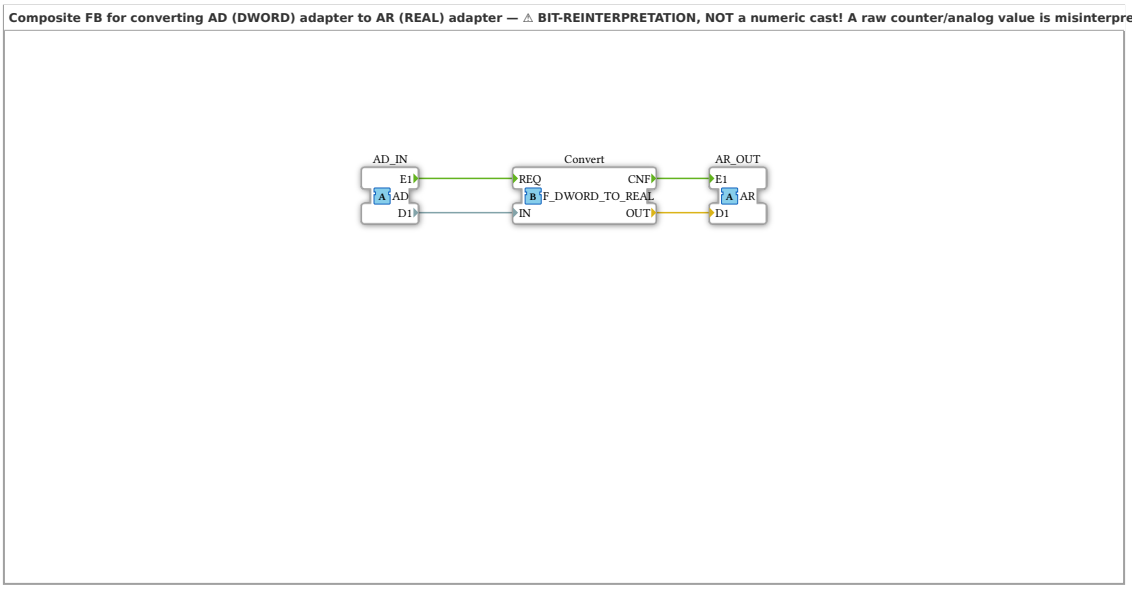
Conclusion

ALI_TO_AD` is a simple yet useful composite component that enables the unidirectional conversion of a LINT adapter to a DWORD adapter. It allows for a clean separation of data types at the adapter level and



simplifies the integration of different systems in an IEC 61499 environment. The use of a standardized IEC 61131 converter ensures defined and reproducible data conversion.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AD_TO_AR

DWORD Adapter Input – *AD*

AR – REAL Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AD_TO_AR** function block is a composite function block that maps a DWORD value from a unidirectional AD adapter (socket) onto a REAL value at an AR adapter (plug).

> ⚠️ **Warning — not a numeric value conversion:** `AD_TO_AR` internally uses `F_DWORD_TO_REAL`, which in the FORTE core is a pure IEEE754 **bit-reinterpretation** for bit-string source types (BYTE/WORD/DWORD/LWORD), not a numeric cast. A raw counter or analog value such as `DWORD#2048` will therefore **not** become `REAL#2048.0`, but a meaningless value near zero. For an actual numeric DWORD→REAL conversion, see `AD_TO_AR_NUM` (via UDINT). `AD_TO_AR` is only correct when `AD_IN` is already a bit pattern meant to be interpreted as REAL (e.g. the result of `F_REAL_TO_DWORD`).

Interface Structure

The function block has no direct (individual) event or data inputs/outputs. All communication takes place via two adapter interfaces:

Event Inputs

- *No direct event inputs* – event control is handled via the incoming adapter.

Event Outputs

- *No direct event outputs* – event output is handled via the outgoing adapter.

Data Inputs

- *No direct data inputs* – data is received via the incoming adapter.

Data Outputs

- *No direct data outputs* – data is output via the outgoing adapter.

Adapters

Name	Type	Direction	Description
AD_IN	`adapter::types::unidirectional::AD`	Socket	Receives an event (E1) and a DWORD value (D1) for conversion.
AR_OUT	`adapter::types::unidirectional::AR`	Plug	Sends an event (E1) with the converted REAL value (D1).

Functionality

The function block operates as an event-driven pipeline:

1. An incoming event at socket **AD_IN.E1** triggers the conversion.
2. The data value **AD_IN.D1** (DWORD) is passed to the internal function block `F_DWORD_TO_REAL`.
3. After successful conversion, the internal function block signals an output event (**CNF**).
4. This event is forwarded to plug **AR_OUT.E1**, and simultaneously, the converted REAL value is output via **AR_OUT.D1**.

`F_DWORD_TO_REAL` merely reinterprets the DWORD's 32-bit pattern as an IEEE754 `REAL` (a bit copy) — **no** numeric value conversion takes place.

Technical Features

- ⚠️ **Bit-reinterpretation, not numeric conversion**: See the warning in the introduction. This affects all bit-string source types (`AB`/BYTE, `AW`/WORD, `AD`/DWORD, `AL`/LWORD) converting to `AR`/REAL or `ALR`/LREAL — the only other instance in this library is `AL_TO_ALR` (LWORD→LREAL).
- **Composite Function Block**: The conversion logic is implemented entirely within an internal network consisting of a single function block.
- **Type Conversion via Adapter**: This function block enables the connection of components that communicate exclusively via adapter interfaces, eliminating the need for additional manual conversions.
- **Standard Compliance**: Utilizes the IEC 61131 library function `F_DWORD_TO_REAL`, making it portable and well-tested.
- **Unidirectional Adapters**: Both input and output adapters are unidirectional, meaning data flows in only one direction.

State Overview

The function block does not have its own state machine. Processing is strictly causal: An event at the input immediately triggers the conversion and output. There are no delays or intermediate states.

Application Scenarios

- **Bit pattern pass-through**: `AD_IN` already carries a bit pattern meant to be interpreted as REAL (e.g. the result of an `F_REAL_TO_DWORD` elsewhere in the network, or deserialized raw float data from a fieldbus/protocol).
- **NOT suitable** for raw counter, analog, or other integer values meant to carry the same numeric value as REAL — use `AD_TO_AR_NUM` for that.

Comparison with Similar Function Blocks

- **`AD_TO_AR_NUM`** (numeric, DWORD→UDINT→REAL): the safe replacement when an actual numeric value is meant.
- **`AI_TO_AR`/`ADI_TO_AR`/`AUDI_TO_AR`** (INT/DINT/UDINT→REAL): already numerically correct, since their source types are `ANY_INT` (not `ANY_BIT`) — no trap.
- **`AL_TO_ALR`** (LWORD→LREAL): the same bit-reinterpretation trap, just with the 64-bit counterparts.

Conclusion

The **AD_TO_AR** block offers a compact way to expose a DWORD bit pattern as REAL via adapter interfaces — **but not a numeric value conversion**. For raw counter or analog values meant to carry the same numeric value in REAL, use AD_TO_AR_NUM.

AD_TO_AR_NUM

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AD_TO_AR_NUM** is the numerically correct alternative to AD_TO_AR: it converts a DWORD value from a unidirectional AD adapter (socket) into a REAL value output via an AR adapter (plug), via an internal UDINT step — an **actual value conversion**, not a bit-reinterpretation.

Why not just use AD_TO_AR?

`AD_TO_AR` internally uses `F_DWORD_TO_REAL`, which in the FORTE core is a pure IEEE754 bit-reinterpretation for bit-string source types (BYTE/WORD/DWORD/LWORD), not a numeric cast. A raw counter or analog value such as `DWORD#2048` would therefore **not** become `REAL#2048.0`, but a meaningless value near zero (see AD_TO_AR and `AD_TO_AR_TODO.md` for the derivation).

Interface Structure

The function block has no direct (individual) event or data inputs/outputs. All communication takes place via two adapter interfaces:

Adapters

Name	Type	Direction	Description
AD_IN	adapter::types::unidirectional::AD	Socket	Receives an event (E1) and a DWORD raw value (D1) for conversion.
AR_OUT	adapter::types::unidirectional::AR	Plug	Sends an event (E1) with the numerically converted REAL value (D1).

Functionality

The function block works in two stages instead of a single (dangerous) one:

1. An incoming event at socket **AD_IN.E1** triggers the conversion.
2. The data value **AD_IN.D1** (DWORD) is passed to `ToUDINT` (`F_DWORD_TO_UDINT`) — a bit-reinterpretation DWORD⟶UDINT that is **valid** here, since both types share the same 32-bit unsigned-integer representation.
3. `ToUDINT.CNF` triggers `ToREAL` (`F_UDINT_TO_REAL`) — a **real numeric cast** that correctly converts the UDINT numeric value to REAL.
4. The result is output via plug **AR_OUT.E1**/**AR_OUT.D1**.

Technical Features

- **Identical interface to `AD_TO_AR`**: `AD_TO_AR_NUM` is a drop-in replacement — same socket/plug types (`AD`/`AR`), easily swapped in once it's clear a numeric value (not a bit pattern) is intended.
- **Two-stage DWORD⟶UDINT⟶REAL chain**: the same chain already wired by hand in several exercises (`Uebung_028a_AR` and others), packaged here as a single block.
- **No precision loss in the relevant value range**: `UDINT` (32 bit, max. 4,294,967,295) transfers into `REAL` (IEEE754 single precision, 24-bit mantissa) without loss as long as the value stays within the exactly representable integers (up to 2^{24} = 16,777,216) — not an issue for typical analog/counter raw values (e.g. 0–64255 or 0–4095).

Application Scenarios

- **Raw analog values**: An analog input or counter delivers a DWORD raw value (e.g. 0–4095, 0–64255) that should be further processed as an actual numeric value in REAL (scaling, display, OPC-UA publish).
- **Replacement for the manual `AD_TO_AUDI` + `AUDI_TO_AR` chain**: where two separate adapter instances were previously needed in the SubApp network, one now suffices.

Comparison with Similar Function Blocks

- `AD_TO_AR`: the bit-reinterpretation variant — use only when `AD_IN` is already a bit pattern meant to be interpreted as REAL.
- **`AI_TO_AR`/`ADI_TO_AR`/`AUDI_TO_AR`**: already numerically correct, since their source types are `ANY_INT` — if the raw value is already available as an INT/DINT/UDINT adapter, no `_NUM` variant is needed.

Conclusion

AD_TO_AR_NUM closes the gap between the tempting-but-dangerous `AD_TO_AR` and the actually needed numeric DWORD⟶REAL conversion — as a single, drop-in-compatible block instead of a manually wired two-block chain.

AR_TO_AD

REAL Adapter Input – *AR*

AD – DWORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AR_TO_AD` serves as a composite function block (FB) for converting a REAL value received via a unidirectional AR adapter into a DWORD value output via a unidirectional AD adapter. The conversion is performed according to IEC 61131-3 using the function block `F_REAL_TO_DWORD`. The FB encapsulates the necessary event and data connections and allows for easy integration into existing adapter-based communication structures.

Interface Structure

Event Inputs

Input	Type	Description
`AR_IN.E1`	Adapter Event	Receives the trigger event from the AR adapter, which starts the conversion.

Event Outputs

Output	Type	Description
`AD_OUT.E1`	Adapter Event	Sends an event to the AD adapter as soon as the converted DWORD value is available.

Data Inputs

Input	Type	Description
`AR_IN.D1`	REAL	The REAL value to be converted, provided by the AR adapter.

Data Outputs

Output	Type	Description
AD_OUT.D1	DWORD	The converted DWORD value that is passed to the AD adapter.

Adapters

The FB has a **socket** of type adapter::types::unidirectional::AR (labeled AR_IN) and a **plug** of type adapter::types::unidirectional::AD (labeled AD_OUT). The actual input and output signals are accessible via the event and data pins of these adapters.

Functionality

1. The function block (FB) waits for an event at the event input AR_IN.E1.
2. Simultaneously, the current value at the data input AR_IN.D1 (REAL) is retrieved.
3. Internally, the function block F_REAL_TO_DWORD (from the IEC 61131-3 library) is called, which performs the conversion.
4. After successful conversion, the resulting DWORD value is assigned to the data output AD_OUT.D1.
5. Subsequently, an event is output at the output AD_OUT.E1 to notify the connected Active Directory adapter.

The entire process occurs synchronously in a single step; that is, the FB is purely event-driven and does not maintain any internal states.

Technical Features

- **Bit-reinterpretation**: extracts the IEEE754 bit pattern of the source value (intentional, e.g. for serialization), not its numeric value.
- **Composite FB:** The logic is implemented exclusively through the combination of the internal F_REAL_TO_DWORD function block. There is no separate state machine or complex algorithms.
- **Adapter Coupling:** The function block encapsulates the conversion at the adapter level, allowing it to be integrated into adapter-based architectures (e.g., distributed systems with 4diac) without additional modifications.
- **IEC 61131-3 Compliance:** The actual conversion is performed by a standardized function block, which increases portability and standards compliance.
- **Package Name:** The function block is provided under the package adapter::conversion::unidirectional and imports iec61131::conversion::F_REAL_TO_DWORD.

State Overview

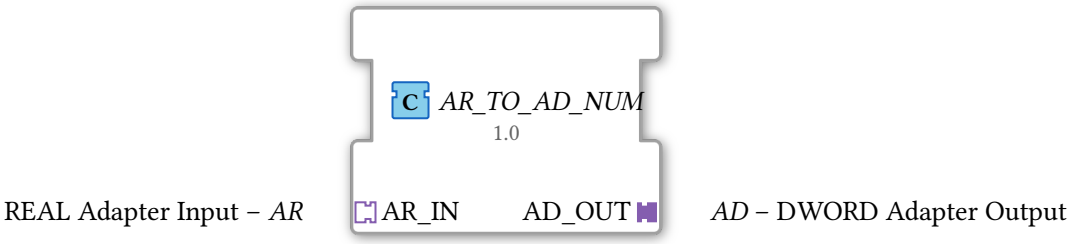
Since this is a combinational composite function block, it does not have an internal state machine. The functionality is purely event-driven and is executed once for each event at the input.

Application Scenarios

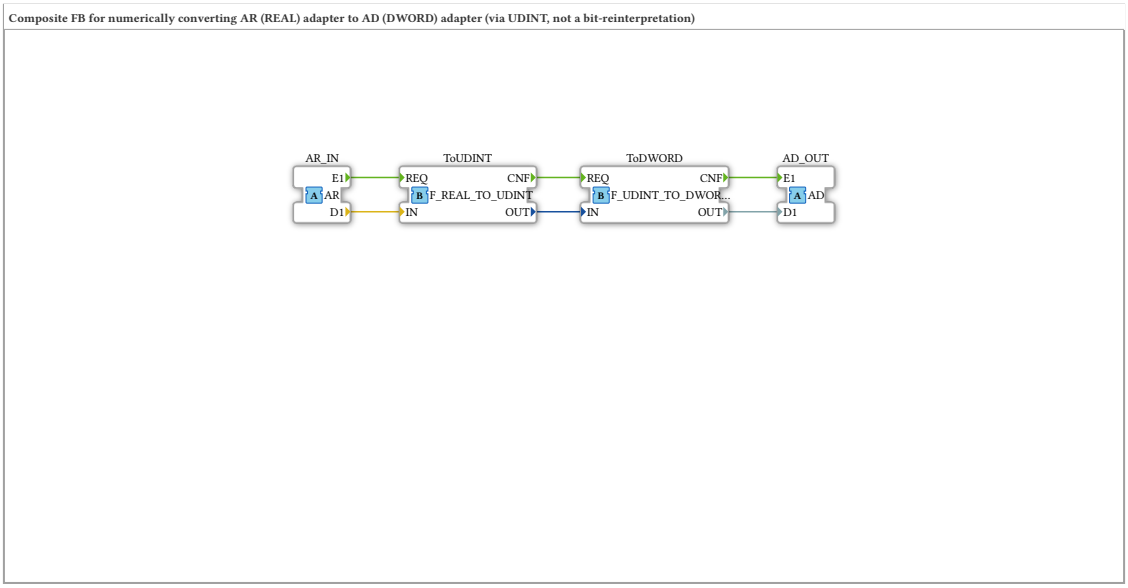
- **Data Protocol Adaptation:** When a REAL value (e.g., a measured value) can only be transmitted as a DWORD (e.g., in many fieldbus protocols) via a bus system.
- **Adapter Bridge:** In systems that use both REAL and DWORD adapters, this function block can serve as a simple conversion unit between the two adapter types.
- **Reusable Conversion:** Due to its encapsulation, the conversion can be used multiple times in different networks without having to manually establish the connections each time.

Comparison with Similar Function Blocks

- **F_REAL_TO_DWORD:** The direct function block from IEC 61131-3 offers the same conversion but requires manual wiring of event and data lines. AR_TO_AD encapsulates this in an adapter interface, simplifying integration into adapter networks.
- **AR_TO_SINT / AR_TO_INT:** Comparable conversions exist for other integer data types, but not as adapter versions. AR_TO_AD is specifically designed for DWORD and adapters.
- **User-defined composite function blocks:** In principle, any user could create similar encapsulation. However, this function block offers a standardized solution with a clear package structure.



Conclusion



The `AR_TO_AD` function block is a specialized composite function block that enables the conversion of a REAL value to a DWORD value at the adapter level. It is characterized by its ease of use, standards compliance, and seamless integration into unidirectional adapter communication. The use of the proven IEC 61131-3 module `F_REAL_TO_DWORD` ensures reliable and portable conversion.

AR_TO_AD_NUM

• – ◦ • – ◦ • – ◦ •

Introduction

`AR_TO_AD_NUM` is a composite function block that converts a REAL adapter input into a DWORD adapter output using a numerically correct conversion path. Instead of reinterpreting the REAL value as its IEEE 754 bit pattern, it first converts REAL to UDINT and then moves the resulting unsigned 32-bit integer into a DWORD. This makes it suitable for applications where a numeric setpoint such as `REAL#50.0` should become `DWORD#50` rather than the raw floating-point bit pattern of 50.0.

The block is a drop-in-compatible alternative to `AR_TO_AD` for adapter-based connections that require numeric REAL-to-DWORD conversion, and it forms the counterpart to `AD_TO_AR_NUM` for the reverse direction.

Interface Structure

Event Inputs

None.
`AR_TO_AD_NUM` has no directly exposed event inputs. The input event is received through the `AR_IN` adapter.

Event Outputs

None.
The output event is delivered through the AD_OUT adapter.

Data Inputs

None.
The input data is received through the AR_IN adapter.

Data Outputs

None.
The output data is delivered through the AD_OUT adapter.

Adapters

Role	Name	Type	Description
Socket	AR_IN	adapter::types::unidirectional::AR	REAL adapter input. Supplies the REAL value on AR_IN.D1 and the corresponding event on AR_IN.E1.
Plug	AD_OUT	adapter::types::unidirectional::AD	DWORD adapter output. Provides the converted DWORD value on AD_OUT.D1 and the completion event on AD_OUT.E1.

Functionality

The internal network consists of two IEC 61131-2 conversion function blocks:

1. F_REAL_TO_UDINT — performs a real numeric conversion from REAL to UDINT.
2. F_UDINT_TO_DWORD — transfers the UDINT bit pattern to DWORD.

When an event arrives through AR_IN.E1, the REAL value from AR_IN.D1 is passed to ToUDINT.IN. The F_REAL_TO_UDINT block converts the value and confirms with CNF. This confirmation triggers ToDWORD.REQ, passing the UDINT result as input. F_UDINT_TO_DWORD then provides the equivalent DWORD representation and confirms with CNF, which causes AD_OUT.E1 to be issued with the result available on AD_OUT.D1.

This two-step conversion chain guarantees that the resulting DWORD carries the same numeric value as the original REAL input, rather than the raw IEEE 754 representation of that value.

Technical Features

- Composite FB implemented entirely through an internal function block network.
- Uses standard IEC 61131 conversion function blocks.
- Converts REAL to DWORD through a UDINT intermediate step.
- Avoids the IEEE 754 bit-reinterpretation behavior of a direct REAL-to-DWORD conversion.
- Unidirectional event flow: input adapter event triggers the conversion pipeline and produces one output adapter event.
- Uses the same adapter types as AR_TO_AD, allowing it to be used as a drop-in replacement in adapter-based networks.
- No custom state machine or internal algorithms are required.

State Overview

AR_TO_AD_NUM has no explicitly defined ECC state machine because it is a composite function block. Its behavior can be described as a three-stage request/confirmation pipeline:

Stage	Active Element	Description
1	ToUDINT	AR_IN.E1 triggers ToUDINT.REQ; AR_IN.D1 is passed as the REAL input.
2	ToDWORD	ToUDINT.CNF triggers ToDWORD.REQ; the converted UDINT value is passed to ToDWORD.IN.
3	AD_OUT	ToDWORD.CNF triggers AD_OUT.E1; the resulting DWORD value is placed on AD_OUT.D1.

The block is idle until an event arrives from the connected REAL adapter.

Application Scenarios

AR_TO_AD_NUM is useful wherever a REAL number must be delivered as the same numeric value in DWORD format, particularly when the DWORD is interpreted by a device or driver as an integer-like value.

Typical use cases include:

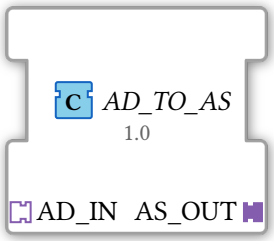
- **PWM duty cycle output**: A controller computes a duty cycle as REAL#50.0 and must send DWORD#50 to a PWM output such as logiBUS_QDA_PWM.
- **Numeric setpoint conversion**: A REAL setpoint from an adapter-based input must be converted into a DWORD value for a downstream integer-oriented interface.
- **Replacing manual conversion chains**: AR_TO_AD_NUM packages the equivalent of AR_TO_AUDI followed by AUDI_TO_AD into a single function block.
- **Interfacing with unidirectional adapters**: The block is designed for use in the adapter::conversion::unidirectional package and fits into adapter-based data flow architectures.

For the opposite direction, AD_TO_AR_NUM provides the corresponding numeric DWORD-to-REAL conversion.

Comparison with Similar Blocks

Approach	Conversion Semantics	Recommended Use
AR_TO_AD_NUM	REAL → UDINT → DWORD; numeric value is preserved	Numeric setpoints, PWM duty cycles, integer-oriented DWORD outputs
AR_TO_AD	REAL → DWORD using IEEE 754 bit reinterpretation	Serializing a REAL value as its floating-point bit pattern for transport to a matching DWORD-to-REAL block
Manual AR_TO_AUDI + AUDI_TO_AD	Same numeric semantics as AR_TO_AD_NUM, but requires two separate blocks and explicit wiring	When a conversion chain must be made visible or extended in the network
AD_TO_AR_NUM	DWORD → UDINT → REAL; reverse numeric conversion	Converting a numeric DWORD setpoint back into a REAL value

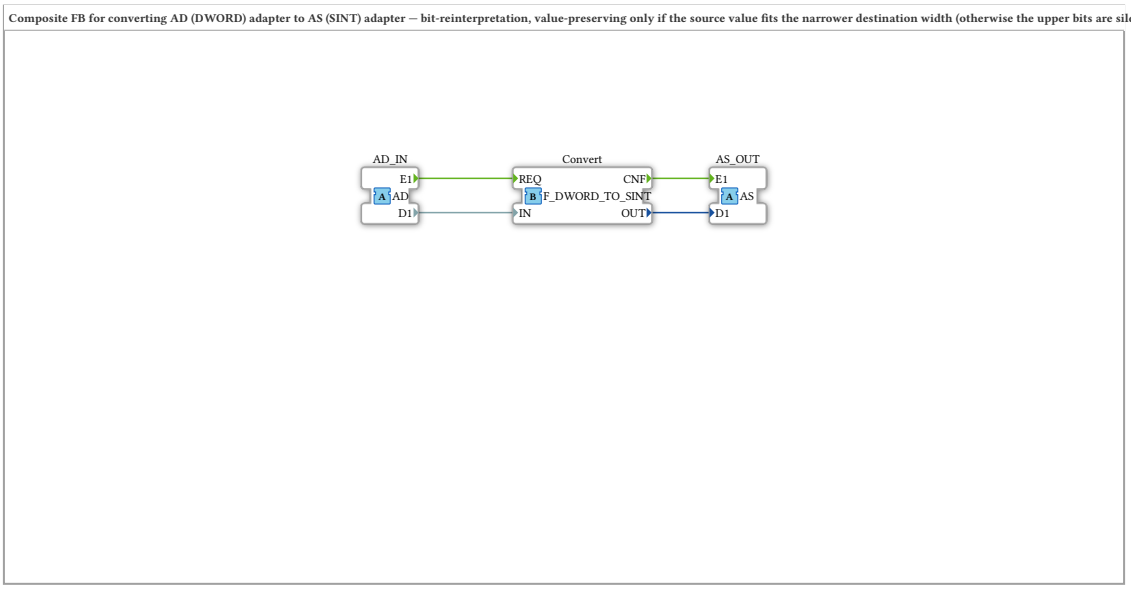
The key difference is whether the REAL value is treated as a number or as a bit pattern. AR_TO_AD_NUM always preserves the numeric value, while a direct REAL-to-DWORD conversion preserves the IEEE 754 bit layout.



Conclusion

AR_TO_AD_NUM provides a safe and semantically correct way to convert a REAL adapter value into a DWORD adapter value. By routing the conversion through UDINT, it ensures that a numeric value such as REAL#50.0 becomes DWORD#50 and not the raw binary representation of the REAL number. This makes it particularly valuable in automation applications where DWORD values are used as setpoints, duty cycles, or other integer-interpreted data.

Numeric Index (unidirectional)



Here you will find all exercises from the unidirectional workspace, listed in ascending order. …

AD_TO_AS

DWORD Adapter Input – *AD*

AS – SINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **AD_TO_AS** function block is a composite block for converting a DWORD adapter (type `AD`) into a SINT adapter (type `AS`). It enables data conversion between different adapter standards within the 4diac IDE and is provided in version 1.0. The internal conversion is performed via the IEC 61131 block `F_DWORD_TO_SINT`.

Interface Structure

Event Inputs

No direct event inputs.

The block receives events exclusively via the adapter socket **AD_IN** (event port E1 of the AD adapter).

Event Outputs

No direct event outputs.

The function block sends events exclusively via the adapter plug **AS_OUT** (event port E1 of the AS adapter).

Data Inputs

No direct data inputs.

The function block receives data exclusively via the adapter socket **AD_IN** (data port D1 of the AD adapter, data type **DWORD**).

Data Outputs

No direct data outputs.

The function block sends data exclusively via the adapter plug **AS_OUT** (data port D1 of the AS adapter, data type **SINT**).

Adapter

- **Socket AD_IN**:

Type: `adapter::types::unidirectional::AD`
Description: Receives a DWORD value and an associated event.

- **Plug AS_OUT**:

Type: `adapter::types::unidirectional::AS`
Description: Sends a SINT value and an associated event.

Functionality

The function block operates in an event-driven manner:

1. An event at socket **AD_IN.E1** triggers processing.
2. The internal block `Convert` (type `F_DWORD_TO_SINT`) is started. It receives the DWORD value from **AD_IN.D1** at its input `IN` and performs the conversion to a SINT value.
3. After the conversion is complete, `Convert` signals an event via its output `CNF`.
4. This event is forwarded to the plug **AS_OUT.E1**, and simultaneously the converted SINT value from `Convert.OUT` is passed to **AS_OUT.D1**.

This establishes a complete, unidirectional coupling between the AD and AS adapters.

Technical Features

- **Bit-reinterpretation**, value-preserving only if the source value fits the narrower destination width (otherwise the upper bits are silently dropped).
- **Value Range Loss**: Converting DWORD (32-bit, unsigned) to SINT (8-bit, signed) can result in data loss. Only the lower 8 bits of the DWORD are used; the SINT value range is between −128 and +127.
- **Library Used**: The function block uses the IEC 61131 conversion function `F_DWORD_TO_SINT`, which is defined in the package group `iec61131::conversion`.
- **Unidirectional Data Flow**: The function block only allows data flow in one direction (from AD to AS) and has no feedback.

State Overview

Since this is a composite function block, there is no explicit internal state machine. The process can be described as a simple state sequence as follows:

- **WAIT**: The function block waits for an event at socket AD_IN.
- **CONVERT**: After receiving the event, the conversion `F_DWORD_TO_SINT` is performed.
- **SEND**: After the conversion is complete, the output event is sent to plug AS_OUT, and the data value is passed on.

This returns the function block to the **WAIT** state.

Application Scenarios

- **Data Conversion Between Different Adapter Types**: If a sending module provides a DWORD value (e.g., a 32-bit counter reading) via an AD adapter, but the receiver expects a SINT value via an AS adapter, this module is used for mediation.
- **Event-Driven Signal Conditioning**: In control applications where events must be transmitted asynchronously between adapters, `AD_TO_AS` serves as a bridge for type conversion.

Comparison with Similar Modules

- **AD_TO_INT / AD_TO_BYTE**: Analog conversion modules that convert DWORD values to other integer types (e.g., INT, BYTE).
- **AD_TO_INT / AD_TO_BYTE**: Analog conversion modules that convert DWORD values to other integer types (e.g., INT, BYTE). - **Direct Type Conversion**: Unlike using a simple `F_DWORD_TO_SINT` as an embedded function block, `AD_TO_AS` offers complete adapter encapsulation, allowing the interfaces to be integrated into a 4diac system without additional connection logic.

Conclusion

The **AD_TO_AS** function block provides a compact and standardized solution for converting DWORD to SINT data in an event-driven adapter environment. By utilizing the IEC 61131 library function and its clear,

event-based execution, it is reliable and easily integrated into existing control projects. The unidirectional structure limits its application to a simple data flow, which is sufficient for many use cases.

]

AS_TO_AD

SINT Adapter Input – *AS*

AD – DWORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AS_TO_AD** is a composite function block (FB) that converts a SINT adapter interface (AS) to a DWORD adapter interface (AD). It serves as a converter between two unidirectional adapter types and is typically used to adapt data from a SINT-based signal path to a DWORD-based signal path.

Interface Structure

The function block does not have its own event or data inputs/outputs, but provides only adapter interfaces.

Event Inputs

- No direct event inputs – event control is handled via the incoming adapter **AS_IN** (socket).

The adapter provides the start signal for the conversion via its event output **E1**.

Event Outputs

- No direct event outputs – event output is handled via the outgoing adapter **AD_OUT** (Plug).

After conversion is complete, the event **E1** is sent to the outgoing adapter.

Data Inputs

- No direct data inputs – the SINT value to be converted is provided via the adapter **AS_IN** (Socket) through its data output **D1**.

Data Outputs

- No direct data outputs – the converted DWORD value is output via the adapter **AD_OUT** (Plug) through its data input **D1**.

Adapters

Adapter Name	Direction	Type	Description
AS_IN	Socket (Input)	adapter::types::unidirectional::AS	Input adapter for the SINT value (including event E1)
AD_OUT	Plug (Output)	adapter::types::unidirectional::AD	Output adapter for the converted DWORD value (including event E1)

Functionality

This function block operates as a simple pass-through with data type conversion:

1. An event is received at output **E1** via the **AS_IN** socket. Simultaneously, a value of type `SINT` is present at the **D1** data output of the socket.
2. The event is forwarded to the internal function block **Convert** (type `F_SINT_TO_DWORD`) and triggers its conversion.
3. The `F_SINT_TO_DWORD` block converts the received `SINT` value into a `DWORD` value and outputs the result at its **OUT** output.
4. After successful conversion, the **CNF** event of the internal block is passed to the **AD_OUT** plug, which then triggers its **E1** event. Simultaneously, the converted `DWORD` value is forwarded to the **D1** data input of the plug.

The entire process is synchronous and without data buffering – each conversion is initiated immediately by an incoming event, and the result is output instantly.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Unidirectional Adapters**: The block uses only unidirectional adapters (socket for input, plug for output). Reverse communication is not supported.
- **Reusable Standard Block**: The conversion is implemented using the IEC 61131-compliant block `F_SINT_TO_DWORD`, which is available in the library `iec61131::conversion`.
- **Composite Architecture**: The block is implemented as a composite function block (FB) and allows for easy adaptation or reuse of the internal network.
- **License**: The block is licensed under the Eclipse Public License 2.0 (EPL-2.0) and includes a corresponding copyright notice.

State Overview

The block does not have its own state machine. Its operation is purely event-driven and data flow-based:

1. **Waiting for Event** – The internal FB `Convert` waits for a `REQ` event (provided by **AS_IN.E1**).
2. **Conversion** – An incoming event initiates the conversion of the SINT value to a DWORD value.
3. **Output** – Upon completion, the **CNF** event is generated by the internal function block, and the converted value is passed to the output adapter.

Note: Since no delay or buffering occurs, no other event can be processed during the conversion.

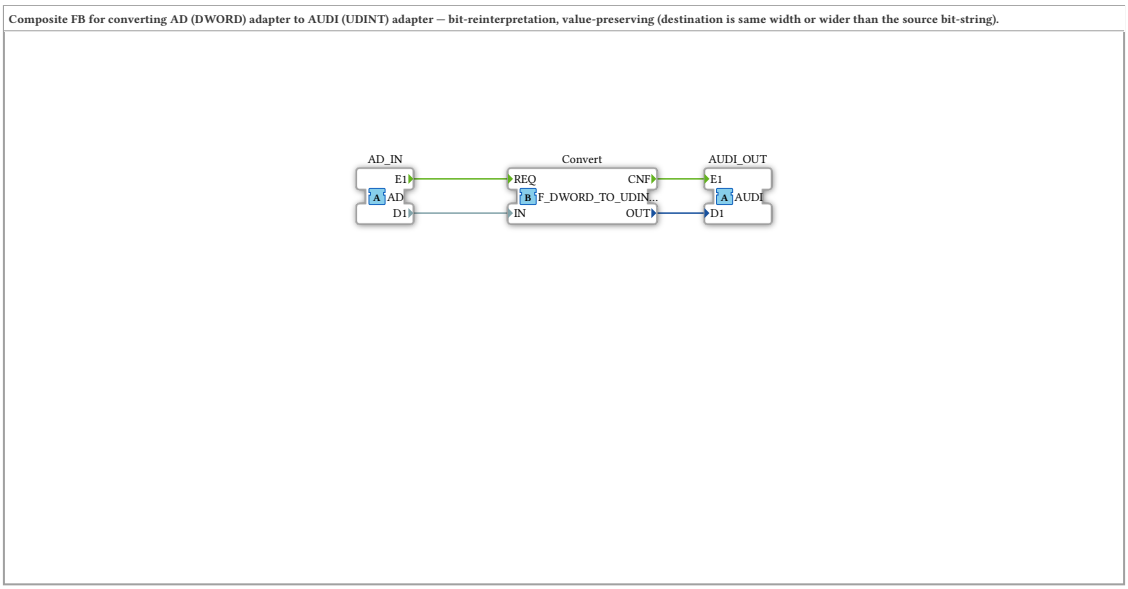
Application Scenarios

- **Sensor Integration**: A sensor provides data as SINT (e.g., 8-bit values), while the control unit processes only DWORD values.
- **System Integration**: Existing SINT-based communication interfaces are to be integrated into a system that expects DWORD adapters.
- **Protocol Conversion**: Modular manufacturing systems use various adapter types that can be interconnected using such converters.

Comparison with Similar Function Blocks

- **BYTE_TO_WORD, BYTE_TO_DWORD, WORD_TO_DWORD** – Corresponding converters for other data types are available in the IEC 61131 library.
- **AS_TO_AD** differs in that it uses adapter interfaces instead of direct inputs/outputs. This makes it particularly suitable for the modular design of adapter chains.
- **Direct Converter FBs** such as `F_SINT_TO_DWORD` offer a simpler interface (inputs/outputs), while the Composite FB has the advantage of adapter compatibility.

Conclusion



The **AS_TO_AD** function block is a specialized adapter converter that enables seamless integration of a SINT-based data path into a DWORD-based architecture. By using the standardized function block `F_SINT_TO_DWORD` and implementing it as a composite function block, it is reliable, extensible, and easy to integrate into existing 4diac projects. Its unidirectional design makes it ideal for applications where data only needs to flow in one direction.

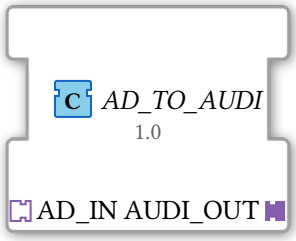
- 🌐 Eclipse 4diac IDE & Color Reference on ms-muc-docs.de

AD_AUDI Conversion



AD_TO_AUDI

Introduction

The AD_TO_AUDI function block is a specialized adapter conversion module. It is used to convert a unidirectional **AD** (DWORD) adapter socket into a unidirectional **AUDI** (UDINT) adapter plug. Internally, the module uses the standard conversion function `F_DWORD_TO_UDINT` to ensure clean type conversion between the bit string format (DWORD) and the numeric format (UDINT).

DWORD Adapter Input – *AD*

AUDI – UDINT Adapter Output

Interface Structure

Adapters

- **AD_IN** (Socket): Input adapter of type `AD` (DWORD).
- **AUDI_OUT** (Plug): Output adapter of type `AUDI` (UDINT).

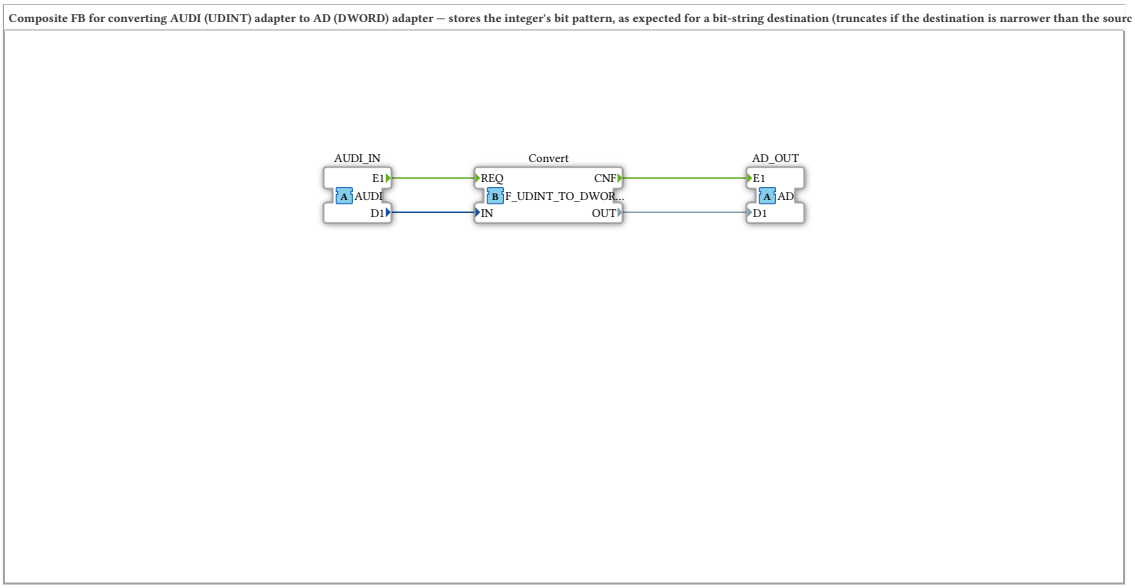
Functionality

As soon as an event (`E1`) arrives at `AD_IN` along with data (`D1`), the DWORD value is internally converted into a UDINT value. This is then immediately passed on via the `AUDI_OUT` adapter (event `E1`, data `D1`).

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).

✓ **Direct adapter-to-adapter coupling**.
✓ **Standard-compliant conversion** through the use of `F_DWORD_TO_UDINT`.
✓ **Event-driven**: Every update at the input immediately triggers an update at the output.

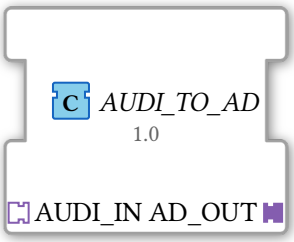


Application Scenarios

- Connecting ISOBUS input blocks (which often return DWORD values) to adapter-based numerical processing logic.
- Protocol and type adaptation in complex block networks.

🛠️ Related Exercises

- Exercise_011_AUDI



AUDI_TO_AD

Introduction

The AUDI_TO_AD function block is a specialized adapter conversion module. It converts a unidirectional **AUDI** (UDINT) adapter socket into a unidirectional **AD** (DWORD) adapter plug. Internally, the module uses the standard conversion function `F_UDINT_TO_DWORD` to ensure clean type conversion between the numeric format (UDINT) and the bit string format (DWORD).

UDINT Adapter Input – *AUDI*

AD – DWORD Adapter Output

Interface Structure

Adapters

- **AUDI_IN** (Socket): Input adapter of type `AUDI` (UDINT).
- **AD_OUT** (Plug): Output adapter of type `AD` (DWORD).

Functionality

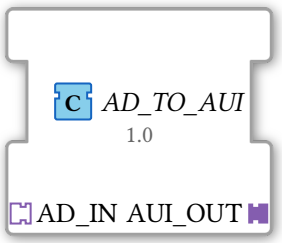
As soon as an event (`E1`) arrives at `AUDI_IN` along with data (`D1`), the UDINT value is internally converted into a DWORD value. This is then immediately passed on via the `AD_OUT` adapter (event `E1`, data `D1`).

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).

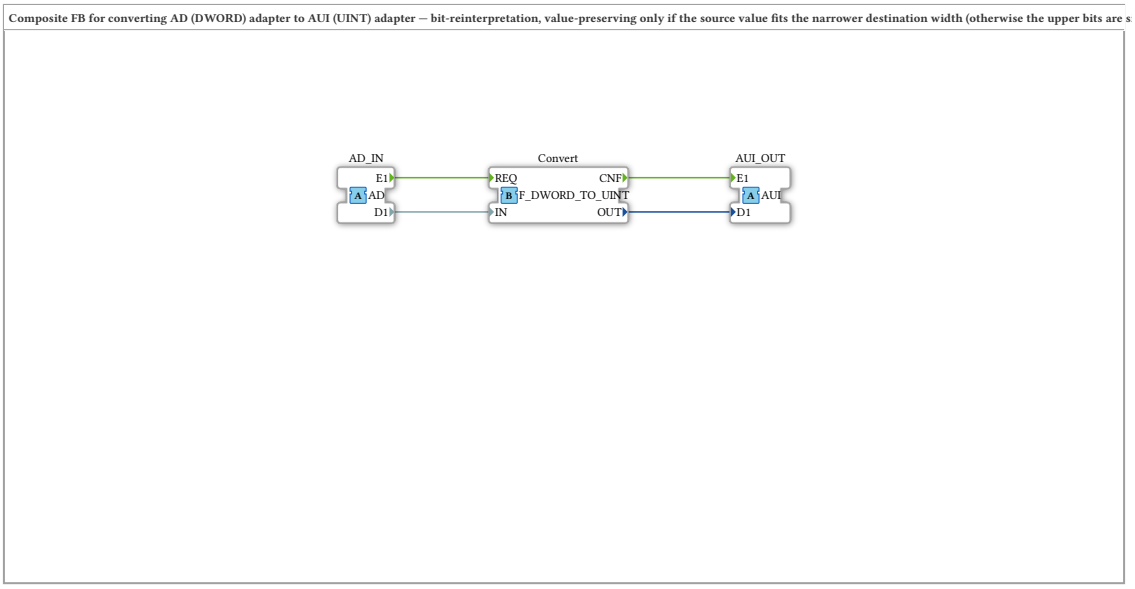
✓ **Direct adapter-to-adapter coupling**.
✓ **Standard-compliant conversion** through the use of `F_UDINT_TO_DWORD`.
✓ **Event-driven**: Every update at the input immediately triggers an update at the output.

Application Scenarios



- Feeding numerical calculation results back to ISOBUS output modules (e.g., bar graph or numeric display), which often expect DWORD as the input format.
- Compatibility layer in adapter-based control architectures.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AD_TO_AUI

DWORD Adapter Input – *AD*

AUI – UINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The function block `AD_TO_AUI` is a composite block that converts an AD adapter (DWORD-based) into an AUI adapter (UINT-based). It enables the seamless integration of components that work with different data types by converting incoming DWORD values to UINT values and forwarding the corresponding events.

Interface Structure

Event Inputs

Name	Type	Description
(none of its own)	-	The function block does not have its own event inputs. Event control is handled via the adapter socket `AD_IN`.

Event Outputs

Name	Type	Description
(none built-in)	-	The function block has no built-in event outputs. Event forwarding is handled via the adapter plug `AUI_OUT`.

Data Inputs

Name	Data Type	Description
(none built-in)	-	All data is provided via the adapter socket `AD_IN`.

Data Outputs

Name	Data Type	Description
(No custom)	-	All data is output via the adapter plug `AUI_OUT`.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::AD`	`AD_IN`	Socket (Input)	Accepts DWORD values and associated events.

adapter::types::unidirectional::AUI	AUI_OUT	Plug (Output)	Outputs converted UINT values and associated events.

The adapter AD_IN provides an event E1 and a data element D1 (type DWORD).
The adapter AUI_OUT expects an event E1 and a data element D1 (type UINT).
The mapping is performed as described in the Functionality section.

Functionality

The function block contains an instance of the standard conversion module iec61131::conversion::F_DWORD_TO_UINT. Internal Circuitry:

1. **Event Control**:

- The event AD_IN.E1 is forwarded directly to the conversion block (Convert.REQ).
- After successful conversion, Convert.CNF signals the event to AUI_OUT.E1.

1. **Data Flow**:

- The data value AD_IN.D1 (DWORD) is passed to the input Convert.IN.
- The output Convert.OUT delivers the converted value (UINT) to AUI_OUT.D1.

The function block thus performs an event-driven, unidirectional type conversion from DWORD to UINT. The conversion is performed according to the IEC 61131-3 standard function DWORD_TO_UINT.

Technical Features

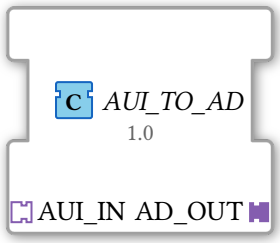
- **Bit-reinterpretation**, value-preserving only if the source value fits the narrower destination width (otherwise the upper bits are silently dropped).
- **Composite Block**: The function block encapsulates an existing standard conversion block and two adapter interfaces. This simplifies reuse in larger applications.
- **Data Type Conversion**: The conversion from DWORD (32-bit, unsigned) to UINT (16-bit, unsigned) can lead to information loss depending on the value range (e.g., if the DWORD value is greater than 65535). The user is responsible for monitoring the value range.
- **Unidirectional Interface**: Both the input and output adapters are unidirectional (only one event/data direction).
- **License**: This function block is available under the Eclipse Public License 2.0 (EPL-2.0).

State Overview

The AD_TO_AUI function block does not have its own internal state. Its behavior is purely combinatorial in conjunction with the event-driven execution of the included conversion block. There are no initialization or error states; the conversion occurs immediately upon each incoming event.

Application Scenarios

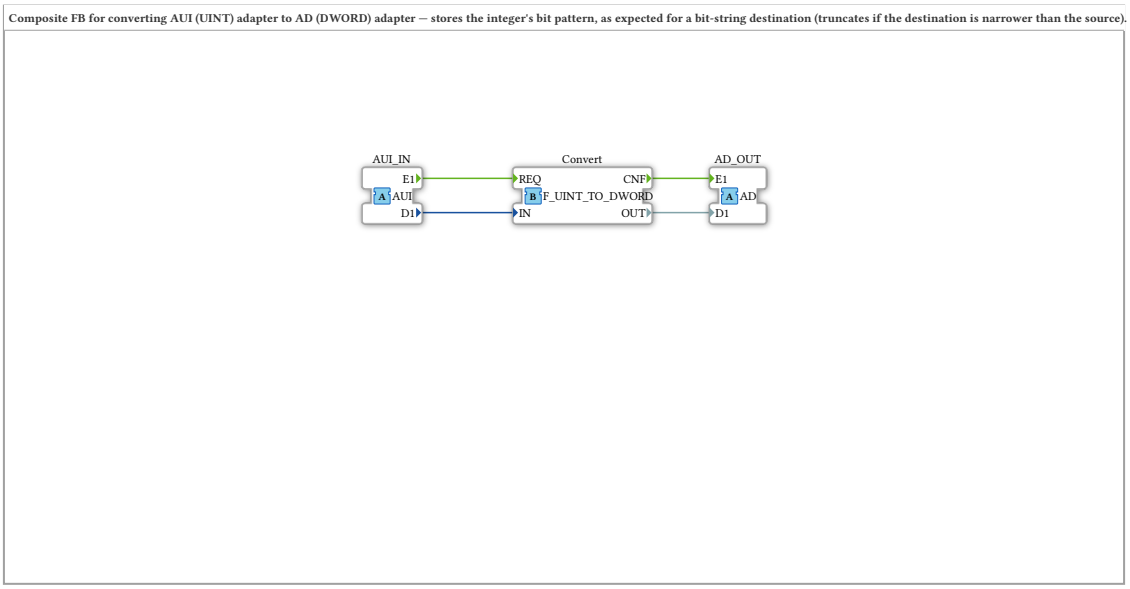
- **Interface Adaptation**: When an existing function block or subsystem only supports an AUI adapter (UINT), but the data source provides an AD adapter (DWORD).
- **Data Reduction**: Targeted reduction of a 32-bit value to 16 bits for downstream processing logic.
- **Integration into Existing Controllers**: Exchange of adapters between different bus systems or communication protocols that use different data types.



Comparison with Similar Function Blocks

- **AUI_TO_AD**: Performs the reverse conversion (UINT to DWORD). Both function blocks are symmetrically structured and utilize the corresponding standard conversion functions.
- **Direct Type Conversion**: Manual implementation using a F_DWORD_TO_UINT function block and adapters would be possible, but the composite function block offers an encapsulated, reusable solution.

Conclusion



The AD_TO_AUI function block provides a simple and reliable way to convert between two common adapter types. It reduces development effort by encapsulating the necessary circuitry and conversion and providing it as a reusable component. Despite the potential value range limitation (DWORD → UINT), it is a useful tool for integrating heterogeneous system components in control engineering.

AUI_TO_AD

UINT Adapter Input – *AUI*

AD – DWORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUI_TO_AD** is a composite function block (FB) that converts an AUI adapter (UINT data type) into an AD adapter (DWORD data type). It serves as a unidirectional conversion interface within an IEC 61499-based control application. The block is implemented as an encapsulation of the standard converter `F_UINT_TO_DWORD` from the library `iec61131::conversion` and enables adapter-based data transfer.

Interface Structure

Event Inputs

Name	Description
AUI_IN.E1	Event from the AUI adapter that triggers the conversion.

Event Outputs

Name	Description
AD_OUT.E1	Event to the AD adapter that signals the availability of the converted value.

Data Inputs

Name	Data Type	Description
AUI_IN.D1	UINT	Input value from the AUI adapter that is converted to a DWORD value.

Data Outputs

Name	Data Type	Description
AD_OUT.D1	DWORD	Output value that passes the converted DWORD value to the AD adapter.

Adapter

Type	Name	Role
`adapter::types::unidirectional::AUI`	AUI_IN	Socket – Input adapter for the UINT value and the associated event.
`adapter::types::unidirectional::AD`	AD_OUT	Plug – Output adapter for the converted DWORD value and the confirmation event.

Functionality

The function block **AUI_TO_AD** operates as an encapsulation of the function block `F_UINT_TO_DWORD`. As soon as an event arrives at the event input `AUI_IN.E1`, the connected internal converter `Convert` is called. This converter reads the value from the data input `AUI_IN.D1` (type UINT) and converts it into a DWORD value. The result is provided at the data output `AD_OUT.D1`. Simultaneously, after successful conversion, an event is generated at the output `AD_OUT.E1`, which signals completion to the downstream AD adapter.

The conversion is performed according to the IEC 61131-3 standard for the function `UINT_TO_DWORD`. The value range of the UINT input (0 to 65535) is mapped to the lower 16 bits of the DWORD output; the upper 16 bits are padded with zeros.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- The function block is implemented as a composite function block (FB) and does not contain its own state machines (ECCs). Its behavior is entirely determined by the integrated converter `F_UINT_TO_DWORD`.
- The connection between the adapters and the internal converter is established via event and data connections.
- The function block is designed for unidirectional data transfer – there is no reverse conversion from AD to AUI.
- The package name (`packageName`) is `adapter::conversion::unidirectional`, indicating a clear structure of the conversion adapters.

State Overview

As a composite function block, **AUI_TO_AD** does not have its own state machine. The functional sequence is purely event-driven: An event at the input triggers the conversion, after which an event is generated at the output. There are no internal states between these events.

•

Application Scenarios

- **Data Integration**: An AUI adapter provides a UINT value (e.g., from a sensor module) that is required in a system that processes only DWORD addresses (e.g., via an AD adapter).
- **Protocol Adaptation**: If existing components work with different data types, this function block can be used as a simple converter between the adapter interfaces.
- **Modularization**: Within a 4diac application, standardized conversion function blocks can be grouped as adapters to increase reusability.

Comparison with Similar Function Blocks

Comparable conversion function blocks exist for other data types, e.g., `WORD_TO_DWORD`, `BYTE_TO_DWORD`, or generic `TO_DWORD` functions. The unique feature of **AUI_TO_AD** lies in the encapsulation of the adapter protocols: Instead of a direct data connection, the values are provided via adapters, enabling loose coupling

between the components. Unlike a direct call to `F_UINT_TO_DWORD` in an application, this function block offers a standardized, reusable interface at the adapter level.

Conclusion

The **AUI_TO_AD** function block provides a clean, adapter-based solution for converting UINT to DWORD values. It is easy to use, requires no custom programming, and integrates seamlessly into the 4diac environment with its event and adapter networks. The encapsulation of the standard converter ensures robust and standards-compliant functionality. This function block is particularly suitable for applications where different adapter types need to be harmonized.

AD_TO_AULI

DWORD Adapter Input – *AD*

AULI – ULINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The AD_TO_AULI function block is a composite FB for converting a DWORD adapter (AD) to a ULINT adapter (AULI). It uses the IEC 61131 conversion function F_DWORD_TO_ULINT and encapsulates the event and data connections for easy adapter-based conversion.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapter

- **AD_IN** (Socket): Type AD (DWORD), unidirectional input adapter for the DWORD.
- **AULI_OUT** (Plug): Type AULI (ULINT), unidirectional output adapter for the converted ULINT.

Functionality

The function block receives a DWORD via the AD_IN adapter. An event at the E1 input of AD_IN triggers the REQ event input of the internal converter F_DWORD_TO_ULINT. This converts the data value (AD_IN.D1) and signals completion via CNF. The CNF event then triggers the E1 event at the AULI_OUT adapter, and the converted value (ULINT) is output via AULI_OUT.D1.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- The function block is implemented as a composite and uses the `iec61131::conversion::F_DWORD_TO_ULINT` library.
- No direct event or data inputs/outputs are used; all communication takes place exclusively via adapters.
- The conversion is performed according to IEC 61499 event control: The output event is only sent after the conversion is complete.

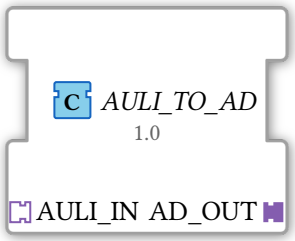
State Overview

The composite block itself does not have its own states. The integrated function block F_DWORD_TO_ULINT goes through the following states:

- **IDLE**: Waiting for a REQ event.
- **REQ**: Conversion is being performed.
- **CNF**: Conversion complete, output data is being updated.

Application Scenarios

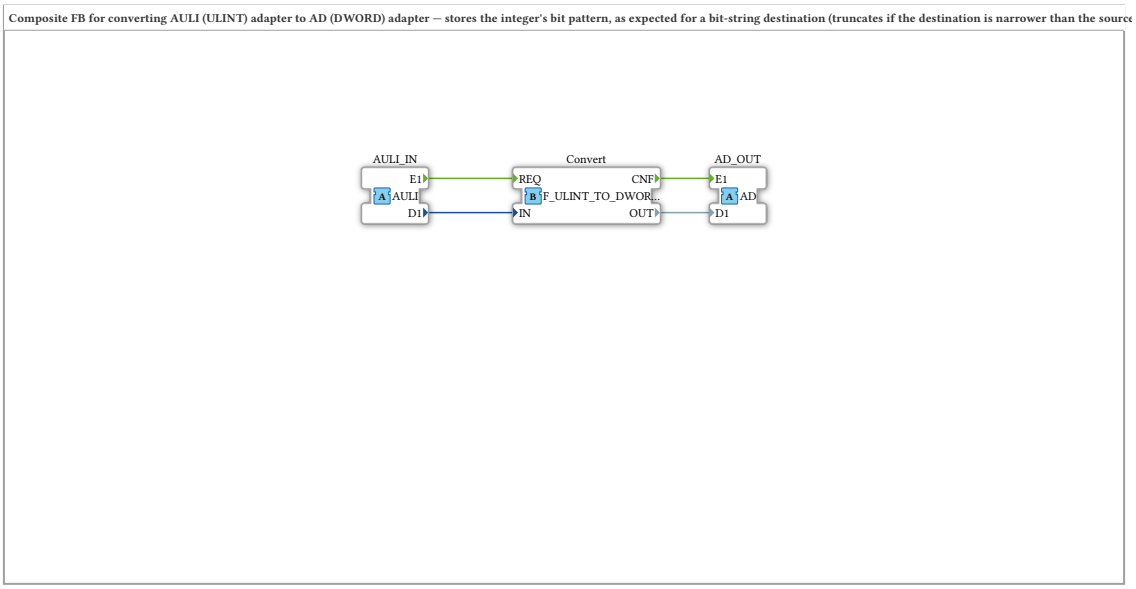
- Conversion of measured values or control data, which are available as DWORD (32-bit), into a ULINT (64-bit) adapter for subsequent processing.
- Use in modular automation systems based on adapter interfaces.
- Bridging between components with different adapter types.



Comparison with Similar Function Blocks

- Direct type conversion function blocks like `F_DWORD_TO_ULINT` operate at the data level, while AD_TO_AULI encapsulates the adapter interfaces.
- Similar composite function blocks exist for other data type combinations (e.g., DWORD_TO_LWORD), specifically utilizing the unidirectional AD and AULI adapters.

Conclusion



AD_TO_AULI offers a simple and reusable solution for adapter-based conversion from DWORD to ULINT. Encapsulating the conversion logic within a composite function block increases reusability and reduces network complexity.

AULI_TO_AD

ULINT Adapter Input – *AULI*

AD – DWORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **AULI_TO_AD** function block is a composite function block that converts a unidirectional adapter of type **AULI** (ULINT) to a unidirectional adapter of type **AD** (DWORD). It serves as a bridge between components that provide data in ULINT format and those that expect a DWORD format. The conversion is performed using the IEC 61131 function `F_ULINT_TO_DWORD`.

Interface Structure

The function block does not have its own event or data inputs/outputs, but communicates exclusively via two adapters:

Event Inputs

Adapter	Event	Description
`AULI_IN`	`E1`	Starts the conversion

Event Outputs

Adapter	Event	Description
`AD_OUT`	`E1`	Signals conversion complete

Data Inputs

Adapter	Variable	Data Type	Description
`AULI_IN`	`D1`	ULINT	Input value for conversion

Data Outputs

Adapter	Variable	Data Type	Description
AD_OUT	D1	DWORD	Converted Output Value

Adapter

Name	Direction	Type	Description	
AULI_IN	Socket	adapter::types::unidirectional::AULI	Input Adapter (ULINT)	
AD_OUT	Plug	adapter::types::unidirectional::AD	Output Adapter (DWORD)	

Functionality

This function block internally connects socket AULI_IN to function block F_ULINT_TO_DWORD and its output to plug AD_OUT. The sequence is controlled via events:

1. An incoming event at AULI_IN.E1 activates the input of the conversion function.
2. The data value AULI_IN.D1 (ULINT) is passed to the input IN of the function.
3. After the conversion, the result (DWORD) is provided at output OUT.
4. Simultaneously, an event is output to AD_OUT.E1 to inform the connected function block about the new data.

The entire process is event-driven and occurs without any delay or state storage.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Structure**: The function block is implemented as a network consisting of a single function block (F_ULINT_TO_DWORD). All connections are hard-wired.
- **Package Import**: The conversion function used comes from the package iec61131::conversion. The function block is organized in the package adapter::conversion::unidirectional.
- **No State Storage**: The function block is purely combinatorial – each input event immediately generates an output event with the converted value.
- **Type Safety**: The adapter interfaces are strictly defined as ULINT or DWORD, so incorrect connections are detected during development.

State Overview

Since this is a composite block without its own algorithms, there is no explicit state machine. The overall state is derived solely from the internal state of the function block used, F_ULINT_TO_DWORD, which returns to its idle state after each execution cycle. During normal operation, the block cycles between:

- **Waiting**: Waiting for an event at AULI_IN.E1.
- **Converting**: Briefly executing F_ULINT_TO_DWORD.
- **Output**: Sending the result and the event to AD_OUT.E1.

Application Scenarios

- **Data Adaptation in Agricultural Engineering**: Conversion of ULINT values (e.g., from sensors or control units) into the DWORD format required by downstream components.
- **Adapter-Based Communication**: Use in modules that are connected exclusively via adapter interfaces, without direct input/output pins.
- **System Integration**: If one existing system provides ULINT data, but another only accepts DWORD adapters, this module serves as a simple converter.

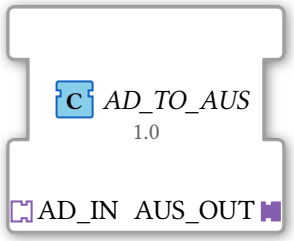
Comparison with Similar Modules

Module	Description
F_ULINT_TO_DWORD	Simple conversion function, but without adapter integration.

AULI_TO_AD	Same functionality, but as a composite block with adapter interfaces.
Other adapter converters	Blocks exist for related types (e.g., LINT, DINT) that operate on the same principle.

The key difference lies in the interface type: While the pure function uses direct data and event pins, AULI_TO_AD encapsulates the conversion in an adapter-based solution.

Conclusion



The AULI_TO_AD function block offers a clean, standardized way to convert ULINT data into the DWORD format of an AD adapter via an AULI adapter. Thanks to its composite nature, it is easy to use, requires no custom programming, and integrates seamlessly into an adapter-oriented architecture. It is particularly useful in environments where components communicate via defined adapter interfaces.

AD_TO_AUS

DWORD Adapter Input – *AD*

AUS – USINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AD_TO_AUS** is a composite function block (FB) that converts a DWORD adapter (AD) into a USINT adapter (AUS). It serves as a unidirectional interface for converting a 32-bit data value into an 8-bit value. The block encapsulates the IEC 61131 conversion function F_DWORD_TO_USINT and provides the adapter interfaces, allowing it to be seamlessly integrated into an adapter-based communication structure.

Interface Structure

Event Inputs

The **E1** event is received via the adapter input **AD_IN**. It triggers the conversion of the incoming DWORD value.

Event Outputs

The **E1** event is sent via the adapter output **AUS_OUT** as soon as the conversion is complete and the converted USINT value is available.

Data Inputs

The adapter input **AD_IN** provides a DWORD value (32-bit) via the **D1** data line.

Data Outputs

The adapter output **AUS_OUT** provides the converted USINT value (8-bit) via the **D1** data line.

Adapters

Adapter	Type	Direction	Description
AD_IN	`adapter::types::unidirectional::AD`	Input (Socket)	Receives DWORD data and control events.
AUS_OUT	`adapter::types::unidirectional::AUS`	Output (Plug)	Outputs USINT data and acknowledgment events.

Functionality

1. The function block waits for an event at the adapter input **AD_IN** (signal **E1**).
2. Upon arrival of the event, the DWORD value present at **AD_IN.D1** is forwarded to the internal function block `F_DWORD_TO_USINT`, and its `REQ` input is activated.
3. The integrated conversion block performs the type conversion from DWORD to USINT (type conversion according to IEC 61131-3).
4. After the conversion is complete, the internal function block (FB) signals the event `CNF`, which is passed to the adapter output **AUS_OUT** (signal **E1**). Simultaneously, the converted USINT value is made available via **AUS_OUT.D1**.

Technical Features

- **Bit-reinterpretation**, value-preserving only if the source value fits the narrower destination width (otherwise the upper bits are silently dropped).
- **Adapter Coupling:** The FB has no direct event or data inputs/outputs, but communicates exclusively via adapter interfaces. This enables loose coupling in a modular control architecture.
- **Library Used:** The conversion is performed using the standardized function block `iec61131::conversion::F_DWORD_TO_USINT`. This ensures IEC 61131 compliance.
- **Package name:** `adapter::conversion::unidirectional` (see CompilerInfo) places the function block (FB) in a specific adapter conversion library.

State Overview

The **AD_TO_OFF** is a pure function block without its own state machine. It operates strictly causally: Each input event leads to exactly one output event. The latency results from the execution time of the internal conversion block.

Application Scenarios

- **Interface Adaptation:** If a sensor or actuator delivers data in DWORD format (32 bits), but the controller can only process USINT values (8 bits), the FB is used as an intermediary.
- **Adapter-based systems:** In a 4diac environment that relies on unidirectional adapters, the function block can be seamlessly integrated into data flow paths without changing the event/data structure of the surrounding components.
- **Data reduction:** Targeted truncation of higher-order bytes when only the lower-order part of a DWORD is relevant (e.g., for counters or simple analog values).

Comparison with similar function blocks

- **AD_TO_AUS** is specific for the unidirectional conversion of a DWORD adapter to a USINT adapter. Alternatively, the IEC 61131 function `F_DWORD_TO_USINT` could be used directly, but then the adapter coupling would have to be performed manually.

Other adapter conversion blocks (e.g., `AD_TO_BYTE` or `AUS_TO_DWORD`) follow the same pattern but work with different data types. This function block fills the gap for the specific combination DWORD ⟶ USINT.

Conclusion

The **AD_TO_AUS** is a simple yet useful composite function block for type conversion between two unidirectional adapter interfaces. It reduces implementation effort by encapsulating the standard conversion and enabling clean, event-driven adapter communication. Thanks to its clear structure, it is suitable for both rapid design and production use in IEC 61499-based controllers.

AUS_TO_AD

USINT Adapter Input – *AUS*

AD – DWORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUS_TO_AD** is a composite block that performs a simple conversion from a USINT adapter (type AUS) to a DWORD adapter (type AD). It encapsulates the conversion of an unsigned 8-bit value (USINT) to a 32-bit DWORD value and makes this accessible via standardized adapter interfaces.

Interface Structure

Event Inputs

Name	Type	Description
`E1`	Event (from socket `AUS_IN`)	Starts the conversion of the incoming USINT value. The input is provided via socket `AUS_IN`.

Event Outputs

Name	Type	Description
E1	Event (to plug AD_OUT)	Signals successful conversion and the presence of the DWORD value at the output. The output is provided via plug AD_OUT.

Data Inputs

Name	Data Type	Description
D1	USINT (from socket AUS_IN)	The 8-bit value to be converted, in the range 0…255.

Data Outputs

Name	Data Type	Description
D1	DWORD (to plug AD_OUT)	The converted 32-bit value (direct type conversion of the USINT to DWORD).

Adapter

Role	Name	Type	Direction	Description
Socket	AUS_IN	adapter::types::unidirectional::AUS	Input	Receives the USINT value and the associated event.
Plug	AD_OUT	adapter::types::unidirectional::AD	Output	Provides the DWORD value and the acknowledgment event.

Functionality

This function block implements a simple, end-to-end data conversion:

1. An incoming event at the adapter input AUS_IN.E1 triggers the internal conversion.
2. The connected USINT value (AUS_IN.D1) is converted into a DWORD value using the standardized IEC 61131 function block F_USINT_TO_DWORD.
3. After successful conversion, the output event AD_OUT.E1 is sent, and the DWORD value is made available as AD_OUT.D1.

The function block operates without its own state logic – it performs the conversion immediately for each event (transparent behavior).

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Design:** The function block consists solely of an internal network with a single function block (F_USINT_TO_DWORD) and direct event and data connections.
- **Reuse:** The conversion uses the IEC 61131-3 standard function F_USINT_TO_DWORD, which is included in the library iec61131::conversion.
- **Adapter Interfaces:** The interfaces are implemented as unidirectional adapters (adapter::types::unidirectional::AUS and AD, respectively). Each adapter consists of exactly one event channel and one data channel.
- **No State Machine:** Since this is a pure composite device without its own ECC, no states are managed.

State Overview

The device does not have its own state machine. Its behavior is purely data flow-driven: For each incoming event, exactly one conversion is performed, and the event is forwarded without delay.

Application Scenarios

- **Interface Adaptation:** When a USINT value (e.g., a byte sensor) needs to be used in a system that internally only processes DWORD values.
- **Adapter Bridging:** Use in modular control architectures where adapter types are not directly compatible and conversion between AUS and AD adapters is required.
- **Prototype/Test Environments:** Fast connection of two components with different adapter definitions without requiring their own conversion logic.

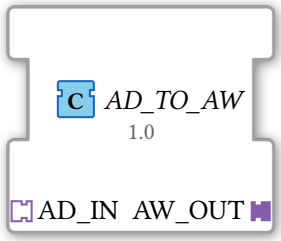
Comparison with Similar Function Blocks

- **F_USINT_TO_DWORD:** The underlying conversion block is a pure data converter without an adapter interface. It requires direct data and event connections.

AUS_TO_AD`, on the other hand, encapsulates this function and offers a standardized adapter interface.

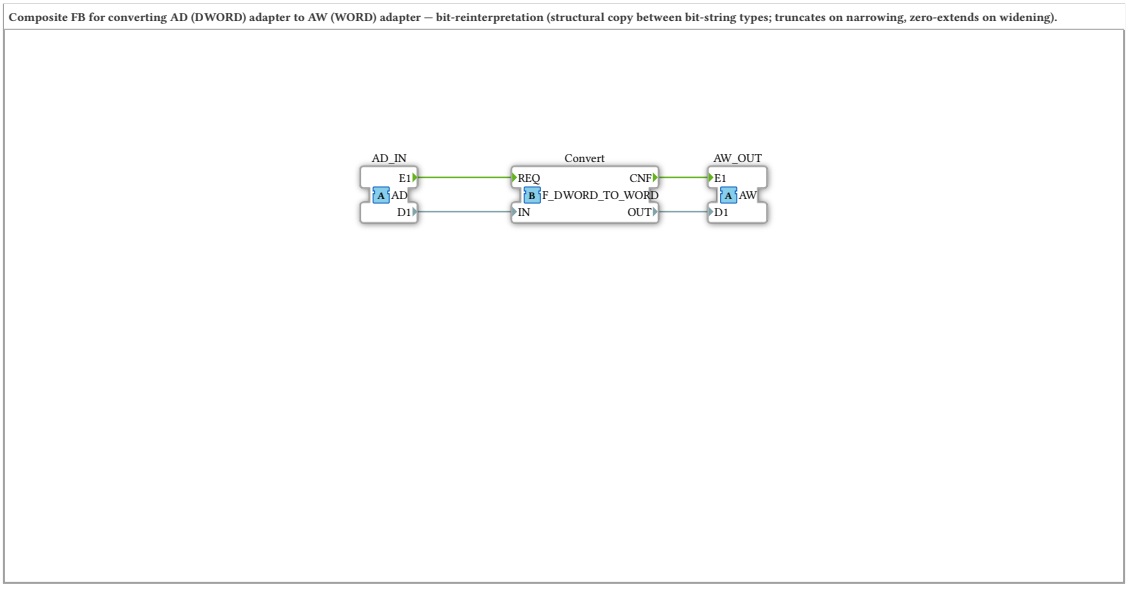
- **Other adapter converters (e.g., BYTE_TO_DWORD, WORD_TO_DWORD):** Similar function blocks exist for other data types, but usually require different adapter types. `AUS_TO_AD` is specifically optimized for the combination of the adapters `AUS` (USINT) and `AD` (DWORD).

Conclusion



The function block `AUS_TO_AD` offers a simple and robust way to convert a unidirectional USINT adapter into a DWORD adapter. By using the standardized conversion module and adapter interfaces, it can be seamlessly integrated into IEC 61499-based automation systems. It reduces the manual effort required for type conversions and ensures clean, reusable interface adaptation.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AD_TO_AW

DWORD Adapter Input – *AD*

AW – WORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AD_TO_AW** is a composite function block that converts a DWORD adapter (type `AD`) into a WORD adapter (type `AW`). It encapsulates the conversion of a DWORD value to a WORD value and provides the corresponding event and data forwarding. The implementation is based on an internal call to the standard conversion block `F_DWORD_TO_WORD` from the IEC 61131 library.

Interface Structure

The block has no direct input/output events or data ports. All signals are routed via the connected adapters (socket and plug).

Event Inputs

- **AD_IN.E1** (via socket `AD_IN`): This event triggers the conversion of the incoming DWORD value.

Event Outputs

- **AW_OUT.E1** (via plug `AW_OUT`): This event is sent after successful conversion.

Data Inputs

- **AD_IN.D1** (via socket `AD_IN`): Input data of type `DWORD`, which is converted into a WORD value.

Data Outputs

- **AW_OUT.D1** (via Plug `AW_OUT`): Output data of type `WORD`, containing the result of the conversion.

Adapters

Role	Name	Type	Direction	Comment
Socket	AD_IN	`Adapter::types::unidirectional::AD`	Input (DWORD)	Returns DWORD data and event.
Plug	AW_OUT	`Adapter::types::unidirectional::AW`	Output (WORD)	Provides WORD data and event.

Both adapters are of type *unidirectional*, i.e., Communication is unidirectional.

Functionality

1. As soon as the event `E1` arrives at socket `AD_IN`, the value of `AD_IN.D1` (DWORD) is passed to the internal conversion module `F_DWORD_TO_WORD`.
2. The internal module performs the conversion and creates the result (WORD) at its output `OUT`.
3. The converted value is immediately forwarded to plug `AW_OUT.D1`.
4. Simultaneously, the event `E1` is triggered at plug `AW_OUT` to inform the downstream logic.

The entire process is event-driven and synchronous.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- **Encapsulation**: The function block uses the standardized IEC 61131 function `F_DWORD_TO_WORD`, which ensures clean and portable conversion.
- **Adapter-based**: Inputs and outputs are implemented exclusively via adapters – there are no separate event/data ports at the block level.
- **Unidirectional**: The adapters used support only one direction of data flow, which simplifies handling in simple conversion chains.
- **Composite Design**: The function block does not have its own ECC (Execution Control Chart); control is handled entirely by the internal block.

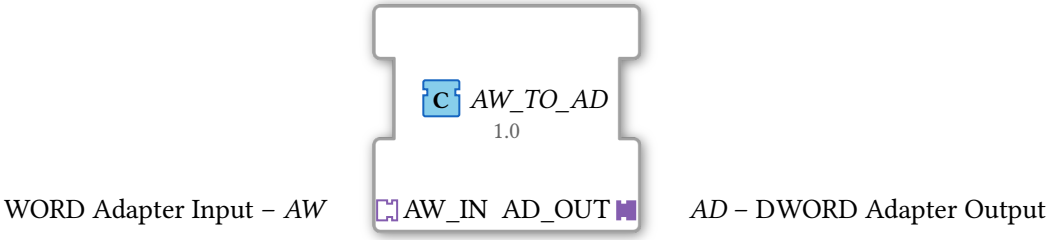
State Overview

As a composite block without its own ECC, **AD_TO_AW** has no internal states. Execution is purely event-driven and occurs atomically with each incoming event at the socket.

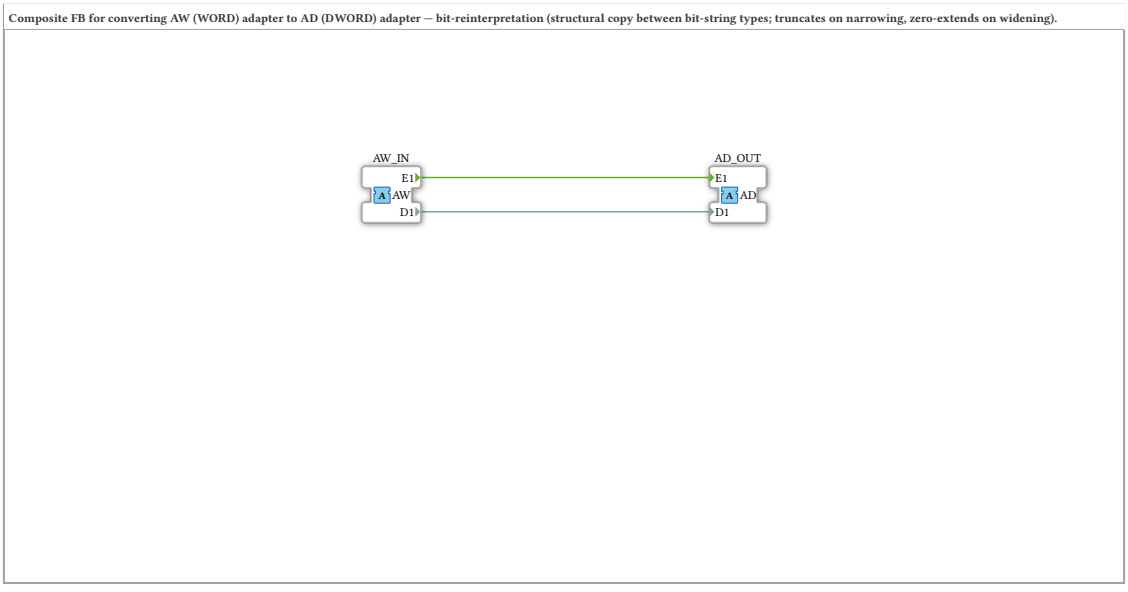
AD_TO_AW

Application Scenarios

- **Adapter Adaptation**: When a control system provides data via a DWORD adapter, but a connected module or component expects a WORD adapter.
- **Data Reduction**: Targeted truncation of a DWORD value to the lower 16 bits (WORD) for subsequent processing steps.
- **Bridging**: Use in heterogeneous system landscapes where different adapter types interact.



Comparison with Similar Components



- **WORD_TO_DWORD**: Performs the reverse conversion (WORD → DWORD) and appends the value (usually by adding zeros).
- **AD_TO_AD (e.g., AD_TO_AD with other types)**: Other composite components can encapsulate similar adapter conversions for additional data types (e.g., BYTE, INT, REAL).
- **Direct use of `F_DWORD_TO_WORD`**: Instead of a composite block, the conversion function could be directly integrated into a function block network – however, the composite offers a reusable, encapsulated solution.

Conclusion

The **AD_TO_AW** function block is a simple yet useful composite block for converting a DWORD adapter to a WORD adapter. It uses a standardized conversion function, is easy to understand, and can be used in many adapter-based automation systems. Encapsulating it in its own function block makes the network topology clearer and increases reusability.

AW_TO_AD

• – ○ • – ○ • – ○ •

Introduction

The function block **AW_TO_AD** is a composite function block (FB) that converts a unidirectional WORD adapter (AW) into a unidirectional DWORD adapter (AD). It serves as an interface converter and enables the connection of components that use different adapter types. The FB forwards events and data directly

from the input to the output adapter, implicitly performing a type conversion from 16-bit WORD to 32-bit DWORD.

Interface Structure

Event Inputs

- **AW_IN.E1** – Event input via socket `AW_IN`. An incoming event is forwarded directly to the output.

Event Outputs

- **AD_OUT.E1** – Event output via the `AD_OUT` socket. The event passed through from the input is output here.

Data Inputs

- **AW_IN.D1** – Data input (Type: WORD, 16-bit) via the `AW_IN` socket.

Data Outputs

- **AD_OUT.D1** – Data output (Type: DWORD, 32-bit) via the `AD_OUT` socket. The received 16 bits are mapped to the lower 16 bits of the DWORD; the upper 16 bits are padded with zeros (implicit conversion).

Adapters

Name	Type	Direction	Description
`AW_IN`	`adapter::types::unidirectional::AW`	Socket (Input)	WORD adapter providing event and data inputs
`AD_OUT`	`adapter::types::unidirectional::AD`	Plug (Output)	DWORD adapter providing event and data outputs

Functionality

This module is designed as a simple forwarder. Within the internal FB network, the event and data lines between `AW_IN` and `AD_OUT` are directly connected:

- An event at `AW_IN.E1` is immediately forwarded to `AD_OUT.E1`.
- The 16-bit data value from `AW_IN.D1` is transferred to `AD_OUT.D1`. This involves an implicit expansion to 32 bits: The WORD value is copied into the less significant 16 bits of the DWORD, and the more significant bits are set to `0`.

No processing or intermediate storage takes place – the FB functions as a simple adapter converter.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- **Composite Function Block without its own state logic:** The function block does not have an ECC (Execution Control Chart) and operates statelessly. All processes are determined by the direct connections within the function block network.
- **Unidirectional operation:** Conversion only occurs in one direction (AW ⟶ AD). A separate function block would be required for the reverse direction.
- **Implicit type conversion:** Data is cast from WORD to DWORD without explicit conversion logic. If a different mapping (e.g., sign handling) is required, a separate function block must be used.
- **Package & License:** The function block is available in package `adapter::conversion::unidirectional` under the Eclipse Public License 2.0.

State Overview

Since the function block is implemented as a composite without an ECC, there is no internal state machine. Its entire functionality is limited to the direct transmission of events and data. The function block (FB) is therefore **stateless** and reacts immediately to every incoming event.

Application Scenarios

- **Interface Migration:** Replacing a component that expects a WORD adapter with a component that uses a DWORD adapter.
- **System Integration:** Connecting an existing WORD-based module to a DWORD-based controller.
- **Protocol Adaptation:** When a subsystem delivers data in WORD format, but the target requires a DWORD input.
- **Testing and Simulation:** Simple conversion for testing purposes without having to implement complex logic.

Comparison with Similar Function Blocks

Function Block	Description
`WORD_TO_DWORD`	Pure data conversion without an adapter interface
`AW_TO_AD`	Converts complete unidirectional adapters (event + data)
`AD_TO_AW` (not available)	Theoretical building block for the reverse direction

Unlike a pure data converter, `AW_TO_AD` also considers event forwarding and can be directly integrated into adapter-based architectures.

Conclusion

AW_TO_AD` is a simple yet useful composite function block for converting adapters from WORD to DWORD. It enables quick and clean adaptation of interfaces in 4diac projects without requiring the writing of custom conversion logic. Due to its statelessness and direct passthrough, it is particularly suitable for unidirectional connections in existing automation solutions.

AD_TO_AX

DWORD Adapter Input – *AD* — *AX* – BOOL Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block `AD_TO_AX` serves as a composite function block for converting an AD adapter (data word – DWORD) into an AX adapter (Boolean value – BOOL). It encapsulates a comparison mechanism that checks whether the incoming DWORD value is non-zero and forwards the result as a BOOL to the output adapter. This block simplifies adapter communication in control systems by converting signal types between different components.

Interface Structure

Event Inputs

No standalone event inputs. The event is provided via the socket adapter `AD_IN` (see section **Adapters**).

Event Outputs

No standalone event outputs. The result event is provided via the plug adapter `AX_OUT` (see section **Adapters**).

Data Inputs

No standalone data inputs. The input data is provided via the socket adapter `AD_IN` (see section **Adapters**).

Data Outputs

No standalone data outputs. The output data is provided via the plug adapter `AX_OUT` (see section **Adapters**).

Adapters

Adapter	Direction	Type	Comment
`AD_IN`	Socket	`adapter::types::unidirectional::AD`	DWORD input adapter – provides an event and DWORD data.
`AX_OUT`	Plug	`adapter::types::unidirectional::AX`	BOOL output adapter – outputs an event and a Boolean result.

The adapters follow a unidirectional pattern and each provides an event output (`E1`) and a data output (`D1`):

- **AD_IN.E1** ⟶ initiates processing.
- **AD_IN.D1** ⟶ contains the DWORD source value.
- **AX_OUT.E1** ⟶ signals the end of processing.
- **AX_OUT.D1** ⟶ contains the Boolean result value.

Functionality

The FB AD_TO_AX is implemented as a composite FB. It contains an instance of the comparison block F_NE ("not equal") from the IEC 61131 library.

1. An incoming event at AD_IN.E1 triggers the input F_NE.REQ.
2. The block F_NE compares the value of AD_IN.D1 with the constant value DWORD#0.
3. The comparison result (BOOL) is provided at the output F_NE.OUT.
4. This result is transmitted to AX_OUT.D1 via a data connection.
5. Simultaneously, F_NE.CNF signals the end of the calculation and triggers AX_OUT.E1.

Thus, a BOOL value is derived from a DWORD value:

- DWORD = 0 ⟶ Output FALSE
- DWORD ≠ 0 ⟶ Output TRUE

Technical Features

- **Parity/LSB test** (odd value => TRUE), not a numeric value or full bit copy.
- **Composite Function Block**: The function block consists of an internal network that implements the actual logic – this facilitates reuse and encapsulation.
- **Use of F_NE**: The comparison function block used, from the IEC 61131 library, is standardized and platform-independent.
- **Adapter-based communication**: Instead of individual inputs/outputs, adapters are used, enabling structured connections to other adapter-compatible modules.
- **Unidirectional adapters**: Both input and output adapters are unidirectional, meaning they only transport data and events in one direction – this avoids feedback loops and simplifies the design.

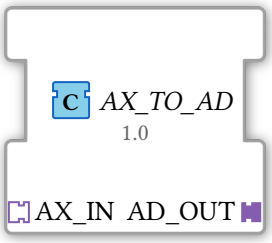
State overview

The function block (FB) does not have an explicit state machine, as it consists solely of a logical operation. The internal process is event-driven:

- **Idle state**: Waiting for an event at input AD_IN.E1.
- **Execution**: After the event, F_NE performs the calculation and forwards the result – this happens in one step without intermediate states.

Application scenarios

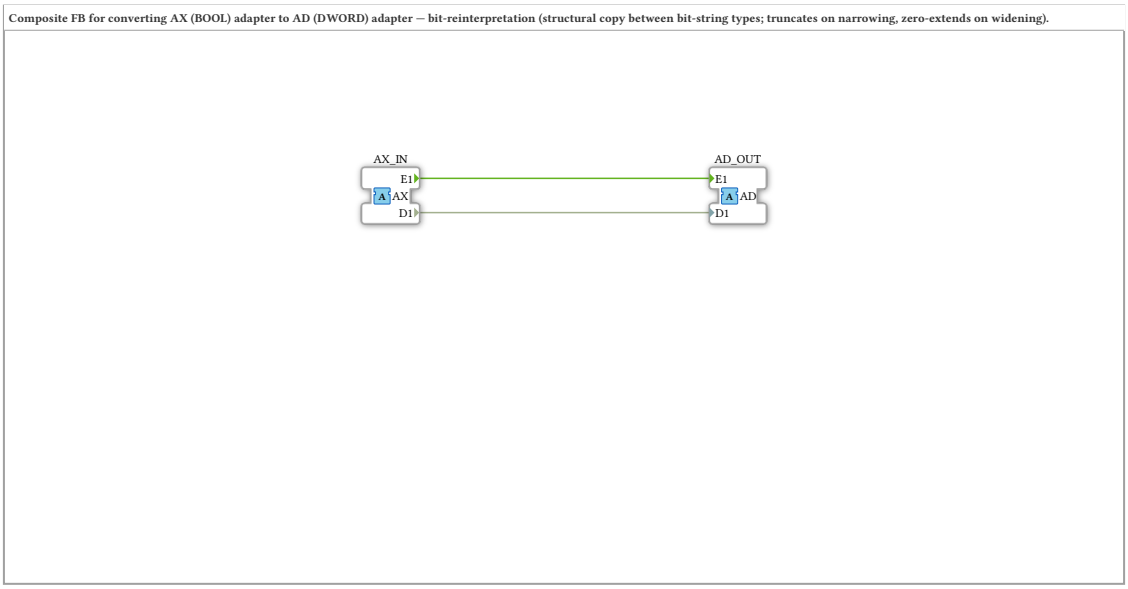
- **Adapter conversion**: A system uses DWORD adapters, but a connected module expects BOOL signals. The AD_TO_AX function block handles the conversion.
- **Threshold Check**: Checks whether a DWORD value deviates from zero (e.g., active signal, counter reading > 0).
- **Signal Conditioning**: Simplifies the integration of sensors or actuators whose output is encoded as a DWORD into Boolean control logic.



Comparison with Similar Function Blocks

- **Direct DWORD_TO_BOOL Converter**: Such a function block would typically only perform the data conversion but would not offer an adapter structure or event handling. AD_TO_AX, on the other hand, encapsulates both event and data paths in adapters.
- **General Adapter Converters**: Similar function blocks exist for other data types (e.g., AD_TO_AX for WORD, INT, etc.). This function block is specifically designed for converting DWORD to BOOL.
- **Composite vs. Basic Function Block**: As a composite function block, this block is easily adaptable because the internal network can be modified as needed.

Conclusion



The function block AD_TO_AX offers an elegant and standardized way to convert DWORD adapter signals into BOOL adapters. By using the established comparison function block F_NE, the logic is robust and traceable. The adapter structure facilitates integration into modular automation systems and promotes reusability. This function block is particularly suitable for scenarios requiring event-driven conversion of digital values to Boolean states.

AX_TO_AD

BOOL Adapter Input – *AX*

AD – DWORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The composite function block `AX_TO_AD` converts a Boolean adapter (AX) to a DWORD adapter (AD). It forwards event and data signals from the input adapter directly to the output adapter and implicitly converts the data type from Boolean to DWORD.

Interface Structure

Event Inputs

The function block has no direct event inputs. Event control is handled via the socket `AX_IN`.

Event Outputs

There are no direct event outputs. Events are passed via the plug `AD_OUT`.

Data Inputs

There are no direct data inputs. Data is acquired via socket `AX_IN`.

Data Outputs

There are no direct data outputs. Data output is handled via plug `AD_OUT`.

Adapters

- **AX_IN** (Socket): Adapter of type `adapter::types::unidirectional::AX`. Provides a BOOL signal (D1) and a trigger event (E1).
- **AD_OUT** (Plug): Adapter of type `adapter::types::unidirectional::AD`. Expects a DWORD signal (D1) and a trigger event (E1).

Functionality

The function block (FB) links the input adapter `AX_IN` directly to the output adapter `AD_OUT`:

- **Event Path**: The event from `AX_IN.E1` is forwarded unchanged to `AD_OUT.E1`.
- **Data Path**: The Boolean value from `AX_IN.D1` is transferred to `AD_OUT.D1`. An implicit type conversion occurs: `TRUE` becomes `1` (DWORD), and `FALSE` becomes `0` (DWORD).

The function block itself contains no internal logic or state machines – it functions purely as a pass-through converter between the two adapter types.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- **Composite FB**: The implementation consists solely of wiring within the FB network, without any additional algorithms.
- **Implicit Data Type Conversion**: The BOOL value is automatically converted to a DWORD value (bits 0-31: 0 or 1).
- **Unidirectional Adapters**: Both the input and output use unidirectional adapters that support only one data and one event connection.

State Overview

The `AX_TO_AD` function block does not have its own internal state. Its behavior is purely reactive: An incoming event at the input is immediately passed on to the output, optionally accompanied by the updated data signature.

- **Implicit Data Type Conversion**: The BOOL value is automatically converted to a DWORD value (bits 0-31: 0 or 1).
- **Unidirectional Adapters**:** Both the input and output use unidirectional adapters that support only one data and one event connection.
- **Composite FB**:**

Application Scenarios

- Integration of a digital sensor (e.g., switch, light barrier) into a system that expects a DWORD adapter for data acquisition.
- Gradual migration of an application from BOOL-based to DWORD-based adapter interfaces.
- Prototypical connection between different libraries or components with incompatible adapter types.

Comparison with Similar Function Blocks

- **BOOL_TO_DWORD** (function block): Performs pure data type conversion, but without adapter encapsulation.
- **AX_TO_AD** specializes in adapter interfaces and is therefore particularly suitable for exchanging data between different communication patterns in 4diac.
- Similar function blocks exist for other type combinations, e.g., `INT_TO_REAL_AD` or `WORD_TO_BOOL_AD`.

Conclusion

The `AX_TO_AD` function block offers a simple and clean way to convert a BOOL adapter to a DWORD adapter without requiring the user to write any conversion logic. It is ideally suited for linking different adapter worlds in 4diac projects.

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AI_TO_AL

INT Adapter Input – *AI*

AL – LWORD Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The composite function block **AI_TO_AL** converts an INT value provided via the unidirectional AI adapter (type `adapter::types::unidirectional::AI`) into an LWORD value output via the unidirectional AL adapter (type `adapter::types::unidirectional::AL`). The block encapsulates the conversion logic, thus enabling a clean separation between INT- and LWORD-based adapter interfaces.

Interface Structure

Event Inputs

No standalone event inputs on the block. Event control is handled exclusively via the integrated socket `AI_IN`, which provides the event `E1` as a trigger for the conversion.

Event Outputs

No independent event outputs on the block. The result of the internal conversion is output via the plug `AL_OUT` as event `E1`.

Data Inputs

No independent data inputs on the block. The INT value to be converted is read into the block via the socket `AI_IN` (data point `D1`).

Data Outputs

No independent data outputs on the block. The converted LWORD value is output via the plug `AL_OUT` (data point `D1`).

Adapter

Label	Type	Direction	Comment

AI_IN	adapter::types::unidirectional::AI	Socket (Input)	INT Adapter Input
AL_OUT	adapter::types::unidirectional::AL	Plug (Output)	LWORD Adapter Output

Functionality

1. An incoming event E1 at the adapter AI_IN activates the data conversion.
2. The internal function block F_INT_TO_LWORD (from the library iec61131::conversion) is triggered via its event input REQ and converts the INT value present at IN into an LWORD value.
3. After the conversion is complete, the function block signals this via the event output CNF.
4. This event is forwarded to the adapter AL_OUT as event E1 and simultaneously outputs the converted LWORD value via D1.

This event is forwarded to the adapter AL_OUT as event E1 and simultaneously outputs the converted LWORD value via D1.

... The data paths are:

- AI_IN.D1 ⟶ Convert.IN
- Convert.OUT ⟶ AL_OUT.D1

The event paths are:

- AI_IN.E1 ⟶ Convert.REQ
- Convert.CNF ⟶ AL_OUT.E1

Technical Features

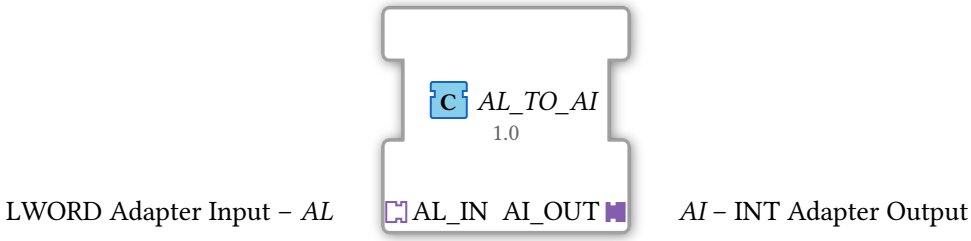
- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Block:** The AI_TO_AL is implemented as a composite and does not contain its own algorithmic logic. It delegates the conversion entirely to the defined function block F_INT_TO_LWORD.
- **Standard Conversion:** The conversion function used is part of the IEC 61131 library and ensures standards-compliant type conversion from INT (16-bit) to LWORD (64-bit).
- **Adapter-Based:** The function block operates exclusively via the specified adapter interfaces and can therefore be seamlessly integrated into an adapter-based architecture.
- **License and Version:** The function block is licensed under the Eclipse Public License 2.0 (EPL-2.0) and was released in version 1.0 by HR Agrartechnik GmbH.
- **Date of Creation:** February 17, 2026, Author: Franz Höpfinger.

State Overview

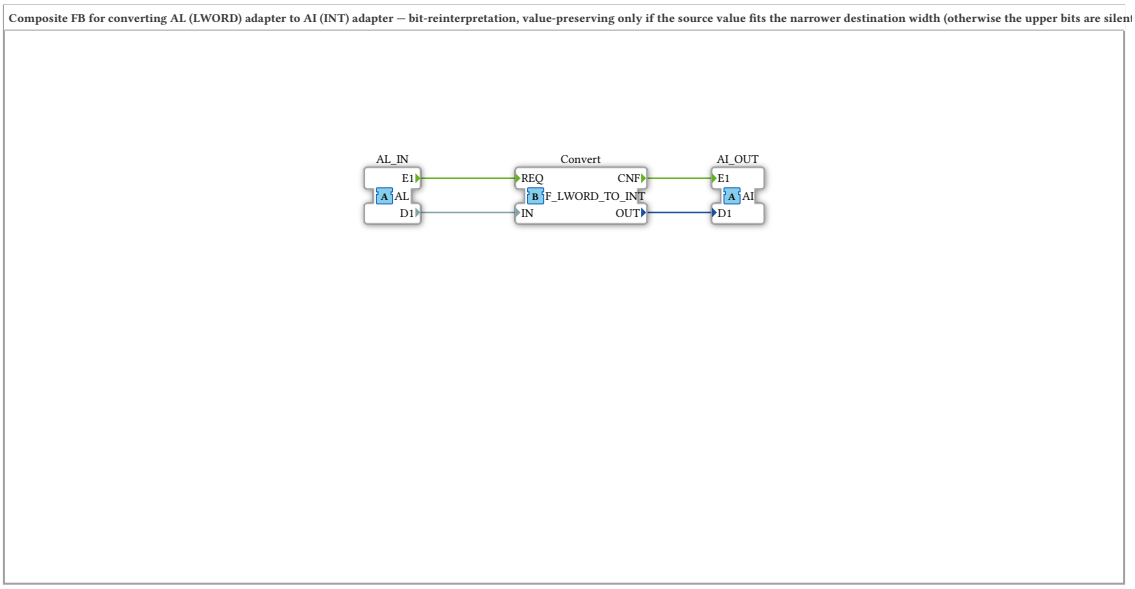
As a composite function block, AI_TO_AL does not have its own internal state machine. The entire state logic is controlled by the integrated function block F_INT_TO_LWORD, which executes a simple request-acknowledgment sequence (REQ/CNF). The function block is therefore purely data flow-driven and does not have persistent states.

Application Scenarios

- **Bus Coupling:** When a sensor or actuator delivers an INT value via an AI adapter, but the downstream system expects an LWORD value via an AL adapter (e.g., when connected to a fieldbus with 64-bit data types).
- **Protocol Adaptation:** In heterogeneous automation systems where different adapter types (AI and AL) need to be interconnected.
- **Data Preparation:** Before further processing of INT data in a controller that internally uses LWORD.



Comparison with Similar Components



- **Other Conversion Adapters:** Similar composite components exist for other data type pairs, such as WORD_TO_DWORD, BYTE_TO_WORD, or DINT_TO_LWORD. The AI_TO_AL is specifically designed for the INT ⟶ LWORD combination.
- **Direct Conversion:** Alternatively, conversion could be performed directly with F_INT_TO_LWORD without adapter encapsulation. The advantage of AI_TO_AL lies in its standardized adapter interface, which facilitates exchange and reusability in adapter-based networks.

Conclusion

The `AI_TO_AL` function block is a simple yet valuable adapter converter that bridges the gap between INT- and LWORD-based adapter interfaces. By encapsulating the conversion logic within a single composite block, the application logic remains clear and reusability is increased. It is particularly well-suited for use in modular automation systems based on unidirectional adapter communication.

AL_TO_AI

• – ○ • – ○ • – ○ •

Introduction

The AL_TO_AI function block is a composite block that converts a unidirectional AL adapter (LWORD) into a unidirectional AI adapter (INT). It serves as an interface converter for adapter-based communication and enables easy integration between components that use different data types. The conversion is performed internally using the standardized IEC 61131-3 function block F_LWORD_TO_INT.

Interface Structure

Event Inputs

The function block does not have explicit event inputs. Event control is handled indirectly via the socket adapter **AL_IN**, which provides the event **E1**.

Event Outputs

The function block does not have explicit event outputs. Event control is handled indirectly via the plug adapter **AI_OUT**, which provides the event **E1**.

Data Inputs

The function block (FB) has no explicit data inputs. The data to be received is provided as an LWORD via the socket adapter **AL_IN**.

Data Outputs

The FB has no explicit data outputs. The converted data is output as an INT via the plug adapter **AI_OUT**.

Adapters

Adapter	Direction	Type	Description
AL_IN	Socket (Input)	`adapter::types::unidirectional::AL`	Provides an LWORD (via data port D1) and an event (E1).
AI_OUT	Plug (Output)	`adapter::types::unidirectional::AI`	Provides an INT (via data port D1) and an event (E1).

Functionality

The FB acts as a transparent converter between the two adapters. As soon as the event **E1** arrives at socket **AL_IN**, the internal function block **F_LWORD_TO_INT** is triggered with the passed LWORD value (from **AL_IN.D1**). The conversion block converts the value to an INT and signals completion via the event **CNF**. This event is forwarded directly to plug **AI_OUT** (E1), and the converted INT (from **F_LWORD_TO_INT.OUT**) is output on **AI_OUT.D1**. The entire conversion occurs synchronously within a single event cycle.

Technical Features

- **Bit-reinterpretation**, value-preserving only if the source value fits the narrower destination width (otherwise the upper bits are silently dropped).
- **Composite Architecture**: The function block (FB) internally uses a standardized IEC 61131-3 function block (`F_LWORD_TO_INT`), which can be implemented platform-independently.
- **Unidirectional Adapters**: Both the input and output adapters are of type `unidirectional`, meaning they only support one data and event direction (from socket to plug).
- **No Internal Logic**: The FB contains no state logic or sequences; it functions solely as a coupler and converter.
- **Type Conversion**: Converting from LWORD (64-bit) to INT (16-bit) can lead to data loss (truncation of higher-order bits), depending on the value range. This must be considered in the application context.

State Overview

The composite function block does not have its own states. The behavior is entirely determined by the internal **F_LWORD_TO_INT** function, which is a pure function without state. The sequence control is event-driven: an input event is immediately followed by an output event.

Application Scenarios

- **Adapter Bridge**: Connecting a component that provides LWORD via an AL adapter to a component that expects INT via an AI adapter.
- **System Integration**: Use in heterogeneous automation systems where different adapter types interact.
- **Protocol Adaptation**: Data conversion in a service-oriented architecture (e.g., 4diac) to adapt interfaces from various IEC 61499 or IEC 61131 libraries.

Comparison with Similar Function Blocks

- **AL_TO_AI** is specific to the combination of unidirectional AL and AI adapters. Other converters, such as `LWORD_TO_INT`, operate at a pure data level without adapter encapsulation.
- The 4diac ecosystem includes other adapter converters (e.g., `AI_TO_AL`) that cover the reverse direction. `AL_TO_AI` fills the gap for unidirectional LWORD→INT conversion.
- Compared to directly using `F_LWORD_TO_INT`, the Composite FB offers the advantage of a standardized adapter interface, enabling simple plug-and-play integration.

Conclusion

The **AL_TO_AI** function block is a useful, lightweight converter for switching between unidirectional LWORD and INT adapters. It encapsulates the proven IEC 61131-3 conversion in an adapter-friendly format, thus facilitating the reuse and replacement of components in IEC 61499-based systems. Thanks to

its event-driven handling, it integrates seamlessly into event-driven workflows and requires no additional configuration.

AI_TO_ALI

INT Adapter Input – *AI*

ALI – LINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The AI_TO_ALI function block is a composite function block that converts an AI (INT) input adapter into an ALI (LINT) output adapter. It serves as a simple conversion interface between different adapter types for unidirectional communication.

Interface Structure

Event Inputs

No dedicated event inputs. Events are transmitted via the AI_IN input adapter.
Adapter AI_IN provides event input E1.

Event Outputs

No dedicated event outputs. Events are transmitted via the ALI_OUT output adapter.
Adapter ALI_OUT provides event output E1.

Data Inputs

No dedicated data inputs. Data transmission occurs via the AI_IN input adapter.
Adapter AI_IN provides data input D1 (data type INT).

Data Outputs

No dedicated data outputs. Data is passed through the output adapter ALI_OUT.
Adapter ALI_OUT provides data output D1 (data type LINT).

Adapters

- **AI_IN** (Socket): Type `adapter::types::unidirectional::AI` – INT input interface.
- **ALI_OUT** (Plug): Type `adapter::types::unidirectional::ALI` – LINT output interface.

Note: The actual event and data interfaces are defined by the adapters. The function block itself does not have its own interfaces.

Functionality

The function block operates as a simple pass-through: The event and data signal from input adapter AI_IN is forwarded directly to output adapter ALI_OUT. The INT data value is implicitly converted to a LINT value, as LINT covers a larger range of values. The conversion occurs without any additional logic or processing.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- This is a composite function block (FB) that does not implement any functionality of its own, but simply connects two adapters.
- The conversion from INT to LINT is lossless, as LINT (64-bit) covers the entire value range of INT (32-bit).
- The FB is designed for use in unidirectional communication paths where data type adaptation between adapter interfaces is required.
- The use of adapters enables loose coupling between components.

State Overview

The FB does not have its own state machine, as its functionality is limited to the pure transmission of events and data. The internal state is irrelevant; the behavior is deterministic and reacts instantaneously to incoming events.

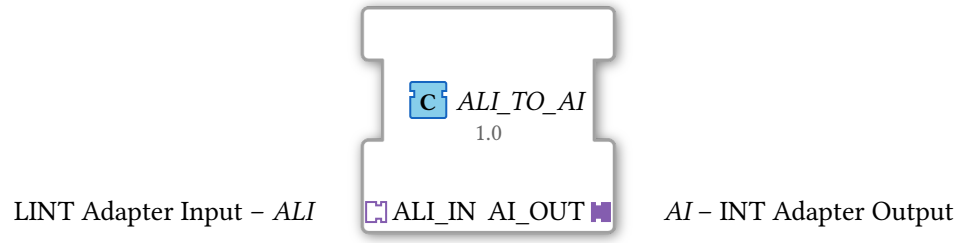
•

Application Scenarios

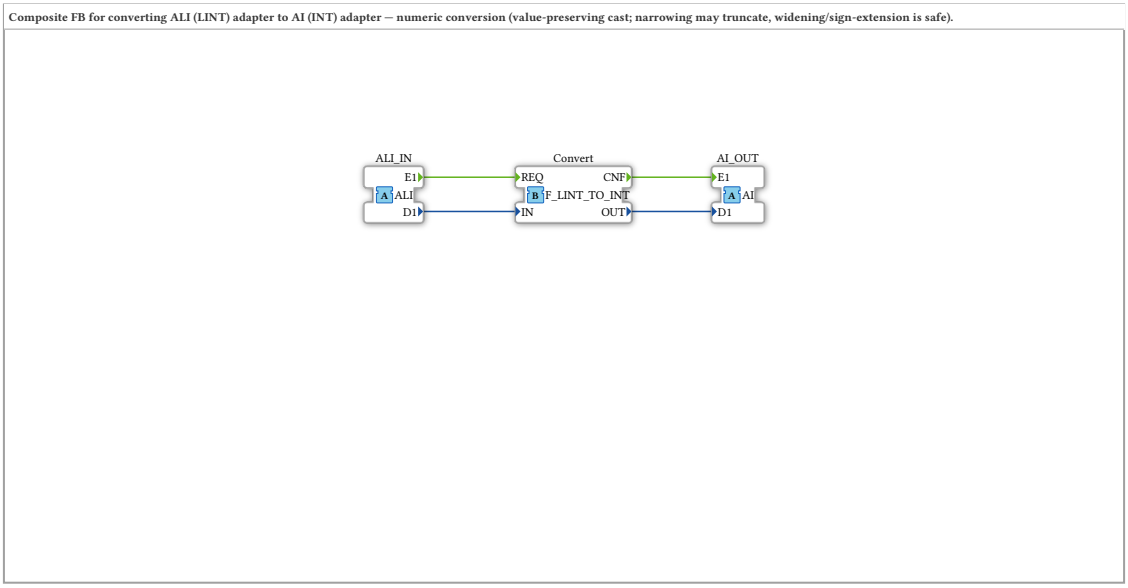
- **Interface Adaptation:** One module returns an INT value via an AI adapter, while a subsequent module expects a LINT value via an ALI adapter.
- **Extension of Value Ranges:** If an existing INT data path needs to be converted to a larger value range, this function block (FB) can be used as an intermediary.
- **Adapter Protocol Conversion:** In heterogeneous systems where different adapter types are used, this FB serves as a simple converter.

Comparison with Similar Function Blocks

- **AI_TO_ALI** is specific for converting from AI to ALI. Other function blocks could, for example, implement AI_TO_AL (INT to WORD) or different directions (ALI_TO_AI).
- Compared to a generic type converter (e.g., with parameterization), this FB is specialized and therefore easier to use, but less flexible.



Composite function blocks like this one offer a clear separation of responsibilities and can be stored in libraries for standard conversions.



Conclusion

The AI_TO_ALI function block is a useful tool for adapter conversion in IEC 61499-based systems. It enables seamless integration of components with different data types at the adapter level. Its simple, pass-

through nature makes it reliable and easy to understand. It is particularly well-suited for projects that rely on the adapter-based, unidirectional communication model.

ALI_TO_AI

• – ○ • – ○ • – ○ •

Introduction

The **ALI_TO_AI** function block is a composite function block (FB) that converts an **ALI adapter** (input of a LINT value interface) into an **AI adapter** (output of an INT value interface). It serves to convert data from a LINT-based adapter to the INT-based adapter type without requiring the user to implement the conversion themselves.

Interface Structure

Event Inputs

Name	Data Type	Description
ALI_IN	Event	Control signal of the ALI adapter, triggers the conversion

Event Outputs

Name	Data Type	Description
AI_OUT	Event	Confirmation signal from the AI adapter after successful conversion

Data Inputs

Name	Data Type	Description
ALI_IN.D1	LINT	The LINT value to be converted

Data Outputs

Name	Data Type	Description
AI_OUT.D1	INT	The converted INT value

Adapter

Direction	Name	Type	Description
Socket	ALI_IN	ALI (unidirectional)	Returns LINT values and control events
Plug	AI_OUT	AI (unidirectional)	Outputs converted INT values and events

Functionality

This function block operates as a simple coupling of an ALI socket to an AI plug. Internally, the available conversion function block **F_LINT_TO_INT** is used.

1. An incoming event at **ALI_IN.E1** triggers the conversion function block.
2. Simultaneously, the current value of **ALI_IN.D1** is passed to the input of the converter. 3. After the conversion is complete, the result is forwarded to **AI_OUT.D1**.
3. An acknowledgment event is output via **AI_OUT.E1**.

The entire process is atomic within a single cycle – delays only occur due to the runtime of the conversion block.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Pure Adapter Coupling**: The block does not contain its own state logic or timing.
- **Use of IEC 61131 Conversion**: The actual type conversion is performed by the standardized block `F_LINT_TO_INT`.
- **Simple Composition**: All connections are direct and without intermediate logic.
- **Type- and Event-Driven**: The conversion is only executed when an event occurs at the ALI input.

State Overview

As a composite function block without its own state diagram, **ALI_TO_AI** does not have its own state machine. The internal conversion function block `F_LINT_TO_INT` operates according to the simple pattern:

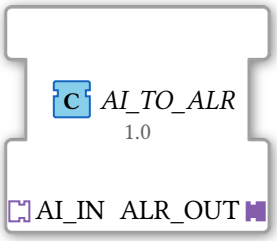
- **IDLE**: Waiting for an event.
- **CONVERT**: Executing the conversion and outputting the result.

Application Scenarios

- **System Coupling**: When a sensor module provides LINT values via an ALI adapter, but the control system expects INT values via an AI adapter.
- **Protocol or Interface Adaptation**: Integration of components from different manufacturers that use different adapter types.
- **Data Path Cleanup**: Simplifying the signal flow through defined conversion at a central location.

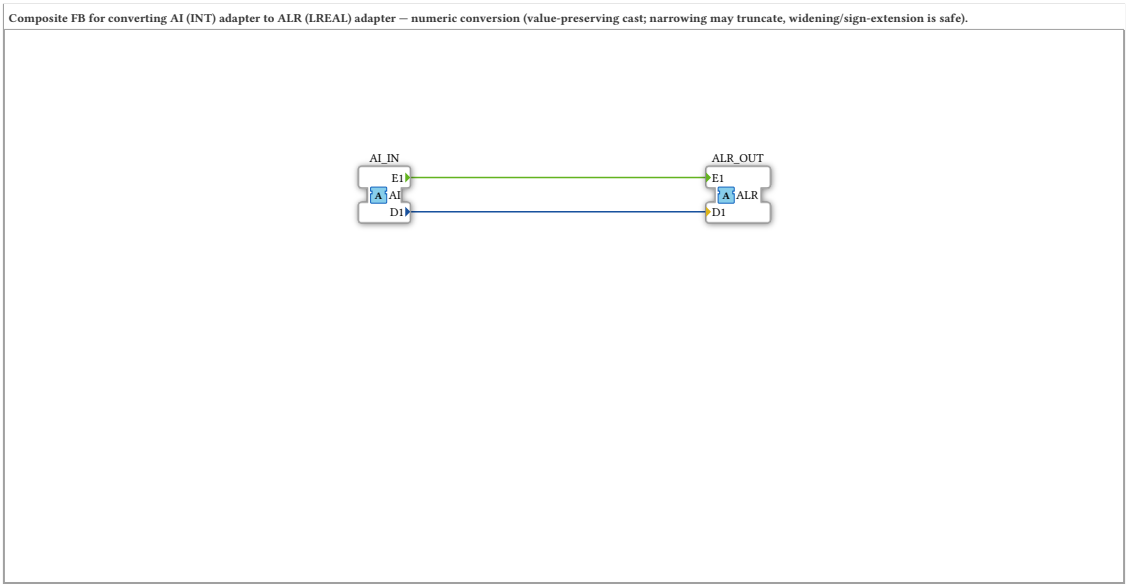
Comparison with Similar Function Blocks

Function Block	Function	Difference
ALI_TO_AI	LINT → INT via adapter	Specifically for unidirectional ALI/AI interfaces
LINT_TO_INT	Direct conversion LINT → INT	No adapter integration – pure data conversion
AI_TO_ALI	INT → LINT (reverse direction)	Same structure, but opposite data direction



Conclusion

ALI_TO_AI is a small but useful compound block that bridges the gap between two common IEC 61499 adapter types. Encapsulating the conversion logic simplifies reuse and accelerates system integration. The block is robust because it uses a standardized IEC 61131 converter and requires no configuration.



Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AI_TO_ALR

INT Adapter Input – *AI* *ALR* – LREAL Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_TO_ALR** is a composite function block that converts an **AI (INT adapter)** to an **ALR (LREAL adapter)**. It serves as a pure conversion interface by directly routing the event and data channels of the input adapter to the output adapter. The actual type conversion from Integer (INT) to Long Real (LREAL) is handled by the underlying adapter definitions.

Interface Structure

Event Inputs

The function block does not have direct event inputs. The event is received via the socket adapter `AI_IN`:

- **AI_IN.E1** – Event of the INT adapter (input).

Event Outputs

There are no direct event outputs here either. The event is sent via the plug adapter `ALR_OUT`:

- **ALR_OUT.E1** – Event of the LREAL adapter (output).

Data Inputs

- **AI_IN.D1** – Data value of type INT (via the adapter).

Data Outputs

- **ALR_OUT.D1** – Data value of type LREAL (via the adapter).

Adapters

- **AI_IN** (Socket) – Adapter of type `AI` (INT adapter), input interface.
- **ALR_OUT** (Plug) – Adapter of type `ALR` (LREAL adapter), output interface.

Functionality

This component connects the signals of the socket adapter `AI_IN` directly to the plug adapter `ALR_OUT`:

- **Event Path:** The event received by `AI_IN.E1` is forwarded unchanged to `ALR_OUT.E1`.
- **Data Path:** The INT value received by `AI_IN.D1` is passed to `ALR_OUT.D1`. The adapters themselves implement the necessary type conversion from INT to LREAL.

Since this is a composite component without its own algorithm or state machine, no further processing takes place. The component functions purely as a routing and adaptation layer between different adapter types.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Pure Passthrough Structure:** No internal logic, no latency, and no buffering.
- **Adapter Definition Dependency:** Correct operation requires that the adapters `AI` and `ALR` are defined according to the 4diac standard and include the INT>LREAL conversion.
- **Composite Component:** Easily extensible, e.g., through additional filters or network scaling.
- **Package Structure:** The component is located in the package `adapter::conversion::unidirectional`.

State Overview

The component does not have its own state diagram (ECC). Signal processing is purely event-driven via the passed-through adapter events. Therefore, a state is not defined.

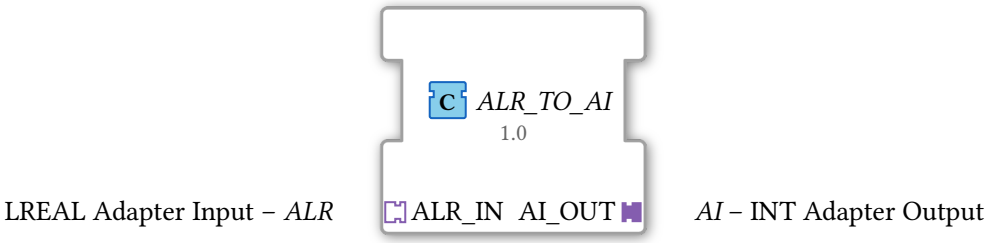
Application Scenarios

- **System Integration:** Connecting an INT-based sensor (e.g., digital value from a counter) to a component that expects LREAL values (e.g., a control algorithm).
- **Adapter Bridge:** Use in modular automation systems where different adapter types interact.
- **Prototype Development:** Rapid coupling of test modules with different data formats.

Comparison with Similar Modules

While 4diac libraries often contain separate converter modules for basic data types (e.g., `INT_TO_REAL`), `AI_TO_ALR` encapsulates the conversion at the adapter level. The advantage lies in the reusability of adapter interfaces and the easy exchange of the conversion logic with other adapters. The disadvantage is the dependence on the specific adapter definitions.

Conclusion



The **AI_TO_ALR** function block is a minimalist yet effective composite function block for type conversion between INT and LREAL adapters. It reduces wiring effort in complex control networks and enables a clean separation of interfaces and conversion logic. It is an ideal solution for applications requiring simple pass-through without additional processing.

ALR_TO_AI

• – ○ • – ○ • – ○ •

The **ALR_TO_AI** function block is a composite block that converts an ALR (LREAL data) adapter to an AI (INT data) adapter. It is used to convert signals from agricultural technology (e.g., sensor values) to a standardized integer-based adapter interface. The block encapsulates the conversion and event forwarding, thus simplifying integration into existing 4diac applications.

The function block does not have its own top-level event inputs. Event control is handled via the connected socket `ALR_IN`:

Input	Type	Description
`ALR_IN`	ALR (Socket)	Adapter that triggers the conversion via its event (`E1`)

The FB does not have any independent event outputs at the top level. Event feedback is provided via the connected plug `AI_OUT`:

Output	Type	Description
`AI_OUT`	AI (Plug)	Adapter that outputs the converted event (`E1`) after successful conversion

The **data input signal** is provided via socket `ALR_IN`:

Adapter Input	Data Type	Description
`ALR_IN.D1`	LREAL	The floating-point value to be converted

The **data output signal** is provided via plug `AI_OUT`:

Adapter Output	Data Type	Description
`AI_OUT.D1`	INT	The converted integer value

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter
The function block has two adapter interfaces:

- **Socket (Input)**: `ALR_IN` – Adapter for unidirectional LREAL data (Type `adapter::types::unidirectional::ALR`)
- **Plug (Output)**: `AI_OUT` – Adapter for unidirectional INT data (Type `adapter::types::unidirectional::AI`)

Functionality
The **ALR_TO_AI** function block contains an internal conversion block `F_LREAL_TO_INT` from the IEC 61131 library.

1. When socket `ALR_IN` sends an event at its output `E1`, it is forwarded to the input `REQ` of the internal converter.
2. The converter transforms the incoming LREAL value (`ALR_IN.D1`) into an INT value and outputs the result via its output `OUT`, along with an acknowledgment event `CNF`.
3. The `CNF` event is passed to plug `AI_OUT.E1`, informing the downstream component about data availability.
4. In parallel, the converted INT value is applied to the data output `AI_OUT.D1`.

The entire process is synchronous and performed in a single step.

- The function block (FB) is a **composite function block** – it does not have its own state machine (ECC) but implements the logic via an internal subnetwork.
- The conversion follows the IEC 61131-3 function `LREAL_TO_INT`: decimal places are truncated (truncation to zero), and overflows or underflows are implementation-dependent.
- The function block is designed as a unidirectional adapter coupling – no feedback channels are supported.

As a composite FB, **ALR_TO_AI** does not have its own state diagram. The internal converter `F_LREAL_TO_INT` operates in an event-driven manner: An event at input `REQ` triggers the conversion, and output `CNF` signals the end of the operation. The function block behaves like a transparent block for event and data forwarding.

- **Sensor Value Processing**: Conversion of an LREAL signal (e.g., from an analog sensor adapter) into an INT signal, which is then processed by a PLC or a controller with integer-based adapters.
- **Adapter Bridge**: Connecting adapter types of different physical units when only the data type, not the scaling, needs to be changed.
- **Interface Adaptation**: Used in agricultural control systems (e.g., HR Agricultural Technology – general), where LREAL values from sensors are mapped to a CAN-based INT adapter interface.

FB	Function	Difference
ALR_TO_AI	Converts LREAL ⟶ INT via adapter	Composite, no dedicated state machine; uses IEC 61131 converter
`F_LREAL_TO_INT`	Pure data conversion without adapter	Direct FB, requires separate adapter connection
`AI_TO_ALR`	Reverse direction INT ⟶ LREAL	Different data type and conversion direction

The **ALR_TO_AI** function block simplifies reuse by encapsulating the adapter logic and conversion in a single block.

The **ALR_TO_AI** is a practical composite function block for the standardized conversion of LREAL-based to INT-based adapter interfaces. It allows for a clean separation of data conversion and adapter logic and facilitates integration into larger automation projects. Thanks to its clear event forwarding and the use of an IEC 61131 basic function, it is reliable and easy to use.

AI_TO_AR

INT Adapter Input – *AI*

AR – REAL Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AI_TO_AR** function block is a composite module that enables interface conversion from an **AI** adapter (integer type) to an **AR** adapter (real type). It serves purely as a pass-through and adaptation unit between different adapter protocols in an industrial control system.

Interface Structure

Since **AI_TO_AR** does not have its own event or data interfaces, all communication takes place exclusively via the connected adapters.

Event Inputs

– not present – Event control is handled via the incoming adapter **AI_IN**.

Event Outputs

– not present – Event forwarding is handled via the outgoing adapter **AR_OUT**.

Data Inputs

– not available – The data is provided as an integer value via the **AI_IN** adapter.

Data Outputs

– not available – The data is output as a real value via the **AR_OUT** adapter.

Adapters

Name	Type	Direction	Description
AI_IN	`adapter::types::unidirectional::AI`	Socket	Integer Adapter (Input)
AR_OUT	`adapter::types::unidirectional::AR`	Plug	Real Adapter (Output)

Functionality

In the FB network of the composite block, the event and data lines of the two adapters are directly connected:

- The event **E1** of the AI_IN adapter is routed to the event **E1** of the AR_OUT adapter.
- The data value **D1** (type INT) of the AI_IN adapter is transferred to the data value **D1** (type REAL) of the AR_OUT adapter.

The block itself does not perform any explicit type conversion; the conversion from integer to real is either implicitly handled by the runtime environment or must be ensured by the connected context. Thus, the block functions purely as a pass-through for events and data between the two adapter interfaces.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- The block does not contain its own event or data interface; all its communication takes place via the adapters.
- There is no internal state machine (ECC) – the block operates purely event-driven through the connections.
- The use of adapters achieves loose coupling between the inputs and outputs, increasing the reusability and interchangeability of the interfaces.

State Overview

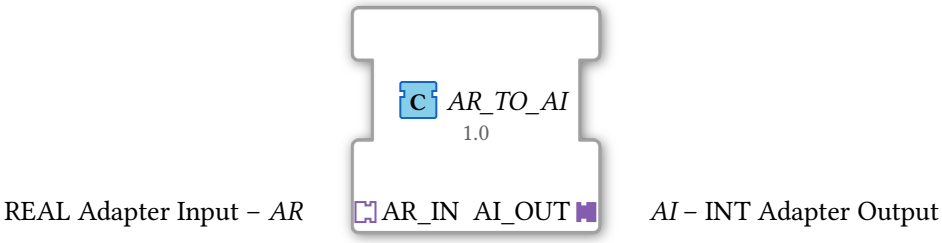
The component does not have a state machine. Processing occurs directly without delay or state dependency.

Application Scenarios

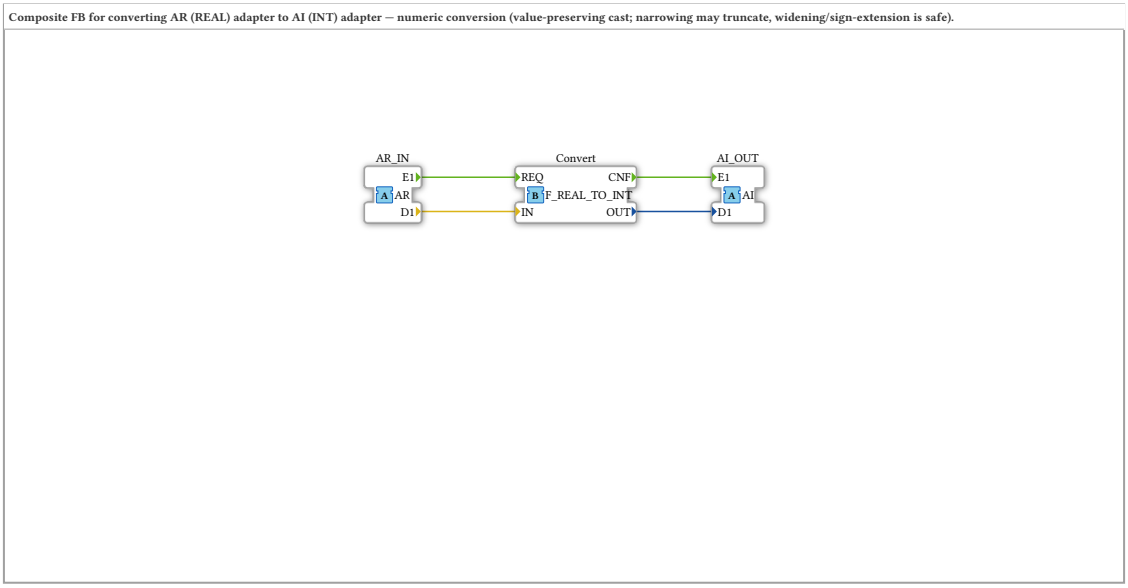
- **Adapter Conversion**: Use in systems where an integer-based sensor signal (AI) must be transferred to a component that expects a real signal (AR).

- **Interface Adaptation**: Use in modular control solutions to mediate between different adapter types without affecting the actual data processing.
- **Prototypes and Testing**: Quick assembly of different adapter components during the development phase.

Comparison with Similar Components



Component	Function	Special Feature
AI_TO_AR	Pass-through from INT to REAL via adapter	No dedicated logic, pure adapter switching
REAL_TO_INT	Conversion from REAL to INT (usually with rounding)	Often includes its own algorithm
ADAPTER_COUPLER	General adapter coupling without type conversion	Requires identical data types



Unlike dedicated converters, **AI_TO_AR** does not perform active value conversion but relies on the compatibility of the connected adapters.

Conclusion

AI_TO_AR is a simple yet effective composite block for connecting two different adapter interfaces (INT to REAL). It is particularly suitable for cross-system signal transmission in IEC 61499-based controllers where the type conversion logic is located outside the block. Its clear structure makes it a useful tool for modular and flexible automation solutions.

AR_TO_AI

• – ○ • – ○ • – ○ •

Introduction

The **AR_TO_AI** function block is a composite module that converts a unidirectional AR adapter (input with data type REAL) into a unidirectional AI adapter (output with data type INT). It is used for numerical type conversion within 4diac networks and encapsulates an IEC 61131 conversion module.

Interface Structure

Event Inputs

The event input is provided via the **AR_IN** socket. The **AR_IN.E1** event triggers the conversion.

Event Outputs

The event output is provided via the **AI_OUT** plug. After successful conversion, the event **AI_OUT.E1** is sent.

Data Inputs

The data input is provided via the socket **AR_IN**. The input value **AR_IN.D1** is of type REAL.

Data Outputs

The data output is provided via the plug **AI_OUT**. The output value **AI_OUT.D1** is of type INT.

Adapters

Label	Direction	Type	Remark
AR_IN	Input	`adapter::types::unidirectional::AR`	REAL Adapter (Input)
AI_OUT	Output	`adapter::types::unidirectional::AI`	INT Adapter (Output)

Functionality

The function block (FB) is implemented as a composite and contains a single **F_REAL_TO_INT** block from the IEC 61131 library (`iec61131::conversion::F_REAL_TO_INT`).

As soon as an event arrives at socket **AR_IN.E1**, the value of **AR_IN.D1** (REAL) is passed to the input `IN` of the converter, and its processing is started (`REQ`). After the conversion is complete, the converter signals via `CNF` that the result is available at output `OUT` (INT). This result is immediately forwarded to the plug output **AI_OUT.D1** (INT), and the event **AI_OUT.E1** is triggered.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- The function block (FB) is fully event-driven; it does not have its own state machine.
- Conversion is performed according to the IEC 61131 standard: REAL is mapped to INT (decimal places are truncated, corresponding to a type conversion).
- The function block is located in the package `adapter::conversion::unidirectional`, which allows for clear separation from other conversion function blocks.
- The use of adapters improves encapsulation and reusability in 4diac projects.

State Overview

The **AR_TO_AI** function block does not have an internal state machine. Its operation is purely combinatorial and depends on the incoming event:

- **Waiting:** No event is pending at AR_IN.E1.
- **Converting:** Upon an event, the REAL value is converted immediately, and the result is output as an INT.

Application Scenarios

- **Sensor Connection:** Real-value sensors (e.g., analog voltage measurement) deliver REAL data via an AR adapter; downstream logic requires INT values (e.g., for counters or index calculations).
- **Protocol Conversion:** When a subsystem sends data in REAL format, but the target system only accepts INT data (e.g., with fieldbus gateways).

- **Test and Simulation Environments:** For easy conversion between REAL and INT adapters in test setups.

Comparison with Similar Function Blocks

- **AI_TO_AR:** Performs the reverse conversion (INT → REAL).
- **F_REAL_TO_INT (Direct):** The encapsulated basic function block is designed for point-to-point connections without an adapter. The AR_TO_AI offers an adapter-based interface that can be better integrated into adapter-oriented networks.
- **Custom Composite Blocks:** Other projects could create similar adapter conversions for other data types (e.g., LREAL, DINT).

Conclusion

The **AR_TO_AI** is a compact, adapter-based conversion block that enables the conversion of REAL to INT data in event-driven 4diac networks. By encapsulating the standard block `F_REAL_TO_INT` in an adapter interface, integration into existing adapter socket architectures is simplified, and the overall system readability is improved.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AI_TO_AS

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_TO_AS** is a composite block that converts an adapter of type `AI` (based on `INT`) into an adapter of type `AS` (based on `SINT`). It serves as an interface converter between different data formats in the IEC 61499 architecture.

Interface Structure

Event Inputs

The function block does not have its own event inputs. Event control is handled entirely via the adapter input `AI_IN` (see section Adapter). Internally, the adapter's event `E1` is processed.

Event Outputs

The function block (FB) does not have its own event outputs. The result event is provided via the adapter output `AS_OUT` (see section Adapter). After successful conversion, the event `E1` is triggered on the output adapter.

Data Inputs

The FB does not have its own data inputs. The value to be converted, `INT`, is read in via the adapter input `AI_IN` (data point `D1`).

Data Outputs

The FB does not have its own data outputs. The converted `SINT` value is output via the adapter output `AS_OUT` (data point `D1`).

Adapter

Adapter	Direction	Type	Description
`AI_IN`	Input (Socket)	`adapter::types::unidirectional::AI`	INT-based adapter input; provides the event `E1` and the data value `D1` (type `INT`).
`AS_OUT`	Output (Plug)	`adapter::types::unidirectional::AS`	SINT-based adapter output; receives the event `E1` and passes on the converted data value `D1` (type `SINT`).

Functionality

The function block performs a **type conversion from `INT` to `SINT`**.

As soon as an event `E1` arrives at the adapter input `AI_IN`, the corresponding data value `D1` (INT) is read. This value is passed to the internal function block `F_INT_TO_SINT`. The conversion is performed according to the IEC 61131-3 definition; the `INT` value is limited to the value range of `SINT` (-128...127). After successful conversion, the event `E1` is generated at the adapter output `AS_OUT`, and the converted `SINT` value is passed via `D1`.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Structure**: The function block is implemented as a composite that uses the standard function block `F_INT_TO_SINT`. This enables easy reuse and a clear separation of the conversion logic.
- **Adapter-based interface**: The inputs and outputs are implemented as unidirectional adapters (`AI` and `AS`), allowing flexible connection to other components with compatible adapter interfaces.
- **No range check**: The underlying function block `F_INT_TO_SINT` does not perform explicit error handling when a value exceeds its range. If the value of `INT` is outside the range of `SINT`, unexpected results or overflows may occur (depending on the target platform).

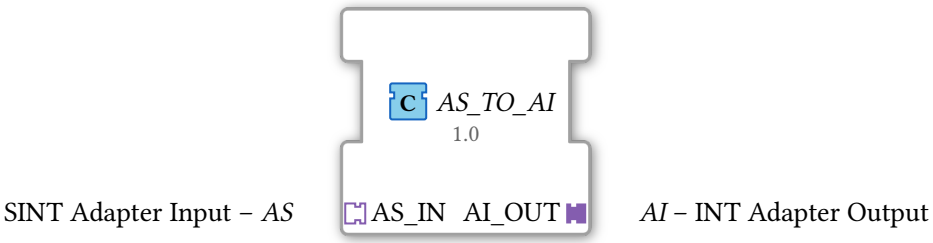
State overview

The function block does not have its own state machine. The internal logic follows the simple sequence of function block `F_INT_TO_SINT`:

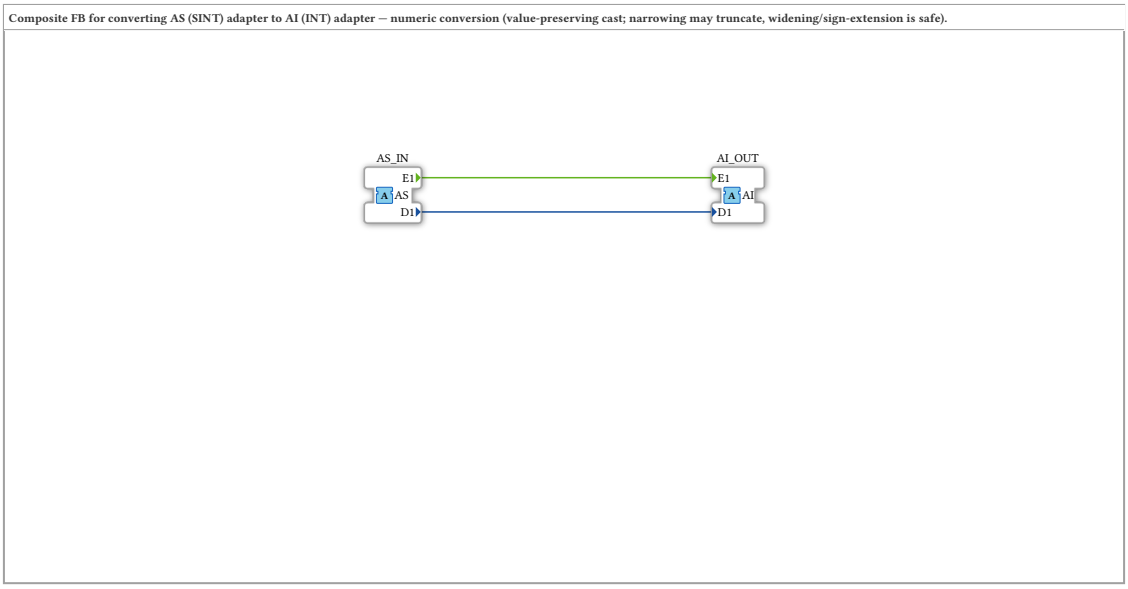
State	Description
Idle	Waiting for an event at `AI_IN.E1`.
Convert	Upon arrival of `E1`, the value from `AI_IN.D1` is read, converted, and passed to `AS_OUT.D1`. Then, `AS_OUT.E1` is triggered. The function block immediately returns to the idle state.

Application Scenarios

- **Data Format Adaptation**: When an existing INT interface needs to be integrated into a system that processes only SINT values (e.g., older controllers or limited bus protocols).
- **Adapter Replacement**: Replacing an AI adapter with an AS adapter in an existing component structure without modifying the internal logic.
- **Prototypes/Test Setups**: Fast conversion of test signals between different data widths.



Comparison with Similar Components



- **AI_TO_AS (INT → SINT)**: Specifically designed for converting INT to SINT using unidirectional adapters.
- **AY_TO_AS (DINT → SINT)**: Converts DINT values to SINT; essentially the same structure, but a different data type.
- **Direct Conversion Without Adapters**: Function blocks like `F_INT_TO_SINT` offer pure type conversion but require separate event and data connections. The `AI_TO_AS` encapsulates these in adapter logic.

Conclusion

The `AI_TO_AS` function block provides a simple and compact solution for converting an INT-based adapter to a SINT-based adapter. Its composite structure and clear interface definition make it easy to integrate into IEC 61499 applications. The lack of range checking should be considered in safety-critical applications. Overall, it is a useful tool for signal conditioning in heterogeneous automation systems.

AS_TO_AI

• — ○ • — ○ • — ○ •

Introduction

The function block `AS_TO_AI` is a composite function block that converts an AS adapter (data type SINT) to an AI adapter (data type INT). It serves as a simple converter for connecting components with different adapter types within the 4diac IDE.

Interface Structure

Event Inputs

- None

Event Outputs

- None

Data Inputs

- None

Data Outputs

- None

Adapter

- **AS_IN** (Socket, Type: `adapter::types::unidirectional::AS`)

Expects a SINT value and a corresponding event E1.

- **AI_OUT** (Plug, Type: `adapter::types::unidirectional::AI`)

Provides an INT value and an event E1.

Functionality

The function block forwards the event E1 from the AS_IN socket directly to the AI_OUT plug. Simultaneously, the data value D1 is transferred from the AS_IN socket to the AI_OUT plug. This involves an implicit type conversion from SINT (8-bit signed) to INT (16-bit signed). No further processing or state logic takes place.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).

- The type conversion from SINT to INT is performed automatically by the 4diac runtime environment without requiring any additional code blocks.
- The function block is implemented as a **Composite FB** and does not contain its own ECC (Execution Control Chart).
- It is located in the package `adapter::conversion::unidirectional`, which indicates unidirectional adapter conversion.

State Overview

Since it is a composite function block, `AS_TO_AI` does not have its own states. Its behavior is determined solely by the wiring of its internal connections.

Application Scenarios

- A sensor provides data via an AS adapter (SINT), but the connected processing component expects an AI adapter (INT).
- Migration from 8-bit to 16-bit data paths without changing the source or target component.
- Prototyping and system integration when different adapter versions interact.

Comparison with Similar Components

- **AI_TO_AS**: Performs the reverse conversion (INT ⟶ SINT).
- **AI_TO_AD** or similar: Converts between other integer data types (e.g., INT to DINT).
- Unlike these function blocks, `AS_TO_AI` operates losslessly, as the target type (INT) can fully map to the source type (SINT).

Conclusion

The `AS_TO_AI` function block is a simple yet effective tool for ensuring adapter compatibility in 4diac applications. It handles the automatic type conversion from SINT to INT, thus simplifying the integration of heterogeneous components without requiring manual adjustment of the data path.

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AI_TO_AUDI

• — ○ • — ○ • — ○ •

Introduction

The function block `AI_TO_AUDI` is a composite module that converts an **AI adapter** (data of type `INT`) into an **AUDI adapter** (data of type `UDINT`). It serves as a unidirectional interface between different adapter types and enables seamless data conversion within the 4diac IDE.

Interface Structure

The module does not have traditional event and data inputs/outputs, but instead implements its inputs and outputs via **adapter interfaces**. The following ports are available via the internal adapters:

Event Inputs

Port	Adapter	Description
`E1`	`AI_IN`	Starts the conversion of the INT value.

Event Outputs

Port	Adapter	Description
`E1`	`AUDI_OUT`	Signals completion of the conversion.

Data Inputs

Port	Adapter	Data Type	Description
`D1`	`AI_IN`	`INT`	Integer value to be converted.

Data Outputs

Port	Adapter	Data Type	Description
`D1`	`AUDI_OUT`	`UDINT`	Converted unsigned integer.

Adapter

Direction	Name	Type	Description
Socket	`AI_IN`	`adapter::types::unidirectional::AI`	Input adapter (INT).

Plug	AUDI_OUT	adapter::types::unidirectional::AUDI	Output adapter (UDINT).

Functionality

The function block is implemented as a composite function block. Internally, it uses the standard conversion function block iec61131::conversion::F_INT_TO_UDINT.

Process:

1. An event arrives at the input E1 of socket AI_IN, accompanied by an INT value at D1.
2. This event is forwarded to the internal function block Convert (type F_INT_TO_UDINT).
3. The internal function block performs the type conversion from INT to UDINT (according to IEC 61131-3).
4. After successful conversion, an event is generated at the output CNF of the internal function block.
5. This event is passed to plug AUDI_OUT (event output E1), and simultaneously the converted UDINT value is available at data output D1.

This event is passed to plug AUDI_OUT (event output E1), and the converted UDINT value is simultaneously available at data output D1.

... The connections in the FBNetwork are:

- AI_IN.E1 ⟶ Convert.REQ
- Convert.CNF ⟶ AUDI_OUT.E1
- AI_IN.D1 ⟶ Convert.IN
- Convert.OUT ⟶ AUDI_OUT.D1

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block:** Simplifies the reuse and encapsulation of the conversion logic.
- **Standard Conversion:** Uses the IEC 61131-3 block F_INT_TO_UDINT, which ensures clean and portable type conversion.
- **Unidirectional Adapters:** Both the input and output adapters are implemented as unidirectional interfaces (socket and plug, respectively) – data flows in only one direction.
- **Event-driven:** The conversion is triggered by an event at the input adapter and acknowledged by an event at the output adapter (handshake principle).

State Overview

The function block itself does not have its own state machine, as it consists solely of a direct chain of adapter ports and the internal conversion block. The internal function block F_INT_TO_UDINT performs the conversion in one step – therefore, a state overview is not required.

Application Scenarios

- **Data Bridge Between Different Adapter Types:** When a higher-level system or library provides adapters of type AI (with INT data), but downstream components expect a AUDI adapter (with UDINT data).
- **Signal Conversion in Automation Solutions:** For example, when processing counter values or position data that arrive as signed 16-bit values but must be passed on as unsigned 32-bit values.
- **Modular Adapter Conversion:** Easily replace or extend the conversion logic by replacing the internal function block.

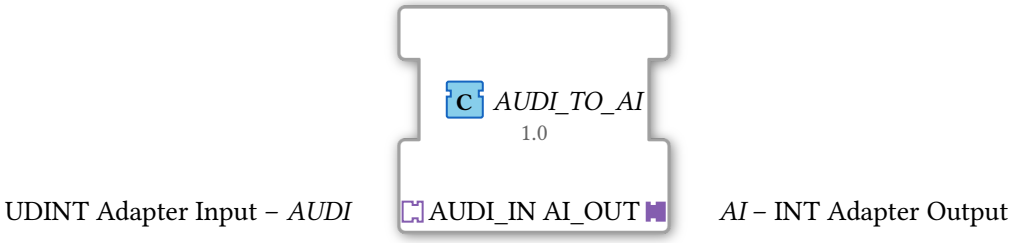
Comparison with Similar Function Blocks

Other adapter conversion function blocks exist in the library, e.g. B.:

- AI_TO_AI – forwarding without conversion
- AUDI_TO_AI – reverse direction (UDINT ⟶ INT)
- Direct use of the F_INT_TO_UDINT block with manual adapter wiring

The AI_TO_AUDI block not only encapsulates the type conversion but also the complete adapter connection, making the design clearer and preventing errors due to incorrect wiring.

Conclusion



The `AI_TO_AUDI` composite block offers a simple yet clean solution for converting an INT-based adapter protocol to a UDINT-based protocol. Thanks to the use of the standardized IEC block and event-driven coupling, it is reliable and easily integrated into larger 4diac projects.

]

AUDI_TO_AI

• – ◦ • – ◦ • – ◦ •

Introduction

The composite function block `AUDI_TO_AI` converts a unidirectional AUDI adapter (data type `UDINT`) into a unidirectional AI adapter (data type `INT`). It encapsulates the conversion logic and enables easy integration into adapter-based communication structures according to IEC 61499.

Interface Structure

Event Inputs

The function block does not have direct event inputs. Event control is handled via socket `AUDI_IN` of type `adapter::types::unidirectional::AUDI`. This adapter provides an event input, `E1`, which triggers the conversion.

Event Outputs

The function block (FB) has no direct event outputs. Event output is provided via the plug `AI_OUT` of type `adapter::types::unidirectional::AI`. This adapter provides an event output, `E1`, which signals the completion of the conversion.

Data Inputs

No direct data inputs. The socket `AUDI_IN` provides the value to be converted, `UDINT`, via its data input `D1`.

Data Outputs

No direct data outputs. Plug `AI_OUT` outputs the converted `INT` value via its data output `D1`.

Adapters

- **Socket `AUDI_IN`**: Type `adapter::types::unidirectional::AUDI` – receives a unidirectional data value of type `UDINT` and an associated event.
- **Plug `AI_OUT`**: Type `adapter::types::unidirectional::AI` – sends a unidirectional data value of type `INT` and an associated event.

Functionality

The function block is implemented as a composite block. Internally, socket `AUDI_IN` is connected to the standard conversion block `iec61131::conversion::F_UDINT_TO_INT`, whose output is in turn linked to plug `AI_OUT`.

When an event is received via the adapter input `AUDI_IN.E1`, the corresponding data value `AUDI_IN.D1` is passed to the conversion block. After successful conversion of `UDINT` to `INT`, the event `Convert.CNF` is generated and output via `AI_OUT.E1`. Simultaneously, the converted value is available at `AI_OUT.D1`.

…

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- Uses a standardized IEC 61131 conversion block that can be implemented platform-independently.
- The conversion from `UDINT` (32 unsigned bits) to `INT` (16 signed bits) is potentially lossy. Depending on the implementation of the conversion block, an overflow or limit may occur if the value range is exceeded.
- The use of unidirectional adapters ensures a clean data flow and facilitates integration into modular systems.
- The function block does not have its own state machine; all logic is executed event-driven via the internal wiring.

State Overview

The function block does not have an internal state machine. Its functionality arises solely from the causal chaining of event and data connections. There is only one active state in which an incoming event-data combination is processed and the output is generated.

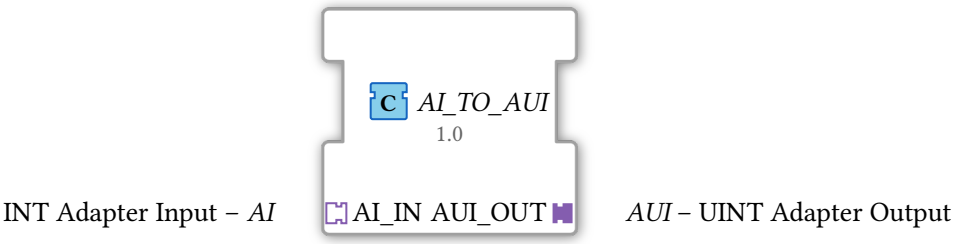
Application Scenarios

- Connecting a sensor that delivers measured values as `UDINT` to a control system that expects `INT` values (e.g., a PLC with 16-bit analog inputs).
- Integration into PROFINET or EtherCAT applications where adapters are required for type conversion between different data formats.
- Reusable encapsulation of the conversion in an adapter-based library for industrial automation solutions.

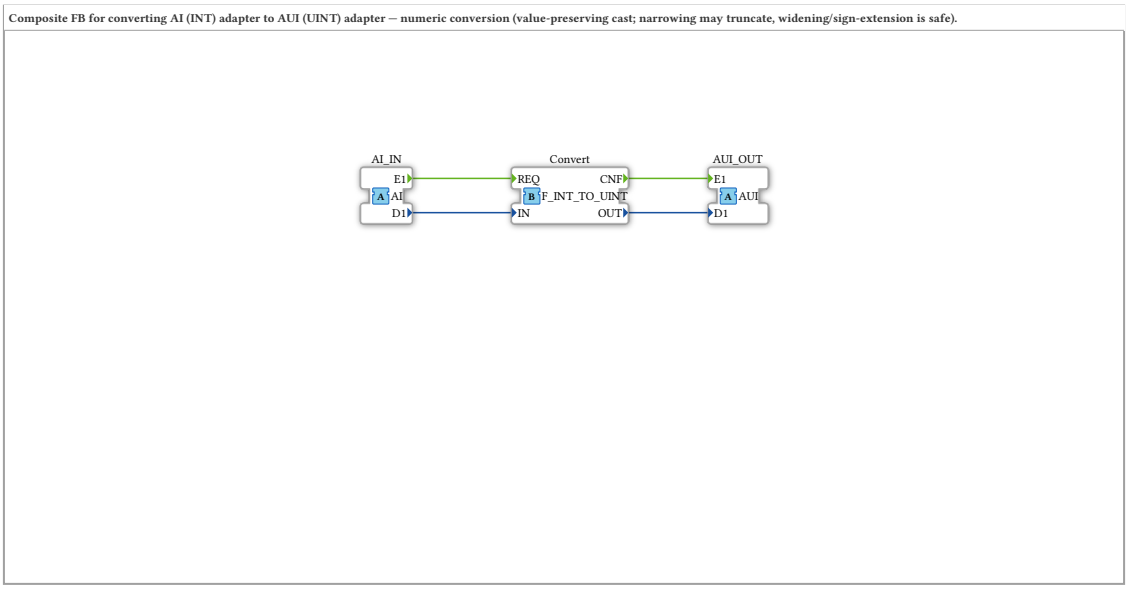
Comparison with Similar Function Blocks

- A direct conversion function block like `F_UDINT_TO_INT` requires separate event and data connections and is not designed for direct use in adapter interfaces.
- `AUDI_TO_AI` encapsulates the entire adapter conversion, thus simplifying reuse in architectures based on unidirectional adapters.
- Analogous function blocks for other data types (e.g., `REAL_TO_INT` or `DINT_TO_INT`) follow the same design pattern and can be implemented using the same scheme.

Conclusion



The composite function block `AUDI_TO_AI` provides a clean and reusable solution for lossy conversion of `UDINT` values to `INT` values using unidirectional adapters. It simplifies integration into IEC 61499 systems



that rely on adapter communication and encapsulates the conversion logic in a single, clearly defined function block.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AI_TO_AUI

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AI_TO_AUI** is a composite block that converts an INT adapter (AI) into a UINT adapter (AUI). It serves as an interface converter in systems that rely on unidirectional adapter communication. Internally, it uses the block `F_INT_TO_UINT` from the IEC 61131 library to convert the integer value of `AI_IN` into an unsigned integer and make it available via `AUI_OUT`.

Interface Structure

Event Inputs

No separate event inputs are available. Event control is handled exclusively via the adapters (`AI_IN.E1` for request, `AUI_OUT.E1` for acknowledgement).

Event Outputs

No separate event outputs are available. Event feedback is provided via the `AUI_OUT.E1` adapter.

Data Inputs

No separate data inputs are available. The value to be converted is received via the `AI_IN.D1` adapter (type INT).

Data Outputs

No separate data outputs are available. The converted value is provided via the `AUI_OUT.D1` adapter (type UINT).

Adapters

Direction	Name	Type	Description
Socket (Input)	`AI_IN`	`adapter::types::unidirectional::AI`	INT adapter input. Returns the event `E1` and the data value `D1` (INT).
Plug (Output)	`AUI_OUT`	`adapter::types::unidirectional::AUI`	UINT adapter output. Provides the event `E1` and the data value `D1` (UINT).

Functionality

The function block operates as a simple pipeline:

1. An event is received via `AI_IN.E1`.
2. This event triggers the internal conversion block `F_INT_TO_UINT` via its `REQ` input.
3. The value of `AI_IN.D1` (INT) is forwarded to `Convert.IN`.
4. After the conversion is complete, an event is sent to `AUI_OUT.E1` via `Convert.CNF`.
5. The converted value (UINT) is available at `AUI_OUT.D1`.

The module is purely causal – it reacts to an incoming event and, after conversion, outputs an outgoing event.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Adapter-based communication**: Instead of classic input/output pins, the interfaces are implemented via adapters (`AI` and `AUI`). This enables loose coupling in modular systems.
- **Unidirectional data flow**: Both adapters are unidirectional, meaning they only transport data and events in one direction (input or output).
- **Packaging**: The module is located in the package `adapter::conversion::unidirectional`, which indicates its role as a converter between adapter types.
- **Type Conversion**: The conversion from `INT` to `UINT` is performed using the IEC 61131 function block `F_INT_TO_UINT`, which ensures value preservation for positive numbers. Negative values are converted to the corresponding UINT space (e.g., two's complement).

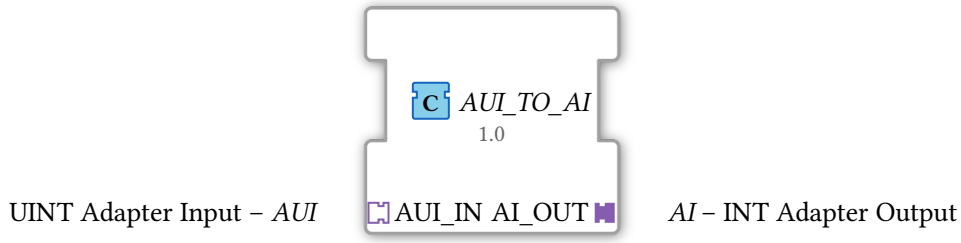
State Overview

The function block does not have an explicit state machine. Internally, it only executes the following sequence: Receive event → Trigger conversion → Send event. There are no delayed responses or persistent states.

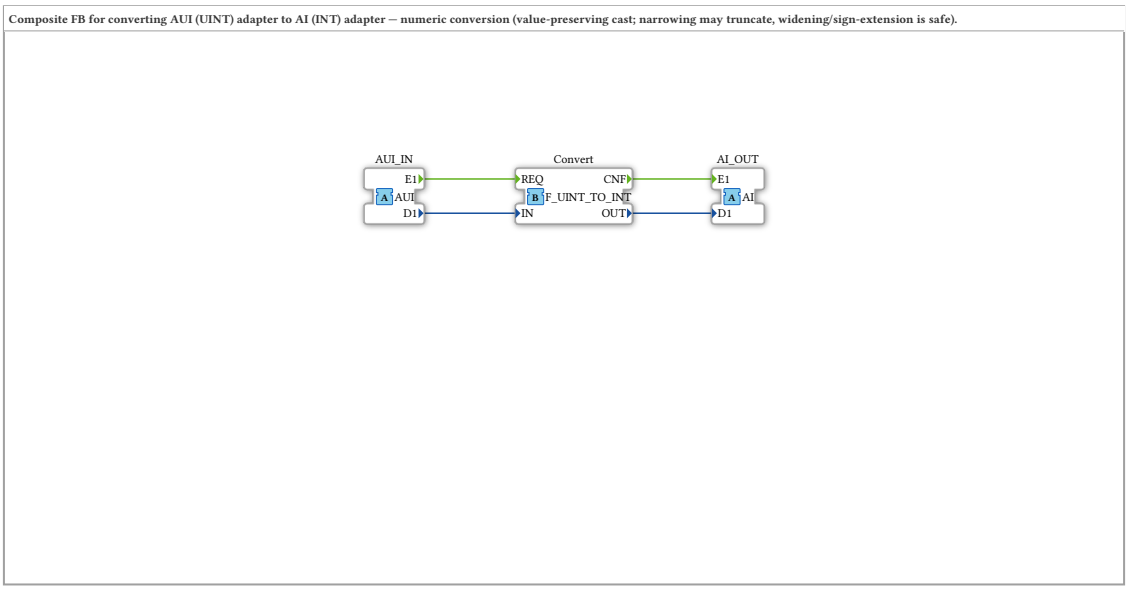
Application Scenarios

- **Sensor Interface Adaptation**: A sensor delivers measured values as `INT` (e.g., temperature or pressure) via an AI adapter; The subsequent controller expects `UINT` via an AUI adapter.
- **System Integration**: In heterogeneous systems using different adapter types, `AI_TO_AUI` enables seamless connection of components.
- **Data Preparation**: Before further processing in a PLC that only supports unsigned values (e.g., for counters or scaling).

Comparison with Similar Function Blocks



- **`AI_TO_AUI` vs. Direct Conversion with `F_INT_TO_UINT`**: The composite function block encapsulates the adapter interfaces and simplifies the application for the developer – individual function blocks with signal connections do not need to be wired.



- **Similar Adapter Converters**: The library may contain other modules such as `AUI_TO_AI` (reverse conversion) or converters for other data types (e.g., `REAL_TO_INT`). `AI_TO_AUI` is specifically designed for combining INT and UINT adapters.

Conclusion

The module `AI_TO_AUI` offers a compact, reusable solution for converting an INT adapter data stream to a UINT adapter data stream. It reduces the complexity of the interconnection and ensures that the data conversion is correct and event-driven. Thanks to its adapter interfaces, it integrates seamlessly into modular, unidirectional architectures.

AUI_TO_AI

• – ○ • – ○ • – ○ •

Introduction

Composite function block (FB) for converting an AUI (UINT) adapter into an AI (INT) adapter. It encapsulates the conversion using the function block `F_UINT_TO_INT` and provides a standardized adapter interface.

Interface Structure

Event Inputs

No direct event inputs at the FB level. The event is received via the **AUI_IN socket** (event `E1`).

Event Outputs

No direct event outputs at the FB level. The event is output via the **AI_OUT plug** (event `E1`).

Data Inputs

No direct data inputs at the FB level. The UINT value is provided via the **Socket AUI_IN** (data point `D1`).

Data Outputs

No direct data outputs at the FB level. The INT value is output via the **Plug AI_OUT** (data point `D1`).

Adapters

- **Socket AUI_IN** (Type: `adapter::types::unidirectional::AUI`) – Receives UINT data and an event.
- **Plug AI_OUT** (Type: `adapter::types::unidirectional::AI`) – Sends INT data and an event.

Functionality

This function block connects the AUI adapter socket to a conversion function block of type `F_UINT_TO_INT` via an FBNetwork:

1. The event `E1` of the AUI_IN adapter triggers the conversion function block at the **REQ** input.
2. The conversion function block reads the UINT value from the data point `AUI_IN.D1` and converts it to INT.
3. After the conversion, the function block sends an acknowledgment event via **CNF**, which triggers the event `E1` of the AI_OUT adapter.
4. The event `E1` of the AI_OUT adapter.
5. The conversion function block reads the UINT value from the data point `AUI_IN.D1` and converts it to INT. 4. The converted INT value is passed to the AI adapter via the data point `AI_OUT.D1`.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- Composite function block without its own state logic (no ECC).
- Uses the standard function block `iec61131::conversion::F_UINT_TO_INT` for type conversion.
- Contains license information according to the Eclipse Public License 2.0.

State Overview

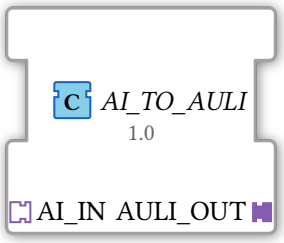
The function block does not have an internal state machine. Control is achieved solely through event chaining in the FBNetwork.

Application Scenarios

- Integration of a component that provides an AUI adapter (UINT) into a system that expects an AI adapter (INT).
- Encapsulation of the conversion to facilitate reuse and maintain a clear network structure.

Comparison with Similar Function Blocks

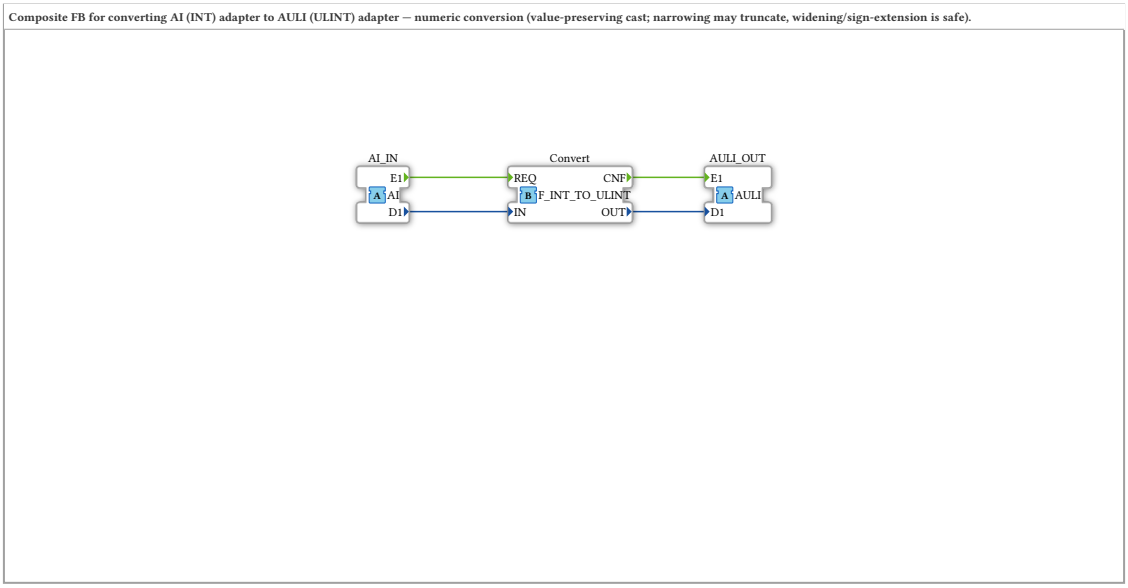
- **AUI_TO_AI** converts UINT to INT.
- An analogous function block **AI_TO_AUI** would provide the reverse conversion (INT to UINT).
- Unlike direct type conversion function blocks (such as `F_UINT_TO_INT`), this function block operates at the adapter level and integrates seamlessly into IEC 61499 adapter concepts.



Conclusion

The **AUI_TO_AI** function block offers a simple and encapsulated solution for converting AUI adapters to AI adapters. It facilitates interoperability between components with different data types and contributes to a clean, modular system architecture.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AI_TO_AULI

INT Adapter Input – *AI*

AULI – ULINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_TO_AULI** serves as a composite block for converting a unidirectional adapter of type `AI` (based on the data type `INT`) into a unidirectional adapter of type `AULI` (based on `ULINT`). It enables the seamless integration of components that use different integer data types without requiring the user to implement the conversion logic

---

Interface Structure

The block does not have traditional event or data inputs/outputs, but only adapter interfaces (socket & plug) through which both events and data are transmitted.

Event Inputs

The event input is provided via the socket adapter `AI_IN`.

Name	Adapter	Comment
`E1`	`AI_IN`	Event that triggers the conversion

Event Outputs

The event output is provided via the plug adapter `AULI_OUT`.

Name	Adapter	Comment
`E1`	`AULI_OUT`	Event after successful conversion

Data Inputs

Data input is provided via the socket adapter `AI_IN`.

Name	Adapter	Type	Comment
D1	AI_IN	INT	Input data (16-bit integer)

Data Outputs

Data output is provided via the plug adapter AULI_OUT.

Name	Adapter	Type	Comment
D1	AULI_OUT	ULINT	Output data (64-bit unsigned integer)

Adapter

- **Socket** AI_IN : Unidirectional adapter with the interfaces E1 (event) and D1 (INT).
- **Plug** AULI_OUT: Unidirectional adapter with the interfaces E1 (event) and D1 (ULINT).

Functionality

This module performs a simple type conversion from INT to ULINT. Internally, the IEC 61131 module F_INT_TO_ULINT is used. The process is event-driven:

1. An incoming event at socket AI_IN.E1 triggers the input REQ of the conversion module.
2. The data value AI_IN.D1 (INT) is passed to the input IN of the conversion block.
3. The conversion is performed, and the result (ULINT) is provided at the output OUT.
4. After the conversion is complete, an event is generated at the output CNF of the conversion block, which is forwarded to the plug AULI_OUT.E1.
5. Simultaneously, the converted value is sent to the plug AULI_OUT.D1.

This ensures a complete, synchronized transfer of the event and data.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Adapter-Based Communication:** The module encapsulates the conversion logic in a composite, so the connected components only need to know the respective adapter interfaces.
- **Unidirectional Data Transfer:** Both AI and AULI are designed as unidirectional adapters; reverse data transfer is not supported.
- **Type Conversion:** The internal module F_INT_TO_ULINT performs an extended conversion from 16-bit integer (INT) to 64-bit unsigned integer (ULINT). Negative INT values are converted into large positive ULINT values using two's complement (e.g., -1 ⟶ 2^64-1).
- **No Eigenstates:** The component does not have its own state machine but forwards events and data directly.

State Overview

Since the component is implemented as a pure composite without its own stateful logic, there is no explicit state machine. Its behavior is determined solely by the coupling of the internal components. The functionality is purely combinatorial and event-triggered.

Application Scenarios

- **Adapter Converter:** Integrating sensors or actuators provided as AI adapters (INT) into a system that expects AULI adapters (ULINT).
- **System Integration:** Use in PLC or automation architectures where different data types need to be standardized.
- **Protocol Adaptation:** Converting 16-bit counter values to 64-bit counter values for extended range.

–

Comparison with Similar Function Blocks

Function Block	Source Type	Target Type	Adapter-Based	Custom States
`F_INT_TO_ULINT`	`INT`	`ULINT`	No (pure function block)	No
`AI_TO_AULI`	`AI`	`AULI`	Yes (adapter)	No
`ANY_TO_ANY`	variable	variable	possible	depending on implementation

While the basic function block `F_INT_TO_ULINT` only performs data conversion, `AI_TO_AULI` encapsulates this along with event control in an adapter-compatible interface. This increases reusability in adapter-based systems.

… —

Conclusion

The function block `AI_TO_AULI` offers a clean, adapter-based solution for converting `INT` to `ULINT` data. It reduces manual effort and the potential for errors during type conversion and integrates seamlessly into existing 4diac projects. Thanks to its simple, event-triggered structure, it is particularly well-suited for unidirectional data flows.

AULI_TO_AI

ULINT Adapter Input – *AULI*

AI – INT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AULI_TO_AI** is a composite function block (FB) that converts an incoming adapter of type **AULI** (ULINT-based) into an outgoing adapter of type **AI** (INT-based). It serves as an interface converter between components that use different data types for analog values.

Interface Structure

Event Inputs

The function block itself has no direct event inputs. Event control is handled via the connected adapters.

Event Outputs

There are also no dedicated event outputs at this level; output events are passed on via the AI_OUT adapter.

Data Inputs

- No direct data inputs at the block level. The data is transferred to the block via socket `AULI_IN`.

Data Outputs

- No direct data outputs at the block level. The converted data is output via plug `AI_OUT`.

Adapters

Name	Direction	Type	Description
`AULI_IN`	Socket	`adapter::types::unidirectional::AULI`	ULINT input adapter (analog value)
`AI_OUT`	Plug	`adapter::types::unidirectional::AI`	INT Output Adapter (Converted Value)

Functionality

The function block internally uses the predefined function block `F_ULINT_TO_INT` from the IEC 61131 library. Its functionality is as follows:

1. An event from socket `AULI_IN.E1` triggers the conversion of the data value `AULI_IN.D1` (ULINT) via the internal function block `Convert`.
2. The function block `Convert` performs the type conversion from `ULINT` to `INT`.
3. After successful conversion, the output event `Convert.CNF` is triggered, which activates the event `AI_OUT.E1`.
4. The converted data value (`Convert.OUT`) is forwarded to `AI_OUT.D1`.

This enables seamless, event-driven conversion from AULI to AI adapters.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composition:** The function block is implemented as a composite function block, meaning it encapsulates the logic in a clear and concise block and uses a standardized conversion block.
- **Unidirectional Adapters:** Both `AULI_IN` and `AI_OUT` are unidirectional adapters that support data flow in only one direction.
- **Event-driven:** The conversion process only starts upon an incoming event, enabling efficient processing.
- **License notice:** This function block is subject to the Eclipse Public License 2.0.

State overview

Since the function block operates purely event-driven and does not store any internal states, there is no explicit state machine. It behaves like a functional transformation: Each input event triggers a conversion and an output event.

Internal flow (simplified):

- **Idle:** Waiting for an event from `AULI_IN`.

- **Processing:** Conversion is running (instant, as it is a synchronous function block).
- **Done:** Output event is sent, return to Idle.

Application scenarios

- **System integration:** Connecting components that use different data types for analog signals (e.g., a sensor provides ULINT, an actuator expects INT).
- **Adapter Cascades:** Extending protocol conversions in automation projects.
- **Data Type Conversion:** When a fieldbus or gateway module only provides ULINT values, but the control system requires INT.

Comparison with Similar Function Blocks

Function Block	Input Type	Output Type	Description
`AULI_TO_AI`	AULI (ULINT)	AI (INT)	Converts entire adapter interfaces.
`F_ULINT_TO_INT`	ULINT	INT	Data conversion only, no adapters.
`AI_TO_AULI` (if applicable)	AI (INT)	AULI (ULINT)	Reverse direction (not available).

The key difference compared to pure data conversion blocks lies in the adapter input/output, which enables complete interface conversion.

Conclusion

The `AULI_TO_AI` block offers an elegant and standardized way to perform adapter-specific type conversions between ULINT and INT-based analog interfaces. Encapsulating the conversion logic in a composite function block increases reusability and clarity. It is particularly well-suited for modular automation architectures where different protocols or data types interact.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AI_TO_AUS

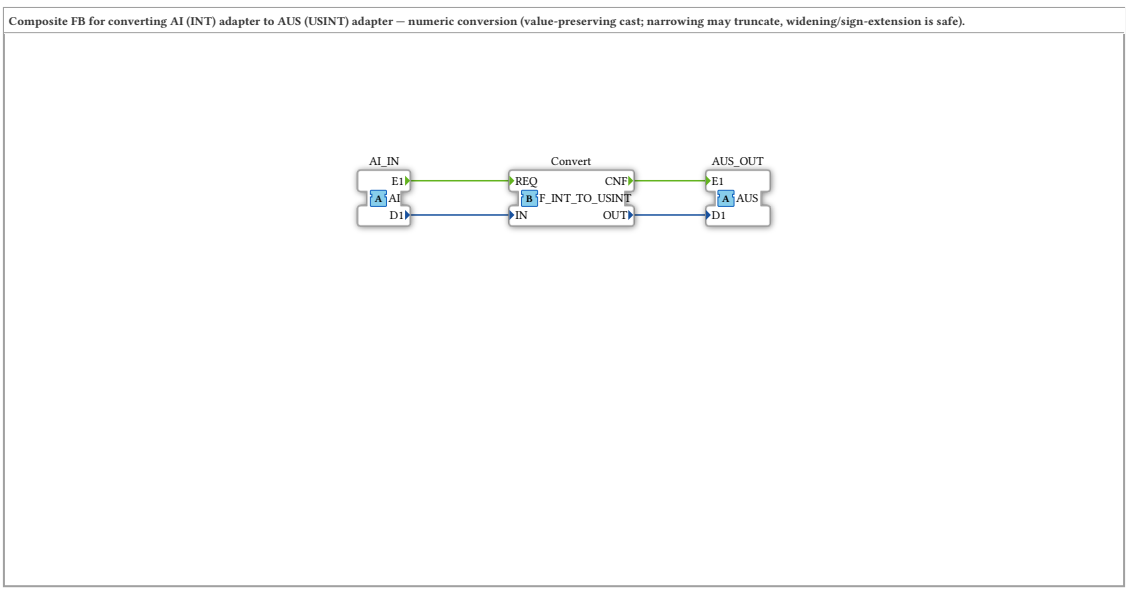

Image of the function block – not included in the XML, therefore no automatically generated image is available.

• – ◦ • – ◦ • – ◦ •

Introduction

The **AI_TO_AUS** function block is a composite function block that converts an **AI adapter** (data stream of type `INT`) into an **AUS adapter** (data stream of type `USINT`). It serves as a bridge between components that use different data types for analog input and output signals. The implementation uses the internal function block `F_INT_TO_USINT` from the `iec61131::conversion` library.

Interface Structure

The function block does not have its own separate event or data ports, but communicates exclusively via adapters.

Event Inputs

- No direct event inputs. Event control is handled indirectly via the `AI_IN` adapter (socket) – this is where the event `E1` is received.

Event Outputs

- No direct event outputs. The converted event is output as `E1` via the `AUS_OUT` adapter (plug).

Data Inputs

- No direct data inputs. The data value to be converted (`INT`) is obtained as `D1` via the `AI_IN` adapter (socket).

Data Outputs

- No direct data outputs. The converted value (`USINT`) is provided as `D1` via the adapter `AUS_OUT` (Plug).

Adapters

- **`AI_IN`** (Socket)

Type: `adapter::types::unidirectional::AI`
Description: Accepts a `INT` value and an associated event.

- **`AUS_OUT`** (Plug)

Type: `adapter::types::unidirectional::AUS`
Description: Outputs the converted `USINT` value along with an event.

Functionality

1. An incoming event at the adapter `AI_IN.E1` triggers the internal function block `Convert` (`F_INT_TO_USINT`) via its event input `REQ`.
2. Simultaneously, the data value `AI_IN.D1` (type `INT`) is passed to the input `IN` of the conversion block.
3. The block `F_INT_TO_USINT` performs the type conversion from `INT` to `USINT`.
4. After the conversion is complete, `Convert` sends an acknowledgment event (`CNF`) to the output adapter, and the converted value (`OUT`) is forwarded to `AUS_OUT.D1`.
5. The event `AUS_OUT.E1` signals to the subsequent component that a new data value is available at the adapter.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Library Used:** The function block uses the IEC 61131 standard function block `F_INT_TO_USINT`, which implements a typical conversion with possible range limitation or overflow behavior.
- **Adapter Encapsulation:** The composite block abstracts the conversion at the adapter level, so only the two matching adapters need to be connected in the network configuration.
- **Data Range Conflict:** `INT` encompasses values from −32,768 to +32,767, while `USINT` can only represent 0…255. For input values outside the USINT range, the behavior depends on `F_INT_TO_USINT` (e.g.,

saturation to 0 or 255, or modular overflow). The exact mapping rule must be verified in the specific target system.

State Overview

Since the block consists exclusively of sequential data processing (repeated conversion with each event), it does not have its own state machines. The states of the internal block `F_INT_TO_USINT` are not visible to the function; the composite block operates event-driven and without internal state storage.

Application Scenarios

- **Sensor-Actuator Coupling:** A sensor provides measured values as `INT` (e.g., temperature −10…50 °C scaled to integers), while a downstream actuator expects a control variable as `USINT` (e.g., 0…100%). The block handles the necessary type conversion.
- **Adapter Compatibility:** In a 4diac application, two modules are defined via different adapters (`AI` and `AUS`). The Composite Function Block (FB) enables direct connection without additional conversion logic in the main network.

Comparison with Similar Function Blocks

- **Direct Converters (`F_INT_TO_USINT`):** Provides pure type conversion at the data level but requires separate event and data connections. `AI_TO_AUS` extends this with adapter connectivity, thus simplifying network design.
- **Other Adapter Converters (`AI_TO_...`, `..._TO_AUS`):** Depending on the required adapter types, corresponding Composite Function Blocks are conceivable. `AI_TO_AUS` covers the specific combination `INT` ⟶ `USINT`.

Conclusion

The **AI_TO_AUS** function block is a compact composite module for easy adapter conversion from `INT` to `USINT`. It encapsulates the IEC 61131 converter and provides data and event flows via standardized adapters. This significantly simplifies the integration of components with different analog interfaces into 4diac applications. When using this module, potential data type overflow should be considered.

AUS_TO_AI

USINT Adapter Input – *AUS*

AI – INT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The function block `AUS_TO_AI` is a composite block that converts a `AUS` adapter (USINT-based) into a `AI` adapter (INT-based). It serves as a unidirectional interface between system components that use different data types for analog inputs. The block encapsulates the conversion logic and facilitates the integration of components based on `USINT` adapters into environments that expect `INT` adapters.

Interface Structure

The function block has **no direct event or data inputs or outputs**. All signal communication is handled via the two built-in adapters:

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Adapter	Direction	Type	Description
`AUS_IN`	Socket	`adapter::types::unidirectional::AUS`	USINT-based adapter input (source of the value to be converted)
`AI_OUT`	Plug	`adapter::types::unidirectional::AI`	INT-based adapter output (destination of the converted value)

The socket `AUS_IN` receives an event signal and a USINT data value. After conversion, the plug `AI_OUT` outputs an event signal and the corresponding INT value.

Functionality

The function block operates purely combinatorially based on an internal instance of the IEC 61131 function block `F_USINT_TO_INT`. Sequence control is implemented via the adapters' event connections:

1. **Event E1 on the OFF_IN adapter** is routed to the **REQ input** of the conversion block `Convert`.
2. The conversion block converts the USINT value at its **IN** input into an INT value and signals completion with the **CNF** event.
3. The **CNF** event is passed to the **E1 input of the AI_OUT adapter**, and simultaneously, the converted INT value is output to the **D1 data output** of the AI_OUT adapter.

This creates a causal chain: An incoming event at the AUS_IN adapter triggers the conversion and results in the output of a corresponding event and the converted data value at the AI_OUT adapter.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Pure Adapter Coupling** – The block does not have its own input/output variables but only defines adapter interfaces (socket/plug). This follows the concept of adapter-based communication in IEC 61499.
- **Unidirectional Conversion** – The direction is fixed: from USINT to INT. Reverse conversion is not supported.
- **Use of a Standard IEC 61131 Function Block** – The actual type conversion is performed by the established function block `F_USINT_TO_INT`, which is already available in many runtime environments.
- **No Internal State** – The composite function block is stateless; the conversion is triggered anew with each incoming event.

State Overview

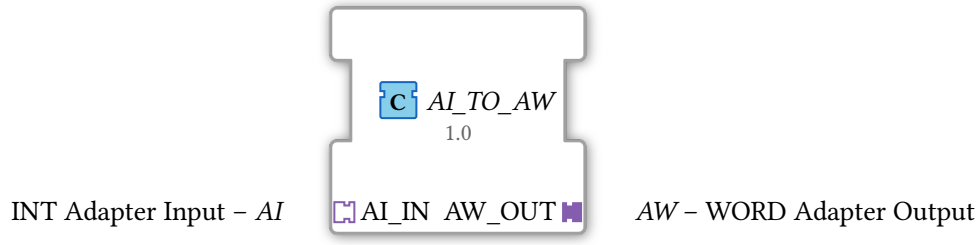
Since the function block does not have its own state machine, only the implicit states of the embedded `F_USINT_TO_INT` exist. In practice, the function block behaves like a **combinatorial function**: After an event is received, the output signal is available for the next execution cycle. No defined error state exists – the conversion is performed according to the IEC component specification.

Application Scenarios

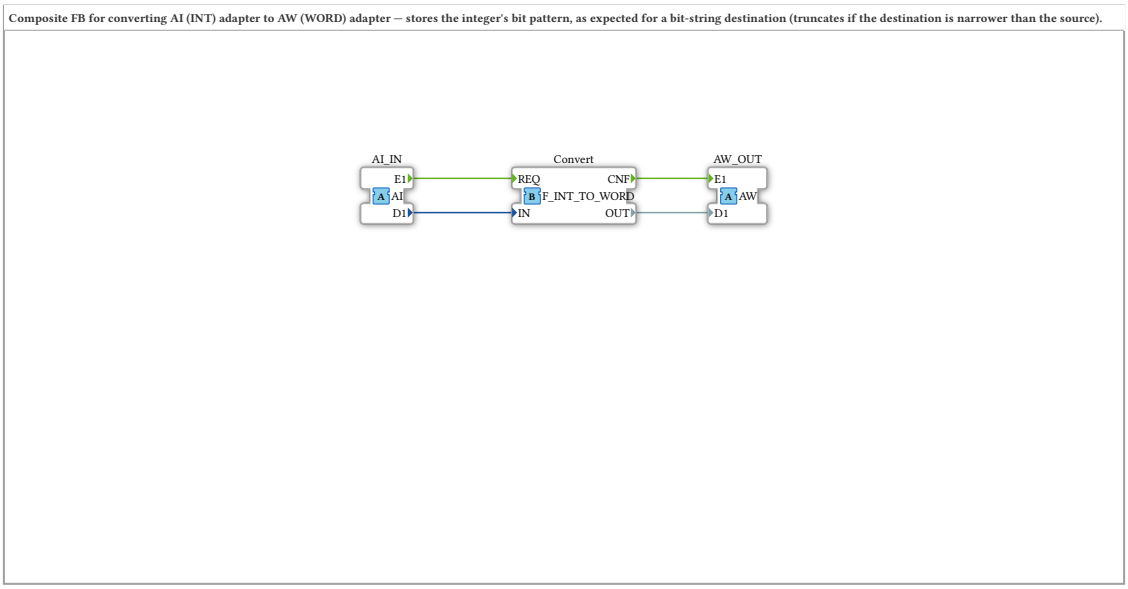
- **Migration from USINT-based hardware to INT-based controllers** – A system that originally operates with 8-bit values (USINT) can be connected via this adapter to components that expect 16-bit analog values (INT).
- **Coupling of different subsystems** – In a modular plant, a sensor adapter uses USINT, while the higher-level control unit provides INT interfaces.
- **Prototypes and test environments** – Rapid integration of components with different data types without separate conversion logic at the application level.

Comparison with Similar Function Blocks

- **Direct Conversion Function Blocks** – Function blocks like `F_USINT_TO_INT` or `F_INT_TO_USINT` offer pure type conversion but require manual wiring of events and data. `AUS_TO_AI` encapsulates this in an adapter-to-adapter concept, simplifying integration into adapter-based architectures.
- **Other Adapter Converters** – Symmetrical function blocks like `AI_TO_AUS` (INT to USINT) or bidirectional variants are conceivable. `AUS_TO_AI` is specifically designed for the unidirectional conversion from `AUS` to `AI`.



Conclusion



The `AUS_TO_AI` composite module offers a clean, adapter-based solution for converting a USINT value to an INT value. By encapsulating the standard `F_USINT_TO_INT` module and providing clear event/data flow control, it is ideally suited for integrating heterogeneous components into IEC 61499 systems. The module requires minimal maintenance, is stateless, and adheres to established adapter interface conventions.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AI_TO_AW

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AI_TO_AW** is a composite module for converting an INT adapter (AI) to a WORD adapter (AW). It is used to convert the interface of an AI adapter (type INT) to an AW adapter (type WORD) so that data and events can be seamlessly transferred between different adapter types.

Interface Structure

Event Inputs

- **AI_IN.E1** (via Socket AI_IN): Event input that triggers the conversion process.

Event Outputs

- **AW_OUT.E1** (via Plug AW_OUT): Event output that is activated after successful conversion.

Data Inputs

- **AI_IN.D1** (via Socket AI_IN): Data input of type **INT**, providing the value to be converted.

Data Outputs

- **AW_OUT.D1** (via Plug AW_OUT): Data output of type **WORD**, providing the converted result.

Adapters

- **AI_IN** (Socket): Expects an adapter of type `adapter::types::unidirectional::AI` (INT-based).
- **AW_OUT** (Plug): Provides an adapter of type `adapter::types::unidirectional::AW` (WORD-based).

Functionality

The function block operates as an encapsulation of a simple type conversion function block (`F_INT_TO_WORD`) within a composite structure. The process is as follows:

1. An event at input **AI_IN.E1** is forwarded to the internal function block `F_INT_TO_WORD`.

2. Simultaneously, the value of **AI_IN.D1** (INT) is passed to input `IN` of the conversion block.
3. The internal function block performs the conversion from INT to WORD and places the result at its output `OUT`.
4. After the conversion is complete, the event **AW_OUT.E1** is sent, and the converted value (WORD) is output to **AW_OUT.D1**.

Thus, the entire adapter conversion is controlled by a single event, and the data is converted automatically.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Block**: The logic is implemented by an internal sub-block, allowing for a clear separation of conversion logic and interface adapters.
- **Reusability**: The block is based on the standard block `iec61131::conversion::F_INT_TO_WORD` and can therefore be used in any IEC 61499-compliant environment.
- **License**: The block is released under the Eclipse Public License 2.0 (EPL-2.0).
- **Naming Scheme**: The block is located in the package `adapter::conversion::unidirectional`, indicating its function as a unidirectional adapter conversion.

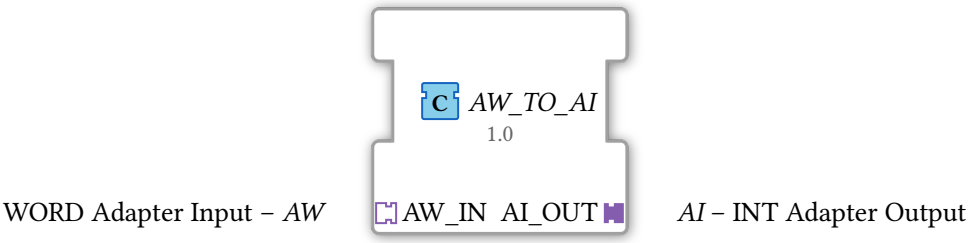
State Overview

Since this is a composite block without its own state machine, the state behavior is entirely determined by the internal `F_INT_TO_WORD` block. There are essentially two states:

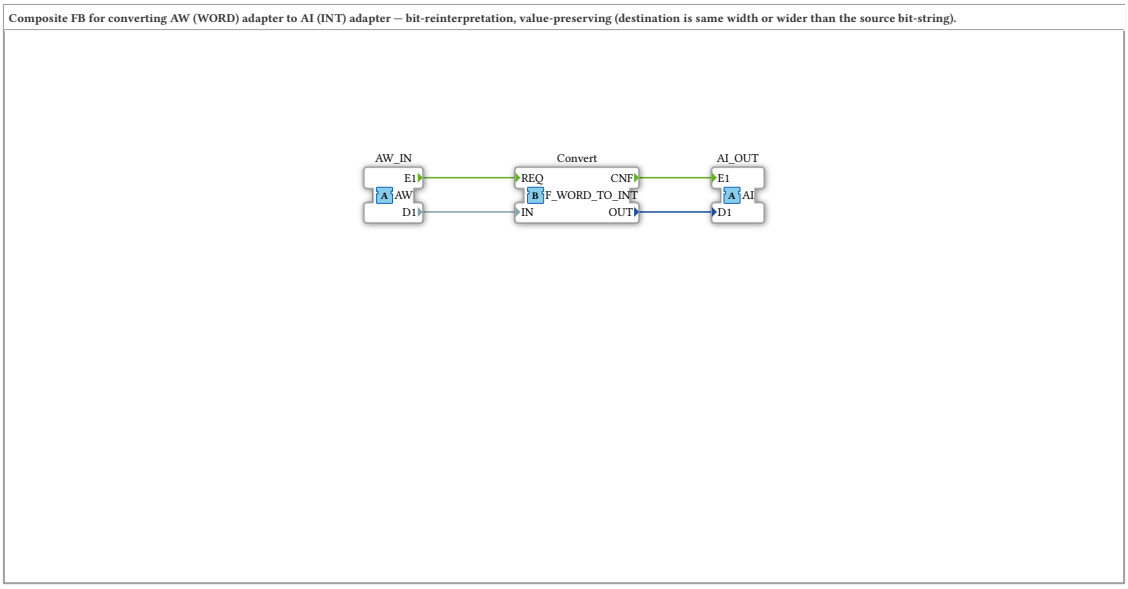
- **Idle**: Waiting for an event at input **AI_IN.E1**.
- **Converting**: After receiving the event, the conversion is performed. No delays or waiting times are implemented – the output occurs immediately in the same cycle.

Application Scenarios

- **System Integration**: When a subsystem or component provides data via an INT adapter (AI), but the target component expects a WORD adapter (AW).
- **Protocol Adaptation**: In plant control systems where sensor data is delivered as INT, but the communication interface is WORD-based.
- **Type Conversion in Adapter Chains**: The function block can be used as part of an adapter chain to connect different adapter types without requiring manual conversion.



Comparison with Similar Function Blocks



Other adapter conversion blocks exist, such as `WORD_TO_INT` or `REAL_TO_DINT` – however, `AI_TO_AW` focuses specifically on the adapter conversion from INT (AI) to WORD (AW). Unlike simple type conversion blocks (e.g., `F_INT_TO_WORD`), this block integrates the adapter interfaces directly, eliminating the need for the developer to create separate adapter instantiations.

Conclusion

The **AI_TO_AW** function block offers a simple and robust solution for converting an INT adapter to a WORD adapter. Its composite structure keeps the logic manageable and extensible. The component is particularly suitable for scenarios in which different adapter types need to be harmonized in an IEC 61499 application, and significantly reduces the implementation effort for such conversions.

AW_TO_AI

• — ○ • — ○ • — ○ •

Introduction

The **AW_TO_AI** function block is a composite function block that converts a unidirectional **WORD adapter (AW)** to a unidirectional **INT adapter (AI)**. It encapsulates the type conversion from 16-bit word values to integer values, thus enabling the seamless integration of components that use different adapter types.

Interface Structure

Event Inputs

The following events are received via the connected AW socket:

Name	Description
E1 (AW_IN.E1)	Trigger for converting the incoming WORD value

Event Outputs

The following events are sent via the AI plug:

Name	Description
E1 (AI_OUT.E1)	Confirms successful conversion and provides the INT value

Data Inputs

Input via the AW socket:

Name	Data Type	Description
D1 (AW_IN.D1)	WORD	The 16-bit word value to be converted

Data Outputs

Output via the AI plug:

Name	Data Type	Description
D1 (AI_OUT.D1)	INT	The converted integer value (16-bit signed)

Adapter

Direction	Adapter	Type	Description

Socket (Input)	AW_IN	adapter::types::unidirectional::AW	Receives WORD values and associated events
Plug (Output)	AI_OUT	adapter::types::unidirectional::AI	Sends INT values and associated events

Functionality

The function block contains an instance of the standard conversion block `F_WORD_TO_INT` from the IEC 61131 library. The internal network is wired as follows:

1. An incoming event **AW_IN.E1** triggers the input `REQ` of the conversion block.
2. Simultaneously, the data value **AW_IN.D1** is set to the input `IN` of the block.
3. The block converts the WORD value to an INT value and outputs it at its output `OUT`.
4. The acknowledgment event `CNF` generated by the block is forwarded directly to **AI_OUT.E1**.
5. The converted integer value (output `OUT`) is written to **AI_OUT.D1**.

All processing is strictly event-driven: Conversion only occurs when a new event is received at the input.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Pure Data Conversion:** No states are stored, nor is any additional logic executed.
- **Standard Library:** The `F_WORD_TO_INT` used is an established conversion module and ensures a correct mapping of the WORD value (0…65535) to the INT value (-32768…32767).
- **Unidirectional:** Both the input and output adapters are unidirectional, meaning they transmit event and data flows in only one direction (input → output).
- **No data loss due to type conversion:** The bit width remains identical (16 bits); only the interpretation as unsigned (WORD) or signed (INT) changes.

State Overview

The FB is a **Composite FB** and does not have its own state machine (ECC). Its behavior is entirely determined by the wiring of the internal block. Only the following implicit states exist:

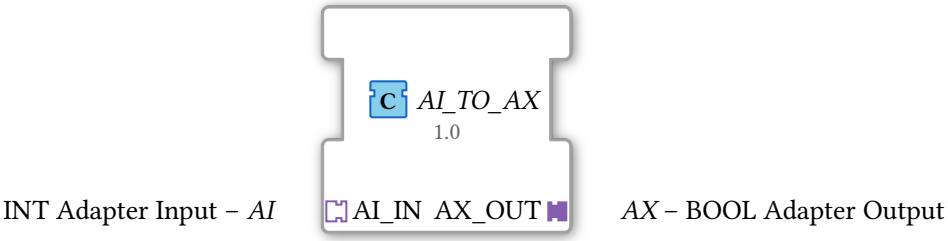
- **Idle:** Waiting for an event at the input.
- **Conversion active:** From the receipt of `AW_IN.E1` until the arrival of `Convert.CNF`.

Application Scenarios

- **Adapter conversion in heterogeneous systems:** A control module operates with INT values, but a connected sensor delivers WORD data via an AW adapter.
- **Library Integration:** Existing function blocks that only accept an AI adapter should be connected to components that provide an AW adapter.
- **Prototype Systems:** Rapid coupling of different function blocks during development without changing the underlying adapter definitions.

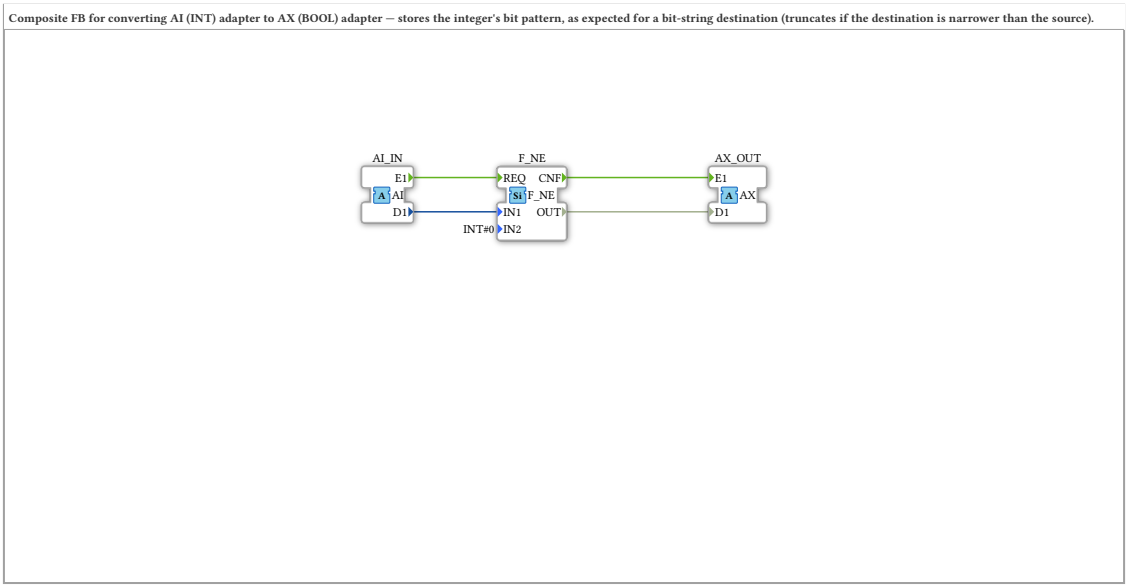
Comparison with Similar Function Blocks

- **AW_TO_AI** converts **WORD → INT** (unidirectionally).
- Comparable converters from the same library (`iec61131::conversion`) cover other type conversions, e.g., `F_INT_TO_WORD` or `F_WORD_TO_DINT`. These are available as traditional function blocks without adapters.
- If bidirectional conversion or other adapter types are required, similar composite function blocks with corresponding conversion blocks are conceivable (e.g., `AI_TO_AW`).



Conclusion

The composite function block **AW_TO_AI** provides a simple and reliable way to convert a unidirectional WORD adapter into an INT adapter. By using the IEC 61131 standard function block, the conversion remains transparent and efficient. The function block is particularly useful when different adapter types need to be harmonized within a system without modifying the original components.



Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AI_TO_AX

INT Adapter Input – *AI* — *AX* – BOOL Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block `AI_TO_AX` is a composite function block (type adapter) that converts a unidirectional interface of an INT adapter (`AI`) into a corresponding BOOL interface of an adapter (`AX`). It is used to convert analog integer signals (e.g., from sensors) into binary Boolean values, which can be used, for example, for switching signals or alarm messages.

Interface Structure

The function block only has adapter connections (socket and plug) through which events and data flow. The following table summarizes the logical inputs/outputs resulting from the connected adapters.

Event Inputs

Label	Data Type	Description
`AI_IN.E1`	EVENT	Input event that triggers the conversion.

Event Outputs

Label	Data Type	Description
`AX_OUT.E1`	EVENT	Output event that is sent after the conversion is complete.

Data Inputs

Label	Data Type	Description

AI_IN.D1	INT	Analog integer input value (e.g., 0…32767).

Data Outputs

Label	Data Type	Description
AX_OUT.D1	BOOL	Boolean output value: TRUE if the input value is not equal to 0, otherwise FALSE.

Adapter

| Type | Name | Direction | | |—–|—–|—–| | AI (Input Adapter) | AI_IN | Socket | | AX (Output Adapter) | AX_OUT | Plug |

Functionality

The module internally uses the IEC 61131 comparison module F_NE (Not Equal). As soon as an event arrives at the event input AI_IN.E1, F_NE.REQ is triggered. This compares the INT value received via AI_IN.D1 with the constant value INT#0.

- If the input value is **not equal to 0**, F_NE.OUT returns the value TRUE.
- If the input value is **equal to 0**, F_NE.OUT returns the value FALSE.

The result is passed to the data output AX_OUT.D1, and simultaneously the event AX_OUT.E1 is triggered to notify downstream components.

```
If the input value is **equal to 0**, thenF_NE.OUTreturns the valueFALSE`.
```

Technical Features

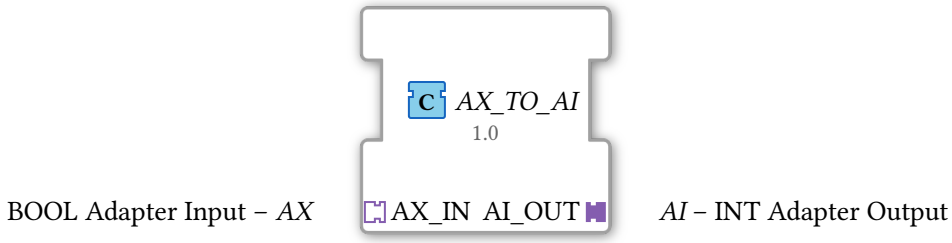
- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Block:** The AI_TO_AX consists of interconnected basic blocks, allowing it to be used as a reusable component in various projects.
- **Use of IEC 61131 Blocks:** The comparison logic is implemented using the standardized block F_NE, which supports portability and compliance with the standard.
- **No Independent State:** The block is stateless – each event pulse generates an immediate calculation without storing intermediate values.

State Overview

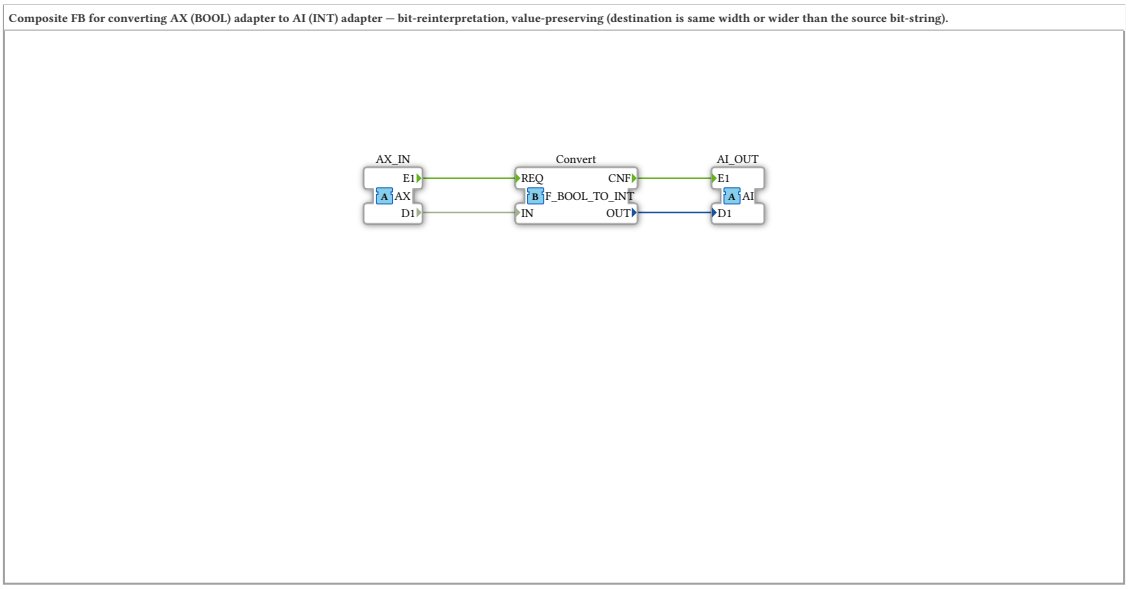
The block does not have an explicit finite state machine. The internal logic is purely combinatorial: Upon the arrival of an event, the data is processed immediately and the result is output.

Application Scenarios

- **Analog-to-Digital Conversion at the Signal Level:** An analog measured value (e.g., pressure sensor, temperature sensor) is converted into an "on/off" signal – e.g., activating a pump when a pressure threshold is exceeded.
- **Threshold Decision:** The function block can be used for simple non-zero detection, e.g., to signal the presence of a signal or an activated counter reading.
- **Adapter Coupling:** In systems that use different adapter interfaces, AI_TO_AX enables seamless connectivity between INT- and BOOL-based components.



Comparison with Similar Function Blocks



- **Direct Comparison Function Blocks (e.g., F_EQ, F_GT):** These provide Boolean results for arbitrary comparisons but require two inputs and are not designed as adapter converters.
- **Custom Adapter Wrappers:** Developers could create their own encapsulation; however, the AI_TO_AX offers a standardized, ready-to-use solution with reduced development effort.
- **Non-Event-Driven Type Converters:** Some converters operate continuously without event triggers; the AI_TO_AX, on the other hand, only responds to events and is therefore better integrated into event-driven architectures.

Conclusion

The `AI_TO_AX` is a convenient composite component that simplifies the conversion of INT adapter signals to BOOL adapter signals. It is ideal for applications where analog measurements need to be interpreted as binary states and, thanks to its event-driven processing, integrates seamlessly into IEC 61499-based automation systems.

AX_TO_AI

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_TO_AI** is a composite function block that converts a BOOL adapter (AX) into an INT adapter (AI). It serves as a bridge between interfaces that process Boolean signals (TRUE / FALSE) and those that expect integer values. The conversion is performed via an internal call to the function block `F_BOOL_TO_INT` from the IEC 61131 library.

Interface Structure

Event Inputs

No direct event inputs. The function block's event input is implemented via socket `AX_IN` (E1).

Event Outputs

No direct event outputs. The event output of the function block is implemented via the plug `AI_OUT` (E1).

Data Inputs

No direct data inputs. The data input of the function block is implemented via the socket `AX_IN` (D1) (BOOL).

Data Outputs

No direct data outputs. The data output of the function block is implemented via the plug `AI_OUT` (D1) (INT).

Adapters

Direction	Name	Type (Adapter)	Explanation
Socket	AX_IN	AX	Boolean Input Adapter (BOOL)
Plug	AI_OUT	AI	Integer Output Adapter (INT)

The adapter AX provides an event input E1 and a data input D1 (BOOL).
The adapter AI provides an event output E1 and a data output D1 (INT).

Functionality

This function block operates as a so-called *Composite FB*, meaning it internally uses another function block to implement its logic.

- A BOOL signal is received at socket AX_IN via the data input D1.
- An incoming event at AX_IN.E1 triggers the internal function block Convert (type: F_BOOL_TO_INT) via its input REQ.
- The function block F_BOOL_TO_INT converts the BOOL value at input IN into an INT value (0 for FALSE, 1 for TRUE).
- The result is provided at output OUT and forwarded to plug AI_OUT.D1.
- After the conversion is complete, the internal block sends an acknowledgment event (CNF), which is output via AI_OUT.E1.

Processing is strictly sequential: first, the Boolean input is processed, then the integer output is provided.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Adapter-based communication:** The block uses only adapter interfaces (socket and plug) and no traditional input/output ports. This enables loose coupling between components and easy reuse in different environments.
- **Unidirectional Data Exchange:** The adapters used, AX and AI, are defined as unidirectional types, meaning data flows only in one direction – from the socket to the plug.
- **External Library:** For conversion, the function block F_BOOL_TO_INT is imported from the library iec61131::conversion. This eliminates the need to implement custom conversion logic.
- **No Internal State Machine:** Because this is a composite function block, it does not have its own Execution Control Chart (ECC). The state logic is fully implemented by the internal function block.

State Overview

The function block does not have its own state machine. Execution is event-driven:

1. **Wait:** The function block waits for an event at socket AX_IN.
2. **Convert:** Upon receiving an event, the internal function block F_BOOL_TO_INT is executed, and the result is passed to plug AI_OUT.
3. **Completed:** An acknowledgment event is sent via AI_OUT.E1; the function block returns to the wait state.

This behavior is implicitly controlled by the event cabling in the network.

Application Scenarios

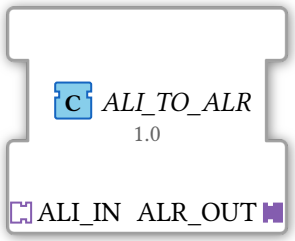
- **Signal Conversion in Automation Technology:** If a sensor or controller delivers Boolean values (e.g., “door open/closed”), but a downstream module expects integer values (0/1), this function block can handle the conversion.
- **Adapter Integration:** It serves as a converter between different adapter types to connect components from different manufacturers or libraries.
- **Protocol Adaptation:** In heterogeneous systems, Boolean signals can be converted into standardized integer formats using this function block.

Comparison with Similar Function Blocks

Function Block	Function	Difference from AX_TO_AI
`DI_TO_AI`	Converts digital input to INT adapter	Requires separate input/output ports; no adapter interface
`AX_TO_DINT`	BOOL adapter ⟶ DINT adapter	Returns a 32-bit integer; 16-bit INT is used here
`F_BOOL_TO_INT`	Standard conversion (BOOL⟶INT)	No adapter wrapper; available only as an internal block

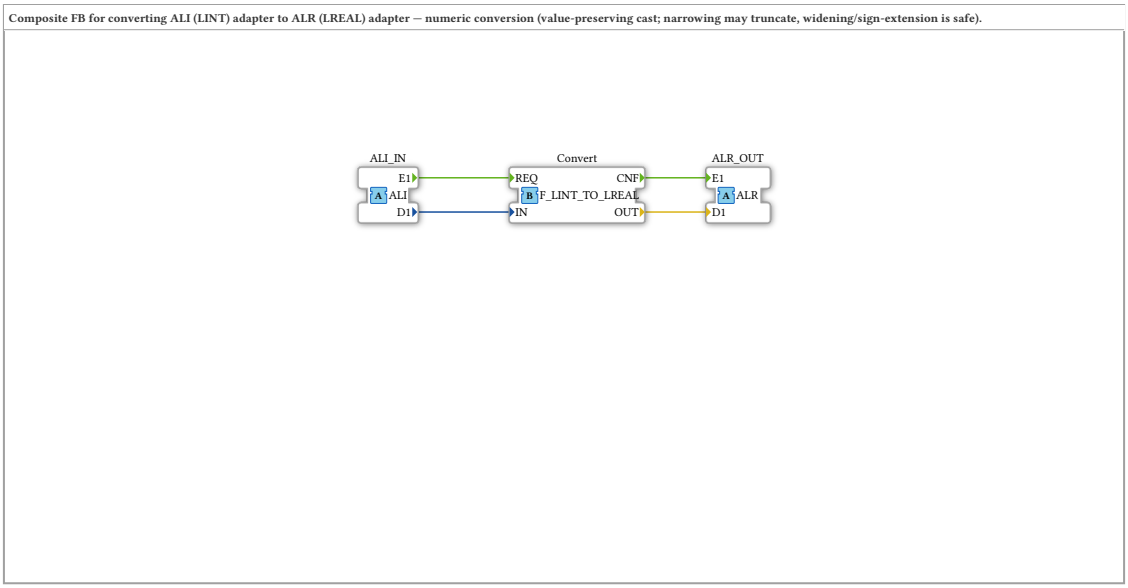
Unlike these alternatives, AX_TO_AI offers an addressable, event-driven adapter interface and facilitates modular interconnection in IEC 61499 projects.

Conclusion



The `AX_TO_AI` function block provides a simple yet effective solution for converting Boolean adapter signals to integer adapter signals. It encapsulates the logic in a reusable composite block, utilizes standard libraries, and enables clean, adapter-based communication. This block is particularly well-suited for modular automation solutions where different interface types need to be coordinated.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALI_TO_ALR

LINT Adapter Input – *ALI*

ALR – LREAL Adapter Output

(Image not available)

• – ○ • – ○ • – ○ •

Introduction

The function block **ALI_TO_ALR** is a composite function block that converts an **ALI adapter** (LINT data type) to an **ALR adapter** (LREAL data type). It acts as a bridge between different adapter interfaces and enables seamless data conversion from 64-bit integers to 64-bit floating-point numbers.

Interface Structure

Event Inputs

The function block does not have separate event inputs. Event-driven processing is handled via the **socket** `ALI_IN`, whose event `E1` triggers the conversion.

Event Outputs

There are no standalone event outputs. The result event is output via the **plug** `ALR_OUT` to its event `E1`.

Data Inputs

The FB has no direct data inputs. The LINT data to be converted is provided via the **socket** `ALI_IN` (data point `D1`).

Data Outputs

Similarly, there are no separate data outputs. The converted LREAL value is output via the **plug** `ALR_OUT` (data point `D1`).

Adapters

Type	Name	Direction	Description
Socket	`ALI_IN`	Input	Adapter type `adapter::types::unidirectional::ALI` (LINT)
Plug	`ALR_OUT`	Output	Adapter type `adapter::types::unidirectional::ALR` (LREAL)

Functionality

The function block operates as a simple forwarder and converter:

1. An event at **Socket** `ALI_IN.E1` triggers the internal function block `Convert` (type `F_LINT_TO_LREAL`).
2. Simultaneously, the LINT value from `ALI_IN.D1` is passed to input `Convert.IN`.
3. The conversion block `Convert` converts the value into an LREAL value according to IEC 61131 conversion logic.
4. After the conversion is complete, `Convert` generates the event `CNF`, which is forwarded to the **plug** `ALR_OUT.E1`.
5. At the same time, the converted LREAL value from `Convert.OUT` is passed to `ALR_OUT.D1`.

The entire process is event-driven and does not use its own state logic.
...

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block**: The logic is implemented exclusively through the interconnection of the standardized conversion block `F_LINT_TO_LREAL` – no proprietary algorithm.
- **Adapter-Oriented Interface**: The function block (FB) completely encapsulates the conversion within the adapter interfaces, allowing it to be used in environments with uniform adapter types (unidirectional).
- **No State Machine**: Due to its pure data flow structure, there is no internal state machine.

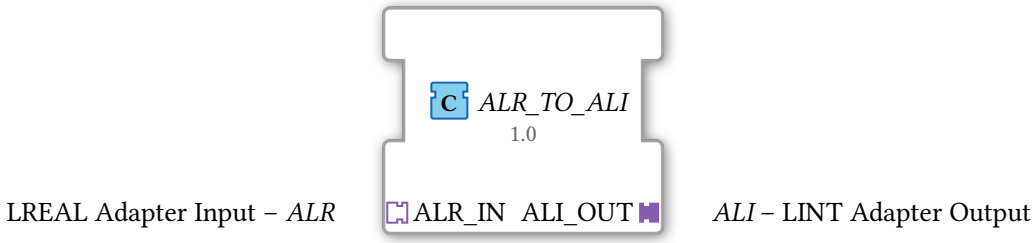
State Overview

The FB does not have its own state machine. Execution follows the event chain of the internal network exclusively:

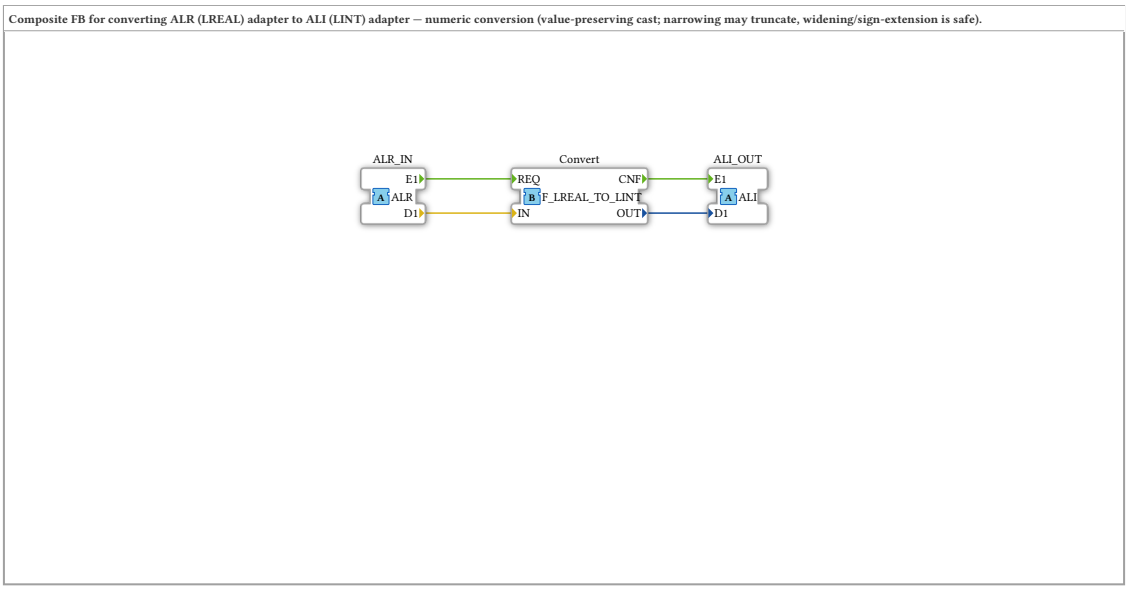
- Idle ⟶ Event sent to `ALI_IN.E1` ⟶ Conversion in progress ⟶ Result event sent to `ALR_OUT.E1` ⟶ Returns to Idle.

Application Scenarios

- Integration of components that provide LINT values (e.g., counters, position sensors) into systems that expect LREAL (e.g., control algorithms with floating-point calculations).
- Conversion from integer-based to floating-point-based adapter interfaces without changing the higher-level architecture.
- Intermediate layer in modular control projects where different data types need to be connected.



Comparison with Similar Components



The library contains analogous converters for other data types (e.g., `LINT_TO_REAL`, `DINT_TO_REAL`). `ALI_TO_ALR` is the adapter-specific variant that integrates the conversion into the standardized unidirectional adapters `ALI` and `ALR`. It allows for easy exchange between different adapter types without the calling environment needing to know the details of the conversion.

Conclusion

The FB `ALI_TO_ALR` offers a clean, maintainable, and standards-compliant solution for converting a LINT adapter to an LREAL adapter. By using a proven IEC 61131 conversion block, the implementation remains reliable and efficient. It is particularly suitable for modular control architectures where data type and adapter compatibility is required.

ALR_TO_ALI

• – ○ • – ○ • – ○ •

Introduction

The function block **ALR_TO_ALI** is a composite block that performs an adapter conversion from **ALR (LREAL)** to **ALI (LINT)**. It enables the simple and structured integration of an LREAL-based adapter interface into a LINT-based environment without requiring the implementation of the conversion logic itself. The block is designed for use in IEC 61499-based industrial controllers and utilizes the internal function block `F_LREAL_TO_LINT` according to IEC 61131-3.

Interface Structure

Event Inputs

The function block does not have explicit event inputs. The triggering event is provided via the incoming adapter **ALR_IN** (type `adapter::types::unidirectional::ALR`):

- **ALR_IN.E1** – Input event that starts the conversion.

Event Outputs

The function block (FB) does not have any explicit event outputs. The confirmation event is provided via the outgoing adapter **ALI_OUT** (type `adapter::types::unidirectional::ALI`):

- **ALI_OUT.E1** – Output event that signals the completion of the conversion.

Data Inputs

The FB does not have an explicit data input. The input value is provided via the adapter **ALR_IN**:

- **ALR_IN.D1** – Value of type LREAL to be converted to LINT.

Data Outputs

The FB does not have an explicit data output. The result is output via the **ALI_OUT** adapter:

- **ALI_OUT.D1** – converted value of type LINT.

Adapter

Direction	Name	Type	Description
Socket (Input)	ALR_IN	`adapter::types::unidirectional::ALR`	Unidirectional adapter for LREAL data and events. Includes event port E1 and data port D1 (LREAL).
Plug (Output)	ALI_OUT	`adapter::types::unidirectional::ALI`	Unidirectional adapter for LINT data and events. Includes event port E1 and data port D1 (LINT).

Functionality

The function block (FB) acts as a wrapper for type conversion from LREAL to LINT. The flowchart is as follows:

1. An event (E1) on the input adapter **ALR_IN** triggers the internal block **Convert** (type `iec61131::conversion::F_LREAL_TO_LINT`).
2. The data value from **ALR_IN.D1** (LREAL) is passed to the input **Convert.IN**.
3. The internal block performs the conversion and outputs the result to **Convert.OUT**.
4. The event at the output **Convert.CNF** is forwarded to **ALI_OUT.E1**, so the outgoing adapter signals that the conversion is complete.
5. The converted LINT value is available at **ALI_OUT.D1**.

Call control is achieved via event chaining (E1 → REQ → CNF → E1), ensuring that conversion occurs blocking within a single execution cycle.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Structure**: The function block is implemented as a composite (network) and internally uses the standard function block `F_LREAL_TO_LINT` from the IEC 61131-3 library.
- **Adapter Encapsulation**: The adapter technology allows the specific LREAL and LINT signals to be connected via standardized interfaces (ALR, ALI), enabling high reusability and interchangeability.
- **License**: The source code is licensed under the Eclipse Public License 2.0 (EPL-2.0).
- **Version**: 1.0, released on February 17, 2026, by HR Agrartechnik GmbH, author: Franz Höpfinger.
- **Package Structure**: `adapter::conversion::unidirectional`.

State Overview

The function block does not have an explicit state machine, as it is implemented as a network by a single internal function block. Its behavior is purely event-driven:

- **Idle**: Waiting for an event at the input adapter (ALR_IN.E1).
- **Processing**: Upon arrival of the event, the internal conversion block is activated.
- **Done**: After completion (CNF), the output event (ALI_OUT.E1) is set, and the function block returns to the idle state.

There is no explicit error state, as the conversion block `F_LREAL_TO_LINT` does not provide error handling.

Application Scenarios

- **Migration**: Replacing an ALI-based (LINT) system with an ALR-based (LREAL) system or vice versa, without changing the higher-level logic.
- **Adapter Bridge**: If a component only provides LREAL values, but the subsequent adapter expects LINT, this function block (FB) can be used as an intermediary.
- **Standardized Conversion**: In libraries or frameworks that require a uniform implementation of type conversions via adapters.

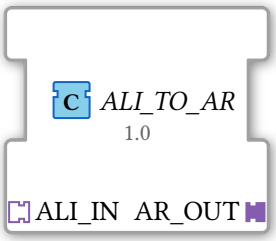
Comparison with Similar Function Blocks

In the IEC 61499 and IEC 61131 worlds, numerous conversion function blocks exist:

- **F_LREAL_TO_LINT** (direct): A single function block that converts a simple value but does not provide an adapter interface.
- **ALR_TO_ALI** (this FB): Encapsulates the direct function block in an adapter structure, enabling connection via standardized adapter ports.
- **Other Type Conversions**: Similarly structured function blocks for, e.g., REAL → DINT or LREAL → DWORD, can be created using the same pattern.

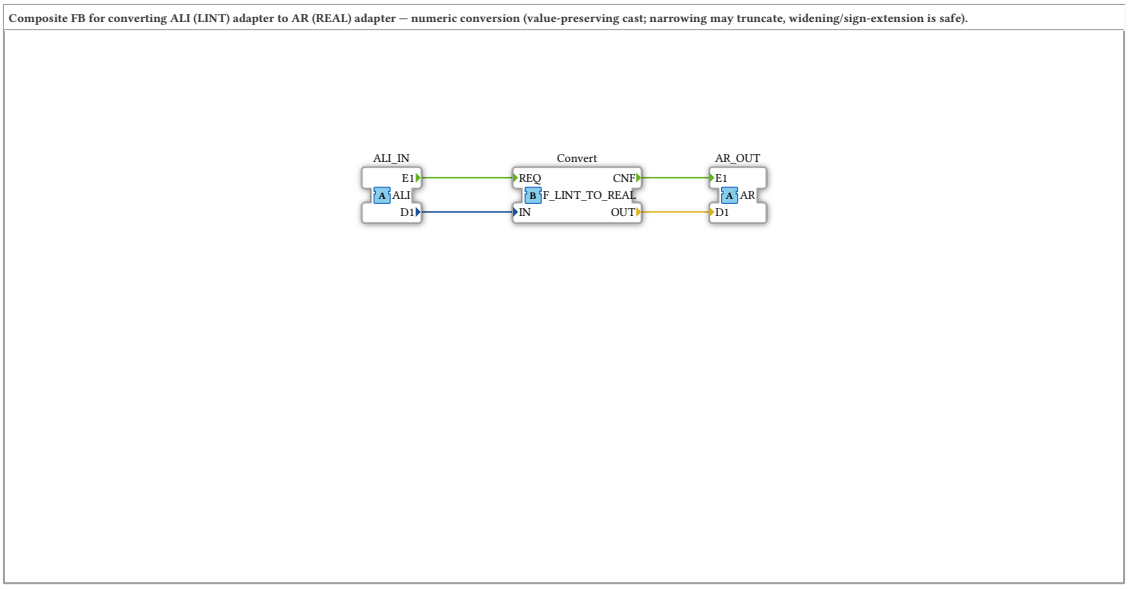
The key advantage of **ALR_TO_ALI** is its reusability within the adapter context and the clean separation of events and data.

Conclusion



The **ALR_TO_ALI** function block is a useful composite block that enables clean and standardized adapter conversion from LREAL to LINT. It inherits the robustness of the IEC 61131-3 conversion block and seamlessly integrates it into the adapter-based communication architecture. Its open license and clear interface make it well-suited for use in modular automation solutions.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALI_TO_AR

LINT Adapter Input – *ALI*

AR – REAL Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The function block **ALI_TO_AR** is a composite function block (FB) that converts a LINT adapter (ALI) into a REAL adapter (AR). It serves as a universal conversion interface to provide 64-bit integer values from the IEC 61131 standard into floating-point values for further processing in control applications. The function block is licensed under the Eclipse Public License 2.0 and is provided by HR Agrartechnik GmbH.

Interface Structure

The function block does not have direct event or data ports. All communication takes place via two predefined unidirectional adapters:

Event Inputs

– None (the event interface is provided via the **ALI_IN** adapter)

Event Outputs

– None (the event interface is provided via the **AR_OUT** adapter)

Data Inputs

– None (the data interface is provided via the **ALI_IN** adapter)

Data Outputs

– None (the data interface is provided via the **AR_OUT** adapter)

Adapter

Direction	Name	Type	Description
Socket	ALI_IN	`adapter::types::unidirectional::ALI`	LINT Input Adapter (64-bit Integer)
Plug	AR_OUT	`adapter::types::unidirectional::AR`	REAL Output Adapter (Floating Point)

Each adapter contains an event channel (E1) and a data channel (D1), which are connected via the module's internal network.

Functionality

The module performs a simple data-driven conversion:

1. An event arrives at the event input **E1** via the **ALI_IN** socket – simultaneously, the corresponding LINT value is provided at the data input **D1**.

2. This event is forwarded to the internal module `iec61131::conversion::F_LINT_TO_REAL` (event **REQ**).
3. The internal module converts the LINT value into a REAL value and signals completion via the event output **CNF**.
4. The converted REAL value is transferred via the data connection to the data input of the plug adapter **AR_OUT** (D1).
5. Simultaneously, the **E1** event of the **AR_OUT** adapter is triggered, allowing the connected logic to process the new REAL value.

The entire conversion process is performed without state storage – each request is processed immediately.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block**: The ALI_TO_AR is a composite function block consisting exclusively of the internal standard block `F_LINT_TO_REAL`.
- **Library Integration**: The conversion utilizes the IEC 61131 library `iec61131::conversion::F_LINT_TO_REAL`, which is declared as an import.
- **Package Structure**: The block is organized within the package `adapter::conversion::unidirectional`.
- **License**: The source code is licensed under the Eclipse Public License 2.0 (EPL-2.0).

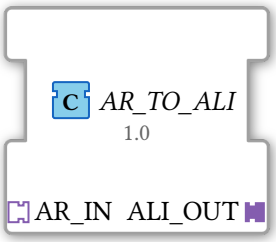
State Overview

The function block has no states of its own. It operates purely event-driven and data-flow-oriented. There are no initialization or error-related states – every incoming request is processed directly.

Application Scenarios

- **Counter Evaluation**: A LINT counter (e.g., pulse counter) delivers a large integer that must be converted into a REAL value for control purposes.
- **Data Preprocessing**: In a PLC application, measured values are available as LINT (e.g., from an encoder) that need to be converted into REAL for further calculations or visualization.
- **Adapter Bridge**: The function block serves as a standardized converter between two different adapter types in a cross-device communication infrastructure.

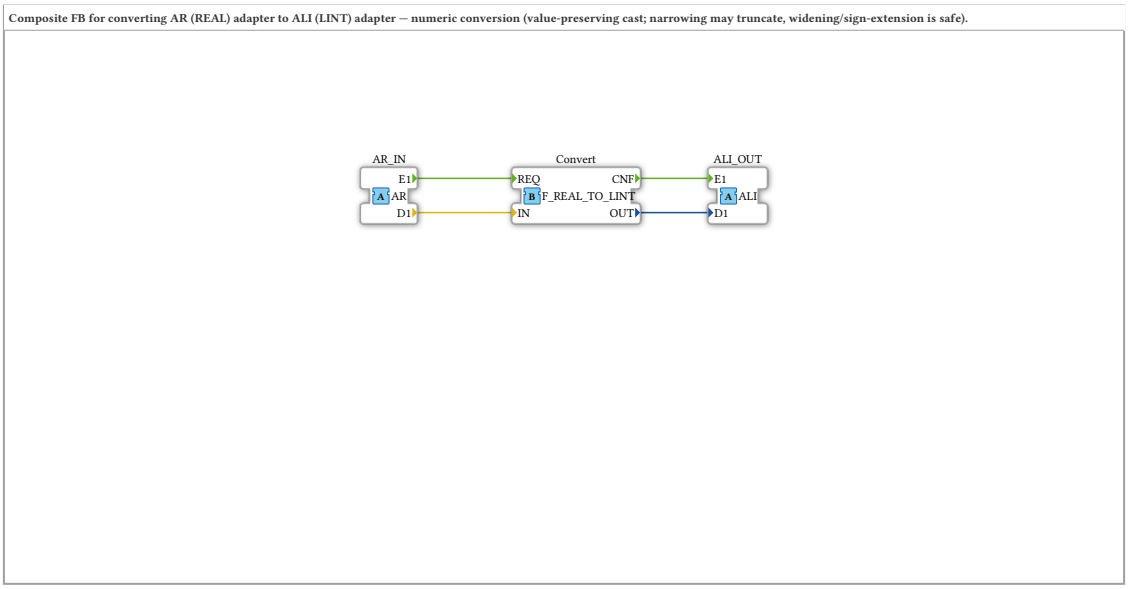
Comparison with Similar Function Blocks



- **ALI_TO_ARI**: Converts LINT to an ARRAY-from-REAL – for multiple values or buffers.
- **LREAL_TO_AR**: Converts LREAL (80-bit floating-point) to REAL – for losses due to lower precision.
- **Direct Type Conversion** to IEC 61131 functions (e.g., `LINT_TO_REAL`) – without adapter encapsulation, requires manual event wiring.

The ALI_TO_AR offers the advantage of a standardized adapter interface over simple function calls, enabling plug-and-play use in modular systems.

Conclusion



The **ALI_TO_AR** is a compact, reusable function block for converting LINT values to REAL values via an adapter interface. Its simple internal structure and clear event-data coupling make it an indispensable component for any application that needs to convert integer sensor data into floating-point values for control or visualization purposes. Licensing under EPL-2.0 allows unrestricted use in open and commercial projects.

AR_TO_ALI

REAL Adapter Input – *AR*

ALI – LINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The composite function block `AR_TO_ALI` converts a REAL adapter (`AR-IN`) into a LINT adapter (`ALI-OUT`). It enables the seamless integration of floating-point values from adapter `AR` into applications that expect 64-bit integer values via adapter `ALI`. The conversion is performed via an internal function block `F_REAL_TO_LINT` according to IEC 61131.

Interface Structure

The function block does not have any independent event or data inputs/outputs at the block level. All signal transmission occurs via adapter sockets or plugs.

Event Inputs

No dedicated event inputs. The event is received via socket `AR_IN` (interface `E1`).

Event Outputs

No dedicated event outputs. The event is sent via plug `ALI_OUT` (interface `E1`).

Data Inputs

No dedicated data inputs. Data is received via socket `AR_IN` (interface `D1`).

Data Outputs

No dedicated data outputs. The data is sent via the plug `ALI_OUT` (interface `D1`).

Adapter

Direction	Label	Type	Compatible Adapter Type	Description

Socket	AR_IN	iec61131::types::unidirectional::AR	AR Adapter (REAL)	Receiving adapter for the REAL value.
Plug	ALI_OUT	iec61131::types::unidirectional::ALI	ALI Adapter (LINT)	Providing adapter for the converted LINT value.

Functionality

The function block `iec61131::conversion::F_REAL_TO_LINT` is instantiated within the internal network. As soon as an event occurs at socket `AR_IN` (via interface `E1`), the internal conversion block is triggered using the designated event connection `AR_IN.E1 -> Convert.REQ`. Simultaneously, the data value `AR_IN.D1` is passed to input `Convert.IN`. After the conversion (REAL ⟶ LINT) is complete, the converter confirms with the event `Convert.CNF`. This event is forwarded to plug `ALI_OUT.E1`, and the converted value `Convert.OUT` is output to `ALI_OUT.D1`.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Pure Adapter Coupling**: The function block does not use direct event or data inputs, but communicates exclusively via the standardized unidirectional adapters `AR` and `ALI`. This makes it easy to integrate into existing adapter structures.
- **IEC 61131 Compliance**: The conversion block used, `F_REAL_TO_LINT`, complies with the IEC standard and ensures a standardized, deterministic conversion.
- **Runtime Behavior**: The conversion is event-driven and occurs without any additional delay. The output value is available in the same execution cycle in which the input event is received.

State Overview

The Composite FB itself does not have its own state machine. Its behavior is entirely determined by its internal circuitry. The following logical states exist:

- **Idle**: No event at the input. The output `ALI_OUT` remains unchanged.
- **Converting**: An event is received at socket `AR_IN`. The internal converter is activated, and the conversion process begins.
- **Completed**: The conversion is complete; the output event is sent, and the new data value is available at the plug.

Application Scenarios

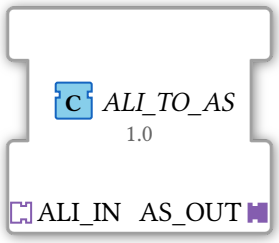
- **Sensor-Actuator Coupling**: A REAL adapter (e.g., from an analog sensor) must be connected to a control module that processes only LINT values via the ALI adapter.
- **Protocol Conversion**: In heterogeneous automation networks where data formats need to be converted to connect different adapter types.
- **Test and Simulation Environments**: Replacing an ALI adapter with a simulated REAL adapter and converting back for testing purposes.

Comparison with Similar Function Blocks

FB	Conversion	Interface	Note
`AR_TO_ALI`	REAL ⟶ LINT	AR / ALI Adapter	Specifically for Adapter Coupling
`F_REAL_TO_LINT`	REAL ⟶ LINT	Standalone I/O (REQ/CNF, IN/OUT)	Direct converter without adapters
The `AR_TO_ALI` encapsulates the `F_REAL_TO_LINT` and adds the adapter connections. The advantage lies in its simple, adapter-			

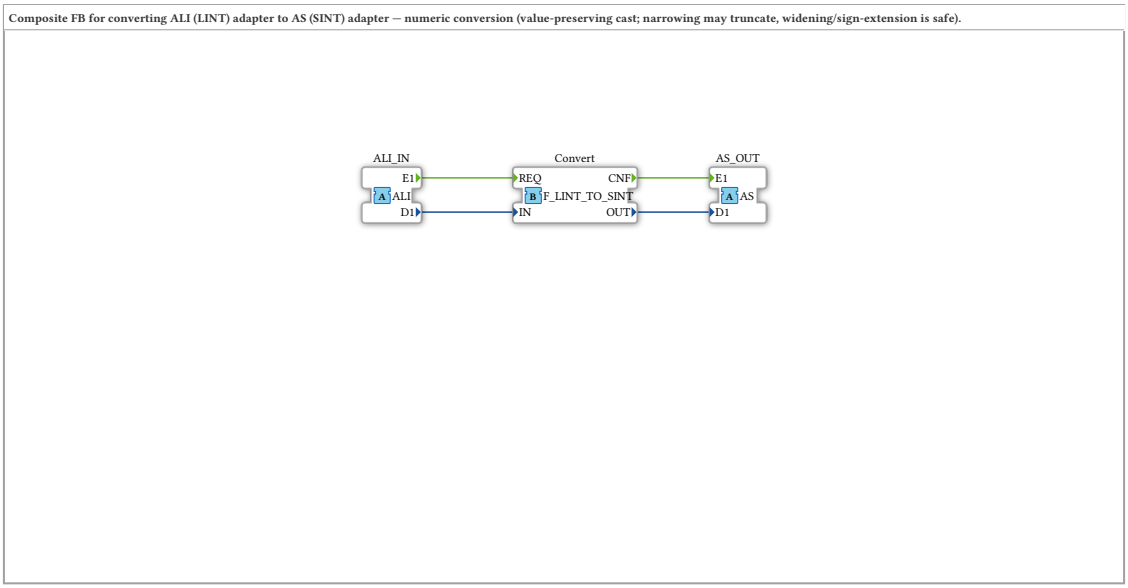
network-compatible connection. A direct converter without adapters would not be usable in adapter structures.			

Conclusion



The `AR_TO_ALI` is a compact, purpose-built composite function block that enables the conversion of REAL to LINT values via the standardized unidirectional adapters `AR` and `ALI`. Its clean encapsulation and the use of an IEC-compliant core component provide a reliable and reusable solution for industrial automation. The FB is particularly suitable for scenarios where a clean separation between data format and adapter interface is required.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALI_TO_AS

LINT Adapter Input – *ALI*

AS – SINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **ALI_TO_AS** function block is a composite function block that converts an ALI adapter (data type LINT) into an AS adapter (data type SINT). It encapsulates the conversion of a 64-bit integer value to an 8-bit integer value, thus enabling seamless integration between different adapter interfaces in the 4diac IDE.

Interface Structure

Event Inputs

None. The function block has no separate event inputs; event control is handled via the connected adapters.

Event Outputs

None. Events are forwarded exclusively via the AS adapter.

Data Inputs

None. The LINT signal to be converted is read in via the ALI adapter.

Data Outputs

None. The converted SINT signal is output via the AS adapter.

Adapters

Name	Type	Direction	Description
ALI_IN	`adapter::types::unidirectional::ALI`	Socket (Input)	Receives a LINT value (64-bit) via event E1 and date D1.
AS_OUT	`adapter::types::unidirectional::AS`	Plug (Output)	Provision of the converted SINT value (8-bit) via event E1 and data D1.

Functionality

The function block operates on the principle of pure data flow without its own state machine.

1. The **ALI_IN** adapter receives the **E1** event and provides the corresponding LINT value via data **D1**.
2. This event triggers the internal function block **F_LINT_TO_SINT**, which performs the conversion.
3. After the conversion is complete, the **CNF** event of the conversion block is activated, which in turn triggers the **E1** output event of the **AS_OUT** adapter and passes the converted SINT value via data **D1**.

The conversion corresponds to the IEC 61131 function `LINT_TO_SINT`. For values outside the SINT range (-128…127), an overflow occurs – the function block does not perform any additional range checks.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Structure**: The function block consists exclusively of a single conversion block (`F_LINT_TO_SINT`).
- **Unidirectional Adapters**: Both the input and output interfaces are defined as unidirectional adapters – data flows in only one direction.
- **No State Machine**: Due to the simple transformation, an internal state machine is not used; the logic is limited to event-data chaining.

State Overview

The function block has **no** internal state machine. It operates purely data/event-driven and performs an immediate conversion upon each incoming event.

Application Scenarios

- **Integration of LINT data sources** (e.g., from high-resolution counters, timestamps) into systems that only process SINT values (e.g., simple actuator controls).
- **Bridges between different adapter types** within a 4diac application, without the need for manual conversion blocks.

Comparison with Similar Blocks

- **ALI_TO_INT**: Converts LINT to INT (16-bit).
- **LINT_TO_DINT** or similar: Direct type conversions without adapter encapsulation.

The **ALI_TO_AS** is distinguished by its specific adapter interface; it simplifies the reuse of pre-built adapter couplings in modules.

Conclusion

The **ALI_TO_AS** is a specialized composite component for lossy conversion of a LINT value to a SINT value, embedded in a unidirectional adapter structure. It offers clean, reusable encapsulation of the conversion logic and facilitates the connection of diverse data sources and sinks within the 4diac development environment.

AS_TO_ALI

SINT Adapter Input – *AS*

ALI – LINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **AS_TO_ALI** function block is a composite block for converting a SINT adapter input (AS) into a LINT adapter output (ALI). It serves as a bridge between components that use different integer data types and enables the easy integration of SINT-based signals into LINT-based systems.

Interface Structure

Event Inputs

The function block has no directly visible event inputs. Event control is handled via the socket adapter **AS_IN**, which provides an event **E1**.

Event Outputs

The function block has no directly visible event outputs. Event output is handled via the plug adapter **ALI_OUT**, which forwards an event **E1**.

Data Inputs

No direct data inputs. The data value **D1** is read via the socket adapter **AS_IN** (data type SINT).

Data Outputs

No direct data outputs. The converted data value **D1** is output via the plug adapter **ALI_OUT** (data type LINT).

Adapters

- **AS_IN** (Socket, type: `adapter::types::unidirectional::AS`) – SINT adapter input with event E1 and data D1 (SINT).
- **ALI_OUT** (Plug, type: `adapter::types::unidirectional::ALI`) – LINT adapter output with event E1 and data D1 (LINT).

Functionality

The AS_TO_ALI function block is implemented as a composite block. When an event arrives at **AS_IN.E1**, it is forwarded directly to **ALI_OUT.E1**. Simultaneously, the incoming SINT data value **AS_IN.D1** is converted to a LINT value and passed to **ALI_OUT.D1**. The conversion is lossless, as the value range of LINT completely covers that of SINT.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Structure** – no independent state logic, only forwarding and conversion.
- **Synchronized Event and Data Paths** – data is only passed after an event.
- **Implicit Type Conversion** – the conversion from SINT to LINT occurs automatically within the composite block's network.

State Overview

The function block (FB) has no states of its own. Its functionality is limited to event-driven data passing with type conversion.

Application Scenarios

- Connecting a SINT-based sensor to a LINT-based control system.
- Migrating existing SINT components to a LINT infrastructure.
- Heterogeneous systems where different integer data types need to be converted.

Comparison with Similar Function Blocks

Similar converters exist for other data types (e.g., BOOL_TO_BYTE, INT_TO_DINT). The AS_TO_ALI function block is specifically designed for converting SINT to LINT and is conceived as an adapter function block, allowing it to be directly integrated into adapter-based communication structures.

Conclusion

The AS_TO_ALI function block offers a simple, reliable, and efficient solution for converting SINT to LINT data. Its composite structure allows it to be integrated into existing 4diac projects without additional programming and facilitates the use of different data types in automation systems.

ALI_TO_AUDI

LINT Adapter Input – *ALI*

AUDI – UDINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALI_TO_AUDI** is a composite block that converts an ALI adapter (LINT) into an AUDI adapter (UDINT). It serves as a unidirectional converter between two different data type adapters for the IEC 61499 profile interface. The conversion is performed using an internal block *F_LINT_TO_UDINT* from the IEC 61131 library.

Interface Structure

The function block has no direct event or data inputs/outputs. All communication takes place via two adapter interfaces.

Event Inputs

No dedicated event inputs are available. The event is received via the ALI adapter.

Event Outputs

No dedicated event outputs are available. The result event is sent via the AUDI adapter.

Data Inputs

No dedicated data inputs are available. The input data value is provided via the ALI adapter.

Data Outputs

No dedicated data outputs are available. The converted data value is output via the AUDI adapter.

Adapters

Adapter	Type	Direction	Description

ALI_IN	adapter::types::unidirectional::ALI	Socket (Input)	Returns the LINT value (64-bit signed) and the associated event.
AUDI_OUT	adapter::types::unidirectional::AUDI	Plug (Output)	Provides the converted UDINT value (32-bit unsigned) and the acknowledgment event.

Functionality

As soon as the ALI_IN adapter receives an event (E1), the associated LINT data value (D1) is read. This data value is passed to the internal function block *F_LINT_TO_UDINT*, which converts it into a UDINT value. After successful conversion, the internal function block sends an acknowledgment event (CNF), which is forwarded via the AUDI_OUT adapter (E1). Simultaneously, the converted UDINT value (OUT) is passed to the AUDI_OUT adapter (D1).

The conversion from LINT (64-bit signed) to UDINT (32-bit unsigned) is unsigned and can lead to overflows or information loss for values outside the UDINT range (0 … 4,294,967,295).

Technical Features

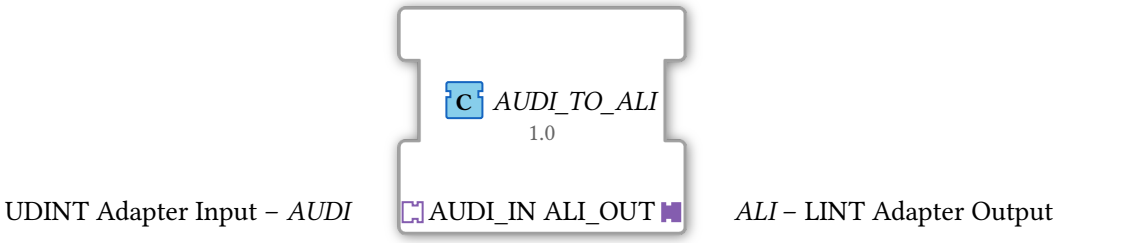
- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Function Block**: The function block consists of an internal network with a single conversion block.
- **Unidirectional Adapter-to-Adapter Converter**: Data flows only from ALI_IN to AUDI_OUT.
- **No State Logic**: The function block has no internal state machine; the conversion occurs deterministically with each event.

State Overview

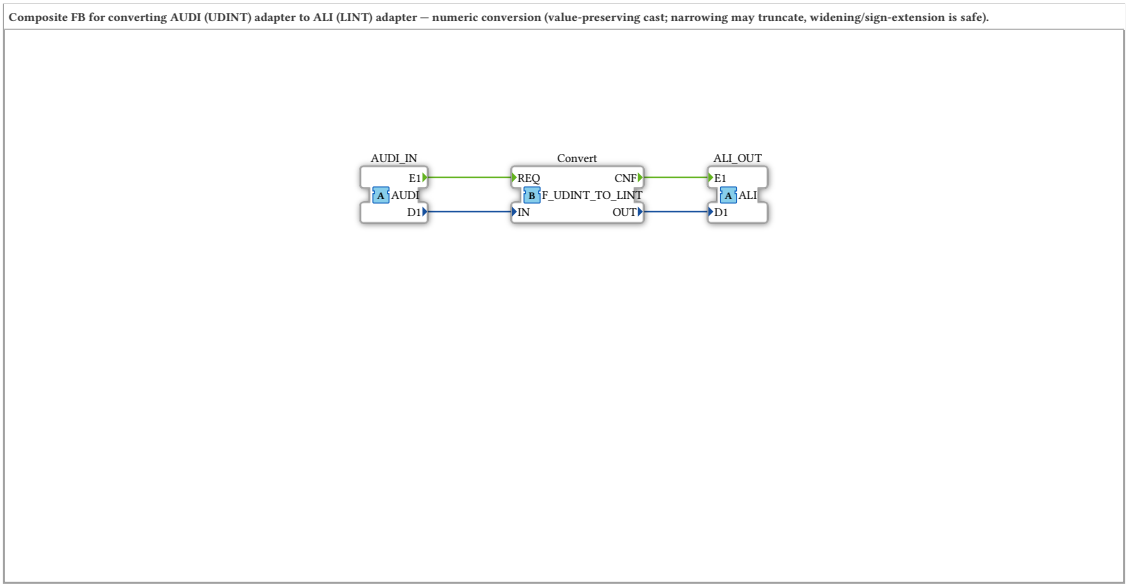
The function block does not have its own state machine. The state is determined solely by the internal block *F_LINT_TO_UDINT*, which performs a one-time conversion with each REQ event and immediately delivers the result.

Application Scenarios

- **System Integration**: When one system component (e.g., sensor, drive) provides an ALI adapter (LINT), while another component expects an AUDI adapter (UDINT).
- **Protocol Adaptation**: In heterogeneous control environments where different IEC 61499 adapter profiles for integers are used.
- **Migration**: Exchange of 64-bit LINT values for 32-bit UDINT values, provided the value range limits are respected.



Comparison with Similar Function Blocks



- **F_LINT_TO_UDINT (direct)**: This function block performs pure data conversion without an adapter. *ALI_TO_AUDI* encapsulates this function in an adapter-based interface.
- **ALI_TO_xxx/Converter**: Other adapter converters (e.g., ALI_TO_BOOL, ALI_TO_REAL) use analogous mechanisms but differ in target type and value range.

Conclusion

The *ALI_TO_AUDI* function block is a lean composite function block for simple adapter conversion from LINT to UDINT. It utilizes an existing IEC 61131 component and extends it with a standardized IEC 61499 adapter interface. This facilitates integration into existing systems without requiring the underlying conversion logic to be reimplemented.

AUDI_TO_ALI

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUDI_TO_ALI** function block is a composite module that bridges an **AUDI** adapter (of type *UDINT*) and an **ALI** adapter (of type *LINT*). It converts incoming UDINT values to LINT values using a standardized conversion function and forwards them to the output adapter. This module is typically used in applications that need to connect different address or integer types within a 4diac adapter concept.

Interface Structure

Event Inputs

Name	Description
No dedicated event inputs	Event control is handled via the internal socket AUDI_IN.E1.

Event Outputs

Name	Description
No custom event outputs	Event forwarding is handled via the internal plug ALI_OUT.E1.

Data Inputs

Name	Data Type	Description
No custom data inputs	–	The data value is supplied by socket AUDI_IN.D1.

Data Outputs

Name	Data Type	Description
No custom data outputs	–	The converted value is provided via the ALI_OUT.D1 plug.

Adapter

Type	Name	Direction	Description
AUDI (unidirectional)	`AUDI_IN`	Socket (Input)	UDINT data adapter that provides a value based on event E1 and date D1.
ALI (unidirectional)	`ALI_OUT`	Plug (Output)	LINT data adapter that outputs the converted value based on event E1 and date D1.

Functionality

The module functions as a pure **type conversion bridge** for adapters:

1. **Event Receipt**: An event on socket `AUDI_IN.E1` activates the internal conversion module `F_UDINT_TO_LINT` via its event input `REQ`.
2. **Data Conversion**: The current UDINT value of `AUDI_IN.D1` is placed on the data input `IN` of the converter. `F_UDINT_TO_LINT` performs the IEC 61131-compliant conversion from an unsigned 32-bit integer (UDINT) to a signed 64-bit integer (LINT).
3. **Output**: After successful conversion, the converter signals with `CNF` that the output value is valid. This event is directly passed to the plug `ALI_OUT.E1`, and the converted LINT value from `Convert.OUT` is placed on `ALI_OUT.D1`.

The entire processing is **event-driven** and takes place within a single execution step (without any additional delay).

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block** – it contains no logic of its own but delegates the conversion entirely to the IEC 61131 block `F_UDINT_TO_LINT`.
- **Adapter-oriented interface** – All inputs and outputs are handled via standardized unidirectional adapters (`AUDI` and `ALI`), enabling easy integration into existing adapter networks.
- **License & Copyright** – This block is licensed under the **Eclipse Public License 2.0** and was developed by **HR Agrartechnik GmbH** (as of 2026).
- **Type safety** – Conversion from UDINT (unsigned 32-bit) to LINT (signed 64-bit) is lossless, as the value is simply sign-extended.
- **Package name** – In the CompilerInfo, the block is listed as `adapter::conversion::unidirectional`.

State overview

As a composite block, `AUDI_TO_ALI` does not have its own states. The state logic is contained within the integrated `F_UDINT_TO_LINT` block, which transitions to a processing state after each `REQ` event and acknowledges this with `CNF`.

Application Scenarios

- **Transition between different automation protocols** – when a system delivers UDINT values via an AUDI adapter, but the target system expects LINT values via an ALI adapter.
- **Data adaptation in adapter hierarchies** – redirection of 32-bit counter values (e.g., speed, pulse counter) to a 64-bit bus.
- **Migration** – legacy systems with UDINT sections can be connected to new 64-bit interfaces without changing the adapter structure.
- **Test Environments** – Simple loop-through of type conversion between two adapters, without separate conversion modules in the network.

Comparison with similar modules

Module	Type	Special Feature
`F_UDINT_TO_LINT`	Pure converter	No adapters, direct data I/O; no event handling via adapters, requires its own control.
`AUDI_TO_ALI` (this one)	Adapter converter	Encapsulates the conversion in an adapter-based interface; events and data are automatically routed via the adapters.
`ALI_TO_AUDI` (hypothetical)	Adapter converter	Would convert LINT backwards to UDINT (potentially lossy).

The **main difference** compared to directly using `F_UDINT_TO_LINT` is the seamless integration into adapter networks and the avoidance of additional lines for event and data connections.

Conclusion

The **AUDI_TO_ALI** function block is a practical adapter converter that bridges the gap between a UDINT-based AUDI adapter and a LINT-based ALI adapter. By internally using the standardized IEC 61131 converter `F_UDINT_TO_LINT`, the conversion is efficient and type-safe. The block is particularly suitable for modular architectures where different address widths are encountered and simplifies the reuse of adapter interfaces in heterogeneous automation environments.

ALI_TO_AUI

LINT Adapter Input – *ALI*

AUI – UINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **ALI_TO_AUI** is a composite block for converting an ALI adapter (LINT data type) into an AUI adapter (UINT data type). It allows the seamless integration of components with different adapter definitions in a 4diac environment. The block is based on the internal conversion block `F_LINT_TO_UINT` from the IEC 61131 library.

Interface Structure

Event Inputs

Not present – event control is handled by the adapters.

Data Inputs

Not present – data transfer is handled by the adapters.

Data Outputs

Not present – data is transferred via the adapters.

Adapters

Type	Name	Comment
Socket	`ALI_IN`	Input adapter of type `adapter::types::unidirectional::ALI` – provides LINT value and associated event.
Plug	`AUI_OUT`	Output adapter of type `adapter::types::unidirectional::AUI` – provides the converted UINT value and associated event.

Functionality

Internally, this function block connects socket `ALI_IN` to the input of the conversion function block `F_LINT_TO_UINT`.

- The converter's `E1` event output from `ALI_IN` controls the `REQ` input.
- The data value `D1` from `ALI_IN` (LINT) is placed on the converter's `IN` input.
- After successful conversion, the converter signals the event to the plug `AUI_OUT` with `CNF`, and the converted value (UINT) is written to its `D1` output.

`The event outputE1fromALI_INis controlled via the converter'sREQ` input.

`The data valueD1fromALI_IN(LINT) is placed on theIN` input. ... The entire process is event-driven: An incoming event at the ALI adapter triggers the conversion and generates a corresponding output event at the AUI adapter.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Data Type Conversion:** The internal module converts a 64-bit signed integer (LINT) to a 16-bit unsigned integer (UINT). Since the value range of UINT (0...65535) is significantly smaller than that of LINT, values outside this range result in an overflow/loss.
- **Dependency:** The module requires the library `iec61131::conversion` (specifically the module `F_LINT_TO_UINT`).
- **Adapter-Free Interface:** All data exchange occurs exclusively via adapters, enabling modular and reusable integration into larger networks.

State Overview

The function block itself does not have its own state machine. The state logic is fully implemented by the internal function block `F_LINT_TO_UINT`. This typically has the states **IDLE** (waiting for REQ) and **BUSY** (performing conversion). Upon completion, the result is provided and the CNF event output is activated.

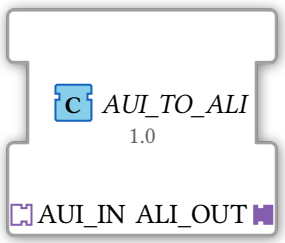
Application Scenarios

- **Adapter Bridge:** A sensor that provides data in ALI format (LINT) is to be connected to an actuator that expects an AUI input (UINT).
- **System Integration:** In heterogeneous automation systems where different adapter definitions are used, the function block serves as a simple converter without manual programming.
- **Prototyping:** Quickly replace adapters during the development phase without having to change the underlying data flow logic.

Prototyping:

Comparison with Similar Components

Analog converter components exist, such as `ALI_TO_UDI` (LINT → UDINT) or `DINT_TO_UINT`. This component specializes in combining the unidirectional ALI and AUI adapters. Unlike directly connecting the adapters via data type conversion at the network layer, this composite function block offers a compact, reusable solution with clearly defined event signals.



Conclusion

The ALI_TO_AUI component is a practical and easy-to-understand tool for converting between ALI and AUI adapters. Its composite structure encapsulates the necessary data conversion and event forwarding, allowing it to integrate seamlessly into existing 4diac projects. Its ease of use and clear interface separation make it a valuable tool for adapter integration.

AUI_TO_ALI

UINT Adapter Input – *AUI* *ALI* – LINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The AUI_TO_ALI function block is a composite function block that converts an AUI adapter (UINT) into an ALI adapter (LINT). Internally, it uses the IEC 61131 function block F_UINT_TO_LINT for the conversion.

Interface Structure

Event Inputs

- **AUI_IN.E1** (Event via Socket AUI_IN): Starts the conversion when an event is present at the socket (via the AUI adapter).

Event Outputs

- **ALI_OUT.E1** (Event via Plug ALI_OUT): Outputs the output after the conversion is complete (via the ALI adapter).

Data Inputs

- **AUI_IN.D1** (Data via Socket AUI_IN): UINT value to be converted to a LINT value.

Data Outputs

- **ALI_OUT.D1** (Data via Plug ALI_OUT): Converted LINT value.

Adapters

- **Socket AUI_IN** (Type: adapter::types::unidirectional::AUI): Receives UINT data and the associated event.
- **Plug ALI_OUT** (Type: adapter::types::unidirectional::ALI): Sends the converted LINT data and the associated event.

Functionality

The function block waits for an event at the input adapter AUI_IN (E1). As soon as this event arrives, the incoming UINT value (D1) is forwarded to the internal conversion block F_UINT_TO_LINT. The conversion is performed according to the IEC 61131 standard, converting the unsigned UINT value into a signed LINT value (64-bit integer). After the conversion is complete, the output event is triggered at the ALI_OUT adapter (E1), and the converted LINT value is passed to ALI_OUT.D1.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).

- The function block (FB) is implemented as a composite type and encapsulates the conversion logic in a reusable adapter interface.
- Uses the standardized function block F_UINT_TO_LINT from the IEC 61131 library.
- License: Eclipse Public License 2.0 (EPL-2.0).
- Developed by HR Agrartechnik GmbH (Version 1.0, 2026-02-17).

State Overview

The function block (FB) does not have its own state machine, as it passively maps the states of the internal block as a composite. The internal F_UINT_TO_LINT operates according to a simple scheme: wait for the REQ event, process the conversion, and trigger the CNF event.

Application Scenarios

- Integration of a system that provides UINT values via an AUI adapter into a system that expects LINT values via an ALI adapter.
- Data bridge between different adapter types in a distributed controller.
- Extension of 4diac applications when type conversion between UINT and LINT is required.

Comparison with Similar Function Blocks

Analogous adapter conversion blocks exist for other data types (e.g., UINT_TO_DINT, UINT_TO_REAL, etc.). The AUI_TO_ALI function block is specifically designed for combining the unidirectional AUI and ALI adapters, enabling a unified adapter interface without additional manual conversion.

Conclusion

The composite function block AUI_TO_ALI offers a simple and reliable way to convert UINT data via AUI adapters to LINT data via ALI adapters. It is well-encapsulated, uses standard function blocks, and can be easily integrated into 4diac projects.

ALI_TO_AULI

LINT Adapter Input – *ALI*

AULI – ULINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The function block `ALI_TO_AULI` is a composite block that implements bidirectional adapter conversion between the LINT adapter (ALI) and the ULINT adapter (AULI). It serves as a standardized interface for converting a signed 64-bit integer value (LINT) into an unsigned 64-bit integer value (ULINT). The block encapsulates the IEC 61131-3 conversion block `F_LINT_TO_ULINT` and simplifies integration into adapter-based architectures.

Interface Structure

The block does not have its own event or data interfaces, but only two adapter connections (socket and plug). The internal logic is handled by the embedded sub-module and the direct connection of the adapter signals.

Event Inputs

– None (events are received via the ALI adapter)

Event Outputs

– None (events are sent via the AULI adapter)

Data Inputs

– None (data is received via the ALI adapter)

Data Outputs

– None (data is output via the AULI adapter)

Adapter

Adapter Type	Direction	Name	Comment
`adapter::types::unidirectional::ALI`	Socket (Input)	`ALI_IN`	LINT adapter input (provides an event and a LINT value)
`adapter::types::unidirectional::AULI`	Plug (output)	`AULI_OUT`	ULINT adapter output (passes on an event and a ULINT value)

Functionality

The module operates as a simple pass-through conversion:

1. An incoming event at socket `ALI_IN.E1` triggers the internal module `Convert` (`F_LINT_TO_ULINT`) via its event input `REQ`.
2. Simultaneously, the LINT value provided by the socket (`ALI_IN.D1`) is passed to the data input `IN` of `Convert`.
3. After successful conversion, `Convert` signals an event at its output `CNF`, which is then forwarded directly to the plug `AULI_OUT.E1`.
4. The converted ULINT value (`Convert.OUT`) is then passed in parallel to the data input `D1` of the AULI adapter.

Thus, a complete, event-driven, and data-synchronous conversion is achieved without any additional delay or logic.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Sub-block used**: `iec61131::conversion::F_LINT_TO_ULINT` – standard-compliant type conversion according to IEC 61131-3.
- **Adapter coupling**: The block utilizes 4diac's unidirectional adapter concept and enables loose coupling between different data type interfaces.
- **No state management**: As a composite block, `ALI_TO_AULI` does not have its own internal state; all decisions are made by the sub-block.
- **Platform independence**: The block can be used in any 4diac environment that provides the IEC 61131 conversion blocks.

State overview

The block itself does not contain a state machine. All state transitions are controlled by the internal `F_LINT_TO_ULINT`, which switches to the "convert" state after an event at input `REQ` and outputs a confirmation event upon completion. Since these states are not externally visible, a detailed description is omitted.

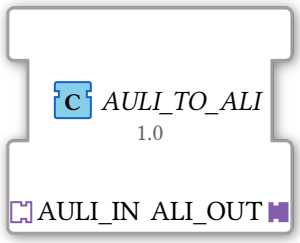
Application Scenarios

- **System Integration**: Connecting an older control system that uses signed LINT values to a modern component that can only process unsigned ULINT values.
- **Data Conversion in Adapter Chains**: Embedding between two adapters, e.g., in a data preprocessing chain that requires a uniform ULINT interface.
- **Migration**: Replacing LINT-based components with ULINT equivalents without having to change the entire adapter infrastructure.

Comparison with Similar Components

The library contains analogous converters for other data types, such as `DINT_TO_UDINT` or `REAL_TO_LREAL`. `ALI_TO_AULI` differs in its specific adapter interface and the encapsulation of the conversion component within a composite. While the pure IEC components have individual data and event interfaces, this component enables direct adapter-to-adapter conversion, which facilitates the design of modular and interchangeable components.

Conclusion



The `ALI_TO_AULI` component offers a simple and reliable way to convert LINT adapters to ULINT adapters. It cleanly encapsulates the standard conversion in an adapter-based architecture, thus contributing to the reusability and interoperability of 4diac applications. By using the proven IEC component, the conversion is correct and platform-independent.

AULI_TO_ALI

ULINT Adapter Input – *AULI*

ALI – LINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **AULI_TO_ALI** function block is a composite module that performs an adapter conversion from **AULI** (ULINT adapter) to **ALI** (LINT adapter). It converts an unsigned 64-bit integer value (ULINT) into a signed 64-bit integer value (LINT) and forwards it via the corresponding adapter interfaces.

Interface Structure

Event Inputs

Events are received via the incoming adapter **AULI_IN**:

- `E1` – Starts the conversion of the incoming ULINT value.

Event Outputs

Events are sent via the outgoing adapter **ALI_OUT**:

- `E1` – Acknowledges the completed conversion and indicates that the LINT value is present at the output.

Data Inputs

Data is provided via the incoming adapter **AULI_IN**:

- `D1` (Data type: ULINT) – The unsigned 64-bit value to be converted.

Data Outputs

Data is output via the outgoing adapter **ALI_OUT**:

- `D1` (Data type: LINT) – The converted signed 64-bit value.

Adapters

- **AULI_IN** (Socket) – Unidirectional adapter of type `adapter::types::unidirectional::AULI` for receiving ULINT values and associated events.
- **ALI_OUT** (Plug) – Unidirectional adapter of type `adapter::types::unidirectional::ALI` for outputting LINT values and associated events.

Functionality

The module internally uses the IEC 61131 conversion module `F_ULINT_TO_LINT`. As soon as the event `E1` arrives at the **AULI_IN** adapter, the ULINT value present at `D1` is read and passed to the converter. After conversion, the resulting LINT value is passed to the **ALI_OUT** adapter, and simultaneously, the event `E1` is sent to its output. The data and event flows are strictly synchronized: Conversion only occurs on demand via the event `E1`.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Adapter-Based Encapsulation**: The function block completely encapsulates the conversion logic behind standardized unidirectional adapters (AULI/ALI), allowing for easy integration into existing adapter-based data flows.
- **Composite Structure**: Because it is a composite function block, no separate state machine is required; the logic is implemented by linking the sub-function block `F_ULINT_TO_LINT`.
- **Type Safety**: The conversion from ULINT to LINT preserves the value range as long as the ULINT value is not greater than `LINT#9223372036854775807` (maximum LINT). Exceeding this limit results in undefined behavior (no error handling in the function block).

State Overview

The function block does not have its own state machine. It reacts event-driven:

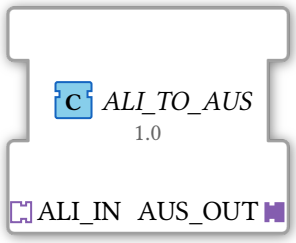
- **Waiting for event `E1`**: No activity.
- **During Conversion**: The internal function block `F_ULINT_TO_LINT` is executed (the duration depends on the clock cycle).
- **Output to `CNF`**: The event `E1` is sent at the output.

Application Scenarios

- **Data type conversion in control systems** when a sensor or source delivers ULINT values, but the subsequent system expects LINT values (signed).
- **Adapter bridge** between components that communicate exclusively via AULI or ALI adapters, e.g., in modular automation architectures.
- **Integration into cross-device data flows** without changing the actual application logic.

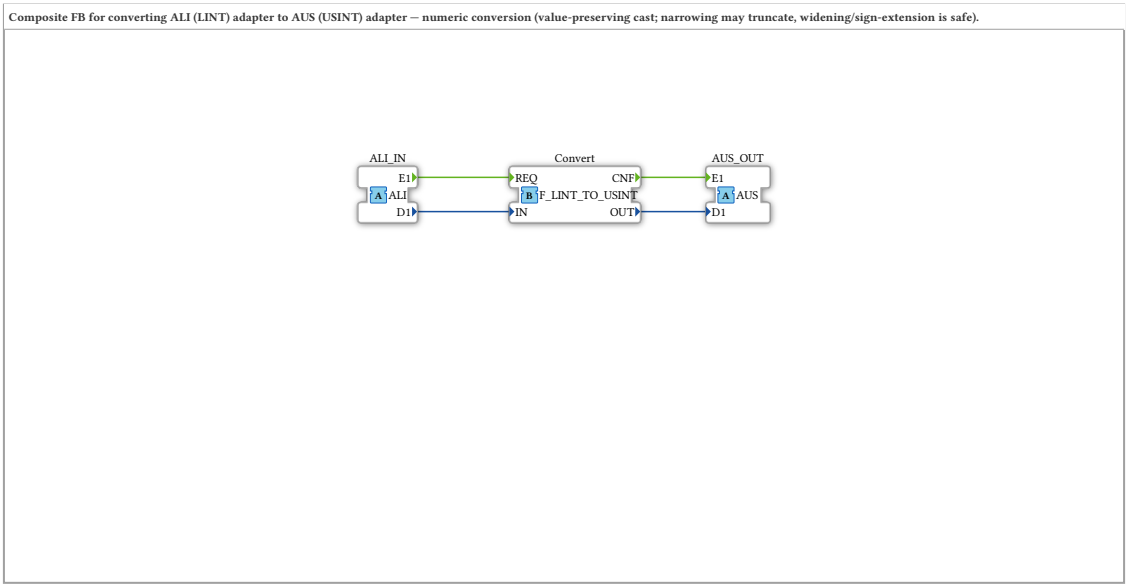
Comparison with similar components

Similar adapter conversions exist for other data types, e.g., `UINT_TO_INT` or `UDINT_TO_DINT`. The **AULI_TO_ALI** module specializes in 64-bit integers (ULINT/LINT) and uses the same adapter interface (unidirectional), allowing it to be seamlessly integrated into existing adapter circuits.



Conclusion

The **AULI_TO_ALI** module is a simple yet effective solution for converting ULINT to LINT values using standardized adapters. It simplifies the integration of different data types into unidirectional communication paths and is particularly well-suited for modular IEC 61499 applications.



Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALI_TO_AUS

LINT Adapter Input – *ALI* *AUS* – USINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **ALI_TO_AUS** is a composite function block according to IEC 61499, used to convert an **ALI adapter** (data of type **LINT**, Long Integer) into an **AUS adapter** (data of type **USINT**, Unsigned Short Integer). The block encapsulates the necessary conversion logic to enable a simple and type-safe connection between differently typed adapter interfaces.

Interface Structure

Event Inputs

- **ALI_IN.E1** (via adapter socket) – triggers the conversion as soon as an event arrives from the connected ALI source.

Event Outputs

- **AUS_OUT.E1** (via adapter plug) – signals the completion of the conversion to the downstream OFF sink.

Data Inputs

- **ALI_IN.D1** (via adapter socket) – the LINT (Long Integer) value to be converted.

Data Outputs

- **AUS_OUT.D1** (via adapter plug) – the converted USINT (Unsigned Short Integer) value.

Adapter

Direction	Name	Type	Description

Socket (Input)	ALI_IN	adapter::types::unidirectional::ALI	Receives the LINT data value and the associated event
Plug (Output)	OFF_OUT	adapter::types::unidirectional::OFF	Provides the converted USINT value and the confirmation event

Functionality

The function block internally contains an instance of the function block **F_LINT_TO_USINT** from the IEC 61131 conversion library. The process is as follows:

1. An event **ALI_IN.E1** triggers the data transfer.
2. The LINT value present at **ALI_IN.D1** is forwarded to the input **IN** of the internal converter.
3. The internal function block performs the type conversion from LINT to USINT (taking value range limits into account).
4. After successful conversion, the internal function block generates a **CNF** event, which is output as **OFF_OUT.E1**.
5. The converted result is sent from **OUT** of the internal block to **AUS_OUT.D1**.

Event and data flows are coupled entirely via the internal network; the user only sees the two adapter interfaces.

Technical Features

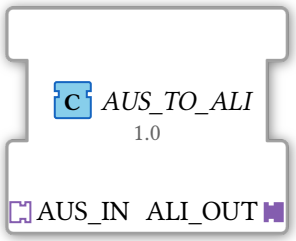
- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Reusable Converter**: The block uses the standardized **F_LINT_TO_USINT** (iec61131::conversion), so the conversion logic does not need to be reimplemented.
- **Adapter-Based**: The entire interface is implemented as a unidirectional adapter, simplifying exchange and reuse in larger systems.
- **License**: The block is provided under the **Eclipse Public License 2.0** (EPL-2.0).

State Overview

Since this is a composite block, there is no explicit top-level state machine. The internal converter **F_LINT_TO_USINT** operates in an event-driven manner and performs exactly one conversion step after each **REQ** event. The function block remains inactive as long as no event is present.

Application Scenarios

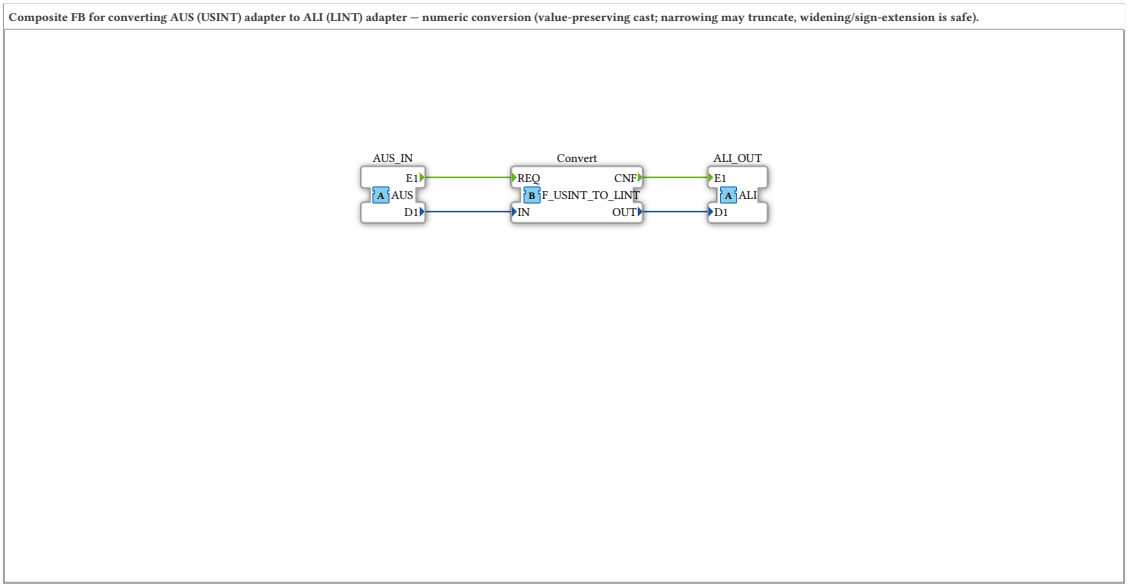
- **Interface Adaptation**: Connecting components that use **LINT** (e.g., high-resolution counters) to those that expect **USINT** (e.g., simple actuator controllers).
- **System Integration**: When a predefined adapter type (ALI) is available and a different adapter type (AUS) is required – e.g., when combining modules from different manufacturers.
- **Protocol Conversion**: Used in data preprocessing chains where long integer values need to be mapped to a smaller range.



Comparison with Similar Function Blocks

Numerous data type-specific conversion blocks exist (e.g., LINT_TO_INT, LINT_TO_DINT, USINT_TO_LINT). The **ALI_TO_AUS** stands out because it not only encapsulates the pure type conversion but also embeds it directly into an **adapter interface**. This reduces the wiring effort at the block level and increases the readability of the overall design.

Conclusion



The **ALI_TO_AUS** is a practical and robust function block for converting LINT adapter data to USINT adapter data. By using a standardized converter and clear adapter encapsulation, a reusable, type-safe, and easy-to-maintain solution is provided for various control systems.

AUS_TO_ALI

USINT Adapter Input – *AUS*

ALI – LINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUS_TO_ALI` is a composite function block (FB) that converts an AUS adapter (USINT values) into an ALI adapter (LINT values). It encapsulates the conversion process and provides a unidirectional interface between these two adapter types. Internally, the function block `F_USINT_TO_LINT` from the IEC 61131 library is used.

Interface Structure

Event Inputs

No dedicated event inputs. Event control is handled via the `AUS_IN` adapter (socket).

Event Outputs

No dedicated event outputs. Event output is handled via the `ALI_OUT` adapter (plug).

Data Inputs

No dedicated data inputs. Data is received via the `AUS_IN` adapter.

Data Outputs

No dedicated data outputs. Data is output via the `ALI_OUT` adapter.

Adapters

- **OFF_IN** (Socket) – Receives an OFF adapter with a unidirectional USINT data type. Includes:
- Event input `E1`
- Data input `D1` (USINT)
- **ALI_OUT** (Plug) – Sends an ALI adapter with a unidirectional LINT data type. Includes:
- Event output `E1`
- Data output `D1` (LINT)

Functionality

The function block operates in an event-driven manner:

1. An event at the `E1` input of the `AUS_IN` adapter initiates processing.
2. The current value of `AUS_IN.D1` (USINT) is passed to the internal function block `Convert` (`F_USINT_TO_LINT`).
3. After conversion, the result (LINT) is output via `ALI_OUT.D1`, and simultaneously an event is sent to the `E1` output of the `ALI_OUT` adapter.

Type conversion is performed according to the IEC 61131 definition of `F_USINT_TO_LINT`: USINT (0..255) is mapped to LINT (64-bit) without loss of sign.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block**: The conversion logic is encapsulated and reusable.
- **Adapter-Based**: Input/output is exclusively via adapters (`AUS` and `ALI`), which facilitates integration into adapter-oriented architectures.
- **Unidirectional**: The function block supports only one data flow direction (OFF → ALI).
- **Library Import**: It uses the function block `iec61131::conversion::F_USINT_TO_LINT` from the IEC 61131 library.
- **Package Structure**: The function block is organized in the package `adapter::conversion::unidirectional`.

State Overview

The `AUS_TO_ALI` function block does not have its own state machines. The internal process is purely event-driven and stateless:

- **Wait**: for an event from `AUS_IN.E1`
- **Convert**: immediate conversion of the USINT value to LINT
- **Output**: immediate sending of the result via `ALI_OUT`

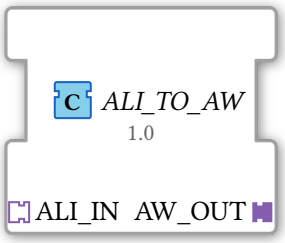
Each conversion is independent of previous calls.

Application Scenarios

- **Interface Adaptation**: A system that provides data as an AUS adapter (USINT) must be connected to a receiver that expects an ALI adapter (LINT).
- **Data Preparation**: Conversion of low-resolution sensor data or manipulated variables (USINT) into a wider range of values (LINT) for further calculations.
- **Adapter Cascading**: As part of a chain of adapter conversions, e.g., in a modular control architecture.

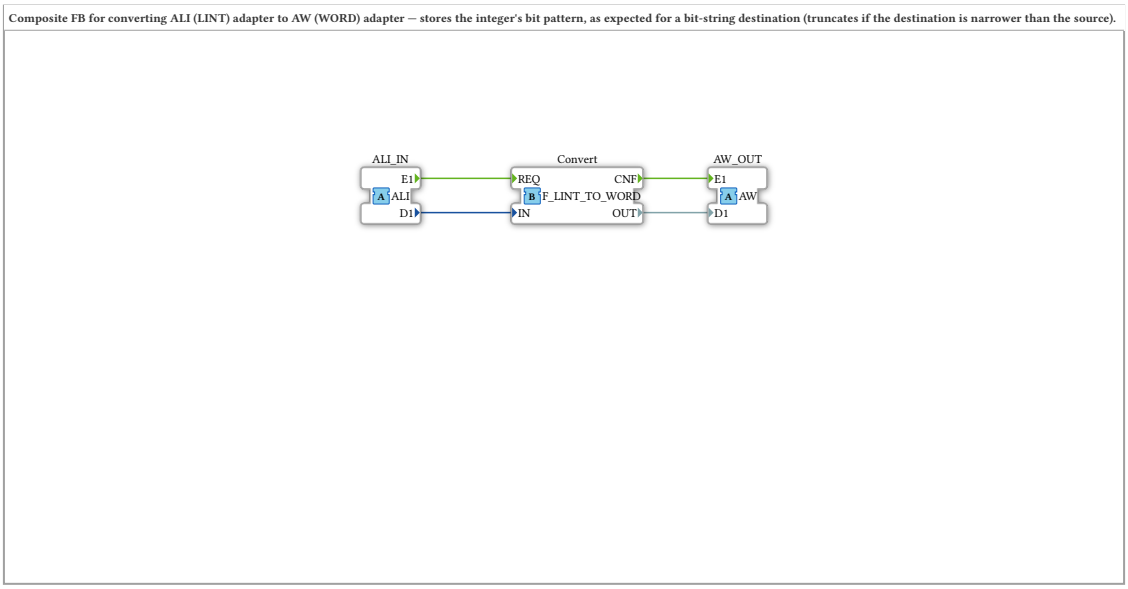
Comparison with Similar Function Blocks

- **Direct Use of `F_USINT_TO_LINT`**: This function block operates at the data level without an adapter. `AUS_TO_ALI` additionally encapsulates the adapter logic and is therefore better suited for adapter-based communication.
- **Further Adapter Conversions**: For other type combinations (e.g., `INT_TO_DINT`, `BYTE_TO_WORD`), analogous composite devices exist that follow the same design pattern.



Conclusion

The `AUS_TO_ALI` device is a simple yet effective solution for unidirectional conversion between USINT and LINT adapters. It increases reusability and clarity in systems that rely on adapter interfaces and avoids the manual wiring of conversion logic.



Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALI_TO_AW

LINT Adapter Input – *ALI* *AW* – WORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALI_TO_AW** is a composite function block (FB) that converts a LINT value (ALI adapter) into a WORD value (AW adapter). It encapsulates the conversion logic of the IEC 61131-3 function block `F_LINT_TO_WORD` in an adapter-based interface. The block is designed for use in unidirectional adapter communication paths and enables a clean separation of data format and application.

Interface Structure

The block has no direct event or data inputs/outputs at the FB level. Communication takes place exclusively via two adapters (a socket and a plug).

Event Inputs

No direct event inputs are available. The incoming event is provided via the adapter `ALI_IN.E1`.

Event Outputs

No direct event outputs are available. The outgoing event is provided via the adapter `AW_OUT.E1`.

Data Inputs

No direct data inputs are available. The LINT value is obtained via the adapter `ALI_IN.D1`.

Data Outputs

No direct data outputs are available. The WORD value is output via the adapter `AW_OUT.D1`.

Adapters

Adapter Name	Type	Direction	Comment

ALI_IN	adapter::types::unidirectional::ALI	Socket (Input)	LINT adapter input; sends event to E1 and LINT data to D1
AW_OUT	adapter::types::unidirectional::AW	Plug (Output)	WORD adapter output; sends event to E1 and WORD data to D1

Functionality

1. The module expects an event (to E1) and a corresponding LINT data value (to D1) via socket ALI_IN.
2. The event is forwarded to the internal conversion module F_LINT_TO_WORD (type iec61131::conversion::F_LINT_TO_WORD) (connection ALI_IN.E1 → Convert.REQ). Simultaneously, the LINT value is passed to the converter's data input IN (connection ALI_IN.D1 → Convert.IN).
3. The internal function block performs the conversion and signals completion via its output CNF.
4. This event is passed to the plug AW_OUT.E1. The converted WORD value (output OUT of the converter) is simultaneously applied to the data input AW_OUT.D1.

Thus, the function block makes the data provided by the input adapter available in converted form at the output adapter, controlled by the event chain.

1. This event is then passed to the plug plug AW_OUT.E1. The converted WORD value (output OUT of the converter) is simultaneously applied to the data input AW_OUT.D1.

Thus, the function block makes the data provided by the input adapter available in converted form at the output adapter.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **IEC 61131-3 Conversion**: The actual conversion is performed using the standardized function block F_LINT_TO_WORD, which performs a lossy conversion from 64-bit (LINT) to 16-bit (WORD) (truncation or range checking depending on the implementation).
- **Adapter-Based Interface**: The function block is fully embedded in 4diac's adapter technology and is suitable for unidirectional communication paths (package adapter::conversion::unidirectional).
- **Versioning**: Version 1.0, released under the Eclipse Public License 2.0 (EPL-2.0).
- **No State Management**: The function block delegates all state logic to the inner F_LINT_TO_WORD.

State Overview

Since it is a composite function block, ALI_TO_AW does not have its own state machine. The internal converter F_LINT_TO_WORD typically implements the following implicit states:

State	Description
IDLE	Waiting for an event at the input ALI_IN.E1.
CONVERT	After receiving REQ, the conversion is performed.
DONE	After the conversion is complete, CNF is activated and the result value is provided at the output.

The internal function block then returns to the IDLE state.

Application Scenarios

- **Control Engineering**: Conversion of a 64-bit counter value (e.g., from an encoder) into a 16-bit value for a simple display or a word-based interface.
- **Data Consolidation**: Use in adapter chains when a subsequent component only accepts WORD inputs, but the source provides LINT data.
- **Test and Simulation Environments**: Generation of WORD data from LINT test values to verify adapter communication paths.

Comparison with Similar Components

- **LINT_TO_DWORD / LINT_TO_BYTE**: Other conversions with different target widths; `ALI_TO_AW` is specifically designed for use with the unidirectional adapters `ALI` and `AW`.
- **Direct use of F_LINT_TO_WORD**: `ALI_TO_AW` offers a higher level of abstraction through adapter interfaces and facilitates integration into adapter-based architectures, whereas the pure function block only has event and data interfaces.

Conclusion

The function block `ALI_TO_AW` is a practical and reusable building block for converting LINT to WORD adapters. It encapsulates the typical IEC 61131-3 conversion in an adapter-friendly package, thus simplifying integration into existing or new 4diac projects. Its clear, unidirectional interface and adherence to the Eclipse Public License model make it a robust component for automation solutions that need to connect different data widths.

]

AW_TO_ALI

WORD Adapter Input – *AW*

ALI – LINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AW_TO_ALI** function block is a composite function block that converts a unidirectional adapter of type **AW** (WORD) into an adapter of type **ALI** (LINT). It is used to convert data between different adapter interfaces without requiring the user to implement the actual conversion logic. Internally, the function block uses the IEC 61131 function block `F_WORD_TO_LINT` and provides typical event/data control via the supplied adapter interfaces.

Interface Structure

Event Inputs

An event of type **E1** is received via the **Socket AW_IN** (Type: `adapter::types::unidirectional::AW`). This event triggers the conversion of the incoming data value.

Event Outputs

An event **E1** is output via the **Plug ALI_OUT** (Type: `adapter::types::unidirectional::ALI`) after successful conversion. This indicates that the converted value is available at the data output.

Data Inputs

Incoming data is received via the **Socket AW_IN**:

- **D1** (Data Type: WORD) – the 16-bit value to be converted.

Data Outputs

The converted data is output via the **ALI_OUT** plug:

- **D1** (Data type: LINT) – the converted 64-bit value (Long Integer).

Adapters

The module has two adapter interfaces:

- **Socket AW_IN** – Unidirectional input adapter (type AW) that establishes a connection to a previous module that provides WORD data.
- **ALI_OUT** – Unidirectional output adapter (type ALI) that passes the converted LINT data to subsequent modules.

Both adapters are unidirectional, meaning they transmit events and data in only one direction (input → output).

Functionality

The process within the composite block is strictly sequential:

1. An event **E1** at socket **AW_IN** is forwarded to the internal function block **F_WORD_TO_LINT** (instance name *Convert*) and activates its **REQ input**.
2. Simultaneously, the incoming data value **D1** (WORD) is placed at the **IN input** of the converter.
3. The converter `F_WORD_TO_LINT` performs the type conversion from WORD to LINT and provides the result at its **OUT output**.
4. After the conversion is complete, the converter generates a **CNF event**, which is passed to the **E1 input** of the output adapter **ALI_OUT**.
5. Simultaneously, the converted value (LINT) is transferred from the **OUT output** of the converter to the data output **D1** of the **ALI_OUT adapter**.

This completes the data conversion at a safe, event-driven time.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Composite Block** – The conversion logic is completely encapsulated in an internal network consisting of only a single conversion function block. The block does not have its own ECC state machine.
- **Adapter-Based Interface** – Instead of individual event/data inputs/outputs, adapters are used. This enables a modular, reusable connection in adapter-based control architectures.
- **Package Structure** – The function block is located in the package `adapter::conversion::unidirectional` and uses the converter `iec61131::conversion::F_WORD_TO_LINT` from the IEC 61131 conversion library.
- **Unidirectional Direction** – Data flows only from the input adapter to the output adapter; reverse communication is not supported.
- **License** – The source code is licensed under the Eclipse Public License 2.0 (EPL-2.0), developed by HR Agrartechnik GmbH.

State Overview

Since this is a composite function block without its own state machine (ECC), there are no defined states. The functionality is entirely controlled by the embedded function block `F_WORD_TO_LINT`, which performs a one-time, event-driven conversion. The function block is always ready when an event arrives at the input adapter. After the conversion, it waits for the next event.

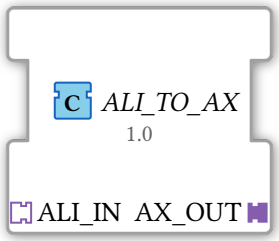
Application Scenarios

- **Data Conversion in Adapter Chains** – If a control system is based on unidirectional adapters and one component delivers WORD data, but a subsequent component expects LINT data, AW_TO_ALI can be inserted as an intermediary.
- **Connecting Field Devices with Different Bit Widths** – For example, integrating a sensor that delivers 16-bit measured values (WORD) into logic that works with 64-bit values (LINT) (e.g., for high-resolution counters or timestamps).
- **Type Conversion in Libraries** – Extending an existing adapter library with convenient conversion blocks to ensure compatibility between different data formats.

Comparison with Similar Blocks

Block	Input (adapter)	Output (adapter)	Conversion	Special Features
AW_TO_ALI	AW (WORD)	ALI (LINT)	WORD ⟶ LINT	Unidirectional, Composite
`F_WORD_TO_LINT` (IEC 61131)	Single REQ input, IN (WORD)	Single CNF output, OUT (LINT)	WORD ⟶ LINT	Standard FB, no adapter
`ALI_TO_AW` (hypothetical)	ALI (LINT)	AW (WORD)	LINT ⟶ WORD	Reverse direction

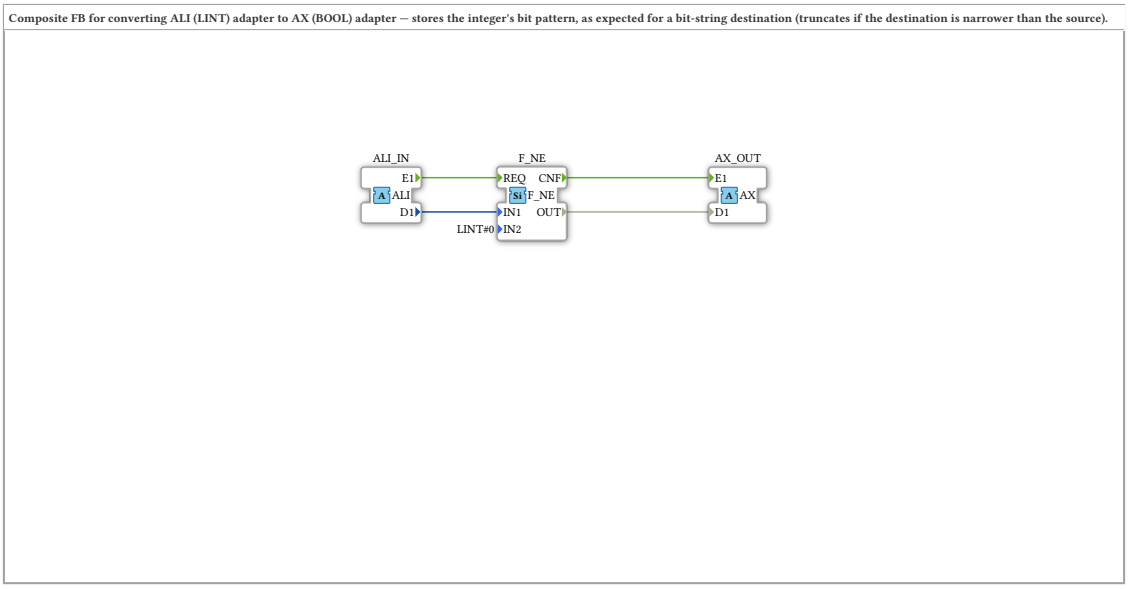
The advantage of AW_TO_ALI lies in its seamless integration into adapter-based systems, whereas the pure IEC component `F_WORD_TO_LINT` would require separate wiring. Components with adapter interfaces simplify control design because they offer standardized plugs/sockets.



Conclusion

AW_TO_ALI is a compact, adapter-based conversion component for converting WORD to LINT data. By utilizing the proven IEC 61131 converter `F_WORD_TO_LINT` and encapsulating it in a composite structure, it offers a clean, event-driven interface for unidirectional adapter applications. The component is particularly suitable for use in modular automation systems where data needs to be exchanged between components with different data widths.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALI_TO_AX

LINT Adapter Input – *ALI*

AX – BOOL Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **ALI_TO_AX** is a composite function block that converts an adapter of type **ALI** (containing a LINT value) into an adapter of type **AX** (containing a BOOL value). The conversion follows the rule: A LINT value other than 0 is interpreted as a BOOL value **TRUE**, and a value equal to 0 as **FALSE**.

The function block serves as a bidirectional bridge between adapters based on different data types.

Interface Structure

Event Inputs

- **ALI_IN.E1** – Input event from the ALI adapter. Triggers processing.

Event Outputs

- **AX_OUT.E1** – Output event to the AX adapter. Sent after successful processing.

Data Inputs

(No direct data inputs. Data is provided via the ALI adapter.)

- **ALI_IN.D1** – LINT input value via the adapter.

Data Outputs

(No direct data outputs. Data is output via the AX adapter.)

- **AX_OUT.D1** – BOOL output value via the adapter.

Adapters

Adapter	Direction	Type	Description
ALI_IN	Socket (Input)	`adapter::types::unidirectional::ALI`	Input adapter with a LINT value.
AX_OUT	Plug (Output)	`adapter::types::unidirectional::AX`	Output adapter with a BOOL value.

Functionality

The function block internally uses the comparison function block **F_NE** (“Not Equal”) from the IEC 61131 library. The process is as follows:

1. A LINT value is received via socket `ALI_IN`.
2. The event `ALI_IN.E1` triggers the function block `F_NE` via its `REQ` input.

3. In F_NE, the input value (IN1) is compared with the constant value LINT#0 (IN2).
4. The result OUT is a BOOL:

- **TRUE** if IN1 ≠ 0
- **FALSE** if IN1 = 0

1. After the comparison is complete, F_NE sends a CNF event, which triggers the output adapter AX_OUT via its E1.
2. Simultaneously, the BOOL value is output as AX_OUT.D1.

Thus, any LINT value (including negative numbers) is converted into a binary signal.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Pure Logic Conversion**: No scaling or thresholding takes place. Any non-zero value is interpreted as TRUE.
- **Composite Function Block Use**: The function block encapsulates the adapter conversion in a reusable unit and allows for easy integration into larger networks.
- **Event-Driven**: Processing only occurs upon an incoming event (ALI_IN.E1). The output is only updated after successful processing.
- **License**: The function block is licensed under the **Eclipse Public License 2.0** (EPL-2.0).

State Overview

Since this is a composite function block without its own state machine, the state logic results from the internal chaining:

1. **Waiting for event**: The function block is inactive until ALI_IN.E1 arrives.
2. **Comparison in progress**: After receiving the event, the F_NE function block is executed.
3. **Output result**: After the comparison is complete, the result is set to AX_OUT.D1, and AX_OUT.E1 is triggered.

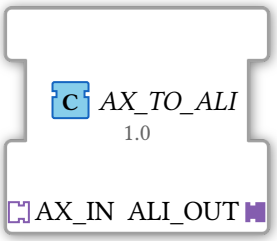
There are no loops, time delays, or error states – the function is deterministic and error-free.

Application Scenarios

- **Signal Conversion in Control Systems**: When a LINT-based protocol (e.g., counter readings, encoders) needs to be converted into simple binary information (e.g., "active," "presence").
- **Adapter Bridges**: Used in systems that employ heterogeneous adapter types to enable communication between components with different data types.
- **Test Environments**: Fast conversion of numerical values into Boolean signals for debugging or simulation.

Comparison with Similar Function Blocks

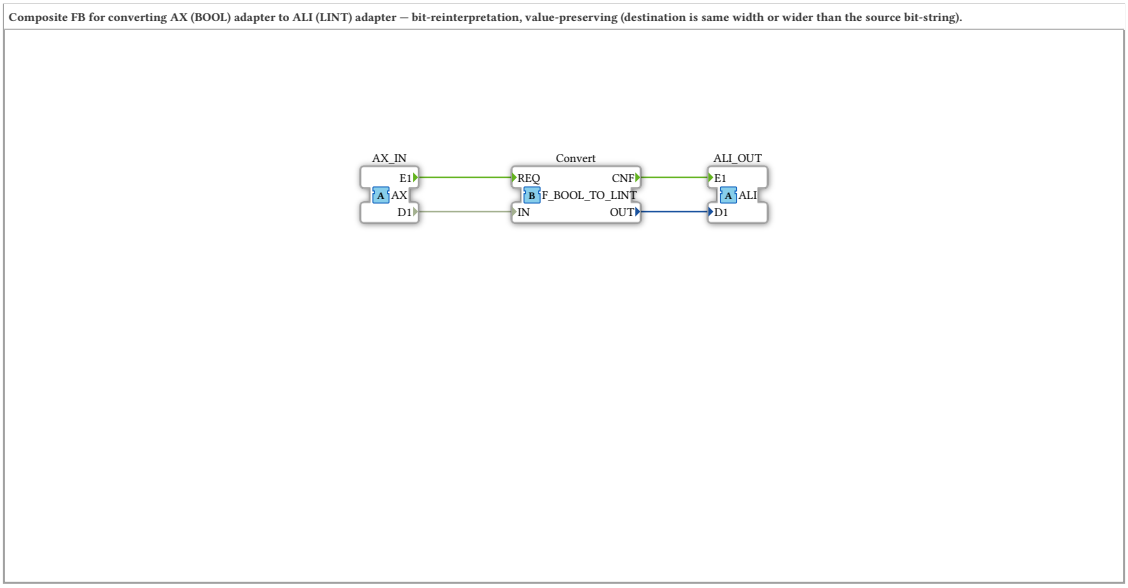
- **Direct Compare Function Block**: Instead of F_NE, a F_EQ (equal) followed by negation could also be used – functionally identical.
- **Threshold Function Blocks (e.g., Greater_than)**: Would require an explicit threshold; ALI_TO_AX makes a hard zero decision.
- **Type conversions (e.g., LINT_TO_BOOL)**: Some libraries offer primitive converters – however, these usually do not operate at the adapter level. ALI_TO_AX is specifically designed for adapter interfaces.



Conclusion

The **ALI_TO_AX** function block provides a simple and reliable method for translating a LINT adapter value to a BOOL adapter value.

Thanks to its clear logic structure and event-driven architecture, it is suitable for both production use and rapid prototyping.



The use of the composite concept promotes modularity and reusability in IEC 61499-based control applications.

AX_TO_ALI

BOOL Adapter Input – *AX*

ALI – LINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AX_TO_ALI** is a composite function block (FB) that converts a unidirectional AX adapter (BOOL) into a unidirectional ALI adapter (LINT). It was developed to convert BOOL values received via an AX socket into LINT values and output them via an ALI plug. The block internally uses the IEC 61131 conversion function `F_BOOL_TO_LINT`.

Interface Structure

The AX_TO_ALI has no direct event or data inputs/outputs. All communication takes place exclusively via adapters.

Event Inputs

No separate event inputs. Events are received indirectly via the AX adapter socket.

Event Outputs

No separate event outputs. Events are output indirectly via the ALI adapter plug.

Data Inputs

No separate data inputs. Data is received indirectly via the AX adapter socket.

Data Outputs

No separate data outputs. Data is output indirectly via the ALI adapter plug.

Adapter

Adapter	Direction	Type	Description

AX_IN	Socket	adapter::types::unidirectional::AX	BOOL adapter input: Receives a BOOL signal via the unidirectional AX adapter.
ALI_OUT	Plug	adapter::types::unidirectional::ALI	LINT adapter output: Outputs the converted LINT value via the unidirectional ALI adapter.

Functionality

The module operates in an event-driven manner and performs the following steps upon each event received via the AX adapter socket:

1. **Event reception**: An event `E1` from the AX adapter is transmitted to the internal conversion module `F_BOOL_TO_LINT` (event `REQ`).
2. **Data Transfer**: The current BOOL value `D1` of the AX adapter is passed to the input `IN` of the conversion function.
3. **Conversion**: The internal function block converts the BOOL value into a LINT value (`FALSE` ⟶ `0`, `TRUE` ⟶ `1`).
4. **Data Output**: The converted LINT result is output via data output `OUT` to the data input `D1` of the ALI adapter.
5. **Event Output**: After successful conversion, an acknowledgment event `CNF` is sent to the ALI adapter output `E1`.

This enables synchronous, event-driven conversion from BOOL to LINT.

Technical Specifications

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **License**: This function block is released under the **Eclipse Public License 2.0 (EPL-2.0)**.

Copyright © 2026 HR Agrartechnik GmbH.

- **Author & Version**: Developed by Franz Höpfinger, Version 1.0, February 17, 2026.
- **Adapter Package**: Uses adapters from the `adapter::types::unidirectional` package, which are designed for one-way data and event transmission.
- **Internal Implementation**: The conversion is performed using the IEC 61131 function block `F_BOOL_TO_LINT` from the library `iec61131::conversion`. This function block operates deterministically and does not require intermediate storage.
- **Hash Attribute**: The function block contains an empty type hash attribute (`eclipse4diac::core::TypeHash`).

State Overview

The AX_TO_ALI function block does not have its own state machine. It forwards events and data directly to the internal conversion function block and outputs the result without delay. Since the internal function block `F_BOOL_TO_LINT` is pure function logic without state management, the entire composite function block behaves stateless. After each event at the AX adapter, the corresponding output is immediately generated at the ALI adapter.

Application Scenarios

- **Type Conversion in Adapter Chains**: When a BOOL value arrives in an IEC 61499 application via a unidirectional AX adapter, but subsequent function blocks expect a LINT value (e.g., for counter functions or analog value processing).
- **Interface Adaptation**: Connecting binary sensors (BOOL) to control logic that works with integer LINT values.
- **Event-Driven Data Conversion**: Simple and fast conversion without intermediate storage, ideal for time-critical paths.

Comparison with Similar Function Blocks

The library `iec61131::conversion` contains numerous function blocks for type conversion, e.g.,... Examples include `F_BOOL_TO_DINT`, `F_BOOL_TO_INT`, and `F_BOOL_TO_USINT`. The AX_TO_ALI differs in that it

is already fully embedded in an adapter package and enables conversion between the unidirectional AX and ALI adapters. This eliminates the need for developers to manually wire sockets/plugs with a separate conversion block and provides a clean, reusable encapsulation.

Conclusion

The AX_TO_ALI is a compact, license-compliant composite function block for reliably converting a BOOL value to a LINT value via unidirectional adapters. Its simple event handling and use of an established IEC function block make it a robust solution for typical conversion tasks in IEC 61499 systems. The clean separation of input and output via adapters facilitates integration into modular control architectures.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALR_TO_AR

No image available

• – ○ • – ○ • – ○ •

Introduction

The **ALR_TO_AR** function block is a composite block that converts an LREAL adapter (ALR) into a REAL adapter (AR). It serves as a link between control components operating with different floating-point accuracies and enables clean, event-driven data conversion within an IEC 61499 network.

Interface Structure

Event Inputs

- **E1** (via socket `ALR_IN`): Starts the conversion of the incoming LREAL value.

Event Outputs

- **E1** (via plug `AR_OUT`): Signals that the converted REAL value at the output is valid.

Data Inputs

- **D1** (via socket `ALR_IN`): LREAL input value (64-bit floating point).

Data Outputs

- **D1** (via plug `AR_OUT`): REAL output value (32-bit floating point).

Adapters

- **ALR_IN** (socket): Adapter type `adapter::types::unidirectional::ALR` – accepts LREAL data.
- **AR_OUT** (Plug): Adapter type `adapter::types::unidirectional::AR` – provides REAL data.

Functionality

1. An event at input **E1** (of the ALR_IN socket) triggers the internal block `F_LREAL_TO_REAL`.
2. Simultaneously, the LREAL value from **D1** (ALR_IN) is passed directly to the conversion block.
3. The conversion block converts the 64-bit value into a 32-bit REAL value.
4. After the conversion is complete, an event is generated at output **E1** (AR_OUT), and the REAL value is passed to **D1** (AR_OUT).

Transmission is strictly sequential: first the event, then the data flow – the internal connection ensures reliable synchronization.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block**: The ALR_TO_AR encapsulates the conversion logic and simplifies reuse in different projects.
- **IEC 61131 Function**: The actual type conversion is based on the standardized library function `F_LREAL_TO_REAL`.
- **Adapter Types**: Both adapters are unidirectional and allow a clear separation of input and output sides.
- **No State Machine**: The block operates purely event-driven without an internal state memory.

State Overview

Since this is a composite block without its own state machine, there are no explicit states. The internal process is deterministic:

- **Ready / Idle** – waits for an input event.
- **Conversion active** – from event input until the output event is generated (typically takes one cycle).

Latency is minimal and determined by the execution order of the underlying IEC 61499 runtime system.

Application Scenarios

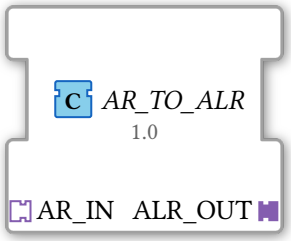
- **Sensor Integration**: A field device provides LREAL measured values, but downstream logic expects REAL values (e.g., PLC communication).
- **Adapter Coupling**: Connecting two modules that use different adapter interfaces without requiring the developer to manually program the conversion.
- **Data Consistency**: Enforces a clean separation of 64-bit and 32-bit data paths and avoids implicit type conversions.

Comparison with Similar Components

- **F_LREAL_TO_REAL** (direct): Offers the same conversion but requires separate event and data connections. ALR_TO_AR encapsulates these connections and provides a unified adapter interface.

- **LINT_TO_INT** (adapter variant): Analog logic for integer types with different bit widths. The basic structure is identical but tailored to different data types.
- **Custom Composite Converters**: ALR_TO_AR reduces the overhead of recurring adapter conversions and improves network readability.

Conclusion



The **ALR_TO_AR** is a simple yet effective composite component that bridges the gap between LREAL and REAL adapter interfaces. It offers clean, event-driven conversion without unnecessary overhead and integrates easily into existing 4diac projects. Thanks to the use of standard library functions, the conversion remains performant and reliable.

AR_TO_ALR

REAL Adapter Input – *AR*

ALR – LREAL Adapter Output

• – ○ • – ○ • – ○ •

Introduction

Composite function block for converting an AR adapter (REAL) to an ALR adapter (LREAL). It is used to adapt data formats in IEC 61499-2 environments and is licensed under the Eclipse Public License 2.0.

Interface Structure

Event Inputs

Name	Description
E1 (from AR_IN)	Event to trigger data transfer

Event Outputs

Name	Description
E1 (from ALR_OUT)	Event output after successful conversion

Data Inputs

Name	Data Type	Description
D1 (from AR_IN)	REAL	32-bit floating-point number

Data Outputs

Name	Data Type	Description
D1 (from ALR_OUT)	LREAL	64-bit floating-point number

Adapters

- **ALR_OUT** (Plug): Type `adapter::types::unidirectional::ALR` – LREAL output adapter
- **AR_IN** (Socket): Type `adapter::types::unidirectional::AR` – REAL input adapter

Functionality

This function block connects the adapter interfaces directly. An incoming event at `AR_IN.E1` is immediately forwarded to `ALR_OUT.E1`. Simultaneously, the data value `AR_IN.D1` (REAL) is copied to `ALR_OUT.D1` (LREAL), with the runtime environment performing an implicit type conversion. There is no state machine; the function is purely combinatorial.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- Composite function block without its own logic (no ECC)
- Use of unidirectional adapters according to IEC 61499-2
- Automatic type conversion via the 4diac runtime (e.g., 4diac-ide)
- Package: `adapter::conversion::unidirectional`

State Overview

No states present – the function block does not have an execution state machine.

Application Scenarios

- Connecting a REAL-providing sensor to a component that expects LREAL
- Migrating existing REAL adapters to LREAL with higher accuracy
- Interface adaptation in heterogeneous automation systems

Comparison with Similar Function Blocks

Similar function blocks exist for other type conversions (e.g., `LREAL_TO_REAL`, `INT_TO_REAL`). This block is specifically designed for the unidirectional adapters `AR` and `ALR` and requires no custom implementation logic.

Conclusion

The `AR_TO_ALR` block enables simple and efficient conversion of REAL to LREAL adapter data. Implemented as a composite function block, it utilizes the direct connection of the adapter interfaces, thus offering high performance with minimal latency.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALR_TO_AS

• – ○ • – ○ • – ○ •

Introduction

The **ALR_TO_AS** function block is a composite function block that converts an **LREAL adapter** (ALR) into a **SINT adapter** (AS). It encapsulates the conversion of a floating-point value (LREAL) into a signed 8-bit integer value (SINT) and provides the result data via the SINT adapter. This function block is typically used in automation technology when data needs to be transferred between different adapter interfaces.

Interface Structure

Event Inputs

The function block does not have separate event inputs. The conversion is controlled by the event of the connected **ALR Adapter Socket** (`ALR_IN.E1`).

Event Outputs

The function block does not have separate event outputs. The completion of the conversion is signaled by the event of the **AS Adapter Plug** (`AS_OUT.E1`).

Data Inputs

The function block does not have separate data inputs. The input data (LREAL value) is provided via the **ALR Adapter** (`ALR_IN.D1`).

Data Outputs

The function block does not have separate data outputs. The output data (SINT value) is provided via the **AS adapter** (`AS_OUT.D1`).

Adapter

Adapter	Direction	Type	Description
`ALR_IN`	Socket	`adapter::types::unidirectional::ALR`	LREAL adapter input: provides the LREAL value to be converted and a trigger event (`E1`).
`AS_OUT`	Plug	`adapter::types::unidirectional::AS`	SINT adapter output: provides the converted SINT value and an acknowledgment event (`E1`).

Functionality

The function block is implemented as a composite FB. Internally, it contains a function block `F_LREAL_TO_SINT` from the IEC 61131 library. The connections within the network cause:

1. **Event-driven activation**: An incoming event at the adapter `ALR_IN` (`E1`) triggers the conversion FB (`Convert.REQ`).
2. **Data conversion**: The LREAL value of `ALR_IN.D1` is forwarded to the input `Convert.IN`. The function block (FB) converts this value into a SINT value (rounding according to IEC 61131 rules).
3. **Result Output**: After successful conversion, `Convert.CNF` signals an event to the output adapter `AS_OUT` (`E1`), and the converted SINT value is passed to `AS_OUT.D1`.

This enables synchronous, event-driven conversion of an LREAL value to a SINT value via adapter interfaces.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Structure**: The function block completely encapsulates the conversion logic in a network, making the implementation transparent and easily extensible.
- **Adapter-based**: Instead of individual event and data ports, standardized unidirectional adapters (`ALR` and `AS`) are used. This simplifies integration into existing adapter-based architectures.
- **Reuse**: The internal function block `F_LREAL_TO_SINT` is a proven IEC function block and ensures correct conversion to the standard.
- **No dedicated state machine**: Since this is a composite function block, there is no independent state machine; control is achieved solely through the connected adapter events.

State Overview

The function block does not have an explicit state machine. Its behavior is determined by the internal function block `F_LREAL_TO_SINT` and the event connections. This internal function block (FB) executes a simple **IDLE → CONVERTING → DONE** cycle, controlled by the events `REQ` and `CNF`. For the user, the block is therefore transparent and usable as an **event-driven converter**.

Application Scenarios

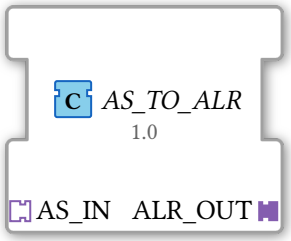
- **Data Bridge Between Systems**: When a control module provides LREAL values via a `ALR` adapter, but a downstream module expects SINT values via a `AS` adapter.
- **Uniform Adapter Interfaces**: Simplifying system design by outsourcing conversions to standalone function blocks.
- **PLC Connection**: Connecting sensors or actuators that operate with LREAL accuracy to a SINT-based bus communication.

Comparison with Similar Components

Compared to directly wiring a `F_LREAL_TO_SINT` component with individual event/data ports, the `ALR_TO_AS` component offers **a higher level of abstraction through adapters**. This facilitates the ex-

change of data between components that are already designed for adapter interfaces. Similar components could be `ALR_TO_ADI` (conversion to INT) or `ALR_TO_UDI` (conversion to UDINT), which are structured analogously but use different target data types.

Conclusion



The `ALR_TO_AS` function block is a clean, adapter-based solution for converting LREAL to SINT values in the 4diac IDE. Its composite structure and use of standardized IEC conversion blocks ensure reliable, event-driven data conversion and facilitate integration into modular automation systems.

AS_TO_ALR

SINT Adapter Input – *AS*

ALR – LREAL Adapter Output

No image available.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AS_TO_ALR** is a composite function block (FB) that converts an **AS adapter** (data type SINT) into an **ALR adapter** (data type LREAL). It serves as a simple interface conversion between these two unidirectional adapter types and is located in the package `adapter::conversion::unidirectional`.

Interface Structure

Event Inputs

Name	Comment
E1	Event from AS adapter (Socket AS_IN)

Event Outputs

Name	Comment
E1	Event for the ALR adapter (Plug ALR_OUT)

Data Inputs

Name	Data Type	Comment
D1	SINT	Data value from the AS adapter (Socket AS_IN)

Data Outputs

Name	Data Type	Comment
D1	LREAL	Data value for the ALR adapter (Plug ALR_OUT)

Adapters

Direction	Name	Type	Comment
Socket	AS_IN	`adapter::types::unidirectional::AS`	Input Adapter (SINT)
Plug	ALR_OUT	`adapter::types::unidirectional::ALR`	Output Adapter (LREAL)

Functionality

The **AS_TO_ALR** block forwards incoming events and data values directly to the output side without further processing.

- The event **E1** at socket `AS_IN` is passed to plug `ALR_OUT` without delay.
- The data value **D1** of type SINT is forwarded to the output of the same name. The conversion from SINT to LREAL is performed implicitly by the runtime environment – the function block itself does not execute any arithmetic operations.

The function block has no state machine (ECC) and no internal algorithms; its entire functionality is implemented through the included connections.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Structure**: The function block consists exclusively of an internal network (FBNetwork) with direct event and data connections between the adapters.
- **Implicit Type Conversion**: Data conversion from SINT to LREAL is handled by the IEC 61499 runtime environment. Explicit type conversion is not required.
- **Packaging**: The function block is organized in the package `adapter::conversion::unidirectional`, providing a clean separation between adapter and converter logic.

State Overview

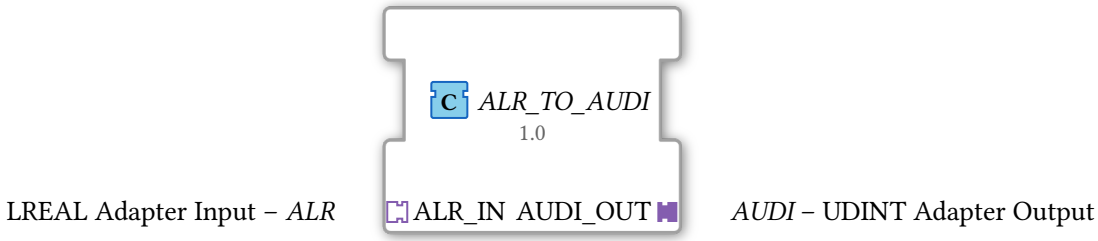
The **AS_TO_ALR** function block does not have its own state machine (no ECC diagram). Its behavior is defined solely by the direct connection of its inputs and outputs. There is no defined start or end state.

Application Scenarios

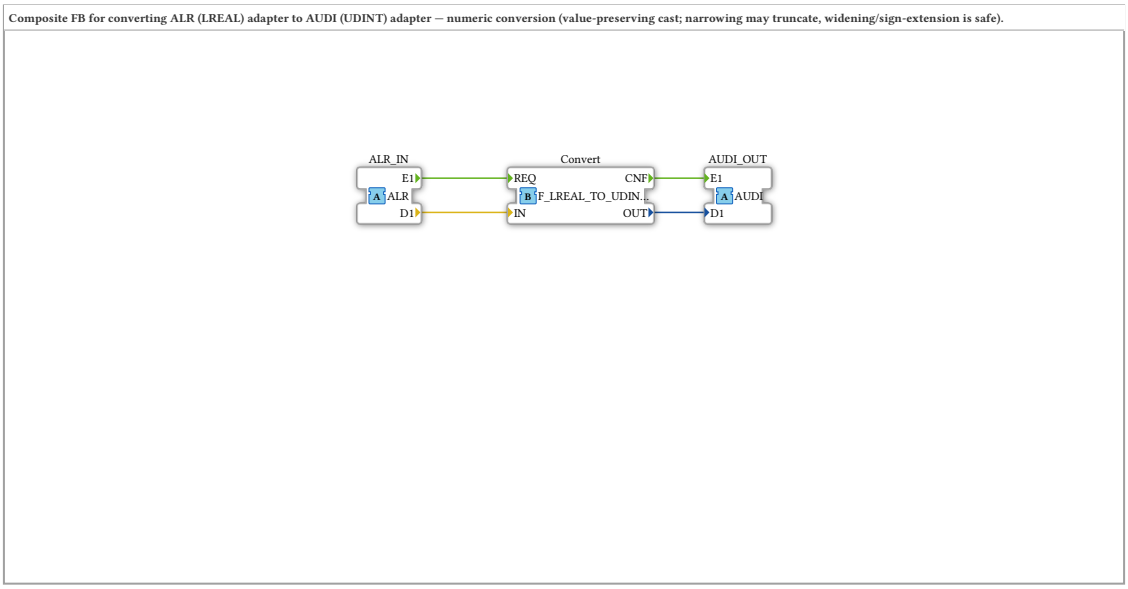
- **Sensor Connection**: A sensor provides data in SINT format (e.g., an 8-bit counter) that needs to be integrated into an environment with an LREAL interface (e.g., an analog adapter) via an AS adapter.
- **Protocol Conversion**: In heterogeneous automation systems where different components expect adapters of various types, **AS_TO_ALR** serves as a simple converter.
- **Interface Migration**: When switching from SINT-based to LREAL-based adapters, this function block can be used as a temporary bridge.

Comparison with Similar Components

- **AS_TO_AR**: Converts an AS adapter (SINT) to an AR adapter (REAL) – similar structure, but with a smaller value range (REAL instead of LREAL).
- **ALR_TO_AS**: The inverse conversion (LREAL ⟶ SINT), which may require explicit range checking or rounding.
- **AS_TO_ALR** is characterized by the larger value range of its output (LREAL), enabling lossless transmission of SINT values.



Conclusion



The **AS_TO_ALR** is a minimal yet useful converter component for easily connecting AS adapters to ALR adapters. Its composite architecture and implicit type conversion make it easy to understand and efficient to use.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALR_TO_AUDI

• – ○ • – ○ • – ○ •

Introduction

The ALR_TO_AUDI function block is a composite function block (FB) that converts an **ALR adapter** (LREAL) into an **AUDI adapter** (UDINT). It serves as an interface between an analog LREAL source and a digital UDINT sink in unidirectional communication paths.

Interface Structure

Event Inputs

- `ALR_IN.E1` – Event input of the ALR adapter; triggers the conversion.

Event Outputs

- `AUDI_OUT.E1` – Event output of the AUDI adapter; signals the completion of the conversion.

Data Inputs

- `ALR_IN.D1` – LREAL input value that is converted to a UDINT value.

Data Outputs

- `AUDI_OUT.D1` – UDINT output value, result of the conversion.

Adapters

- **Socket** `ALR_IN` of type `adapter::types::unidirectional::ALR` – Input interface for LREAL values with event.
- **Plug** `AUDI_OUT` of type `adapter::types::unidirectional::AUDI` – Output interface for UDINT values with event.

Functionality

The function block internally uses the conversion function block `iec61131::conversion::F_LREAL_TO_UDINT`. The process is as follows:

1. An event on `ALR_IN.E1` is forwarded to input `REQ` of the internal converter.
2. Simultaneously, the data value from `ALR_IN.D1` is transferred to input `IN` of the converter.
3. After successful conversion, the converter sends an acknowledgment event (`CNF`) to `AUDI_OUT.E1`.
4. The converted UDINT value is at output `OUT` of the converter and is passed on to `AUDI_OUT.D1`.

Thus, the conversion is strictly event-driven and data-synchronous.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Adapter-Based Encapsulation** – Data and events are exchanged via standardized adapters of type `unidirectional`, enabling a clean separation of interfaces and implementation.
- **Unidirectional Communication** – The function block supports only one direction of data flow (LREAL ⟶ UDINT). Feedback or error status is not provided.
- **Type Conversion** – The conversion from LREAL (64-bit floating-point) to UDINT (32-bit unsigned integer) can lead to rounding or overflow losses, but is performed according to the IEC 61131 standard.

State Overview

The ALR_TO_AUDI does not have its own internal state machine. Its behavior is entirely determined by the included function block `F_LREAL_TO_UDINT`, which operates as a simple, event-driven conversion instance.

Application Scenarios

- **Analog-to-Digital Conversion in Agricultural Control** – Conversion of LREAL sensor values (e.g., pressure, fill level) into integer UDINT values for displays or digital control loops.
- **Interface Adaptation** – Connecting components that rely on different adapter types (e.g., ALR from a measurement module and AUDI in a controller).
- **Protocol Conversion** – Simple conversion within adapter chains without having to implement custom logic.

Comparison with Similar Components

- **LREAL_TO_DINT** – Converts to a signed 32-bit integer. ALR_TO_AUDI, on the other hand, uses the unsigned UDINT variant.
- **REAL_TO_UDINT** – Works with 32-bit floating-point instead of 64-bit LREAL, resulting in correspondingly lower accuracy.
- **LREAL_TO_LWORD** – Converts to a 64-bit integer, but using a different adapter type (LWORD instead of UDINT).

The ALR_TO_AUDI is specifically designed for unidirectional adapter coupling with the aforementioned types.

Conclusion

The ALR_TO_AUDI is a specialized yet simple component for converting LREAL to UDINT values via adapter interfaces. Thanks to its clear structure and the use of a standardized IEC converter, it can be easily integrated into existing 4diac projects and contributes to the interoperability of different adapter types.

AUDI_TO_ALR

UDINT Adapter Input – *AUDI* *ALR* – LREAL Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUDI_TO_ALR** function block is a composite module that converts a unidirectional adapter of type **AUDI** (data type `UDINT`) into an adapter of type **ALR** (data type `LREAL`). It serves as a simple link between two different adapter interfaces, thus enabling the integration of components based on different data formats.

Interface Structure

Event Inputs

Name	Comment
`AUDI_IN.E1`	Event input of the AUDI adapter (passed through to the ALR output)

Event Outputs

Name	Comment
ALR_OUT.E1	Event output of the ALR adapter (inherited from the AUDI input)

Data Inputs

Name	Data Type	Comment
AUDI_IN.D1	UDINT	Data input of the AUDI adapter (passed directly as LREAL)

Data Outputs

Name	Data Type	Comment
ALR_OUT.D1	LREAL	Data output of the ALR adapter (value from the AUDI input, type-converted)

Adapter

Direction	Name	Type	Comment
Socket (Input)	AUDI_IN	adapter::types::unidirectional::AUDI	Receives the UDINT data and the associated event
Plug (Output)	ALR_OUT	adapter::types::unidirectional::ALR	Provides the converted LREAL data and the event

Functionality

The function block forwards the incoming event E1 from socket AUDI_IN directly to plug ALR_OUT. Simultaneously, the data value D1 (type UDINT) is transferred unchanged to the output data channel D1 (type LREAL). The actual type conversion from UDINT to LREAL takes place within the adapter interfaces used; the composite block itself does not perform any arithmetic or logical transformation, but merely serves as a wiring aid.

...

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Pure Adapter Passthrough:** The module contains no logic or state machines of its own – it simply connects the corresponding channels of the two adapters.
- **Unidirectional Communication:** Both the AUDI and ALR adapters support only one direction of data flow, which simplifies their use in simple sensor/actuator interfaces or when coupling different protocols.
- **No Type Conversion in the Module:** The conversion from UDINT to LREAL is handled by the adapter infrastructure. The developer must ensure that the adapter implementations used provide the necessary conversion.

State Overview

As a composite module, AUDI_TO_ALR does not have its own state machine. Its behavior is purely combinatorial: An incoming event is immediately passed on to the output – without delay or condition.

Application Scenarios

- **Integration of UDINT-based sensors** (e.g., rotary encoders with 32-bit counters) into an LREAL-processing control system.
- **Adapter bridge** between different libraries or components based on different data types but using uniform adapter interfaces.

- **Prototype development** and rapid wiring of adapters without having to create separate conversion logic.

Comparison with Similar Function Blocks

In the 4diac ecosystem, simple conversion function blocks such as `INT_TO_REAL` or `UDINT_TO_LREAL` exist, which are usually implemented as Basic or Service FBs. The present Composite FB differs in that it does not convert the data value itself, but rather connects two complete adapters. It is therefore specifically designed for environments that rely on adapter interfaces and not for simple data flow conversion.

Conclusion

AUDI_TO_ALR` is a minimal yet useful composite block for connecting two unidirectional adapters with different data types. It reduces wiring complexity and makes the type conversion explicitly visible. This block should always be used when a clean separation between adapter types and simple event and data transmission are required.

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

ALR_TO_AUI

LREAL Adapter Input – *ALR* *AUI* – UINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **ALR_TO_AUI** is a composite function block (FB) that converts an LREAL value, received via an **ALR** adapter (unidirectional), into a UINT value and makes it available via an **AUI** adapter (unidirectional). The conversion is performed using the internal IEC 61131 function block

F_LREAL_TO_UINT. This block encapsulates the adapter conversion and provides a clean interface for data exchange between the two adapter types.

Interface Structure

Event Inputs

The FB does not have its own event inputs. Events are received indirectly via the **ALR_IN** adapter:

- **ALR_IN.E1** – Event to trigger the conversion.

Event Outputs

The FB does not have its own event outputs. Events are sent via the **AUI_OUT** adapter:

- **AUI_OUT.E1** – Confirmation event after successful conversion.

Data Inputs

The data is also provided via the **ALR_IN** adapter:

- **ALR_IN.D1** – Input value of type **LREAL** (according to the ALR adapter).

Data Outputs

The converted data is output via the **AUI_OUT** adapter:

- **AUI_OUT.D1** – Output value of type **UINT** (according to the AUI adapter).

Adapters

Name	Type	Direction	Description
ALR_IN	`adapter::types::unidirectional::ALR`	Socket (Input)	Returns the LREAL value and the trigger event.
AUI_OUT	`adapter::types::unidirectional::AUI`	Plug (Output)	Outputs the converted UINT value and the confirmation event.

Functionality

The function block operates as a pure translation layer between two adapters:

1. An incoming event at socket **ALR_IN.E1** triggers the internal conversion block F_LREAL_TO_UINT via its **REQ** input.
2. Simultaneously, the data value **ALR_IN.D1** is forwarded to the **IN** input of the conversion block.
3. The internal block performs the type conversion from **LREAL** to **UINT** and places the result at its **OUT** output.
4. Once the conversion is complete, the internal block sends an acknowledgment event (**CNF**), which is passed to the plug **AUI_OUT.E1**.
5. Simultaneously, the converted value (**OUT**) is transferred to the data output **AUI_OUT.D1**.

The entire process is event-driven and occurs once per triggering event.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Adapter Encapsulation:** The block combines two different adapter types (ALR and AUI), thus enabling type-safe communication between components that use these adapters.
- **Unidirectional Adapters:** Both the input and output adapters are unidirectional, meaning there is only one direction of data and events (input → output).
- **Internal Conversion:** The actual conversion is performed by the standardized IEC 61131 function block F_LREAL_TO_UINT. This ensures well-defined and platform-independent conversion behavior.
- **No Control:** The composite function block itself does not have its own state machine. Its behavior is entirely determined by the embedded function block.

State Overview

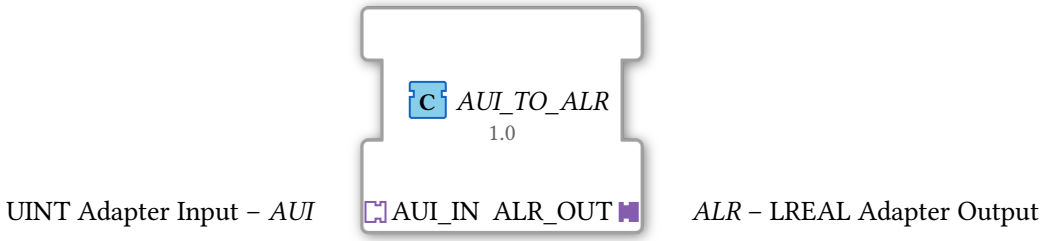
Since this is a composite function block without its own Execution Control Chart (ECC), there is no internal state machine. The process is controlled by the event links:

- **IDLE:** Waiting for an event at socket **ALR_IN.E1**.
- **CONVERT:** After receiving the event, the conversion is triggered; The internal function block iterates through its own state machine (e.g., REQ → CNF).
- **OUTPUT:** After the conversion is complete, the output event **AUI_OUT.E1** and the converted value are output.

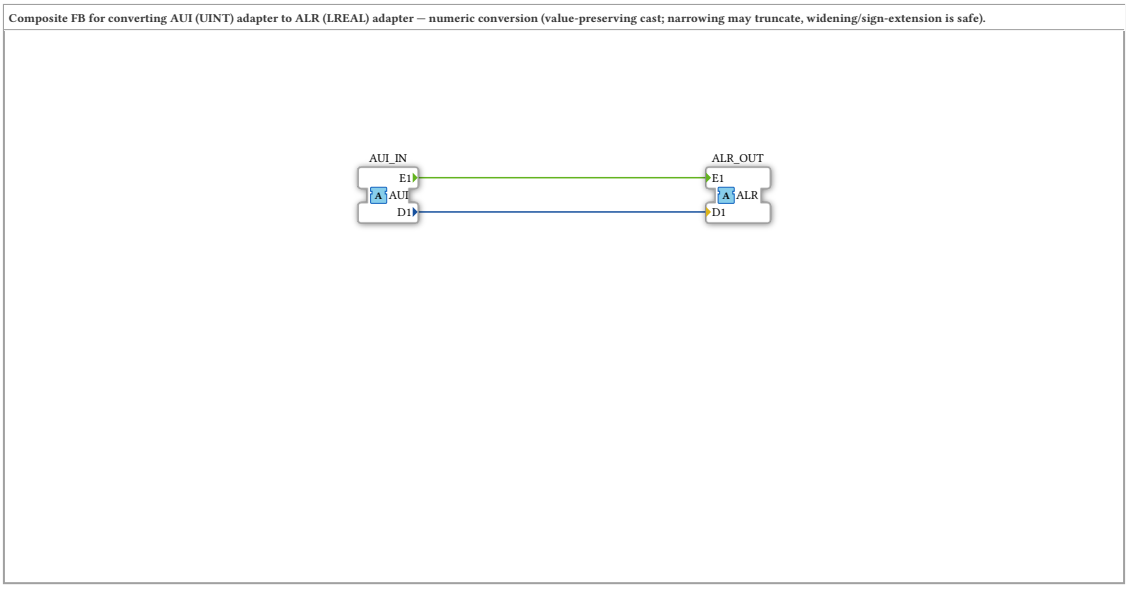
Application Scenarios

- **Connecting Sensors/Actuators:** A sensor provides an LREAL value (e.g., temperature, pressure) which is read into a PLC via an ALR adapter. For display or transmission to a system that only processes integers (UINT), the function block is used.
- **Adapter Migration:** In existing systems, adapters need to be converted from ALR to AUI without changing the connected components. The function block acts as an intermediary.
- **Test and Simulation Environments:** Generating UINT values from LREAL sources for testing purposes.

Comparison with Similar Function Blocks



Function Block	Input Type	Output Type	Description
ALR_TO_AUI	ALR (LREAL)	AUI (UINT)	Adapter-based conversion LREAL→UINT.
`F_LREAL_TO_UINT`	LREAL	UINT	Pure data conversion without an adapter.
`LREAL_TO_INT`	LREAL	INT	Conversion to a signed integer.



Unlike pure data converters, **ALR_TO_AUI** operates at the adapter level, so both the data and the associated events are exchanged via the adapter interfaces. This simplifies integration into adapter-based architectures.

Conclusion

The **ALR_TO_AUI** function block is a useful tool for converting LREAL values from an ALR adapter to UINT values from an AUI adapter. Encapsulating the conversion in a composite function block increases reusability and clearly defines the system interface. This block is particularly suitable for applications where adapter types need to be harmonized or adapted without altering the internal logic of the connected components.

AUI_TO_ALR

• — ○ • — ○ • — ○ •

Introduction

The AUI_TO_ALR function block is a composite module that enables interface conversion between an AUI adapter (data type UINT) and an ALR adapter (data type LREAL). It acts as a simple pass-through, transmitting both event and data signals from the input to the output adapter.

Interface Structure

Event Inputs

- **Event via Socket AUI_IN (E1)** – Event input from the AUI adapter.

Internally, this is directly connected to the event output of the ALR adapter.

Event Outputs

- **Event via Plug ALR_OUT (E1)** – Event output to the ALR adapter.

Corresponds to the passed-through event from socket AUI_IN.

Data Inputs

- **Data value via socket AUI_IN (D1)** – Data input from the AUI adapter (type UINT).

Internally, it is directly connected to the data output of the ALR adapter.

Data Outputs

- **Data value via plug ALR_OUT (D1)** – Data output to the ALR adapter (type LREAL).

Corresponds to the passed-through data value from socket AUI_IN.

Adapters

- **Socket: AUI_IN** – Source (type `adapter::types::unidirectional::AUI`)

Accepts the input signals (event + UINT data).

- **Plug: ALR_OUT** – Sink (Type `adapter::types::unidirectional::ALR`)

Provides the output signals (event + LREAL data).

Functionality

The FB AUI_TO_ALR functions purely as a coupling point. Events and data are forwarded directly from the socket AUI_IN to the plug ALR_OUT. The actual conversion from UINT to LREAL is not performed within this block, but rather implicitly through the adapter type definitions used (unidirectional protocols). Thus, the composite functions as a standardized interface to connect two different adapter protocols.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Type:** The FB does not have its own Execution Control Chart (ECC), but consists solely of a network connection between its two adapters.
- **Direct Pass-Through:** No internal logic, delays, or state changes – the function block is purely passive.
- **Adapter-Based:** The adapters used are defined as unidirectional interfaces, each carrying one event and one data value.

State Overview

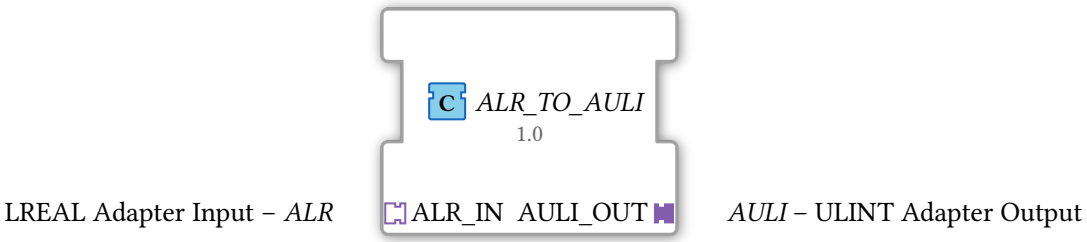
The function block has no states of its own, as it is implemented as a composite without ECC. Its behavior is entirely determined by the connected adapters.

Application Scenarios

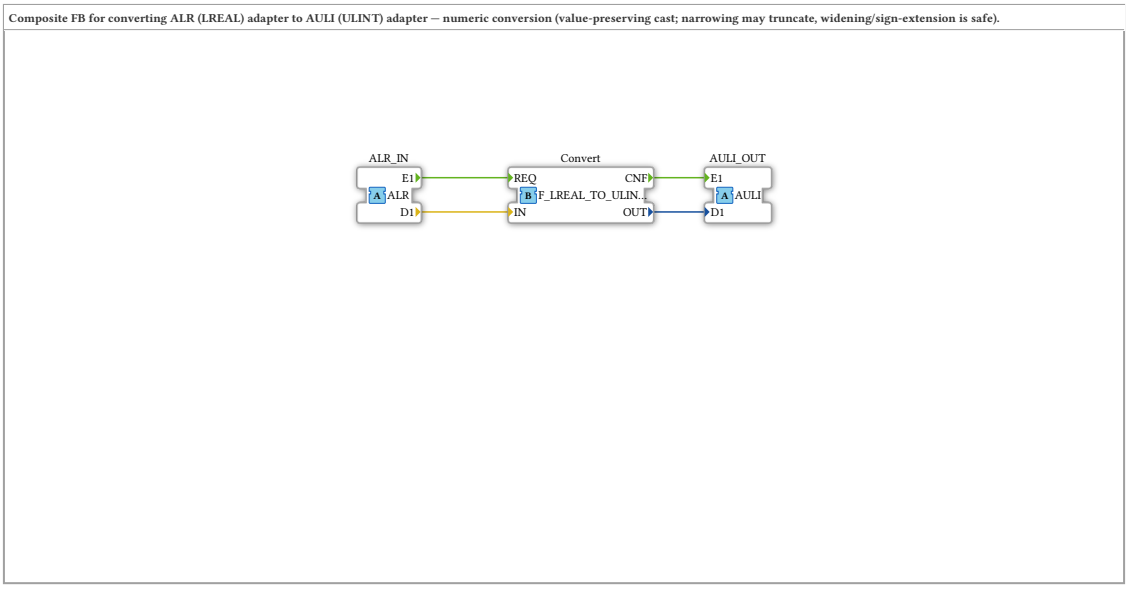
- **Protocol Adaptation in Agricultural Technology:** Use in controllers that need to mediate between different sensor or actuator interfaces.
- **Retrofit or Migration:** Enables the use of an ALR-compatible device on an existing AUI connection without having to implement the actual conversion itself.
- **Modular Cabling:** As a simple connecting link in a chain of adapter function blocks, e.g., in a fieldbus or communication hierarchy.

Comparison with Similar Function Blocks

Similar converter function blocks exist for other adapter pairs (e.g., `AUI_TO_AREAL`, `AUI_TO_BOOL`). Unlike these, AUI_TO_ALR does not perform active data conversion but relies on implicit type conversion through the adapter definition. This makes it particularly lightweight and suitable for simple pass-through tasks.



Conclusion



AUI_TO_ALR is a minimal yet clearly defined composite function block that establishes the connection between an AUI and an ALR adapter. Due to its simplicity and transparency, it is ideally suited for structured cabling in IEC 61499-based automation systems, especially in environments where different adapter protocols need to be coordinated.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALR_TO_AULI

• — ○ • — ○ • — ○ •

Introduction

The function block **ALR_TO_AULI** is a **composite FB** for the unidirectional conversion of an **LREAL adapter signal** (type `ALR`) into a **ULINT adapter signal** (type `AULI`). By internally using the IEC 61131 standard FB `F_LREAL_TO_ULINT`, the floating-point number (LREAL) is converted into an unsigned integer (ULINT) and provided via an output adapter. This block is particularly suitable for integrating floating-point data sources into systems that expect an integer adapter interface.

Interface Structure

The FB has **no direct** event or data inputs/outputs. Communication takes place exclusively via the two **adapters** (socket & plug). The following tables describe the signals provided via the adapters.

Event Inputs

Signal	Source	Data Type	Description
E1	via Socket `ALR_IN`	(Event)	Starts the conversion of an incoming LREAL value.

Event Outputs

Signal	Destination	Data Type	Description
E1	via Plug `AULI_OUT`	(Event)	Signals that the converted ULINT value is present at the output.

Data Inputs

Signal	Source	Data Type	Description
D1	via Socket `ALR_IN`	LREAL	The floating-point value to be converted.

Data Outputs

Signal	Destination	Data Type	Description
D1	via Plug `AULI_OUT`	ULINT	The converted unsigned integer value.

Adapter

Name	Type	Direction	Description
ALR_IN	adapter::types::unidirectional::ALR	Socket (Input)	Receives the LREAL value and its associated event.
AULI_OUT	adapter::types::unidirectional::AULI	Plug (Output)	Outputs the converted ULINT value with an acknowledgment event.

Functionality

The FB operates according to the **gearbox principle** of a composite block:

1. An incoming **event E1** at socket ALR_IN activates the internal FB F_LREAL_TO_ULINT (type iec61131::conversion::F_LREAL_TO_ULINT).
2. Simultaneously, the **data value D1** (LREAL) present at socket ALR_IN is forwarded to the input IN of the internal FB.
3. The internal FB immediately performs the conversion from LREAL to ULINT and outputs the result at its output OUT.
4. The event CNF of the internal function block triggers the **output event E1** at plug AULI_OUT.
5. The converted ULINT value is simultaneously applied to the data output D1 of plug AULI_OUT.

The entire conversion is **event-driven** and without its own state logic.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **License**: The function block is provided under the **Eclipse Public License 2.0** (see copyright notice).
- **Standard Compliance**: The internally used conversion block F_LREAL_TO_ULINT complies with the IEC 61131-3 standard.
- **No State Machine**: As a composite function block (FB), this block has no inherent state logic – the conversion is purely combinatorial.
- **Unidirectional Adapters**: Input and output are separate adapter types that define a clear signal direction.

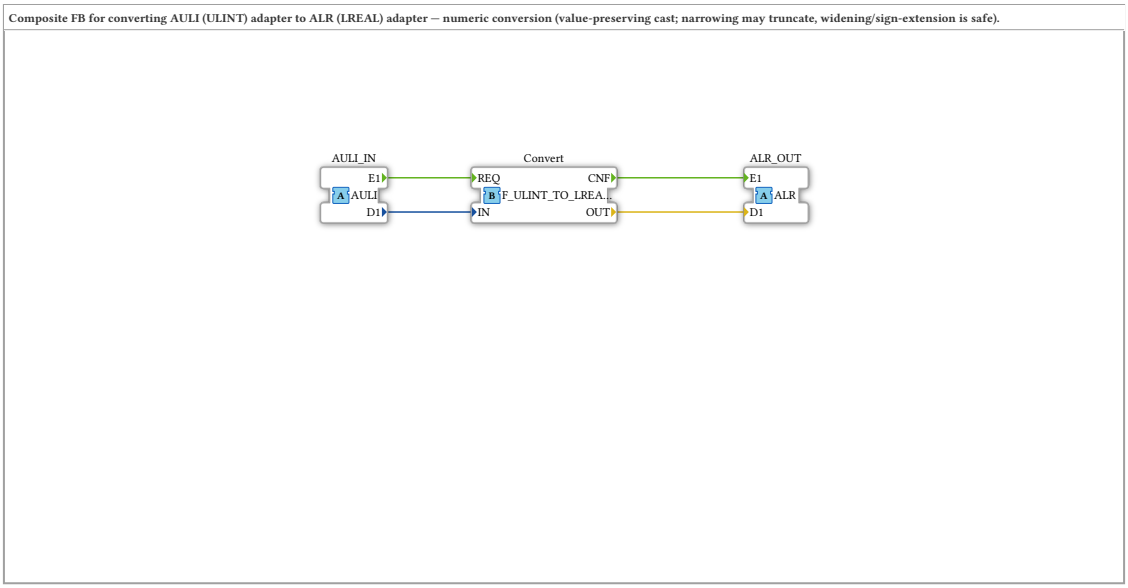
State Overview

Since this is a **composite FB without its own state machine**, there is no explicit state overview. The functionality is event-triggered and behaves like a **combinatorial function**: An event at the input, after internal processing, results in exactly one event at the output.

Application Scenarios

- **Connecting floating-point sensors** to a controller that only processes integer adapter signals (e.g., in agricultural technology).
- **Data processing** in an adapter-based communication chain when the source delivers LREAL, but the destination expects ULINT.
- **Replacement of manual type conversions** in systems that rely on the standardized IEC 61131 functions.

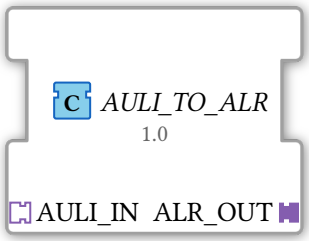
Comparison with similar function blocks



Other conversion adapters (e.g., REAL_TO_DINT, LREAL_TO_LINT) follow the same pattern: They use an internal IEC function block and encapsulate the type conversion in an adapter interface. The advantage of ALR_TO_AULI lies in the **targeted combination of LREAL and ULINT** – a type combination that is not offered as a ready-made adapter in many standard libraries.

Conclusion

ALR_TO_AULI` is a specialized **composite adapter function block** for lossy conversion of floating-point numbers to integers. Thanks to the use of a standardized IEC function block, the conversion is



deterministic and easily testable. The function block is ideally suited for creating a clean adapter interface between LREAL and ULINT domains in heterogeneous automation systems.

AULI_TO_ALR

No image available.

ULINT Adapter Input – *AULI*

ALR – LREAL Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **AULI_TO_ALR** is a composite function block (FB) that converts an incoming AULI adapter (ULINT data) into an outgoing ALR adapter (LREAL data). It serves as a standardized interface between components that communicate different data types via adapters.

Interface Structure

Event Inputs

The block has no direct event inputs. The incoming event is provided via the socket adapter **AULI_IN**:

- **AULI_IN.E1** (Event) – Receives the trigger signal for the conversion.

Event Outputs

The block has no direct event outputs. The outgoing event is provided via the **ALR_OUT** plug adapter:

- **ALR_OUT.E1** (Event) – Signals that the converted data is available at the data output.

Data Inputs

Direct data inputs are not available. The input data is provided via the **AULI_IN** socket adapter:

- **AULI_IN.D1** (ULINT) – The value to be converted in unsigned long integer format.

Data Outputs

Direct data outputs are not available. The output data is provided via the **ALR_OUT** plug adapter:

- **ALR_OUT.D1** (LREAL) – The converted value in long real format (64-bit floating-point number).

Adapters

The function block uses exactly two adapters:

- **Socket AULI_IN** (Type: AULI from `adapter::types::unidirectional`) – Receives the ULINT values and the associated trigger event.
- **Plug ALR_OUT** (Type: ALR from `adapter::types::unidirectional`) – Provides the converted LREAL values and an acknowledgment event.

Functionality

The function block operates according to the request-acknowledgment principle:

1. As soon as an event arrives at **E1** on the input adapter **AULI_IN**, the internal function block **F_ULINT_TO_LREAL** (from the library `iec61131::conversion`) is called.
2. The value **AULI_IN.D1** is fed to the input **IN** of the converter. 3. The converter performs the conversion from ULINT to LREAL (integer to floating-point number).
3. After the conversion is complete, the result is forwarded to **ALR_OUT.D1**.
4. Simultaneously, the event **ALR_OUT.E1** is triggered at the output adapter to signal the downstream function block that the data is being processed.

All logic runs within a function block network and is transparent to the user.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Adapter-based communication:** The function block encapsulates the type conversion in an adapter interface, allowing it to be seamlessly integrated into systems with standardized adapter types (e.g., AULI and ALR). This increases compatibility between components.
- **Reuse of existing function blocks:** As a composite function block, it uses the standardized conversion block `F_ULINT_TO_LREAL`, ensuring the maintainability and correctness of the conversion logic.
- **Compatibility with IEC 61499-2:** The function block complies with the standard and can be used in any 4diac IDE project.
- **No State Machine:** The conversion is purely combinatorial, controlled by events – there are no internal states.

State Overview

The function block has no independent states. The sequence control is triggered by the event at **AULI_IN.E1** and ends with the event at **ALR_OUT.E1**. During the conversion, the function block is in the state “waiting for confirmation from the internal function block.” This is not visible to the user.

Application Scenarios

- **Integration of sensors or actuators** that deliver their internal counter values as ULINT into a controller that requires LREAL for calculations (e.g., control algorithms).
- **Adapter bridge** between two subsystems with different adapter definitions, enabling type conversion without changing the interface definitions.
- **Data preparation** in communication protocols where received integers need to be converted into floating-point values for further processing.

Comparison with similar function blocks

Instead of a dedicated adapter converter, one could also use the function block `F_ULINT_TO_LREAL` directly and connect the events/data manually. The advantage of **AULI_TO_ALR** lies in the encapsulation of the adapter interfaces: It saves the developer from manually wiring the adapter events and data and ensures a clean, reusable component. Compared to a custom solution, it offers a standardized, documented interface.

Conclusion

The **AULI_TO_ALR** is a useful, specialized function block for converting ULINT to LREAL values in the context of adapters. It simplifies the integration of components with different data types into uniform adapter structures and increases the maintainability of IEC 61499 systems. Thanks to its standardized conversion function and clear, event-driven operation, it is reliable and easy to understand.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALR_TO_AUS

• – ○ • – ○ • – ○ •

Introduction

The composite function block **ALR_TO_AUS** serves as a universal converter between two unidirectional adapter protocols. It converts an LREAL value (64-bit floating-point) into a USINT value (8-bit unsigned integer). The block was developed for use in IEC 61499-based automation systems and internally uses the standard function block `F_LREAL_TO_USINT` from the library `iec61131::conversion`.

Interface Structure

Since this is a composite block, all inputs and outputs are implemented via adapters.

Event Inputs

- No direct event inputs at the top level.

The adapter connected via the **Socket ALR_IN** has an event input **E1** that triggers the conversion.

Event Outputs

- No direct event outputs at the top level.

The adapter connected via the **Plug AUS_OUT** provides the event output **E1**, which signals the completion of the conversion.

Data Inputs

- No direct data inputs at the top level.

The **ALR_IN** adapter provides the data input **D1** (type: LREAL), which supplies the floating-point value to be converted.

Data Outputs

- No direct data outputs at the top level.

The **AUS_OUT** adapter provides the data output **D1** (type: USINT), which outputs the converted integer result.

Adapters

Name	Type	Direction	Comment
`ALR_IN`	`adapter::types::unidirectional::ALR`	Socket	Unidirectional LREAL input
`AUS_OUT`	`adapter::types::unidirectional::AUS`	Plug	Unidirectional USINT output

Functionality

The function block operates in an event-driven manner:

1. An incoming event at the adapter input `ALR_IN.E1` is internally connected to the **REQ** input of the conversion block `F_LREAL_TO_USINT`.
2. Simultaneously, the data value `ALR_IN.D1` is transferred to the data input `IN` of the conversion block.
3. The converter performs the conversion from LREAL to USINT. The floating-point value is rounded or truncated to the nearest USINT integer value (0–255) according to IEC 61131-3.
4. After successful conversion, the converter generates the event `CNF`, which is forwarded directly to the adapter output `AUS_OUT.E1`.
5. The converter's result `OUT` is transferred to the data output `AUS_OUT.D1`.

This enables synchronous, data-driven conversion without any additional delay.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Structure**: The block encapsulates the conversion logic in a reusable unit and utilizes the standardized adapter types `ALR` and `AUS`. This allows for seamless integration into existing unidirectional communication protocols.
- **Standard-Compliant Conversion**: The actual conversion is performed by the IEC 61131 block `F_LREAL_TO_USINT`, which guarantees defined behavior (e.g., rounding or capping) according to the standard.
- **EPL 2.0 License**: The block is released under the Eclipse Public License 2.0, which allows unrestricted use in proprietary and open-source projects.
- **No State Machine**: As a composite, the block does not have its own state machine; the internal control is handled entirely by the converter block.

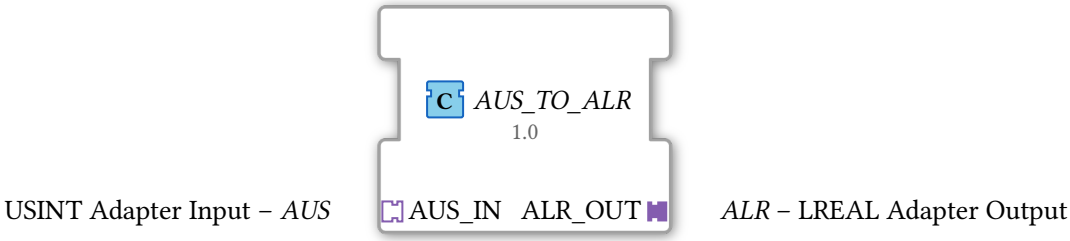
State Overview

The block itself does not have an explicit state machine. The embedded function block `F_LREAL_TO_USINT` typically implements the states **IDLE**, **BUSY**, and **ERROR** during this conversion. For invalid inputs (e.g., USINT overflow), the converter can trigger an error, which, however, is not passed on to the adapter outputs in this version.

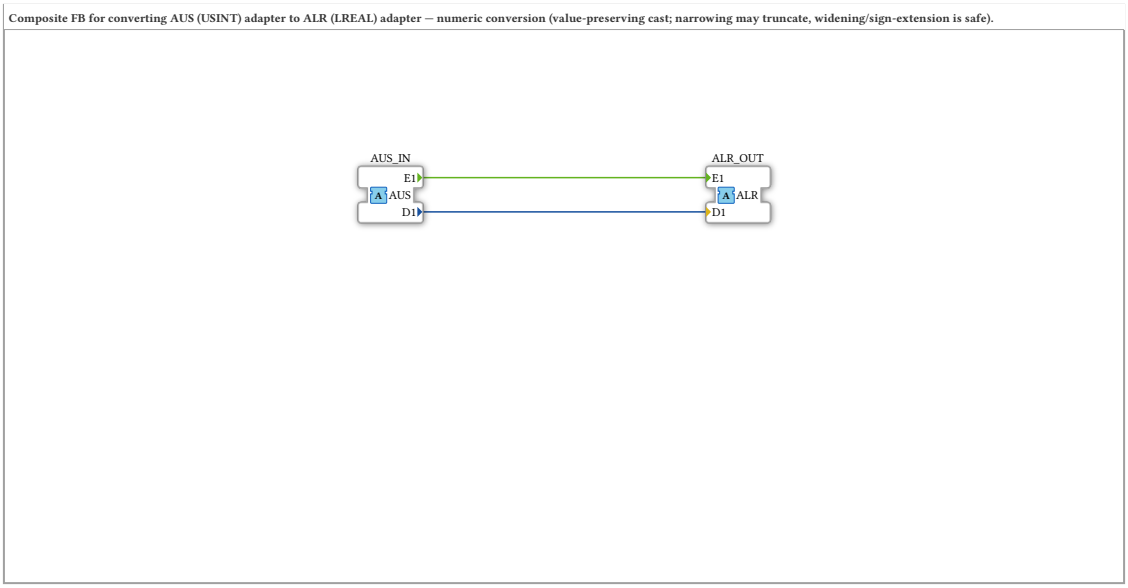
Application Scenarios

- **Sensor/Actuator Connection**: When a floating-point sensor value (e.g., pressure, temperature) needs to be converted into an 8-bit signal for a simple actuator (e.g., switch position, brightness).
- **Protocol Adaptation**: In systems that mediate between different adapter types for data transmission, such as in fieldbus couplers or gateway functions.

- **Testing and Simulation**: For the easy conversion of LREAL test data to USINT formats to test the functionality of downstream components.



Comparison with Similar Components



- **LREAL_TO_INT / LREAL_TO_DWORD**: These components provide different output types (INT, DWORD) and are therefore suitable for target platforms with wider or signed integers.
- **REAL_TO_USINT**: A corresponding variant is available for 32-bit floating-point numbers (REAL). However, this component uses the more precise LREAL type.
- **Scaling with Arithmetic Blocks**: Manual conversion using `MUL` and `ADD` would be possible, but less standardized and more prone to errors. The `ALR_TO_AUS` block offers a tested, standards-compliant solution.

Conclusion

The **ALR_TO_AUS** function block is a specialized but indispensable tool for converting LREAL to USINT data in IEC 61499 applications. Its composite design allows for a clean separation of the conversion logic and easy integration via standardized adapters. It is particularly suitable for scenarios where precise floating-point values need to be mapped to a narrow integer range.

OFF_TO_ALR

• – ○ • – ○ • – ○ •

Introduction

The **OFF_TO_ALR** function block is a composite function block that converts an **OFF adapter** (with USINT data) into an **ALR adapter** (with LREAL data). It serves purely as a forwarding interface and does not perform any complex logic or conversion calculations.

Interface Structure

Event Inputs

No separate event inputs are available. Event forwarding is handled via the **OFF_IN** adapter.

Event Outputs

No separate event outputs are available. Event forwarding is handled via the **ALR_OUT** adapter.

Data Inputs

No separate data inputs are available. Data is forwarded via the **AUS_IN** adapter.

Data Outputs

No separate data outputs are available. Data is forwarded via the **ALR_OUT** adapter.

Adapters

Role	Name	Type	Comment
Socket (Input)	AUS_IN	`adapter::types::unidirectional::AUS`	USINT Adapter Input
Plug (Output)	ALR_OUT	`adapter::types::unidirectional::ALR`	LREAL Adapter Output

- The **AUS_IN** adapter provides the interface for incoming USINT data, including an associated event.
- The **ALR_OUT** adapter provides the interface for outgoing LREAL data, including an associated event.
- Inside the function block, the events (`E1`) and data (`D1`) are directly routed from the *AUS_IN* interface to the *ALR_OUT* interface.

Functionality

1. **Event Forwarding**: The event (`E1`) received by the **AUS_IN** adapter is passed unchanged to the **ALR_OUT** adapter (`E1`).
2. **Data Forwarding**: The data value (`D1`) from the **OFF_IN** adapter is passed directly to the **ALR_OUT** adapter (`D1`).
3. **Data Type Conversion**: The actual conversion from `USINT` (8-bit integer value) to `LREAL` (64-bit floating-point number) does **not take place within the function block** – the **OFF_TO_ALR** block merely provides a structural framework for this. The conversion must be implemented either by the connected adapters or by upstream function blocks.

The function block itself contains no computation logic or state machine; it consists solely of connections between the adapters.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Function Block**: The function block is implemented as a composite function block (CFB) whose internal network contains only two connections.
- **No Internal Logic**: All functionality is provided by external function blocks or the adapter implementation.
- **Type Compliance**: The connection between `AUS.D1` (USINT) and `ALR.D1` (LREAL) requires that the underlying adapter implementation allows implicit type conversion. For caution, explicit conversion outside the function block is necessary.

State Overview

The function block has **no internal state machine**. It operates transparently: As soon as an event arrives at the input adapter, it is immediately forwarded to the output adapter. There are no delays, storage, or internal states.

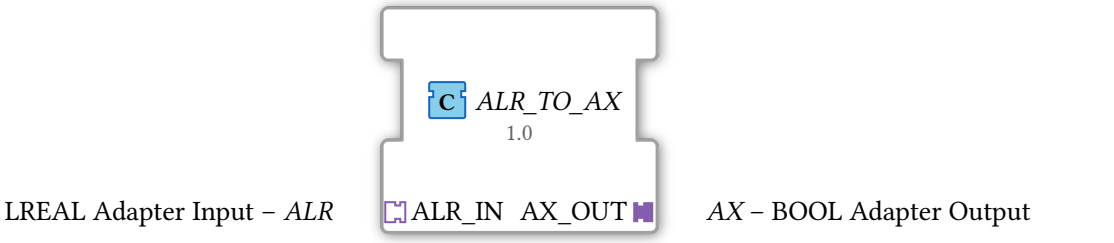
Application Scenarios

- **Connecting Heterogeneous Control Systems**: A sensor delivers values as USINT via an AUS adapter, while the subsequent control module expects LREAL via an ALR adapter.
- **Structural Adaptation**: The function block (FB) serves as a pure conversion adapter when protocol/interface adapter types use different data formats.
- **Test and Simulation Environments**: Simple pass-through of data and events for testing adapter communication.

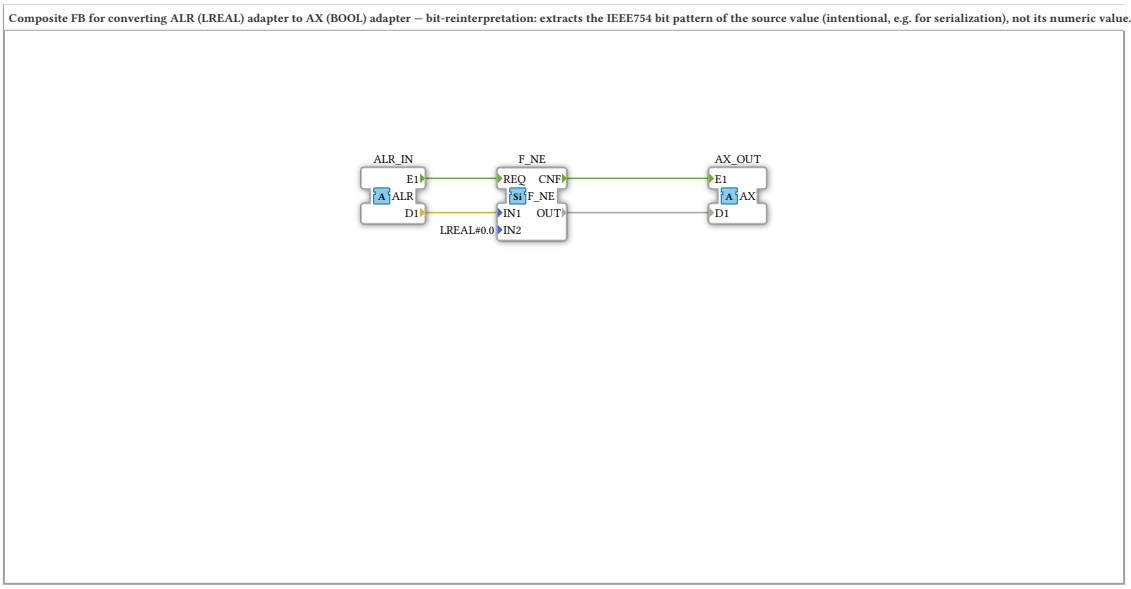
Comparison with Similar Function Blocks

Feature	AUS_TO_ALR	Typical Conversion FBs (e.g., USINT_TO_LREAL)
Input / Output	Adapter Interfaces	Individual Data Inputs/Outputs
Event Processing	Pass-Through via Adapter	Custom Event I/C Pairs
Implementation	Composite (Connections Only)	Executable Algorithms
Type Conversion	Not Included in the Function Block	Explicit Conversion via Algorithm

While a classic *USINT_TO_LREAL* function block performs the value conversion itself, **AUS_TO_ALR** only provides adapter adaptation. A separate function block must be interposed for the actual data conversion.



Conclusion



The **AUS_TO_ALR** function block is a simple yet useful composite block for structural adaptation between an AUS and an ALR adapter. It does not perform data conversion but enables the seamless forwarding of events and values between different adapter interfaces. Due to its minimalist design, it is particularly suitable for integration and testing tasks where the actual type conversion is performed externally.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALR_TO_AX

• – ◦ • – ◦ • – ◦ •

Introduction

The **ALR_TO_AX** function block is a composite function block for converting an LREAL value (via the unidirectional ALR adapter) into a BOOL value (via the unidirectional AX adapter). It is typically used to convert an analog input signal into a digital output signal – for example, to detect a threshold being exceeded. The function block is based on a simple zero comparison and triggers the output event as soon as a valid value is present at the input.

Interface Structure

Event Inputs

- **ALR_IN.E1** – Event from the ALR adapter; indicates that a new LREAL value is available.

Event Outputs

- **AX_OUT.E1** – Event to the AX adapter; Indicates that the converted BOOL value is valid.

Data Inputs

- **ALR_IN.D1** – LREAL input value (via the ALR adapter).

Data Outputs

- **AX_OUT.D1** – BOOL output value (via the AX adapter); derived by comparing the input value to 0.0.

Adapters

- **ALR_IN** – Socket (Type: *adapter::types::unidirectional::ALR*): unidirectional LREAL input adapter.
- **AX_OUT** – Plug (Type: *adapter::types::unidirectional::AX*): unidirectional BOOL output adapter.

Functionality

When an event arrives via **ALR_IN.E1**, the data value **ALR_IN.D1** (LREAL) is passed to the internal IEC 61131 block **F_NE**. This compares the value with the constant `LREAL#0.0` and returns **TRUE** if the input is not zero, otherwise **FALSE**. The result is then passed directly to **AX_OUT.D1**, and an acknowledgment event is triggered via **AX_OUT.E1**.

The entire process takes place within a single cycle, as this is a composite block without its own state machine.

Technical Details

- **Bit-reinterpretation**: extracts the IEEE754 bit pattern of the source value (intentional, e.g. for serialization), not its numeric value.
- **License & Origin**: The block is licensed under the Eclipse Public License 2.0 and was provided with version information 1.0.
- **Libraries Used**: The comparison block *F_NE* is from the IEC 61131 library (*iec61131::comparison*).
- **Package Name**: The function block belongs to the package *adapter::conversion::unidirectional*.
- **Compatibility**: It requires the adapter specification of the 4diac framework and is designed for unidirectional adapter types.

State Overview

The function block does not have an explicit state machine. Its logic is purely combinational and event-driven:

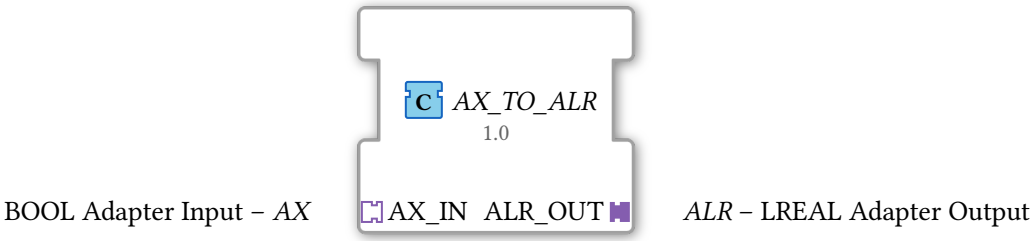
1. Wait for an event at **ALR_IN.E1**.
2. Data processing (comparison with 0.0).
3. Output the BOOL result to **AX_OUT.D1** and send the acknowledgment event to **AX_OUT.E1**.

Application Scenarios

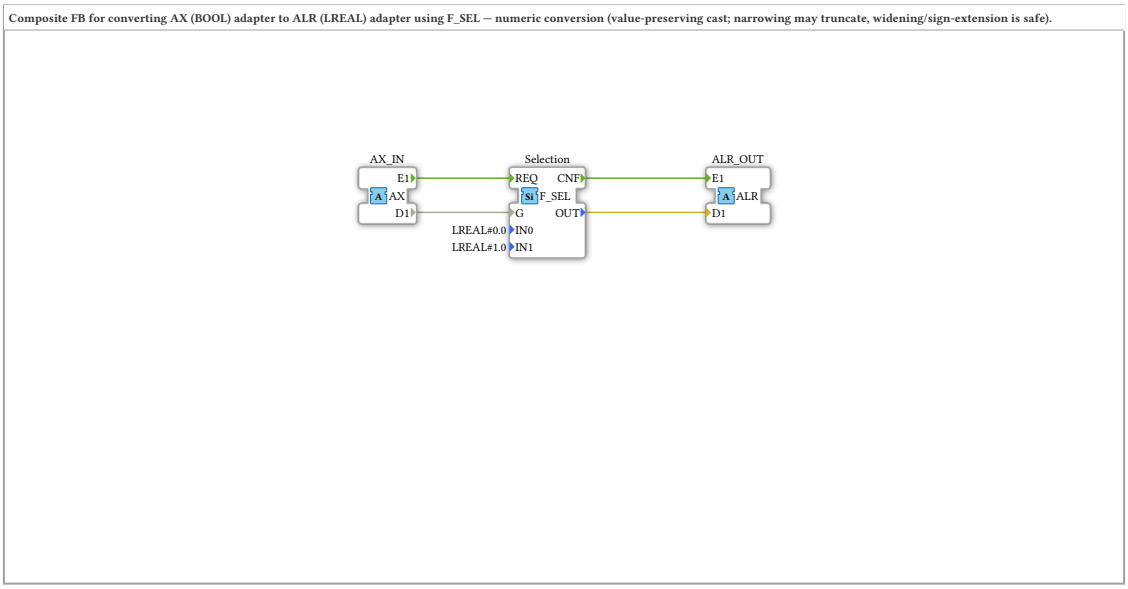
- **Analog-to-Digital Conversion**: Detects whether an analog measurement value (e.g., pressure sensor, temperature) is non-zero.
- **Threshold Detection**: Any threshold logic can be implemented through simple modification (replacing *F_NE* with *F_GT* or *F_LT*).
- **Adapter Coupling**: Integrates ALR-based sensors into AX-based control logic without requiring complex type conversions at a higher level.

Comparison with Similar Function Blocks

- **LREAL_TO_BOOL**: While a dedicated LREAL-to-BOOL function block often supports a threshold and hysteresis, *ALR_TO_AX* implements the simplest form – null ≠ null ⟶ TRUE.
- **Comparison blocks (F_NE, F_EQ, etc.)**: These operate directly on data, while *ALR_TO_AX* handles complete adapter integration and event control.
- **Adapter-Converter blocks**: The same package contains additional unidirectional/bidirectional converters that perform similar tasks for other types (e.g., BOOL_TO_ALR).



Conclusion



The **ALR_TO_AX** function block offers a streamlined and reliable way to convert an LREAL adapter output to a BOOL adapter input. Thanks to its simple structure, it is ideally suited for basic digitization tasks in IEC 61499-based control systems. It is easy to understand, readily extensible, and follows common design patterns for unidirectional adapter conversion.

AX_TO_ALR

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_TO_ALR** is used to convert a BOOL adapter signal (AX) into an LREAL adapter signal (ALR). Internally, it uses the IEC 61131 standard function `F_SEL` (Selection) to generate a discrete LREAL value from a Boolean input. The block is implemented as a composite function block and is suitable for the simple, adapter-based conversion of digital states into numerical values.

Interface Structure

Event Inputs

Name	Data Type	Description
AX_IN.E1	EVENT	Event from the connected AX adapter; triggers processing.

Event Outputs

Label	Data Type	Description
ALR_OUT.E1	EVENT	Confirmation event after the converted value has been output to the ALR adapter.

Data Inputs

Label	Data Type	Description
AX_IN.D1	BOOL	Boolean value to be converted to an LREAL value.

Data Outputs

Label	Data Type	Description
ALR_OUT.D1	LREAL	Conversion result: 0.0 for FALSE, 1.0 for TRUE.

Adapters

Direction	Label	Type	Description
Socket (Input)	AX_IN	adapter::types::unidirectional::AX	Receives a BOOL signal via the unidirectional AX adapter.
Plug (Output)	ALR_OUT	adapter::types::unidirectional::ALR	Provides the converted LREAL signal via the unidirectional ALR adapter.

Functionality

The function block operates according to the following scheme:

1. An incoming event at AX_IN.E1 triggers the internal processing.
2. The Boolean value of AX_IN.D1 is passed to the gate input (G) of the embedded function F_SEL.
3. Depending on the Boolean value, F_SEL selects one of two constant values:

- FALSE (G = 0) ⟶ Output of **0.0** (LREAL#0.0)
- TRUE (G = 1) ⟶ Output of **1.0** (LREAL#1.0)

1. The result is passed to ALR_OUT.D1, and the acknowledgment event ALR_OUT.E1 is simultaneously output.

`ALR_OUT.D1is passed to the gate input (G) of the embedded functionALR_OUT.E1``. The conversion is event-driven: Each incoming event causes exactly one conversion of the current BOOL value.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Adapter Interface**: The function block uses only unidirectional adapters (socket/plug), allowing it to integrate seamlessly into adapter-based architectures.
- **Internal Use of F_SEL**: The IEC 61131 standard function guarantees deterministic and portable behavior.

- **Fixed Thresholds**: The output values are fixed at `0.0` and `1.0`. Adjusting these thresholds requires modifying the internal network.
- **Packaging**: The function block is packaged in `adapter::conversion::unidirectional`.
- **License**: The function block is available under the Eclipse Public License 2.0.

State Overview

Since this is a composite function block (FB) without its own execution state, the state logic is derived from the event and data processing of the included `F_SEL` block. Two stable states exist:

- **Waiting for Event**: No event at `AX_IN.E1` – no output.
- **Processing Active**: An event is being processed: the Boolean value is read, converted into an LREAL value, and made available at the output; subsequently, the acknowledgment event is sent.

Application Scenarios

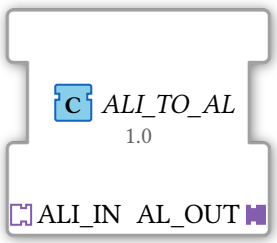
- **Digital-to-Analog Conversion**: A digital sensor (e.g., switch, limit switch) provides a Boolean value that is to be further processed in the controller as an LREAL signal (0.0/1.0).
- **Adapter Integration**: Integration into existing systems that already use unidirectional AX and ALR adapters – e.g., in agricultural technology or industrial automation.
- **State Scaling**: Simplified conversion of on/off signals into numerical values for calculations or visualizations.

Comparison with Similar Function Blocks

Function Block	Input Type	Output Type	Special Feature
`AX_TO_ALR`	BOOL (Adapter)	LREAL (Adapter)	Adapter-based, fixed values 0.0 / 1.0
`BOOL_TO_REAL`	BOOL (direct)	REAL (direct)	Conventional IEC function block, values freely configurable
`SEL` / `F_SEL`	BOOL + 2x ANY	ANY	General selection without adapter, values configurable

Compared to direct function blocks, `AX_TO_ALR` offers the advantage of clean adapter encapsulation and easy reuse in adapter-oriented projects.

Conclusion



The function block `AX_TO_ALR` provides a compact and reliable solution for converting a Boolean adapter signal into an LREAL adapter value. By using the IEC standard function `F_SEL`, its behavior is deterministic and portable. It is particularly suitable for applications that require a clean separation of digital and analog signal paths via adapters.

ALI_TO_AL

LINT Adapter Input – *ALI*

AL – LWORD Adapter Output

• – ○ • – ○ • – ○ •

The **ALI_TO_AL** function block is a composite function block that converts an **ALI adapter** (data type LINT) into an **AL adapter** (data type LWORD). It serves as an interface converter between different adapter types and enables seamless data transfer in 4diac and IEC 61499 systems.

- **No direct event inputs**

Events are received exclusively via the **ALI_IN** socket adapter.

- **No direct event outputs**

Output events are sent exclusively via the **AL_OUT** plug adapter.

- **No direct data inputs**

Input data (LINT) is provided via the socket adapter **ALI_IN** (data point D1).

- **No direct data outputs**

Output data (LWORD) is provided via the plug adapter **AL_OUT** (data point D1).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

Adapter	Direction	Type	Description
ALI_IN	Socket	`adapter::types::unidirectional::ALI`	Receives a LINT value and an event.
AL_OUT	Plug	`adapter::types::unidirectional::AL`	Sends an LWORD value and an event.

Functionality

The function block operates internally with a single conversion function block (FB) `F_LINT_TO_LWORD`. As soon as an event (E1) arrives at the socket adapter **ALI_IN**, it is forwarded to the internal converter (`REQ` input). Simultaneously, the LINT value (D1) provided by the adapter is passed to the converter's `IN` input.

The converter transforms the LINT value into an LWORD value and signals completion with its `CNF` output. This event is sent to the plug adapter **AL_OUT** (E1), along with the converted LWORD value (OUT) on data channel D1.

- **Composite Function Block**: The actual type conversion is performed by the embedded function block `F_LINT_TO_LWORD` from the IEC 61131 standard library.
- **Unidirectional Adapters**: The data and event flow is defined from ALI_IN to AL_OUT. Reverse communication is not supported.
- **No Internal States**: The function block does not have its own execution state (no ECC), but forwards events and data directly.

The function block has no internal states. It reacts strictly event-driven: Each incoming event at socket **ALI_IN** triggers exactly one conversion and one output at plug **AL_OUT**.

- **Adapter Bridge**: Used in systems that utilize an ALI adapter (LINT) but require an AL interface (LWORD).
- **Compatibility**: Retrofitting older components that expect LINT to an environment that uses LWORD via AL adapters.
- **AL_TO_ALI**: Performs the reverse conversion from LWORD to LINT.
- **F_LINT_TO_LWORD**: Pure conversion function block without adapter integration; direct data exchange without encapsulation.
- **Other Adapter Converters** (e.g., AL_TO_AL): Same adapter type, no type conversion.

The ALI_TO_AL function block stands out due to its simple plug-and-play capability within an adapter-based design, as it encapsulates all conversion logic and event control in a single block.

The composite function block **ALI_TO_AL** enables clean and standards-compliant conversion of LINT to LWORD data via unidirectional adapters. It is ideal for use in modular automation systems that need to integrate different adapter data types. Reliable and high-performance execution is ensured by utilizing the proven IEC 61131 conversion function.

AL_TO_ALI

LWORD Adapter Input – *AL* — *ALI* – LINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The function block `AL_TO_ALI` is a composite function block (FB) for converting an AL adapter (LWORD) to an ALI adapter (LINT). It serves as an interface between LWORD-based and LINT-based data communication within the control logic. Internally, the block uses the conversion block `F_LWORD_TO_LINT` to perform the actual type conversion.

Interface Structure

Event Inputs

The function block does not have its own event inputs. Event control is handled via the connected adapters.

Event Outputs

The function block does not have its own event outputs. Event control is handled via the connected adapters.

Data Inputs

This function block does not have its own data inputs. Input data is provided via socket `AL_IN`.

Data Outputs

This function block does not have its own data outputs. Output data is provided via plug `ALI_OUT`.

Adapters

Type	Name	Direction	Data Type	Description
`adapter::types::unidirectional::AL`	`AL_IN`	Socket (Input)	LWORD	LWORD adapter as input interface. Provides the data to be converted.
`adapter::types::unidirectional::ALI`	`ALI_OUT`	Plug (Output)	LINT	LINT adapter as output interface. Delivers the converted data.

Functionality

1. **Event Triggering:** The `AL_IN` adapter sends a signal via its event output `E1` as soon as new data is available.
2. **Conversion:** This event triggers the internal function block `Convert` (`F_LWORD_TO_LINT`) at its event input `REQ`. Simultaneously, the current data value of `AL_IN.D1` (LWORD) is transferred to the data input `IN` of the conversion module.

3. **Output:** After successful conversion, `Convert` sends an acknowledgment via its event output `CNF` to the `ALI_OUT` adapter (event input `E1`). In parallel, the converted LINT value is forwarded from output `OUT` to the data input `ALI_OUT.D1`.
4. **Result:** The `ALI_OUT` adapter now forwards the new LINT data to the connected function block.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Type Conversion:** This function block converts an LWORD (64-bit sequence) into a LINT (64-bit signed integer). The conversion is bit-for-bit, meaning the binary representation is interpreted as a signed integer.
- **Composition:** This is a composite function block that does not contain its own logic but relies on the standardized conversion function block `iec61131::conversion::F_LWORD_TO_LINT`.
- **Adapter-Based Interface:** Input and output are exclusively via unidirectional adapters (`AL` and `ALI`), enabling a modular and type-checked connection in the 4diac IDE.
- **Adapter-Based Interface: - Package Structure:** The FB is located in the package `adapter::conversion::unidirectional`.

State Overview

Since this is a composite FB, there is no separate state machine. The state logic is entirely determined by the internally used block `F_LWORD_TO_LINT`. This block operates in an event-driven manner:

- **IDLE:** Wait for an event at the `REQ` input.
- **PROCESSING:** Convert the LWORD to LINT (takes one step).
- **FINISHED:** Output the converted value and send the `CNF` event.

Application Scenarios

- **PLC Data Conversion:** When a control program receives LINT values (e.g., counter readings or times) via an LWORD-based adapter and a LINT interface is required.
- **Communication Adapter:** Used as an intermediary in an adapter chain to translate different data types between various hardware or software modules.
- **Protocol Adaptation:** For example, converting raw LWORD data (e.g., from a bus system) into a LINT representation for further processing in the control logic.

Comparison with Similar Function Blocks

- **AL_TO_AL (LWORD ↔ LWORD):** Simple pass-through without conversion.
- **ALI_TO_AL (LINT ↔ LWORD):** Performs the reverse conversion.
- **F_LWORD_TO_LINT (direct conversion block):** Offers the same functionality, but without an adapter interface. `AL_TO_ALI` encapsulates this block and adds the adapter connection.

Conclusion

The `AL_TO_ALI` function block is a simple yet important converter that bridges the gap between LWORD-based and LINT-based adapter interfaces. Its composite structure keeps it clear and allows for flexible integration into existing 4diac projects. The use of standard conversion blocks ensures correct and efficient type conversion.

ALR_TO_AL

LREAL Adapter Input – *ALR* *AL* – LWORD Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **ALR_TO_AL** function block is a composite function block according to IEC 61499-2. It is used to convert an **ALR adapter** (LREAL data type) into an **AL adapter** (LWORD data type). The conversion is implemented via the internal function block `F_LREAL_TO_LWORD` from the IEC 61131-3 library.

Interface Structure

Event Inputs

The function block has **no independent event inputs**. Events are provided via the **socket adapter** `ALR_IN`:

| Adapter | Event / Signal | Description | | Adapter | Event / Signal | Description | |---|---|---|---|---|---|---| | ALR_IN | E1 | Trigger event to initiate the conversion |

Event Outputs

This function block has **no independent event outputs**. Events are output via the **plug adapter** `AL_OUT`:

Adapter	Event / Signal	Description
AL_OUT	E1	Confirmation event after conversion is complete

Data Inputs

There are also **no direct data inputs**. Data is supplied via the socket adapter `ALR_IN`:

| Adapter | Data / Signal | Data Type | Description | | Adapter | Data / Signal | Data Type | Description | |---|---|---|---|---|---|---|---| | ALR_IN | D1 | LREAL | Input value in LREAL format |

Data Outputs

No direct data outputs. Output data is provided via the plug adapter `AL_OUT`:

Adapter	Data / Signal	Data Type	Description
AL_OUT	D1	LWORD	Converted output value in LWORD format

Adapters

The module is connected to the environment via two adapters:

- **Socket** `ALR_IN`: Of type `adapter::types::unidirectional::ALR` – provided by a preceding component.
- **Plug** `AL_OUT`: Of type `adapter::types::unidirectional::AL` – offered to a subsequent component.

The adapters transmit both events and data via their respective ports (E1, D1).

Functionality

When an event **E1** arrives at socket `ALR_IN`, the internal module `F_LREAL_TO_LWORD` (type `iec61131::conversion::F_LREAL_TO_LWORD`) is activated via its event input `REQ`. Simultaneously, the data value `D1` of the adapter socket is transferred to the data input `IN` of the conversion module. After successful conversion, the internal module outputs a confirmation event at its output `CNF`. This event is forwarded to the event input `E1` of the plug adapter `AL_OUT`. The converted value (LWORD) is transferred to the adapter plug via the data connection `Convert.OUT` ⟶ `AL_OUT.D1`.

... The conversion itself corresponds to the IEC 61131-3 function `LREAL_TO_LWORD`, which maps the bitwise structure of an LREAL value to an LWORD value (e.g., for transferring floating-point numbers as raw data).

Technical Features

- **Bit-reinterpretation**: extracts the IEEE754 bit pattern of the source value (intentional, e.g. for serialization), not its numeric value.
- **Composite Block**: The functionality is implemented by an internal network circuit that uses the block `F_LREAL_TO_LWORD`.
- **Packaging**: The block is stored in the package `adapter::conversion::unidirectional`, indicating its use in unidirectional adapter chains.
- **Import**: `iec61131::conversion::F_LREAL_TO_LWORD` must be available in the project.
- **Copyright**: This block was developed for HR Agrartechnik GmbH and is licensed under the Eclipse Public License 2.0 (EPL-2.0).

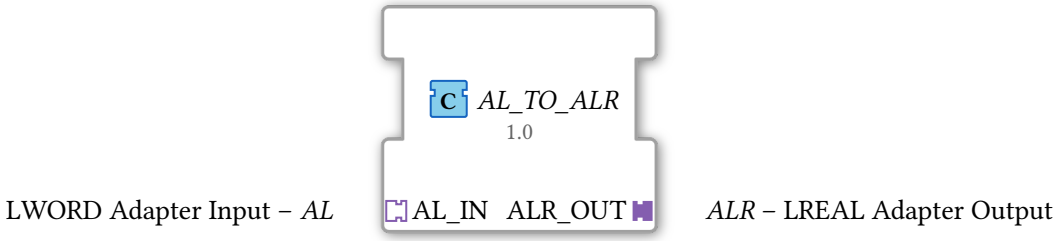
State Overview

Since this is a **composite function block** without its own state machine, its behavior is determined by that of the internal function block `F_LREAL_TO_LWORD`. This block performs a pure, stateless conversion: An event triggers the calculation, and the result is provided immediately. The function block has no internal state that persists across multiple calls.

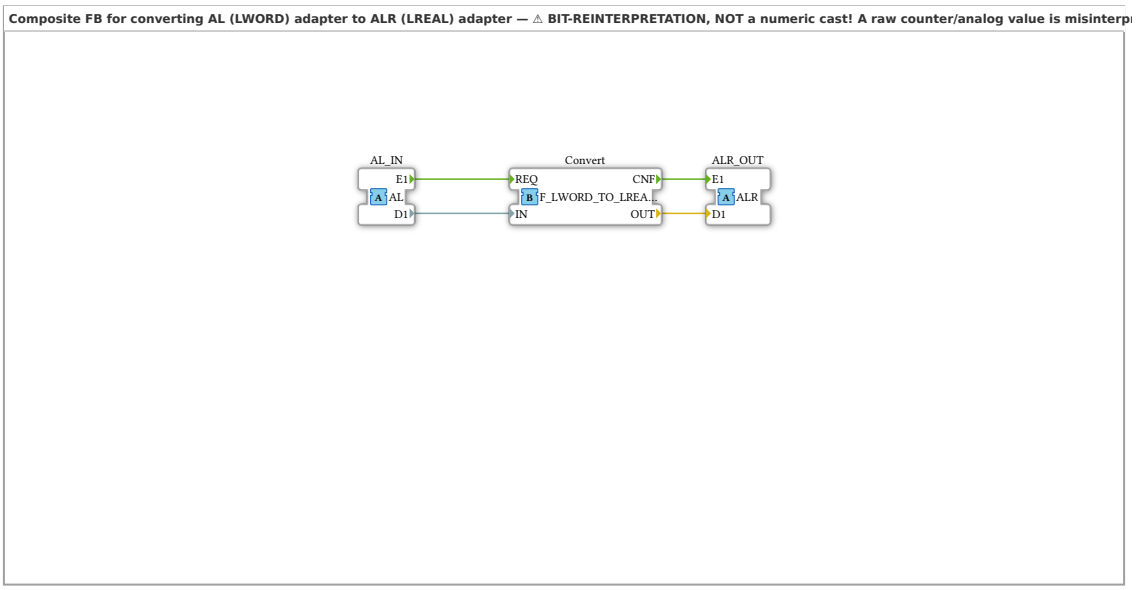
Application Scenarios

- **Data Format Adaptation**: When a system component delivers data in ALR format (LREAL via adapter), but a subsequent component only understands AL interfaces (LWORD via adapter).
- **Communication Between Different Control Levels**: For example, transferring physical measured values from a PLC (LREAL) to a higher-level control system that expects LWORD as the raw data format.
- **Test and Simulation Setups**: Generating defined LWORD values from LREAL sources without changing the actual adapter logic.

Comparison with Similar Function Blocks



- **AL_TO_ALR**: Performs the reverse conversion (LWORD ⟶ LREAL).
- **Direct Conversion Functions**: IEC 61131-3 provides `LREAL_TO_LWORD` and `LWORD_TO_LREAL` as elementary function blocks – `ALR_TO_AL` encapsulates these in an adapter-compliant composite function block, allowing it to be directly integrated into adapter chains.



Conclusion

The **ALR_TO_AL** function block is a specialized conversion block for converting an LREAL adapter to an LWORD adapter. Its composite structure enables seamless integration into existing adapter-based

architectures without requiring the user to manually configure the underlying conversion function. The unambiguous event control and the use of standardized data types make it a robust solution for adapting data formats in IEC 61499 control systems.

AL_TO_ALR

• – ○ • – ○ • – ○ •

Introduction

The function block **AL_TO_ALR** is a composite function block (FB) that maps a unidirectional AL adapter (LWORD) onto a unidirectional ALR adapter (LREAL). Internally, it uses the block `F_LWORD_TO_LREAL`.

> ⚠ **Warning — not a numeric value conversion:** `LWORD` is a bit-string type (not a signed integer), and `F_LWORD_TO_LREAL` in the FORTE core merely reinterprets the 64-bit pattern as an IEEE754 `LREAL` (a bit copy) — the same trap as `AD_TO_AR` (DWORD→REAL), just with the 64-bit counterparts. A raw counter or analog value will therefore **not** become the corresponding LREAL number, but a meaningless value. For an actual numeric conversion: chain `AL_TO_AULI` (bit-reinterpretation LWORD→ULINT, valid here since both share the same 64-bit unsigned-integer representation) followed by `AULI_TO_ALR` (a real numeric cast) — the same pattern as `AD_TO_AR_NUM` for the 32-bit case.

Interface Structure

Event Inputs

The FB does not have direct event inputs. The event required to trigger the conversion is provided via the socket **AL_IN** (type `AL`). This event (E1) is internally connected to the `REQ` input of the conversion block.

Event Outputs

The function block (FB) does not have direct event outputs. The conversion completion event is output via the plug **ALR_OUT** (type `ALR`). The event (E1) of the internal block (`CNF`) is forwarded to the output adapter.

Data Inputs

The function block (FB) does not have direct data inputs. The LWORD value to be converted is provided via the **AL_IN** socket (data signal D1) and passed to the `IN` input of the conversion block.

Data Outputs

The function block has no direct data outputs. The converted LREAL value is output via the **ALR_OUT** plug (data signal D1); it originates from the `OUT` output of the internal block.

Adapters

Adapter	Direction	Type	Description
AL_IN	Socket (Input)	`adapter::types::unidirectional::AL`	LWORD adapter that provides the input signal (LWORD) and a trigger event.
ALR_OUT	Plug (Output)	`adapter::types::unidirectional::ALR`	LREAL adapter that outputs the converted signal (LREAL) and an acknowledgment event.

Functionality

`F_LWORD_TO_LREAL` reinterprets the LWORD's 64-bit pattern as an IEEE754 `LREAL` (a bit copy) — **no** numeric value conversion takes place. The function block operates in a simple event-driven sequence:

1. An incoming event at socket **AL_IN.E1** is forwarded to the `REQ` input of the internal function block `F_LWORD_TO_LREAL`.
2. Simultaneously, the data value from **AL_IN.D1** (LWORD) is passed to the `IN` input of the converter.
3. The internal function block (FB) performs the conversion `LWORD → LREAL`.
4. After the conversion is complete, the event `CNF` is sent to the plug **ALR_OUT.E1**.
5. The converted LREAL value is output to **ALR_OUT.D1**.

The entire processing takes place within one clock cycle (no blocking).

Technical Features

- **Adapter-based interface**: The FB uses only unidirectional adapters (`AL` and `ALR`). This enables loose coupling between sender and receiver and easy reuse in different system architectures.
- ⚠️ **Bit-reinterpretation, not numeric conversion**: See the warning in the introduction — affects all bit-string source types converting to AR/REAL or ALR/LREAL; the only other instance in this library is `AD_TO_AR` (DWORD⟶REAL).
- **Pass-Through Event Control**: The function block does not execute any internal state logic; it transparently forwards events and data. The call time corresponds to the execution time of the internal converter.

State Overview

The assembled function block itself has **no states of its own**. The processing is entirely controlled by the internally used function block `F_LWORD_TO_LREAL`, which exhibits the following minimal state behavior:

- **IDLE**: Waiting for a `REQ` event.
- **CONVERT**: Executing the conversion (immediately after `REQ`).
- **SEND**: Outputting the `CNF` event and the converted value.

Since the internal function block operates in a single execution step, the states are not externally observable.

Application Scenarios

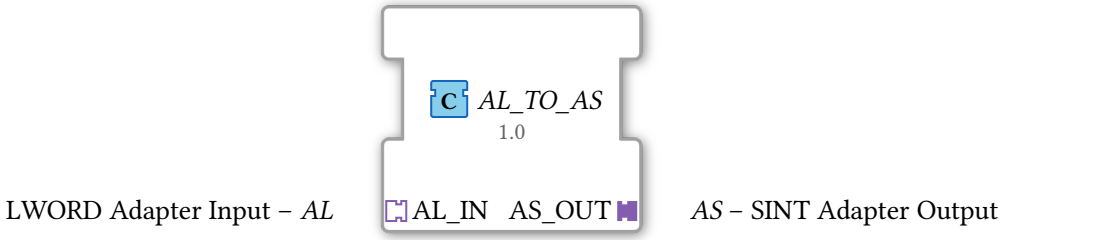
- **Bit pattern pass-through**: `AL_IN` already carries a bit pattern meant to be interpreted as LREAL (e.g. serialized raw double data from a fieldbus/protocol).
- **NOT suitable** for raw counter, analog, or other integer values meant to carry the same numeric value as LREAL — use `AL_TO_AULI` + `AULI_TO_ALR` for that.

Comparison with Similar Function Blocks

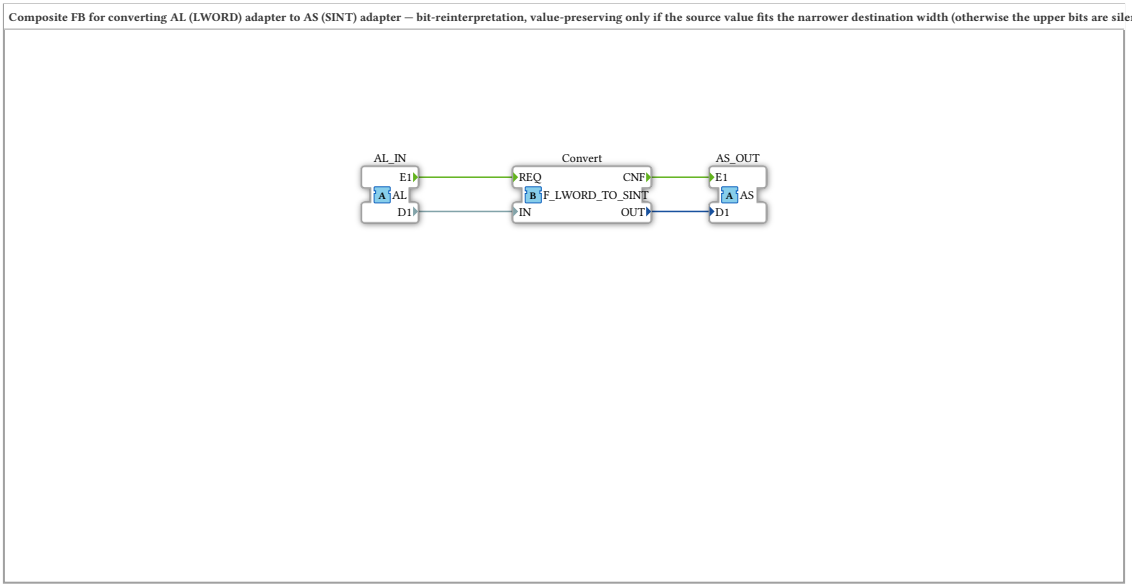
- **`AL_TO_AULI` + `AULI_TO_ALR`** (numeric, LWORD→ULINT→LREAL): the safe replacement when an actual numeric value is meant.
- **`ALI_TO_ALR`/`AULI_TO_ALR`** (LINT/ULINT→LREAL): already numerically correct, since their source types are `ANY_INT` (not `ANY_BIT`) — no trap.
- **`AD_TO_AR`** (DWORD→REAL): the same bit-reinterpretation trap, just with the 32-bit counterparts.

Conclusion

`AL_TO_ALR` offers a compact way to expose an LWORD bit pattern as LREAL via adapter interfaces — **but not a numeric value conversion**. For raw counter or analog values meant to carry the same numeric value in LREAL, use `AL_TO_AULI` + `AULI_TO_ALR`.



📖 Background



- Numeric vs. bitwise: the FORTE conversion trap

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AL_TO_AS

• – ○ • – ○ • – ○ •

Introduction

The **AL_TO_AS** function block is a composite function block that converts a unidirectional AL adapter (LWORD data) into a unidirectional AS adapter (SINT data). It enables the seamless integration of components that work with different data types by converting the signals and passing them on via the respective adapter interfaces.

Interface Structure

Event Inputs

- None

Event Outputs

- None

Data Inputs

- None

Data Outputs

- None

Adapter

Type	Name	Direction	Description
Socket	AL_IN	Input	Unidirectional AL adapter that provides LWORD data.
Plug	AS_OUT	Output	Unidirectional AS adapter that outputs the converted SINT data.

Functionality

The function block receives events and LWORD data via the `AL_IN` socket. Internally, a function block of type `F_LWORD_TO_SINT` (from the IEC 61131 library) is used to convert the input data (LWORD) to the output data type SINT. The event control works as follows:

- An incoming event at socket `AL_IN.E1` triggers the input `REQ` of the internal conversion module.
- After successful conversion, the output `CNF` of the converter signals an event, which is then passed to plug `AS_OUT.E1`.
- Simultaneously, the converted data value is transferred from the output `OUT` of the converter to the data output `AS_OUT.D1`.

The entire process is event-driven: Only an event at `AL_IN` triggers the conversion and an event at `AS_OUT`.

Technical Features

- **Bit-reinterpretation**, value-preserving only if the source value fits the narrower destination width (otherwise the upper bits are silently dropped).
- The function block (FB) is implemented as a composite and uses the predefined conversion function `F_LWORD_TO_SINT`, ensuring high reusability and standards compliance.
- Conversion is **unidirectional**, only from LWORD to SINT; a reverse direction is not supported.
- Event forwarding is direct: An event at the input results in exactly one event at the output.
- The data width is reduced from 64 bits (LWORD) to 8 bits (SINT), therefore only values in the range [−128, 127] can be represented. If this range is exceeded, the internal converter behaves according to the IEC 61131 definition (e.g., overflow indication or modulo behavior).

State Overview

The FB does not have its own state machine. Its behavior is purely combinatorial with event-driven triggering. There is no internal state; The conversion always occurs based on the current input data at an event.

Application Scenarios

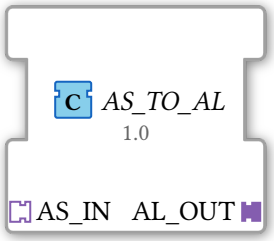
- **System Integration**: If a software system or device uses LWORD interfaces (AL adapter), but another part of the system only supports AS adapters (SINT), this function block can serve as a bridge.
- **Data Reduction**: Targeted conversion of 64-bit data to an 8-bit value, e.g., for transfer to simple actuators or displays that only process SINT.
- **Protocol Adaptation**: In heterogeneous automation networks where different adapter types are used (unidirectionally), this function block simplifies the conversion at a single logical level.

Comparison with Similar Function Blocks

Function Block	Input Type	Output Type	Special Feature
AL_TO_AS	LWORD (Adapter)	SINT (Adapter)	Composite; uses `F_LWORD_TO_SINT`
`F_LWORD_TO_SINT`	LWORD (Data)	SINT (Data)	Data converter only, no adapter integration
`F_LWORD_TO_DINT`	LWORD	DINT	Conversion to 32-bit integer
`F_SINT_TO_LWORD`	SINT	LWORD	Reverse direction (if available)

The **AL_TO_AS** stands out due to its adapter-to-adapter interface, which enables a direct connection between two different adapter types without the need for additional manual wiring of individual events and data.

Conclusion



The **AL_TO_AS** function block is a practical, standards-compliant converter module for unidirectional adapters. It encapsulates the necessary type conversion from LWORD to SINT and simplifies integration into existing 4diac projects. Thanks to its composite structure and the use of an established conversion function, it is reliable, easy to understand, and extensible. It is particularly suitable for scenarios where data widths need to be reduced or interfaces adapted.

AS_TO_AL

SINT Adapter Input – *AS* *AL* – LWORD Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The function block **AS_TO_AL** is a composite block that converts a SINT adapter (AS) into an LWORD adapter (AL). It serves as a bridge between different adapter types in a unidirectional communication path. The block encapsulates the conversion logic and makes it usable for the user as a single, integrated unit.

Interface Structure

The block has **no direct event or data interfaces** at the top level. All input and output is handled via adapters.

Event Inputs

- None (Events are passed in via the AS_IN socket adapter)

Event Outputs

- None (Events are output via the AL_OUT plug adapter)

Data Inputs

- None (Data is provided via the AS_IN socket adapter)

Data Outputs

- None (Data is provided via the AL_OUT plug adapter)

Adapters

Name	Type	Direction	Description
AS_IN	adapter::types::unidirectional::AS	Socket	SINT adapter (input)
AL_OUT	adapter::types::unidirectional::AL	Plug	LWORD adapter (output)

Functionality

The function block internally uses the IEC 61131 conversion block **F_SINT_TO_LWORD**. As soon as an event arrives at the event output **E1** of the socket adapter **AS_IN**, it is forwarded to the input **REQ** of the conversion block. This converts the SINT data value from **AS_IN.D1** into an LWORD value and outputs it to **AL_OUT.D1**. After successful conversion, an acknowledgment event is sent to the event input **E1** of the plug adapter **AL_OUT**.

Technical Specifications

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Standard Compliance**: Complies with IEC 61499-2.
- **Copyright**: The function block is subject to the Eclipse Public License 2.0 (Copyright 2026 HR Agrartechnik GmbH).
- **Version**: 1.0, created by Franz Höpfinger on February 17, 2026.
- **Package Structure**: Organized in the package `adapter::conversion::unidirectional`.
- **Dependencies**: Uses the function block `iec61131::conversion::F_SINT_TO_LWORD`.

State Overview

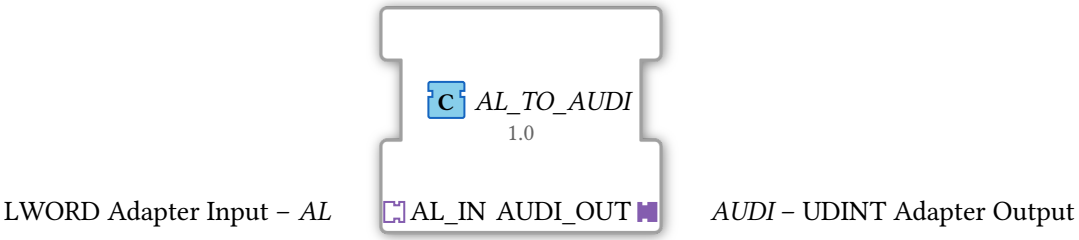
Since this is a composite function block, it does not have its own state machine. The state logic is implemented by the integrated function block **F_SINT_TO_LWORD**, which performs a simple conversion internally without delay or error states. Execution is strictly event-driven.

Application Scenarios

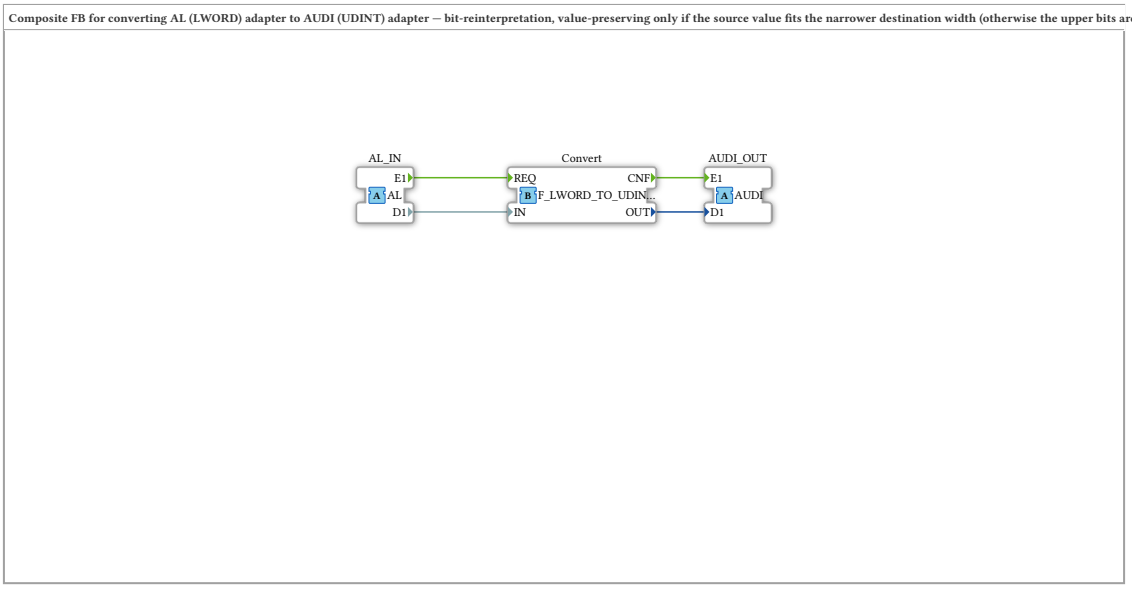
- **Adapter Conversion**: Connecting components that provide a SINT adapter with components that expect an LWORD adapter.
- **Data Adaptation**: Used in heterogeneous automation systems where different data types need to be harmonized at the adapter level.
- **Modular Reuse**: The function block can be included in libraries for unidirectional conversions.

Comparison with Similar Function Blocks

Similar adapter conversion blocks exist for other data types (e.g., BOOL, INT, DWORD). The **AS_TO_AL** block is specifically designed for converting **SINT** (Signed Short Integer, 8-bit) to **LWORD** (Long Word, 64-bit). Unlike generic function blocks, the conversion is performed directly at the adapter level, simplifying network wiring.



Conclusion



The **AS_TO_AL** composite block offers a compact and standards-compliant solution for converting a SINT adapter to an LWORD adapter. Encapsulating the conversion logic improves the clarity of the application network and promotes reusability. This block is particularly well-suited for modular automation projects where different data types need to be combined at the adapter level.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AL_TO_AUDI

• – ○ • – ○ • – ○ •

Introduction

The function block **AL_TO_AUDI** is a composite block that converts an LWORD adapter input (type `AL`) into a UDINT adapter output (type `AUDI`). It encapsulates the IEC 61131-3 conversion function `F_LWORD_TO_UDINT` and provides a clean, adapter-based interface for unidirectional data flows.

Interface Structure

Event Inputs

The function block does not have direct event inputs. Event control is handled entirely via the integrated socket adapter `AL_IN`.

Event Outputs

The function block (FB) does not have direct event outputs. Events are passed to subsequent logic via the integrated plug adapter `AUDI_OUT`.

Data Inputs

The FB does not have direct data inputs. The LWORD data to be converted is received via the socket adapter `AL_IN`.

Data Outputs

The FB does not have direct data outputs. The converted UDINT data is output via the plug adapter `AUDI_OUT`.

Adapters

Adapter Type	Name	Description
Socket	`AL_IN`	LWORD adapter input (Type: `adapter::types::unidirectional::AL`)
Plug	`AUDI_OUT`	UDINT adapter output (Type: `adapter::types::unidirectional::AUDI`)

Functionality

1. An incoming event at socket `AL_IN` (via its event output `E1`) triggers the conversion instance `Convert` (Type `F_LWORD_TO_UDINT`).
2. Simultaneously, the LWORD data value from `AL_IN.D1` is transferred to the input `IN` of `Convert`.
3. The conversion function converts the LWORD value into a UDINT value.

4. After successful conversion, `Convert` signals this via its event output `CNF`, causing the plug `AUDI_OUT` to receive an event at its event input `E1`.
5. The converted UDINT value is passed from the output `OUT` of `Convert` to the data input `D1` of `AUDI_OUT` and is thus available at the output adapter.

Technical Features

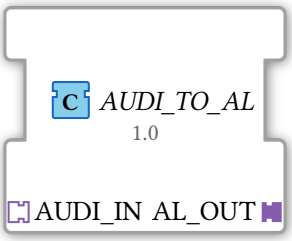
- **Bit-reinterpretation**, value-preserving only if the source value fits the narrower destination width (otherwise the upper bits are silently dropped).
- **Composite Architecture**: The function block consists solely of the internal use of the function block `F_LWORD_TO_UDINT` and the adapters. It has no independent state logic or additional control.
- **Unidirectional Adapters**: Both `AL_IN` and `AUDI_OUT` are unidirectional adapters (input to output).
- **IEC 61131-3 Compliance**: The conversion uses a standardized IEC 61131-3 function, which increases reusability and interchangeability.

State Overview

The function block has no states of its own. Its behavior is purely combinatorial and is entirely determined by the internal conversion function – the conversion occurs per event without internal storage.
Unidirectional Adapters: ** ...

Application Scenarios

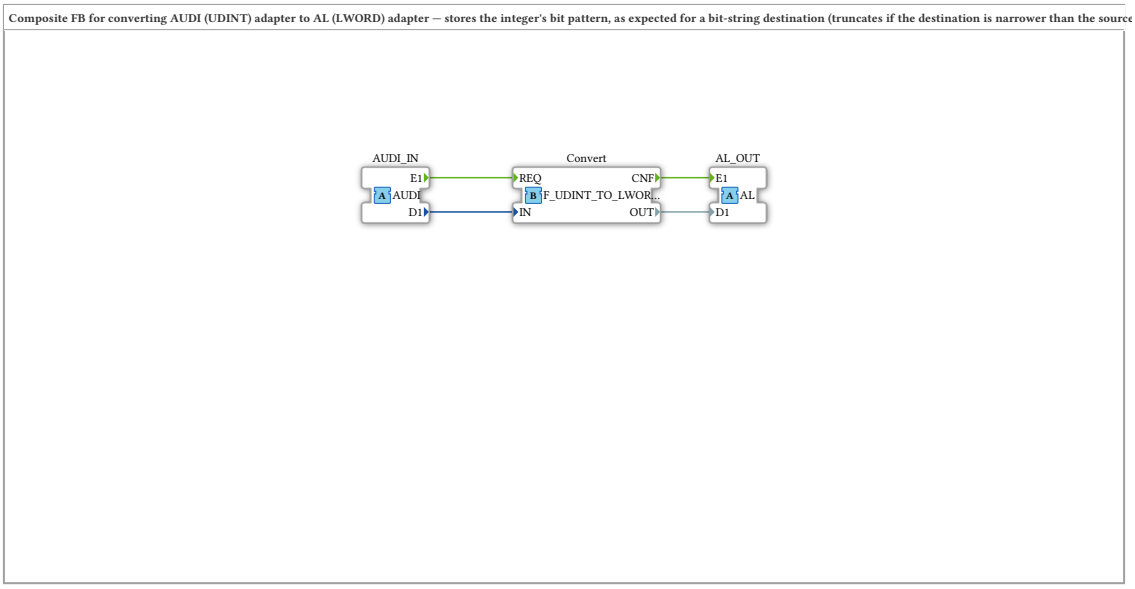
- **System Integration**: Connecting components that use different data types for addresses, counters, or configuration values (e.g., LWORD for wide addresses, UDINT for embedded systems).
- **Adapter Architectures**: Use in modular automation solutions where standardized interfaces are provided via adapters.
- **Data Preparation**: Converting LWORD signals from sensors or bus systems to UDINT for further processing in controllers.



Comparison with Similar Components

- **Simple Type Converters** (e.g., `F_LWORD_TO_UDINT`): These work directly with input/output variables, while `AL_TO_AUDI` encapsulates the conversion in an adapter interface, thus offering a higher level of abstraction.
- **Other adapter converters** (e.g., `UDINT_TO_DINT`): Similar concepts, but for different data types and directions. `AL_TO_AUDI` is specifically for the unidirectional conversion of LWORD to UDINT.

Conclusion



The function block `AL_TO_AUDI` is a compact and reusable building block for converting LWORD to UDINT data via standardized adapters. It simplifies the integration of components with different data types and promotes a modular, adapter-based architecture in automation technology.

AUDI_TO_AL

UDINT Adapter Input – *AUDI*

AL – LWORD Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The **AUDI_TO_AL** function block is a composite function block that converts an **AUDI** adapter (UDINT data format) into an **AL** adapter (LWORD data format). It serves as an interface converter between different adapter types in automation systems based on the IEC 61499 standard.

Interface Structure

Event Inputs

The function block does not have its own event inputs. Event-driven processing is handled via the **AUDI_IN** socket:

- **E1**: Event input of the AUDI adapter – triggers the conversion.

Event Outputs

The function block does not have its own event outputs. The result is passed via the **AL_OUT** plug:

- **E1**: Event output of the AL adapter – signals completion of the conversion.

Data Inputs

This function block does not have its own data inputs. The data to be converted is provided via the **AUDI_IN** socket:

- **D1**: Data input of the AUDI adapter (Type: UDINT) – the value to be converted.

Data Outputs

This function block does not have its own data outputs. The converted result is provided via the **AL_OUT** plug:

- **D1**: Data output of the AL adapter (Type: LWORD) – the converted value.

Adapter

Name	Direction	Type	Description
AUDI_IN	Socket	`adapter::types::unidirectional::AUDI`	UDINT adapter as input interface
AL_OUT	Plug	`adapter::types::unidirectional::AL`	LWORD adapter as output interface

Functionality

This function block is a pure encapsulation of the IEC 61131 function `F_UDINT_TO_LWORD`.

When an event occurs at **AUDI_IN.E1**, the internal function block **Convert** (type `F_UDINT_TO_LWORD`) is activated via its event input **REQ**. Simultaneously, the UDINT value present at **AUDI_IN.D1** is passed to the **IN** data input of **Convert**. Upon completion of the conversion, **Convert** signals its completion via its **CNF** event output. This event is forwarded directly to **AL_OUT.E1**, and the converted LWORD value is output by **Convert.OUT** to **AL_OUT.D1**.

The entire process is event-driven and requires no additional runtime logic within the composite function block.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- The function block is implemented as a **composite function block** and uses only the standardized IEC 61131 conversion function `F_UDINT_TO_LWORD`.
- The conversion is performed directly: **UDINT** (32-bit unsigned integer) is mapped to **LWORD** (64-bit logical word).

Note: When converting a 32-bit value to a 64-bit word, the upper 32 bits are set to zero.

- This function block is licensed under the **Eclipse Public License 2.0**.
- The interfaces (adapters) are unidirectional: Data flows only from the socket to the plug.

State Overview

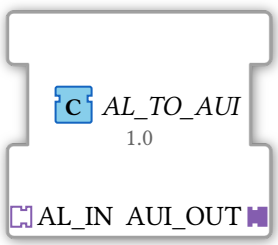
Since this is a composite function block without its own state machine, **AUDI_TO_AL** does not have an internal state machine. Its behavior is entirely determined by the interconnected function block `F_UDINT_TO_LWORD`, which implements a simple REQ/CNF handshake.

Application Scenarios

- **Adapter Conversion** in IEC 61499 systems where an existing AUDI adapter (UDINT-based) needs to be connected to an AL adapter (LWORD-based) – e.g., to connect sensor data to a 64-bit data processing chain.
- **Interface Adaptation** when replacing hardware components or migrating from 32-bit to 64-bit automation solutions.
- **Prototypical Implementation** in agricultural technology or other areas where UDINT and LWORD data formats are used interchangeably.

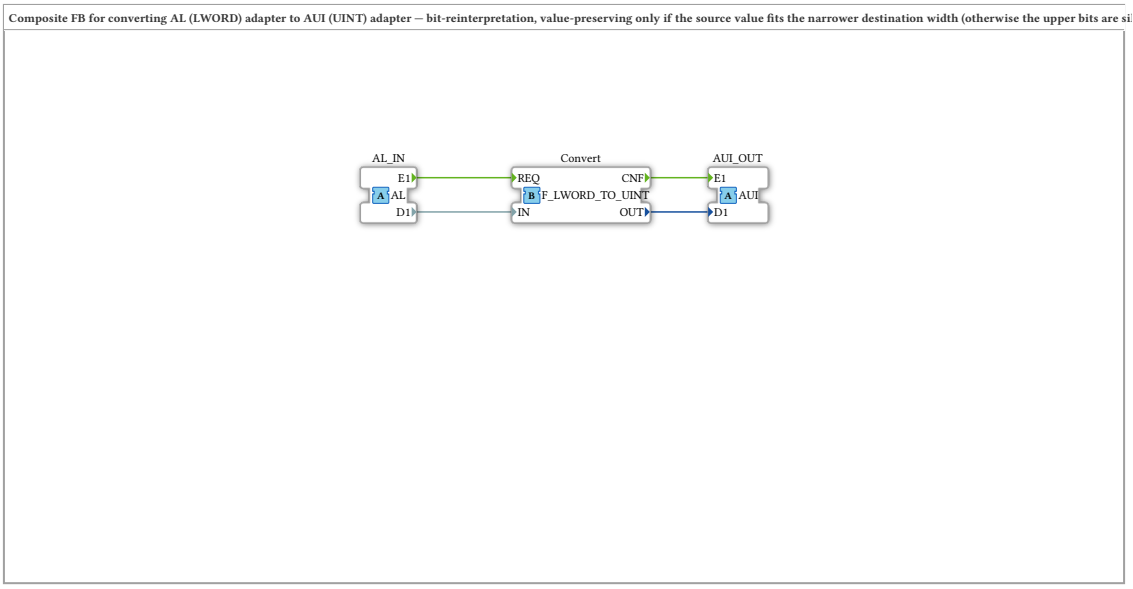
Comparison with Similar Components

Unlike generic converters such as `UDINT_TO_LWORD` (an atomic component), **AUDI_TO_AL** offers a pre-configured adapter coupling, freeing developers from manually connecting event and data lines. Similar composite components exist, for example, for `UDINT_TO_DWORD` or `LREAL_TO_LWORD`, but these are specific to different target adapters.



Conclusion

The **AUDI_TO_AL** function block is a compact, reusable component for cleanly separating adapter types. By encapsulating the conversion in a composite, it simplifies the maintainability and readability of applications based on different data format adapters.



Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AL_TO_AUI

LWORD Adapter Input – *AL* *AUI* – UINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The **AL_TO_AUI** function block is a composite component that converts an LWORD adapter (AL) into a UINT adapter (AUI). It enables the seamless integration of LWORD-based interfaces into systems that expect UINT data by encapsulating the conversion within a standardized adapter structure.

Interface Structure

Event Inputs

No standalone event inputs. The **AL_IN** socket provides the trigger signal for the conversion via its event output `E1`.

Event Outputs

No standalone event outputs. The plug **AUI_OUT** provides confirmation of the completed conversion via its event input `E1`.

Data Inputs

No standalone data inputs. The socket **AL_IN** provides the value to be converted to `LWORD` via its data output `D1`.

Data Outputs

No standalone data outputs. The plug **AUI_OUT** provides the converted `UINT` value via its data input `D1`.

Adapter

Type	Direction	Name	Description
Socket	Input	**AL_IN**	Adapter type `adapter::types::unidirectional::AL` – provides an LWORD data and an event to trigger the conversion.
Plug	Output	**AUI_OUT**	Adapter type `adapter::types::unidirectional::AUI` – receives the converted UINT data and forwards the confirmation event.

Functionality

The module consists of an internal network with a single conversion module `F_LWORD_TO_UINT` from the IEC 61131 library. The process is strictly event-driven:

1. An event at socket `AL_IN.E1` is forwarded to the `REQ` input of the conversion module.
2. The conversion block reads the date from `AL_IN.D1` (type `LWORD`) and converts it to a `UINT` value according to IEC 61131 rules.

3. After the conversion is complete, the block generates an event at its `CNF` output, which is directly passed to the plug `AUI_OUT.E1`.
4. Simultaneously, the converted value is passed from the data output `OUT` to the data input `AUI_OUT.D1`.

This completes the entire conversion in a single, unidirectional pass.
...

Technical Features

- **Bit-reinterpretation**, value-preserving only if the source value fits the narrower destination width (otherwise the upper bits are silently dropped).
- **Composite Structure**: The function block (FB) does not contain its own state machine but delegates all functionality to the embedded conversion block.
- **Unidirectional Adapters**: Both the input and output adapters are of type `unidirectional`. Only forward conversion takes place; reverse conversion and status feedback are not supported.
- **Package Assignment**: The FB is located in the package `adapter::conversion::unidirectional`, indicating its use in modular adapter chains.
- **Reusability**: The function block can be used as a universal converter in any IEC 61499 application that requires LWORD-to-UINT conversion via adapters.

State Overview

Since this is a composite block without its own state machine, the state logic is entirely determined by the internal block `F_LWORD_TO_UINT`. This block operates according to a simple REQ/CNF scheme:

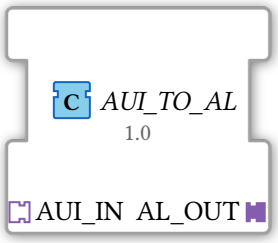
- **Waiting for REQ**: Inactive, no event at the input.
- **Conversion active**: The conversion is performed upon receipt of `REQ`.
- **Output CNF**: Upon completion, `CNF` is set and the output data is updated.

A detailed state description of the conversion block can be found in the IEC 61131 documentation.

Application Scenarios

- **Sensor Data Connection**: A sensor provides values in LWORD format (e.g., 64-bit counter readings), which are fed into the system via an AL adapter. The `AL_TO_AUI` function block converts these values into UINT (16-bit) for transmission to a controller with a UINT interface.
- **Protocol Conversion**: In modular adapter chains, the function block serves as an intermediate stage to switch from LWORD-based to UINT-based subsystems without requiring changes to the original adapter logic.
- **Data Reduction**: If the upper 48 bits of an LWORD value are not needed, the function block can selectively extract only the lower 16 bits as UINT (according to IEC 61131 conversion rules).

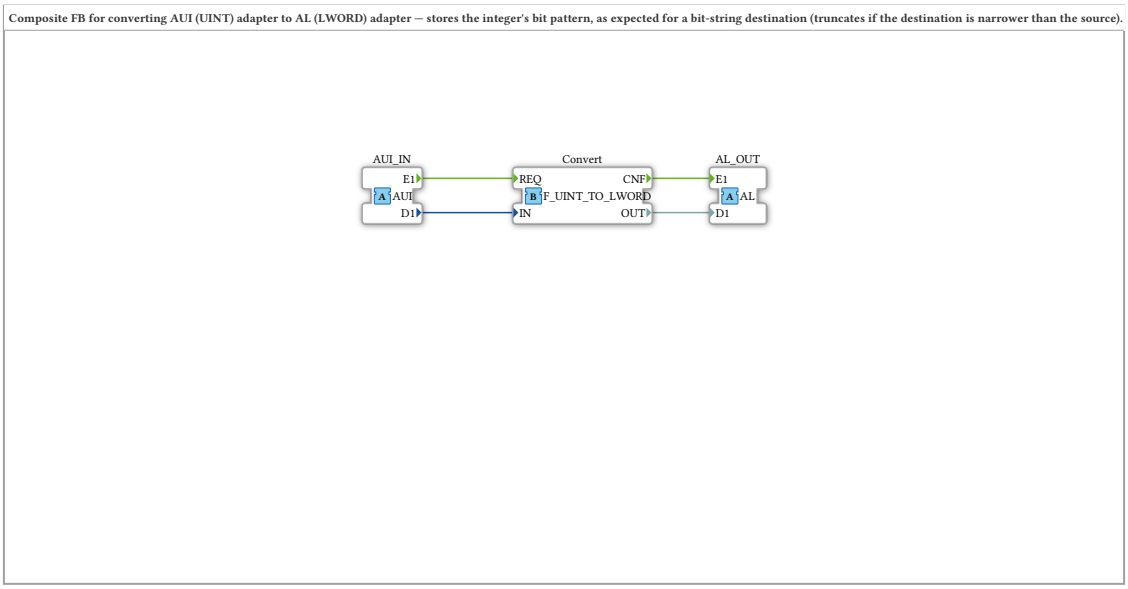
Comparison with Similar Function Blocks



Function Block	Output Type	Special Feature
`AL_TO_AUI`	UINT	Direct Adapter Converter, Unidirectional, Composite
`AL_TO_AUD`	DINT	Converts LWORD to DINT (32-bit)
`AUI_TO_AL`	LWORD	Reverse conversion from UINT to LWORD (not included, would need to be implemented separately)

Compared to directly using `F_LWORD_TO_UINT`, `AL_TO_AUI` offers the advantage of easy integration into adapter interfaces without the need to manually establish event and data connections.

Conclusion



The **AL_TO_AUI** is a convenient, standardized adapter converter for converting LWORD to UINT. Thanks to its composite structure and the use of proven IEC 61131 conversion logic, it integrates seamlessly into modular adapter chains. It is particularly suitable for applications where heterogeneous data types need to be connected via uniform adapter interfaces.

AUI_TO_AL

UINT Adapter Input – *AUI*

AL – LWORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUI_TO_AL** is a composite function block that enables the conversion of an AUI adapter (based on the UINT data type) to an AL adapter (based on the LWORD data type). It encapsulates the standardized conversion function `F_UINT_TO_LWORD` and provides a simple, event-driven interface for unidirectional data transfer.

Interface Structure

Event Inputs

The block does not have explicit individual event inputs, as event control is handled by the connected adapters. The **E1** event of the **AUI_IN** socket is internally routed to the `REQ` input of the conversion block.

Event Outputs

The function block outputs the event **E1** via the **AL_OUT** plug after the conversion is complete (signal from `CNF` of the internal function block).

Data Inputs

The data input is provided exclusively via the socket:

- **AUI_IN.D1** (Type: UINT) – The value to be converted.

Data Outputs

The data output is provided via the plug:

- **AL_OUT.D1** (Type: LWORD) – The converted value (LWORD).

Adapter

Type	Name	Direction	Description
AUI	**AUI_IN**	Input (Socket)	Input adapter for the UINT value and the trigger event.
AL	**AL_OUT**	Output (Plug)	Output adapter for the converted LWORD value and the acknowledgment event.

Functionality

The function block operates in an event-driven manner:

1. An incoming event at socket **AUI_IN.E1** (triggered by the connected transmitter) activates the internal block F_UINT_TO_LWORD via its event input REQ.
2. The value of **AUI_IN.D1** (UINT) is passed to the data input IN of the conversion block.
3. The conversion is performed according to the IEC 61131 standard: A UINT value is converted into an LWORD value (the upper 48 bits are padded with zeros).
4. After the conversion is complete, the result is passed to **AL_OUT.D1** (LWORD).
5. Simultaneously, the acknowledgment event from CNF is sent to **AL_OUT.E1** to signal the availability of the new value to the receiver.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Function Block (FB)**: The implementation hides the internal logic and facilitates reuse in larger adapter chains.
- **Standard Conversion**: Uses the IEC 61131-compliant function F_UINT_TO_LWORD, making it portable and platform-independent.
- **Unidirectional Transmission**: The adapters are designed for one-way data flow only (no return channel).
- **No State Logic**: The function block does not have its own state machine; sequence control is achieved purely through event chaining.

State Overview

The **AUI_TO_AL** function block does not implement explicit states, as it is a purely event-driven mapping. The following deterministic sequence applies:

- **Wait**: The function block waits for an event at the input socket.
- **Convert**: After an event is received, the conversion is performed.
- **Output**: Upon completion, the result is output, and the function block returns to the wait state.

Application Scenarios

- **Protocol Adaptation**: When a data provider supplies UINT values via an AUI adapter, but the consumer expects an AL adapter (LWORD).
- **System Integration**: In distributed automation systems with different data types at the communication layer.
- **Adapter Chaining**: As an intermediate link in an adapter cascade for stepwise type conversion.

Comparison with Similar Function Blocks

In the 4diac environment, other conversion adapters exist, such as AUI_TO_AB (UINT to BYTE) or AUI_TO_AW (UINT to WORD). **AUI_TO_AL** differs in its target size of LWORD (64 bits), which is used for time-critical applications or for combining multiple data words into a single, contiguous value. It does not replace a universal type conversion but offers a dedicated, event-driven adaptation for the aforementioned adapter types.

Conclusion

The **AUI_TO_AL** function block provides a clean, standardized solution for converting a UINT-based adapter (AUI) to an LWORD-based adapter (AL). It is easy to use, event-driven, and utilizes a proven IEC 61131 conversion function. Thanks to its composite nature, it integrates seamlessly into existing 4diac networks and facilitates the integration of different data widths in automation technology.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AL_TO_AULI

LWORD Adapter Input – *AL* *AULI* – ULINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AL_TO_AULI** is a composite function block (FB) that performs a data type conversion from an **AL adapter** (type `LWORD`) to an **AULI adapter** (type `ULINT`). It serves as a bridge between components that work with different data types and enables seamless integration into IEC 61499-based systems.

Interface Structure

Event Inputs

The **E1** event is received via the **AL_IN** socket (adapter `AL`). This event triggers the conversion of the incoming LWORD value.

Event Outputs

The **E1** event is sent via the **AULI_OUT** plug (adapter `AULI`) as soon as the conversion is complete and the ULINT value is available at the output.

Data Inputs

Name	Adapter Port	Data Type	Description
AL_IN	D1	LWORD	Input value in LWORD format

Data Outputs

Name	Adapter Port	Data Type	Description
AULI_OUT	D1	ULINT	Converted Value in ULINT Format

Adapter

Type	Direction	Name	Description	
`AL`	Socket	AL_IN	Input adapter with LWORD data	
`AULI`	Plug	AULI_OUT	Output adapter with ULINT data	

Functionality

The function block (FB) performs the conversion using an internal block `F_LWORD_TO_ULINT` from the library `iec61131::conversion`.

- As soon as an event **E1** arrives at the input adapter **AL_IN**, it is forwarded to the input **REQ** of the internal conversion block.
- Simultaneously, the data value **D1** (LWORD) is passed to the **IN** input of the converter.
- After successful conversion, the internal function block signals this via its **CNF** output, which triggers the **E1** event of the **AULI_OUT** output adapter.
- The converted ULINT value is then available at the **D1** data output of the output adapter.

Technical Specifications

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **License:** This function block is provided under the **Eclipse Public License 2.0**.
- **Version:** 1.0 (as of 2026-02-17)
- **Dependencies:** It requires the function `F_LWORD_TO_ULINT` from the `iec61132::conversion` library.
- **Portability:** As a composite function block, it is platform-independent and can be used in any 4diac IDE environment.
- **Type Hash:** The function block has an attribute `eclipse4diac::core::TypeHash` for unique identification (value empty).

State Overview

The function block **AL_TO_AULI** does not have its own state machine – it delegates all conversion logic to the internal function block `F_LWORD_TO_ULINT`. This makes it behave like a transparent conversion layer that only becomes active upon an incoming event and returns to its idle state after the conversion.

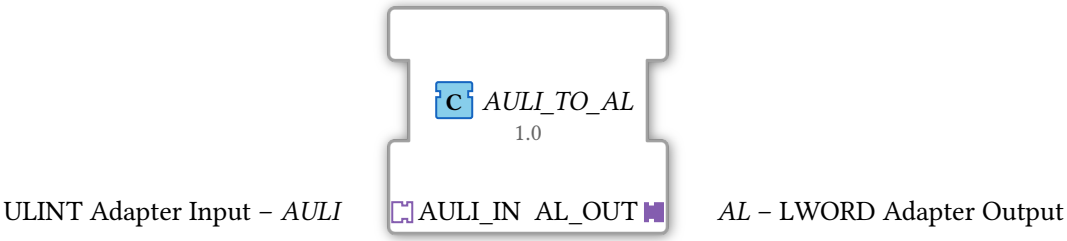
Application Scenarios

- **Data Type Conversion** in PLC or automation systems when an LWORD signal (e.g., from a communication module) needs to be converted into a ULINT value for subsequent processing (e.g., counters or arithmetic).
- **Adapter bridge** between function blocks that work exclusively with the AULI adapter and those that use the AL adapter.
- **Migration** of existing LWORD-based components to ULINT-based systems without changing the signal chain.

Comparison with similar function blocks

- **F_LWORD_TO_ULINT (direct converter):** This pure function block performs the same conversion, but without adapter interfaces. It is suitable for simple data flow models, while **AL_TO_AULI** is specifically optimized for use in adapter-based architectures.
- **Other adapter converters (e.g., AL_TO_UDINT, AL_TO_DWORD):** Similar function blocks exist for other target types (UDINT, DWORD). They differ only in the output data type but follow the same design pattern.

Conclusion



The **AL_TO_AULI** function block offers a simple and robust way to convert LWORD data to ULINT data via adapters. By encapsulating the conversion logic in a composite function block, the interface remains clear and reusable. It is particularly suitable for modular IEC 61499 projects where adapters are used as standardized communication interfaces.

AULI_TO_AL

• – ○ • – ○ • – ○ •

Introduction

The function block `AULI_TO_AL` is a composite function block for converting an AULI adapter (data type ULINT) into an AL adapter (data type LWORD). Internally, it uses the IEC 61131 conversion function `F_ULINT_TO_LWORD` and is intended for use in unidirectional adapter structures.

Interface Structure

Event Inputs

Name	Description
AULI_IN.E1	Event input via the AULI_IN socket. Starts the conversion.

Event Outputs

Name	Description
AL_OUT.E1	Event output via the AL_OUT plug. Signals the completion of the conversion.

Data Inputs

Name	Data Type	Description
AULI_IN.D1	ULINT	Input value to be converted to LWORD.

Data Outputs

Name	Data Type	Description
AL_OUT.D1	LWORD	Converted output value.

Adapter

Name	Type	Direction	Description
AULI_IN	AULI (ULINT)	Socket	Unidirectional input adapter.
AL_OUT	AL (LWORD)	Plug	Unidirectional output adapter.

Functionality

This function block operates as a simple forwarder: An incoming event at `AULI_IN.E1` triggers the internal function block `F_ULINT_TO_LWORD`, which reads the current value of `AULI_IN.D1` and converts it into an LWORD value. After the conversion is complete, the result value is output to `AL_OUT.D1`, and a completion event is simultaneously sent to `AL_OUT.E1`. The internal logic is limited to the data and event connections between the socket and the internal converter.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Implementation**: The function block does not contain its own execution control logic (ECC) but consists exclusively of a linked function block from the IEC 61131 library.
- **Adapter Architecture**: Both the input and output are designed as unidirectional adapters (socket/plug), enabling loose coupling and easy reuse in various applications.
- **Type Conversion**: The conversion from ULINT (unsigned 64-bit integer) to LWORD (64-bit bit field) is performed according to the IEC 61131 standard.

State Overview

This function block does not have its own state machine. All functionality is implemented by the internal function block `F_ULINT_TO_LWORD`, which operates as a stateless function. Event control is handled exclusively via the connections defined in the netlist.

Application Scenarios

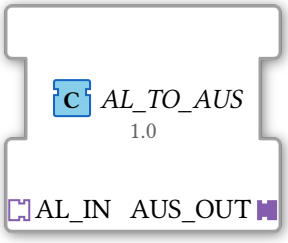
- Integration of sensor systems that deliver ULINT data via an AULI adapter into controllers that expect LWORD data via an AL adapter.
- Data type migration or protocol adaptation in existing automation solutions.

- Uniform adapter interfaces for libraries that represent different physical quantities or address spaces.

Comparison with Similar Function Blocks

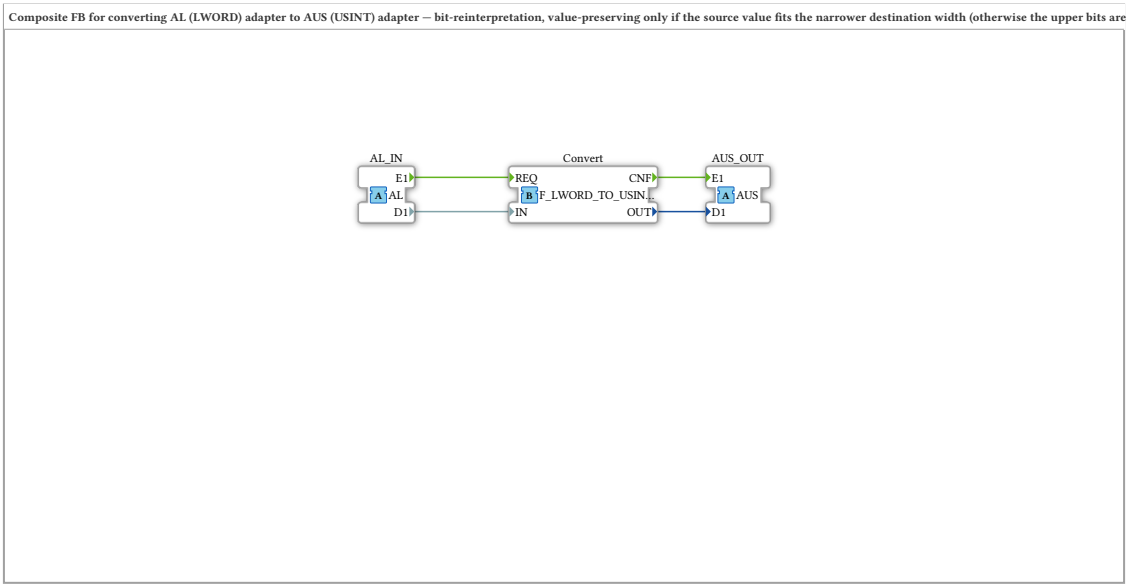
Unlike generic converter function blocks (e.g., `ULINT_TO_LWORD`), `AULI_TO_AL` is specifically designed for adapter-based data exchange. Similar adapter converters exist for other data types (e.g., `BOOL_TO_BYTE`, `INT_TO_DINT`), but they differ in the adapter types used and the internal conversion function. This function block adds a clean, typed interface for ULINT↔LWORD to the library.

Conclusion



AULI_TO_AL` is a simple yet reliable composite function block for converting between AULI and AL adapters. Direct use of the standardized IEC 61131 function ensures high compatibility and accuracy of the conversion. The adapter interfaces enable modular integration into complex automation systems.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AL_TO_AUS

LWORD Adapter Input – *AL*

AUS – USINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block AL_TO_AUS converts an AL adapter (LWORD) into an AUS adapter (USINT). It is implemented as a composite function block and encapsulates the conversion logic using the function block F_LWORD_TO_USINT. Input and output are handled via unidirectional adapter interfaces.

Interface Structure

Event Inputs

The function block does not have direct event inputs. Instead, events are received via the adapter socket `AL_IN`. This socket provides the event input `E1`.

- **`AL_IN.E1`** (event): Trigger for data conversion.

Event Outputs

The FB has no direct event outputs. Events are sent via the adapter plug `AUS_OUT`. This plug provides the event output `E1`.

- **`AUS_OUT.E1`** (Event): Signals the completion of the conversion and the availability of the output value.

Data Inputs

The data is provided via the adapter socket `AL_IN`.

- **`AL_IN.D1`** (LWORD): The LWORD value to be read and converted into a USINT value.

Data Outputs

The converted data is output via the adapter plug `AUS_OUT`.

- **`AUS_OUT.D1`** (USINT): The converted USINT value.

Adapters

- **Socket `AL_IN`** (Type: `adapter::types::unidirectional::AL`): Unidirectional LWORD input adapter.
- **Plug `AUS_OUT`** (Type: `adapter::types::unidirectional::AUS`): Unidirectional USINT output adapter.

Functionality

The function block waits for an event at the input adapter `AL_IN.E1`. As soon as this event occurs, the LWORD value at `AL_IN.D1` is read and passed to the internal conversion function block `F_LWORD_TO_USINT`. This performs the conversion to a USINT value. After successful conversion, the result is forwarded to the output adapter `AUS_OUT.D1`, and an event is simultaneously sent to `AUS_OUT.E1`.

The internal connections are:

- From the event input of the socket to the `REQ` input of the converter.
- From the `CNF` output of the converter to the event output of the plug.
- From the data input of the socket to the `IN` input of the converter.
- From the `OUT` output of the converter to the data output of the plug.

Technical Features

- **Bit-reinterpretation**, value-preserving only if the source value fits the narrower destination width (otherwise the upper bits are silently dropped).
- The function block is implemented as a composite function block (FB) that utilizes the IEC 61131 conversion function `F_LWORD_TO_USINT`.
- The adapters are unidirectional, meaning data and event flows only in one direction.
- The conversion function block is from the library `iec61131::conversion`.
- Encapsulating the conversion logic in a composite function block increases its reusability and interchangeability.

State Overview

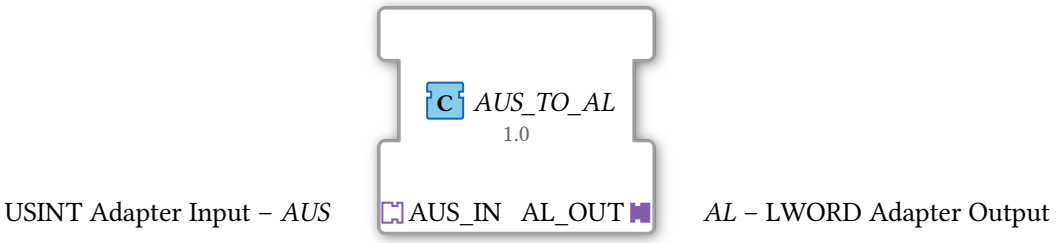
The function block does not have its own defined state machine. The internal logic consists of a single conversion function block and fixed connections. The process is purely event-driven:

1. Wait for an event at the input (`AL_IN.E1`).
2. Perform the conversion.
3. Output the result and set an event at the output (`AUS_OUT.E1`).

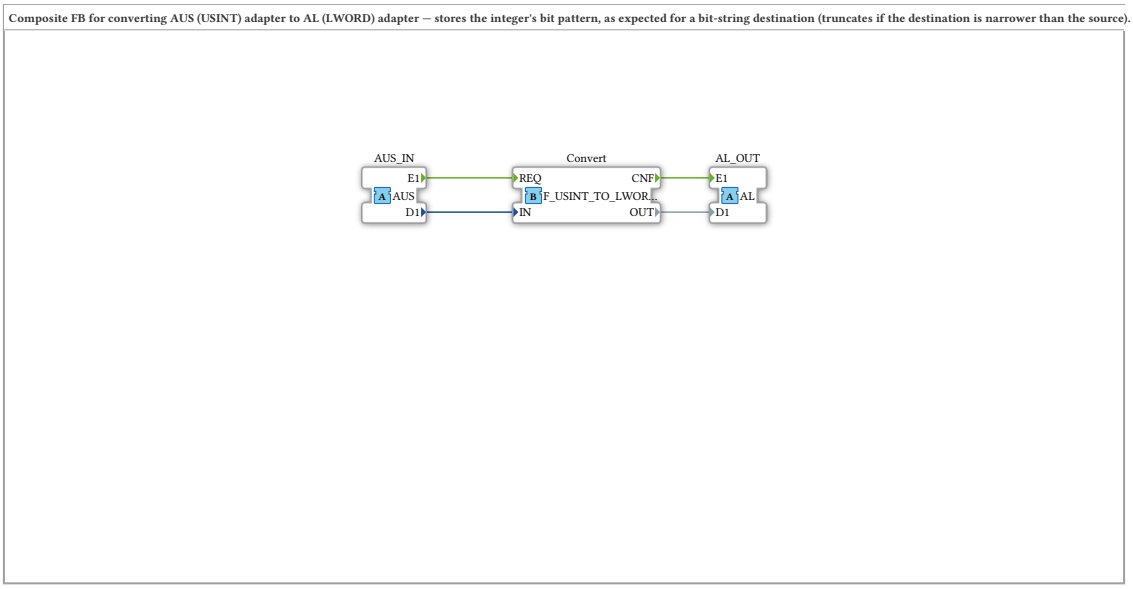
Application Scenarios

- Connecting sensors or actuators that provide an LWORD value to a system that expects USINT.
- Protocol implementation in automation systems where different data types need to be converted between adapters.
- Integration into larger composite function blocks that combine multiple conversion steps.

Comparison with Similar Function Blocks



- **F_LWORD_TO_UINT**: Converts LWORD to UINT (16 bits).
- **F_LWORD_TO_DWORD**: Converts LWORD to DWORD (32 bits).



- **F_LWORD_TO_BYTE**: Converts LWORD to BYTE (8 bits), but returns a signed/unsigned value. USINT is unsigned 8 bits.
- This function block fills the gap for direct conversion to the USINT data type within the adapter context.

Conclusion

The composite function block AL_TO_AUS offers a simple and clean solution for converting an LWORD adapter input to a USINT adapter output. By using standardized conversion blocks and encapsulating the conversion in a dedicated function block type, the maintainability and readability of the overall system are improved. It is particularly suitable for scenarios where unidirectional adapter interfaces with different data types need to be connected.

OFF_TO_AL

• – ◦ • – ◦ • – ◦ •

Introduction

The **OFF_TO_AL** function block is a composite function block (FB) that converts a unidirectional **OFF** adapter (USINT data type) into a unidirectional **AL** adapter (LWORD data type). It serves as a bridge between different data formats in a 4diac IDE environment, with the conversion being performed internally by the IEC 61131 FB `F_USINT_TO_LWORD`. The function block facilitates the integration of components based on different adapter types.

Interface Structure

Because it is a composite FB, all I/O signals are provided via the two adapters. The FB itself does not have any independent event or data inputs/outputs.

Event Inputs

- No standalone event inputs.

Event Outputs

- No standalone event outputs.

Data Inputs

- No standalone data inputs.

Data Outputs

- No standalone data outputs.

Adapter

Name	Type	Direction	Description
OFF_IN	adapter::types::unidirectional::AUS	Socket (Input)	Receives the USINT value and the associated event. The adapter provides an internal event input E1 and a data input D1 (USINT).
AL_OUT	adapter::types::unidirectional::AL	Plug (Output)	Outputs the converted LWORD value. The adapter also provides an internal event output E1 and a data output D1 (LWORD).

Functionality

1. The **AUS_IN** socket receives an event at its internal input E1 and the corresponding USINT value at D1.

AL_OUT | adapter::types::unidirectional::AL | Plug (Output) | Outputs the converted LWORD value. 2. This event is internally forwarded to the **REQ** input of the conversion function block F_USINT_TO_LWORD; the USINT value is placed at its **IN** input.

1. The function block F_USINT_TO_LWORD performs the conversion from USINT (8-bit unsigned) to LWORD (64-bit unsigned).
2. After the conversion is complete, an event is generated at the **CNF** output of F_USINT_TO_LWORD, which is sent to the internal event input of the **AL_OUT** adapter (E1). Simultaneously, the converted LWORD value is placed at the data output D1 of the adapter.

The conversion is then performed by the function block F_USINT_TO_LWORD. 5. The parent function block can then retrieve the LWORD value via the **AL_OUT** plug and use the event.

The entire sequence is strictly causal: The conversion is only triggered when an event arrives at **AUS_IN**.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite FB**: The function block encapsulates the conversion logic in a reusable adapter pair.
- **Library Used**: The actual type conversion is performed by iec61131::conversion::F_USINT_TO_LWORD from the IEC 61131 standard library.
- **No State**: The function block is purely combinatorial with event-driven execution; it does not store any internal states.
- **Adapter Unidirectionality**: Both AUS and AL are defined as unidirectional adapters, meaning data flows in only one direction (input → output).

State Overview

This function block does not have its own state diagram. Its behavior is determined exclusively by the event/data flows of the embedded function block F_USINT_TO_LWORD:

- **Idle**: Waiting for an event at **OFF_IN**.
- **Conversion Active**: As soon as an event arrives, the conversion is performed. Upon completion, the output event is generated, and the function block returns to the idle state.

Application Scenarios

- **Data Format Adaptation**: A sensor or controller delivers data as a USINT value (e.g., counter readings), but the downstream component expects LWORD (e.g., for large data ranges or timestamps).

- **Adapter Bridges**: If components with different adapter types need to be connected in a 4diac application, this function block enables clean, type-safe conversion.
- **Legacy System Support**: Legacy systems that output USINT data can be integrated into modern LWORD interfaces using this function block.

Comparison with Similar Function Blocks

- **F_USINT_TO_LWORD**: A pure function block (Basic FB) without adapter encapsulation. It can be used directly in a network but requires manual cabling of events and data.
- **AUS_TO_AL**: Offers a higher level of abstraction through the use of adapters. This improves the reusability and interchangeability of components because the adapter interfaces are standardized.
- **Other Type Converters** (e.g., `INT_TO_DWORD`): Similar logic, but for different data types; this function block fills the specific gap between USINT and LWORD.

Conclusion

The **AUS_TO_AL** function block is a practical composite function block for converting USINT to LWORD data, packaged in an adapter-based interface. It utilizes the proven IEC 61131 conversion and allows for seamless integration into modular 4diac applications. Thanks to the adapter encapsulation, the interface remains clearly defined, and the block can be easily integrated into existing communication structures.

AL_TO_AW

LWORD Adapter Input – *AL* *AW* – WORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The AL_TO_AW function block is a composite module that converts an LWORD input adapter of type AL (unidirectional) into a WORD output adapter of type AW (unidirectional). It encapsulates the conversion function and provides a simple interface for converting 64-bit data to 16-bit data in the 4diac IDE.

Interface Structure

The module has no discrete event or data ports, but only adapter interfaces (socket/plug). The following overview shows the available adapters:

Event Inputs

No separate event inputs. The event signal is routed via the AL_IN adapter (socket).

Event Outputs

No separate event outputs. The event signal is output via the AW_OUT adapter (Plug).

Data Inputs

No separate data inputs. Data is read via the AL_IN adapter.

Data Outputs

No separate data outputs. Data is output via the AW_OUT adapter.

Adapters

- **AL_IN** (Socket) – Type: `adapter::types::unidirectional::AL`

LWORD input adapter; contains one event signal and one data signal (E1, D1).

- **AW_OUT** (Plug) – Type: `adapter::types::unidirectional::AW`

WORD output adapter; Contains one event signal and one data signal (E1, D1).

Functionality

The function block operates in an event-driven manner:

1. An event at socket **AL_IN** (E1) triggers the internal conversion function block `F_LWORD_TO_WORD`.
2. Simultaneously, the LWORD data (D1) is forwarded from the input adapter to the `IN` input of the conversion function block.
3. The conversion function block performs the conversion from LWORD (64-bit) to WORD (16-bit).
4. After successful conversion, an event is generated at the `CNF` output of the conversion function block, which is then passed to the output adapter **AW_OUT** (E1).
5. The converted WORD data (16 bits) is retrieved from the `OUT` output of the conversion function block and passed to the data output of the adapter (D1).

The entire logic consists of a direct connection chain without intermediate states or delays.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- **Use of standardized IEC 61131 conversion** – Internally, the function block `F_LWORD_TO_WORD` from the IEC 61131 library is used.
- **Adapter-based interface** – The function block is fully integrated into 4diac's adapter concepts and can be easily integrated into existing systems with unidirectional AL and AW adapters.
- **No side effects** – The conversion occurs without storage or buffering; each incoming event triggers exactly one output.
- **Compatibility** – Suitable for applications where 64-bit LWORD data signals need to be reduced to 16-bit WORD signals (e.g., when connecting older controllers or fieldbuses).

State Overview

The function block has no internal states. It is a purely combinational transformation without sequential logic or state machines.

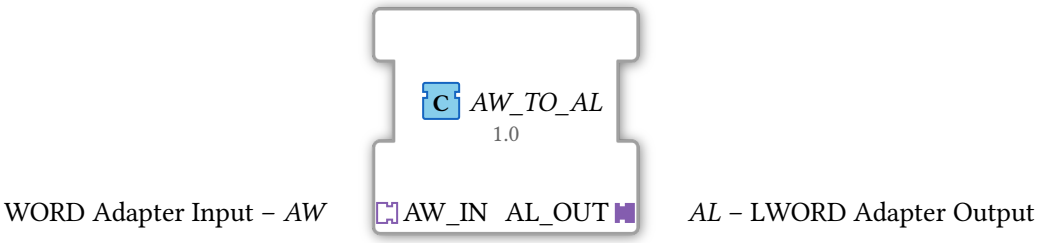
Application Scenarios

- **Protocol Conversion** – In automation systems that use different data word widths (e.g., converting 64-bit measured values to 16-bit outputs).
- **Interface Adaptation** – When a system provides LWORD data, but a downstream adapter only processes WORD data.
- **Testing and Simulation Tasks** – For easily converting test data between different adapter types.

Comparison with Similar Function Blocks

- **F_LWORD_TO_WORD** (direct function block) – Offers the same conversion, but without adapter encapsulation. AL_TO_AW integrates this conversion directly into an adapter-based environment.
- **Other Adapter Conversions** – Similar function blocks exist for other data type pairs (e.g., DWORD_TO_WORD). AL_TO_AW is specifically designed for the LWORD↔WORD combination.
- **Custom Composite Function Blocks** – This function block demonstrates how to efficiently implement recurring conversion tasks in the 4diac IDE through encapsulation.

Conclusion



AL_TO_AW is a compact and clearly structured composite function block for converting an LWORD adapter to a WORD adapter. It utilizes the proven IEC conversion function, offers an adapter-compliant interface, and is ideally suited for integration into 4diac projects that require clean separation of data word widths.

AW_TO_AL

WORD Adapter Input – *AW* *AL* – LWORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The AW_TO_AL function block is a composite block for converting a WORD adapter (AW) to an LWORD adapter (AL). It is used to convert data from a 16-bit format to a 64-bit format, typically in control and automation systems. The block forwards events and data directly from the input side to the output side, ensuring the data type conversion.

Interface Structure

Event Inputs

None (Events are transmitted exclusively via the AW_IN adapter)

Event Outputs

None (Events are output exclusively via the AL_OUT adapter)

Data Inputs

None (Data is received exclusively via the AW_IN adapter)

Data Outputs

None (Data is sent exclusively via the AL_OUT adapter)

Adapters

- **AW_IN** (Socket): Adapter type `adapter::types::unidirectional::AW` – WORD input (16-bit) with event and data channels (E1, D1).
- **AL_OUT** (Plug): Adapter type `adapter::types::unidirectional::AL` – LWORD output (64-bit) with event and data channels (E1, D1).

Functionality

The function block implements a simple passthrough function: The event (E1) received by the AW_IN adapter is directly forwarded to the event output AL_OUT.E1. Simultaneously, the 16-bit data signal from AW_IN.D1 is transferred to the 64-bit data output AL_OUT.D1. Since the AL adapter expects LWORD, the WORD value is implicitly converted to an LWORD (by zero expansion or explicit type conversion according to the runtime environment used). The function block does not perform any further operations.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- The function block is implemented as a composite function block, meaning it contains an internal network that connects the adapters.
- The type conversion from WORD to LWORD occurs automatically through the concatenation of the data lines (implicit type conversion).
- The event and data paths are synchronized: Each incoming event triggers an outgoing event, accompanied by the current data value.
- The function block is unidirectional and does not support reverse communication.

State Overview

Since the function block does not have its own state logic but only implements pass-through, there are no explicit states. Its function is purely combinatorial or event-driven without memory behavior.

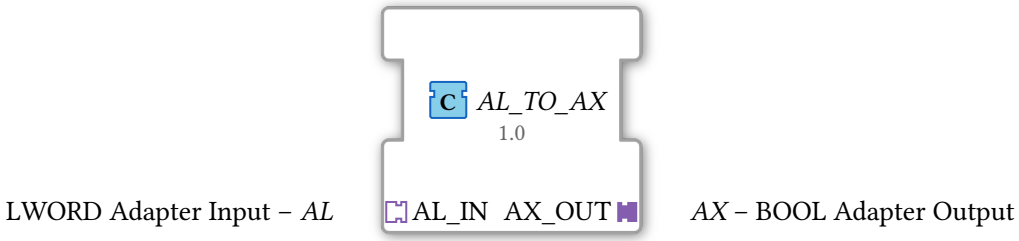
Application Scenarios

- **Format Adaptation**: If a sensor or controller only delivers WORD data (16 bits), but the downstream system expects LWORD data (64 bits), this function block can be used for adaptation.
- **Adapter Bridge**: In communication chains where different adapter types are used, the function block enables seamless integration.
- **Protocol Conversion**: As part of a larger adapter chain for converting from 16-bit to 64-bit data buses.

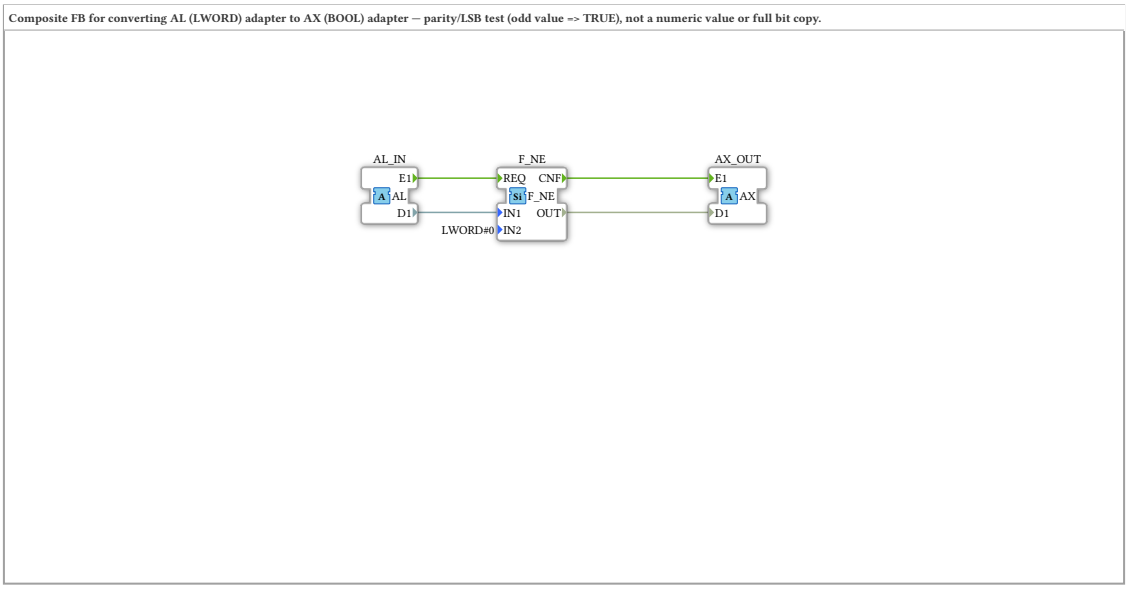
Comparison with Similar Function Blocks

- **AW_TO_AW**: Identical type, no conversion.

- **AL_TO_AW**: Reverse conversion from LWORD to WORD (potentially resulting in data loss).
- **Direct connection without conversion**: If the systems use the same adapter type, no conversion module is required.
- The AW_TO_AL function block is characterized by its simplicity and specific type adaptation.



Conclusion



The AW_TO_AL function block offers a straightforward way to convert WORD data to an LWORD format. It is particularly suitable for scenarios where pure type adaptation without additional logic is required. Its implementation as a composite function block ensures transparent and efficient data transfer.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AL_TO_AX

• – ○ • – ○ • – ○ •

Introduction

The function block `AL_TO_AX` is a composite function block that performs a unidirectional adapter conversion from a `AL` adapter (data type `LWORD`) to a `AX` adapter (data type `BOOL`). It enables the simple conversion of an LWORD signal into a Boolean signal, which is then typically passed to subsequent BOOL-based adapters or function blocks. The function block checks whether the incoming LWORD value is non-zero and returns `TRUE` if so.

Interface Structure

The function block does not have its own event or data inputs/outputs, but uses only adapter interfaces:

- **Socket (Input):** `AL_IN` – Receives a `AL` adapter (contains an LWORD and an event).
- **Plug (Output):** `AX_OUT` – Provides a `AX` adapter (contains a BOOL and an event).

Internal connections are handled via the adapter elements:

Event Inputs

(via the AL_IN adapter)

- **`AL_IN.E1`** – Event input; triggers the conversion.

Event Outputs

(via the AX_OUT adapter)

- **`AX_OUT.E1`** – Event output; signals the completion of the conversion.

Data Inputs

(via the AL_IN adapter)

- **`AL_IN.D1`** (`LWORD`) – The LWORD value to be converted.

Data Outputs

(via the AX_OUT adapter)

- **`AX_OUT.D1`** (`BOOL`) – The result of the conversion: `TRUE` if `AL_IN.D1 ≠ 0`; otherwise `FALSE`.

Adapter

- **AL_IN** – Socket for the `adapter::types::unidirectional::AL` adapter (LWORD-based)
- **AX_OUT** – Plug for the `adapter::types::unidirectional::AX` adapter (BOOL-based)

Functionality

The function block internally uses the function block `F_NE` ("not equal") from the IEC 61131 library. This compares the incoming LWORD value (`AL_IN.D1`) with the constant value `LWORD#0`. If the values are not equal, `F_NE.OUT` returns the value `TRUE`; otherwise, it returns `FALSE`.

The event-driven sequence is as follows:

1. An event at `AL_IN.E1` triggers the input `F_NE.REQ`.
2. `F_NE` performs the comparison and places the result at `F_NE.OUT`.
3. Upon completion, `F_NE` sends an event to `F_NE.CNF`, which is connected to `AX_OUT.E1`.
4. Simultaneously, the result `F_NE.OUT` is transferred to `AX_OUT.D1`.

Thus, with each event at the input, an updated Boolean output is provided at the output.

Technical Features

- **Parity/LSB test** (odd value => TRUE), not a numeric value or full bit copy.
- **Type Conversion:** The function block converts an LWORD value not bitwise, but as an integer into a BOOL value. Any non-zero LWORD results in `TRUE`.
- **Adapter-Based:** By using the standardized unidirectional adapters (`AL` and `AX`), the function block can be used in any 4diac network that supports these adapter types.
- **Latency:** Processing occurs synchronously with the input event. The output is updated in the same execution cycle.
- **No State Storage:** The function block is purely combinatorial; it does not store any values between calls.

State Overview

The `AL_TO_AX` function block does not have its own state machine. Its behavior is purely data flow-driven by the incoming event. Therefore, a state overview is not available.

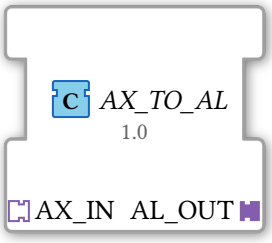
Application Scenarios

- **Threshold Detection:** Conversion of an LWORD sensor signal (e.g., counter reading, bitmask) into a Boolean signal that indicates whether a non-zero value is present.
- **Coupling of LWORD and BOOL Adapters:** In heterogeneous systems where one functional block provides an LWORD-based adapter, but the next block expects a BOOL adapter.
- **Error Detection:** An LWORD error register (e.g., 0 = no error, ≠0 = error) is translated into a simple BOOL signal "error present".

Comparison with Similar Components

- **Direct Converters (e.g., `LWORD_TO_BOOL`):** These usually only convert the least significant bit or define a fixed bit. The `AL_TO_AX` block, on the other hand, uses zero comparison, so any set bit or non-zero value is interpreted as `TRUE`.
- **Adapter Converters:** Generic adapter converters exist that handle various data types (e.g., `ANY_TO_BOOL`). The specialized `AL_TO_AX` block is tailored to the aforementioned adapter combination and requires no external parameterization.

Conclusion



The `AL_TO_AX` function block offers a simple and reliable way to convert a unidirectional LWORD-based adapter into a BOOL-based adapter. The use of zero comparison ensures unambiguous interpretation. Integration into existing 4diac networks is straightforward thanks to the standardized adapter interfaces. This component is particularly well-suited for fast, event-driven conversions without requiring additional memory and is a practical addition to adapter conversion in industrial automation.

AX_TO_AL

BOOL Adapter Input – *AX* — *AL* – LWORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AX_TO_AL** is a composite block for bidirectional coupling of an AX adapter (BOOL) with an AL adapter (LWORD). It enables the forwarding of events and data between these two adapter interfaces without requiring the implementation of custom logic. The function block serves as a simple conversion bridge and is typically used in automation systems to connect components with different adapter formats.

Interface Structure

Event Inputs

Name	Adapter	Description
AX_IN.E1	AX (BOOL)	Event input connected via the AX adapter.

Event Outputs

Name	Adapter	Description
AL_OUT.E1	AL (LWORD)	Event output that passes the incoming event on unchanged.

Data Inputs

Name	Adapter	Type	Description
AX_IN.D1	AX (BOOL)	BOOL	Data input for a Boolean signal.

Data Outputs

Name	Adapter	Type	Description
AL_OUT.D1	AL (LWORD)	LWORD	Data output that represents the Boolean signal as an LWORD (64-bit memory). Type conversion is performed outside the function block.

Adapter

Type	Name	Direction
Socket	AX_IN	Input (BOOL)
Plug	AL_OUT	Output (LWORD)

Functionality

The FB **AX_TO_AL** functions purely as a pass-through function block. Within the FB network, the event connection `AX_IN.E1 → AL_OUT.E1` and the data connection `AX_IN.D1 → AL_OUT.D1` are established directly. An incoming event at the AX socket immediately triggers the corresponding event at the AL plug. Simultaneously, the Boolean value of `AX_IN.D1` is passed to `AL_OUT.D1`.

The function block itself does not perform any value conversion; the conversion of the Boolean signal to an LWORD (e.g., 1 or 0 in a 64-bit word) is provided by the underlying adapter implementation or the host environment.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- **Composite Architecture**: The function block contains no internal ECC (Execution Control Chart) or its own logic. It consists solely of two adapter connections and simple passthroughs.
- **Type Mapping**: The mapping from BOOL to LWORD is implicit. The user must ensure that the connected adapters correctly support the conversion.
- **Project Structure**: The function block is located in the package `adapter::conversion::unidirectional`, which indicates its function as a unidirectional conversion adapter.

State Overview

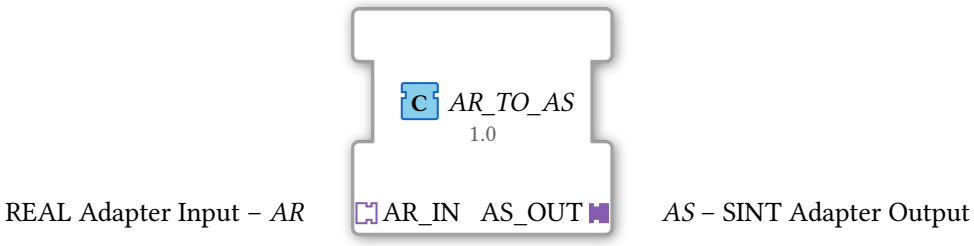
The function block has no state machine and no states of its own. It operates in an event-driven manner and reacts passively to signals from the AX adapter.

Application Scenarios

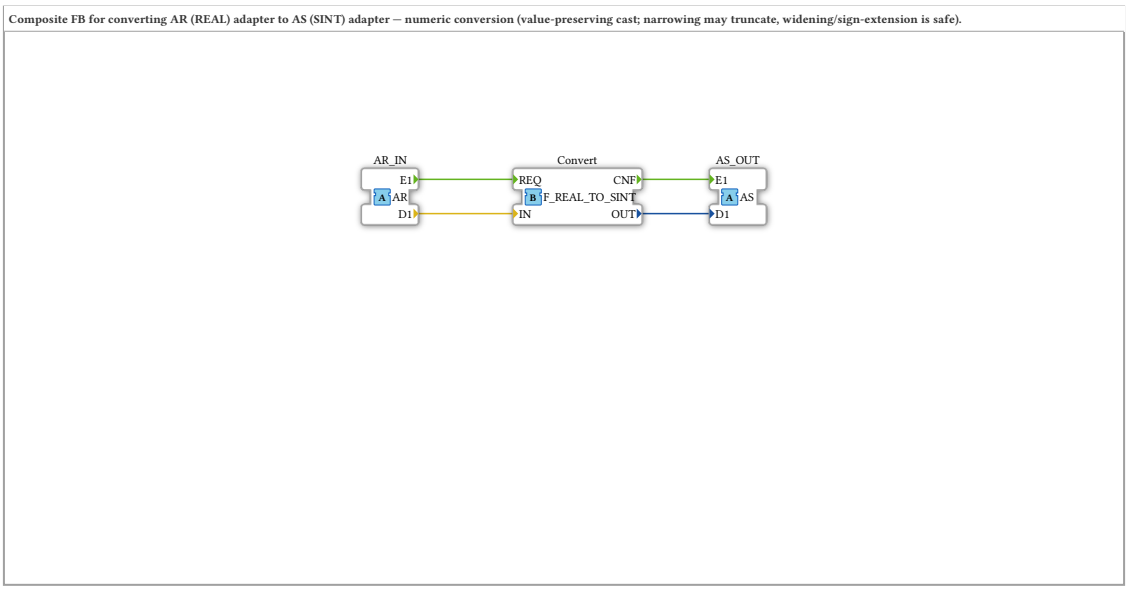
- Integrating an old Boolean interface (AX) into a system that only supports LWORD adapters (AL).
- Temporary bridging circuit during the migration of fieldbus protocols.
- Test environments where a Boolean signal needs to be interpreted as a 64-bit value.

Comparison with Similar Function Blocks

Other conversion function blocks exist, such as... Examples include `AL_TO_AX` (reverse conversion from LWORD to BOOL) or `BOOL_TO_LWORD` (direct conversion without adapter encapsulation). Unlike these pure value converters, **AX_TO_AL** encapsulates the entire adapter interface, so the user only needs to connect the adapters.



Conclusion



The **AX_TO_AL** function block is a lean yet useful adapter coupler. It reduces the effort required when different adapter formats need to be combined in an automation system and does not require any custom logic or state definitions. Its simple structure facilitates quick integration into existing IEC 61499 networks.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AR_TO_AS

• – ○ • – ○ • – ○ •

The function block **AR_TO_AS** is a composite block that converts a **REAL adapter** (AR) into a **SINT adapter** (AS). It enables simple and standardized conversion between the adapter types and encapsulates the necessary logic in a reusable block. The function block does not have separate event or data ports at the IEC 61499 level. All communication takes place via the integrated adapters. The following table describes the available adapters.

No dedicated event inputs are available. Events are received via the **AS_OUT adapter** (see Adapters).
No dedicated event outputs are available. Events are sent via the **AR_IN adapter** (see Adapters).
No dedicated data inputs. Data is received via the **AS_OUT adapter** (see Adapters).

No dedicated data outputs. Data is sent via the **AR_IN adapter** (see Adapters).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

Adapter	Type	Direction	Description
AR_IN	adapter::types::unidirectional::AR	Socket (inbound)	Unidirectional REAL adapter. Returns a REAL value (D1) and an associated event (E1).
AS_OUT	adapter::types::unidirectional::AS	Plug (outbound)	Unidirectional SINT adapter. Receives a SINT value (D1) and an associated event (E1).

Functionality

The function block performs the conversion as follows:

1. An incoming event on **AR_IN.E1** triggers the internal conversion block **F_REAL_TO_SINT**.
2. The REAL value associated with the event from **AR_IN.D1** is forwarded to the input `IN` of the conversion block.
3. **F_REAL_TO_SINT** converts the REAL value into a SINT value and outputs the result to its output `OUT`. 4. After the conversion is complete, an event is sent via **AS_OUT.E1**, along with the converted SINT value to **AS_OUT.D1**.

A synchronous 1:1 conversion takes place – each incoming REAL request generates exactly one outgoing SINT response.

- **Reusability**: The function block is based on the standard FB `F_REAL_TO_SINT` from the IEC 61131 library. This ensures that the conversion logic is standards-compliant and available on many platforms.
- **Adapter Interface**: The use of adapters allows for loose coupling between function blocks and facilitates the exchange or extension of the interface.
- **Value Range**: When converting from REAL (approx. $\pm 3.4 \times 10^{38}$) to SINT (−128 ... 127), value range exceedances can occur. The internal function block `F_REAL_TO_SINT` behaves according to the IEC 61131 definition (overflow or use of saturation behavior). The user should limit the input values accordingly.

The **AR_TO_AS** does not have its own state machine. Since it is a pure composite function block that only establishes the connection between the incoming and outgoing adapters, there is no internal state behavior. The function block operates combinatorially at the event level.

- **Integration of REAL-based function blocks in SINT environments**: If a component provides a REAL adapter, but the subsequent function block expects a SINT adapter, **AR_TO_AS** can be used as an intermediary adapter.
- **Type-safe conversion in modular controllers**: By using adapters, the typing is preserved, and the conversion is explicitly visible in the network.
- **Library extension**: The function block can be used as part of an adapter conversion library to standardize data exchange between different numerical resolutions.

Analogous conversion adapters exist, e.g.,... B.:

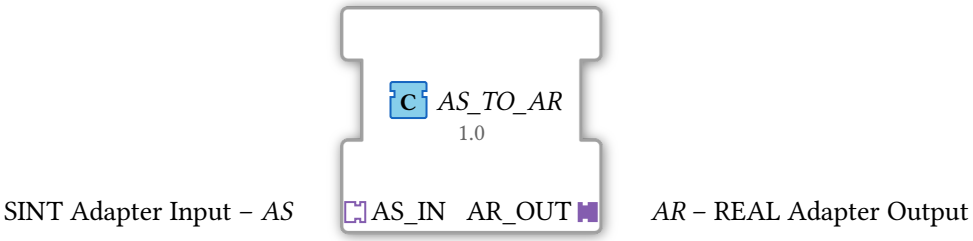
- **AR_TO_INT** – REAL ⟶ INT
- **AR_TO_UDINT** – REAL ⟶ UDINT
- **AR_TO_LREAL** – REAL ⟶ LREAL

All of these modules share the use of the corresponding IEC 61131 conversion block. The difference lies in the target type and the adapter definition. **AR_TO_AS** is specifically designed for conversion to the narrow, signed 8-bit SINT type.

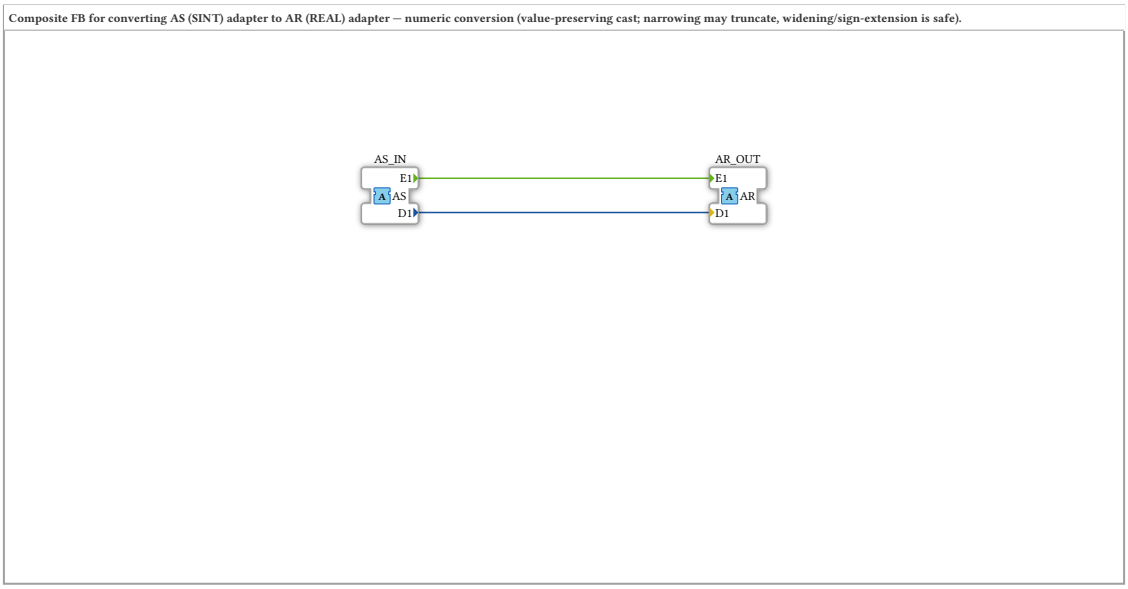
The **AR_TO_AS** is a simple yet effective composite module for converting a REAL adapter to a SINT adapter. It cleanly encapsulates the conversion logic and enables type-safe, event-driven communication between function blocks with different numeric interfaces. Thanks to the use of standard libraries, it is reliable and platform-independent.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).



State Overview



Application Scenarios

Comparison with Similar Function Blocks

Conclusion

AS_TO_AR

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AS_TO_AR` is a composite function block that converts a unidirectional adapter of type **AS** (SINT) to an adapter of type **AR** (REAL). It is used to establish a logical connection between components based on different data types – specifically, from a signed 8-bit integer (SINT) to a floating-point number (REAL).

Interface Structure

Event Inputs

The function block does not have its own dedicated event inputs. Events are received exclusively via the integrated adapter **AS_IN**.

- **AS_IN.E1** – Event from the connected SINT adapter.

Event Outputs

Events are passed on via the integrated adapter **AR_OUT**.

- **AR_OUT.E1** – Event for the connected REAL adapter.

Data Inputs

Data is provided exclusively via the adapter **AS_IN**.

- **AS_IN.D1** – Data value of type **SINT** (signed 8-bit integer).

Data Outputs

Data is output exclusively via the adapter **AR_OUT**.

- **AR_OUT.D1** – Data value of type **REAL** (floating-point number).

Adapters

Type	Name	Direction	Comment
`adapter::types::unidirectional::AS`	**AS_IN**	Socket	Input adapter for SINT data
`adapter::types::unidirectional::AR`	**AR_OUT**	Plug	Output adapter for REAL data

Functionality

The `AS_TO_AR` block behaves as a pure type conversion passthrough. Within the integrated function network, the event `AS_IN.E1` is directly connected to `AR_OUT.E1`, and the data value `AS_IN.D1` is directly connected to `AR_OUT.D1`. The actual conversion from **SINT** to **REAL** is performed implicitly through the adapter definitions of the respective types. The block itself does not execute any additional logic or calculations.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block**: Conversion is achieved solely through the interconnection of adapters in the function network. It does not have its own state machine (ECC).
- **Package Membership**: The block is included in the package `adapter::conversion::unidirectional`.
- **No Data Storage**: All values are passed on instantly; the block has no internal memory.
- **Implicit Type Conversion**: The conversion from integer (SINT) to floating-point number (REAL) takes place in the periphery of the adapter types.

State Overview

The `AS_TO_AR` block does not have a state machine (ECC). Its behavior is purely combinatorial and is limited to the direct forwarding of events and data.

Application Scenarios

- Connecting a sensor that provides its measured values as a SINT adapter to a processing component that expects REAL adapters.
- Transitioning between different '4diac' adapter types in heterogeneous control projects.
- Preparing values for mathematical operators or visualization components that require REAL inputs.

Comparison with Similar Function Blocks

- **AR_TO_AS** – Performs the reverse conversion from REAL to SINT.

- **General type converters** (e.g., `INT_TO_REAL`) operate at the level of individual data ports, while `AS_TO_AR` converts entire adapter interfaces.
- This function block does not offer adjustable parameters (e.g., rounding modes); more specific conversion would have to be implemented using separate function blocks.

Conclusion

AS_TO_AR` is a simple yet useful composite block for adapter type conversion from SINT to REAL. It enables the lossless integration of components with different data types in continuous control sequences and is characterized by its low complexity and direct passthrough.

AR_TO_AUDI

REAL Adapter Input – *AR*

AUDI – UDINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block `AR_TO_AUDI` is a composite function block (FB) that receives a REAL value from a unidirectional **AR** adapter, converts it to a **UDINT** value, and outputs it via an **AUDI** adapter. It encapsulates the type conversion `REAL_TO_UDINT` and simplifies integration into adapter-based communication structures.

Interface Structure

The function block has no dedicated event or data inputs/outputs. All communication takes place via two adapters (socket and plug).

Adapter (Socket – Input)

Name	Type	Comment
AR_IN	adapter::types::unidirectional::AR	Unidirectional REAL adapter as input

The adapter AR_IN provides an event E1 and a data input D1 of type REAL.

Adapter (Plug – Output)

Name	Type	Comment
AUDI_OUT	adapter::types::unidirectional::AUDI	Unidirectional UDINT adapter as output

The adapter AUDI_OUT expects an event E1 and a data output D1 of type UDINT.

Functionality

The function block internally contains an instance of the conversion function block F_REAL_TO_UDINT from the library iec61131::conversion. The signal connections implement a simple data flow:

1. **Event from the input adapter**

The event AR_IN.E1 triggers the conversion function block via its event input REQ.

1. **Data Conversion**

Simultaneously, the REAL value of AR_IN.D1 is transferred to the data input IN of F_REAL_TO_UDINT. The conversion occurs without delay within the event cycle.

1. **Output Event and Result**

After successful conversion, F_REAL_TO_UDINT sends an acknowledgment event (CNF) to the output adapter (AUDI_OUT.E1). The converted UDINT value is forwarded to AUDI_OUT.D1 via the data output OUT.

The conversion is synchronous: Each incoming event triggers exactly one output.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block** – The logic is implemented entirely through an internal network; there is no standalone algorithm or state machine.
- **Unidirectional Adapters** – Both the input and output interfaces are unidirectional and transmit only one event/data channel.
- **Library Used** – Conversion is performed using the IEC 61131 block F_REAL_TO_UDINT, which is hardware-independent and widely used.
- **No Error Handling** – The block does not perform range or type checking; the REAL to UDINT conversion follows standard rules (rounding, delimiting).

State Overview

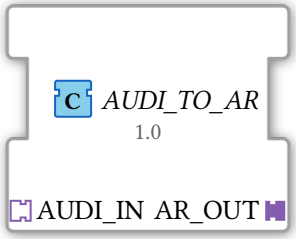
Since the block does not have its own state machine, its operation is determined solely by the event network:

- **Idle** – No event is active at AR_IN.E1; the output adapter remains inactive.
- **Active** – An incoming event immediately triggers the conversion and produces an output event. Upon completion, the function block returns to its idle state (no internal memory).

Application Scenarios

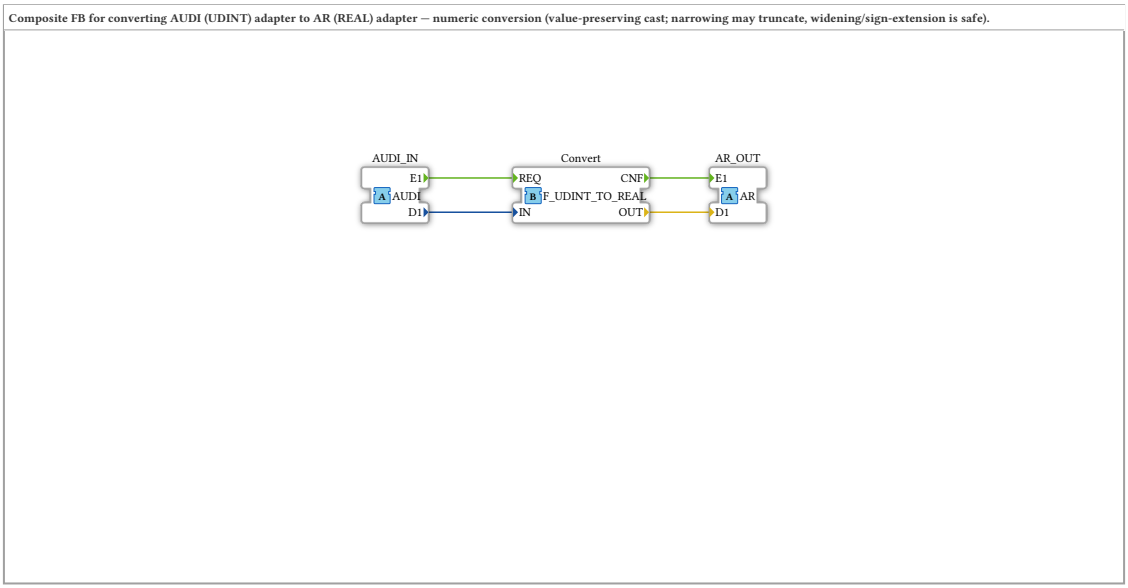
- **Bridging** between system components that provide REAL values (e.g., floating-point sensors) and components that process UDINT values (e.g., counters, index management).
- **Adapter-based communication** in distributed automation systems according to IEC 61499, when the interfaces are defined as unidirectional adapters.
- **Type conversion** in data preprocessing paths before values are passed to programmable logic controllers (PLCs) or visualizations.

Comparison with Similar Function Blocks



- **REAL_TO_DINT** – converts REAL to a signed 32-bit integer; here, the conversion is to an unsigned integer (UDINT).
- **AR_TO_xx blocks** – Other variants could convert to, for example, `AR_TO_BYTE` or `AR_TO_DWORD`, but without the adapter frame.
- **Direct converter** – The internal block `F_REAL_TO_UDINT` can also be integrated directly without an adapter; `AR_TO_AUDI` offers an encapsulated, easily replaceable interface.

Conclusion



The block `AR_TO_AUDI` provides a cleanly encapsulated, adapter-based type conversion from REAL to UDINT. It reduces wiring effort in modular IEC 61499 projects and ensures reliable, event-driven implementation. The use of standardized conversion blocks makes the solution portable and easy to understand.

AUDI_TO_AR

UDINT Adapter Input – *AUDI*

AR – REAL Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block `AUDI_TO_AR` is a composite function block (FB) that converts a UDINT-sized integer received via a unidirectional AUDI adapter into a REAL value and outputs it via a unidirectional AR adapter. It encapsulates the conversion logic, thus enabling clean interface adaptation between different adapter types.

Interface Structure

This FB has no direct event or data inputs/outputs. All communication takes place exclusively via adapter interfaces.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Name	Type	Direction	Description
AUDI_IN	adapter::types::unidirectional::AUDI	Socket (Input)	Returns a UDINT value and an associated event. The adapter provides an internal event output E1 and a data output D1 (UDINT data type).
AR_OUT	adapter::types::unidirectional::AR	Plug (Output)	Outputs the converted REAL value. The adapter has an internal event input E1 and a data input D1 (data type REAL).

Functionality

1. An external signal triggers the event AUDI_IN.E1.
2. This event is forwarded to the internal conversion block F_UDINT_TO_REAL (type iec61131::conversion::F_UDINT_TO_REAL) (Convert.REQ).
3. Simultaneously, the UDINT value of AUDI_IN.D1 is passed to the data input Convert.IN.
4. The conversion block performs the conversion from UDINT to REAL.
5. Upon completion, it triggers the event Convert.CNF, which is passed on to the event input AR_OUT.E1.
6. The converted REAL value is written from Convert.OUT to the data input AR_OUT.D1 and is thus available at the AR adapter.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- The conversion uses an IEC 61131-3 standard function block (F_UDINT_TO_REAL), which is instantiated within the Composite FB.
- The adapters are implemented as unidirectional interfaces, which enforces a clear data flow direction (from the AUDI to the AR adapter).
- The Composite FB does not generate any state logic of its own, but delegates all processing to the internal conversion function block.

State Overview

The function block does not have its own state machine. Its functionality follows the simple sequence:

- **Waiting for input event** – as long as AUDI_IN.E1 is not active, the function block remains passive.
- **Conversion** – after AUDI_IN.E1 arrives, the integrated F_UDINT_TO_REAL is executed.
- **Output** – after successful conversion, AR_OUT.E1 is triggered and the real value is provided.

Application Scenarios

- Connecting a UDINT-based counter (e.g., pulse counter) to a controller that expects real values for calculations or visualizations.
- Converting adapter signals between different data types in a modular, adapter-based communication architecture.
- As a building block in a library for type-safe adapter conversions.

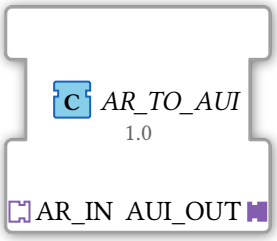
Comparison with similar building blocks

This function block is specifically designed for the combination of AUDI (UDINT) and AR (REAL) adapters. Comparable building blocks exist for other data types, e.g.:

- `SINT_TO_AR` (SINT ⟶ REAL)
- `AUDI_TO_AI` (UDINT ⟶ INT)

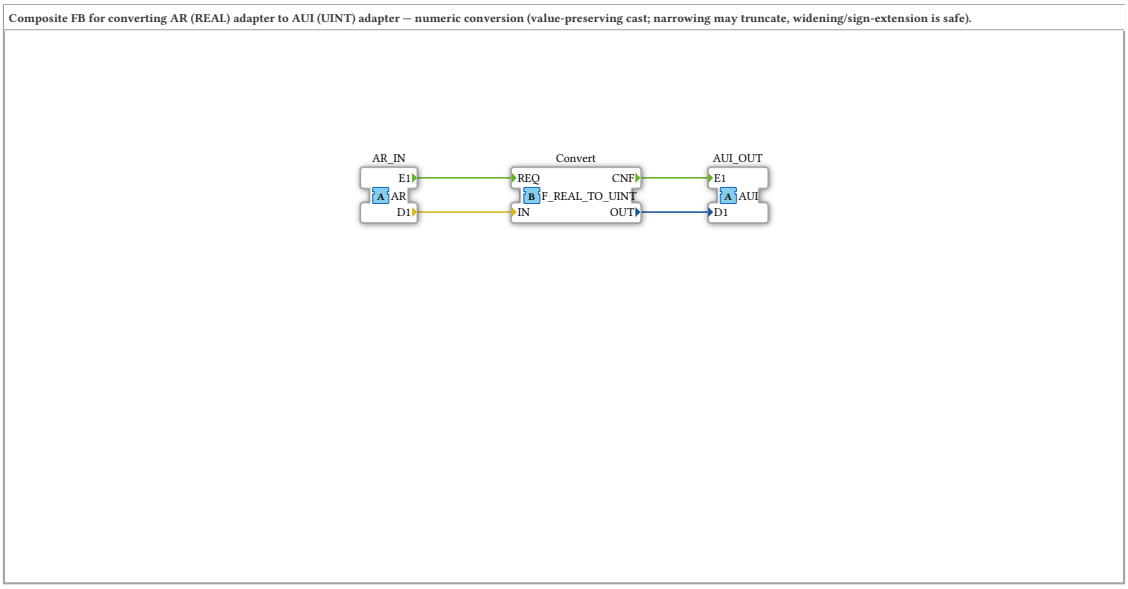
The advantage of this building block lies in its clear encapsulation and reusability within an adapter-based system design.

Conclusion



The `AUDI_TO_AR` function block offers a simple yet effective way to convert UDINT data to REAL data via adapter interfaces. By using an IEC standard component and purely adapter-based communication, it is easy to understand, maintain and can be used in many automation projects.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AR_TO_AUI

REAL Adapter Input – *AR*

AUI – UINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AR_TO_AUI** is a composite function block (FB) that implements a uniform and bidirectional conversion from an AR adapter (REAL) to an AUI adapter (UINT). It encapsulates the type conversion and simplifies communication between components that use different data types via adapters.

Interface Structure

Event Inputs

- **AR_IN.E1** – Conversion trigger: This event is received by the connected AR adapter and starts the conversion of the REAL value.

Event Outputs

- **AUI_OUT.E1** – Conversion completion: After successful conversion, this event is sent to the AUI adapter.

Data Inputs

- **AR_IN.D1** – REAL input value: The floating-point value (REAL) to be converted, provided via the AR adapter.

Data Outputs

- **AUI_OUT.D1** – UINT output value: The result of the conversion (UINT) is passed to the AUI adapter via this data output.

Adapters

- **AR_IN** – Socket of type `AR` (unidirectional REAL adapter)
- **AUI_OUT** – Plug of type `AUI` (unidirectional UINT adapter)

The adapters each combine an event signal and a data signal, so the function block offers a clean, type-safe interface.

Functionality

1. An incoming event on **AR_IN.E1** triggers the processing.
2. The current value of **AR_IN.D1** (REAL) is passed to the integrated conversion block **F_REAL_TO_UINT**.
3. The conversion transforms the REAL value into an unsigned integer value (UINT) – according to IEC 61131-3 rounding rules.
4. Upon completion, the result is output to **AUI_OUT.D1**, and the event **AUI_OUT.E1** is sent simultaneously.

The entire process occurs without intermediate storage or delay – each pulse triggers an immediate conversion.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Stateless Design**: The block has no internal state memory; each conversion is independent of previous ones.
- **Uniform Adapter Interface**: By using unidirectional standard adapters (AR and AUI), the function block can be easily integrated into various architectures.
- **No Side Effects**: No global variables or system resources are affected.

State Overview

The AR_TO_AUI is a pure function block without an internal state machine (ECC). Its execution is strictly event-driven and deterministic. Therefore, a separate state machine is not required.

Application Scenarios

- **Connecting Analog Sensors**: When a sensor delivers its measured value as a REAL via an AR adapter, but the downstream control system expects UINT.
- **Data Bridge**: Mediation between different communication modules or libraries with different adapter types.
- **Protocol Conversion**: For example, in agricultural technology, where REAL values (e.g., speed) often need to be converted into integers (e.g., for counters).

Comparison with Similar Function Blocks

- **AR_TO_ADI**: Converts REAL to INT (signed). AR_TO_AUI, on the other hand, generates unsigned values (UINT), which is advantageous for certain applications such as counter readings or HMI indices.
- **Direct Conversion with F_REAL_TO_UINT**: This single function block offers the same logic but requires manually connecting events and data. The Composite FB encapsulates this effort and reduces the potential for errors in complex networks.

Conclusion

The **AR_TO_AUI** is a practical and reliable function block for easy adapter conversion from REAL to UINT. Its clear interface, purely functional behavior, and reusability make it a useful tool in the 4diac ecosystem. It is particularly suitable for applications requiring a clean separation of adapter types and easy integration into existing projects.

AUI_TO_AR

UINT Adapter Input – *AUI*

AR – REAL Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUI_TO_AR** function block is a composite component that converts an AUI adapter (UINT) into an AR adapter (REAL). It enables the seamless integration of an unsigned integer signal into systems that expect a REAL value by passing the event and data value through one-to-one.

Interface Structure

Event Inputs

The component does not have a direct event input, as events are provided exclusively via the **AUI_IN** input adapter:

- **E1** (from the AUI_IN adapter): Event that triggers data transmission.

Event Outputs

Event outputs are also implemented via the **AR_OUT** output adapter:

- **E1** (from the AR_OUT adapter): Event output after successful conversion.

Data Inputs

Data inputs are only available indirectly via the **AUI_IN** adapter:

- **D1** (from the AUI_IN adapter): Value to be converted as **UINT**.

Data Outputs

Data outputs are provided via the **AR_OUT** adapter:

- **D1** (from the AR_OUT adapter): Converted value as **REAL**.

Adapters

Name	Type	Direction	Description
AUI_IN	`adapter::types::unidirectional::AUI`	Input (Socket)	Provides a UINT signal and an associated event.
AR_OUT	`adapter::types::unidirectional::AR`	Output (Plug)	Outputs the converted REAL signal and an event.

Functionality

The **AUI_TO_AR** function block acts as a simple pass-through component. It connects 1:1:

- **AUI_IN.E1 → AR_OUT.E1**
- **AUI_IN.D1 → AR_OUT.D1**

This means: As soon as an event arrives at the AUI_IN input, the corresponding **UINT** data is passed to the **AR_OUT** output without any additional processing or type conversion. The actual conversion from **UINT** to **REAL** must be performed either by the sending adapter or by a downstream function block – the **AUI_TO_AR** itself does not perform any arithmetic conversion. It merely ensures that the event and data paths between the two different adapter types are compatible.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Function Block:** The implementation is purely via the network of adapter connections, without any internal logic or state machines.
- **No Type Conversion:** The **AUI_TO_AR** does not perform any explicit data type conversion. It assumes that the **AUI_IN** adapter already provides REAL-compliant data or that the type conversion is performed externally.
- **Unidirectional Adapter Type:** Both adapters are unidirectional, meaning they only transmit data and events in one direction (from AUI_IN to AR_OUT).

State Overview

Since the function block is implemented as a pure interconnection network without its own state machine, no state machine exists. Its functionality is limited to the immediate forwarding of incoming events and data.

Application Scenarios

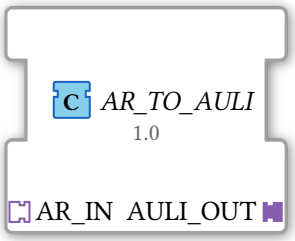
- **System Integration:** Integrating sensors or controllers that provide their measured values as UINT via an AUI adapter into a system that expects REAL values via AR adapters.
- **Protocol Adaptation:** If two subsystems use different adapter types for the same physical quantity, **AUI_TO_AR** can serve as an adapter translator (provided the UINT value already numerically represents the desired REAL value).
- **Library Extension:** As a reusable function block in a library project to streamline adapter conversions.

Comparison with Similar Function Blocks

Function Block	Function	Difference

AUI_TO_AR	Adapter switching UINT ⟶ REAL	Pass-through only; no type conversion, expects compatible data.
AR_TO_AUI	Adapter switching REAL ⟶ UINT	Reverse direction, also pass-through only.
CONV_UINT_TO_REAL	Type conversion from UINT to REAL	Performs actual conversion, but requires direct data inputs/outputs instead of an adapter.

Conclusion



The **AUI_TO_AR** is a simple yet useful composite component that connects the **AUI** and **AR** adapter types without modifying the data. It is particularly suitable for systems where type compatibility is already provided at the adapter level or where subsequent conversion takes place. Its streamlined structure makes it a reliable tool for integrating different adapter protocols.

AR_TO_AULI

REAL Adapter Input – *AR*

AULI – ULINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AR_TO_AULI** is a composite function block that converts a REAL input adapter (AR) into a ULINT output adapter (AULI). It serves as a unidirectional interface between components that work with the REAL data type and those that expect ULINT (unsigned long integer). The function block encapsulates the necessary conversion and automatically ensures event and data forwarding.

Interface Structure

Event Inputs
- **AR_IN.E1** – Input event from the AR adapter; triggers the conversion.

Event Outputs
- **AULI_OUT.E1** – Output event to the AULI adapter; signals that the converted value is available.

Data Inputs
- **AR_IN.D1** – REAL value from the AR adapter to be converted.

Data Outputs
- **AULI_OUT.D1** – ULINT value converted from the REAL input.

Adapters
- **AR_IN** (Socket) – Unidirectional AR adapter (Type: adapter::types::unidirectional::AR) as input.
- **AULI_OUT** (Plug) – Unidirectional AULI adapter (Type: adapter::types::unidirectional::AULI) as output.

Functionality

The function block is implemented as a composite FB and internally contains a single function block **F_REAL_TO_ULINT** from the IEC 61131 library. The operation is as follows:

1. An event at socket **AR_IN.E1** triggers the execution of the converter.
2. The data value **AR_IN.D1** is forwarded to input **Convert.IN**.
3. The converter performs the type conversion from REAL to ULINT and provides the result at output **Convert.OUT**.
4. The acknowledgment event **Convert.CNF** generates an event at plug **AULI_OUT.E1**, which informs the connected function block about the new value.
5. The converted ULINT value is output in parallel to **AULI_OUT.D1**.

The event and data connections are wired directly without additional logic, so the function block is a pure transformation module.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Unidirectionality:** Both the input and output adapters are unidirectional. There is no feedback or acknowledgment from the output to the input.
- **Converter Used:** The embedded function block **F_REAL_TO_ULINT** implements the standardized IEC 61131 conversion. Rounding and overflow behavior comply with IEC standards.
- **Event-Driven Execution:** The conversion is only performed when an event occurs at the input; without an event, the output remains unchanged.
- **Adapter Types:** The adapters are based on a unidirectional variant, meaning they transmit exactly one event and one data value per direction.

State Overview

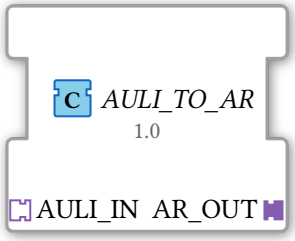
As a composite function block, **AR_TO_AULI** has no states of its own. The internal state logic is determined solely by the embedded **F_REAL_TO_ULINT**, which typically implements a simple, event-driven sequence without state storage (REQ → Processing → CNF). The function block is therefore stateless and waits for a new input event after each conversion.

Application Scenarios

- **Interface Adaptation:** When a component (e.g., a control algorithm) delivers REAL values, but a downstream module (e.g., a counter or index logic) expects ULINT inputs.
- **Adapter Bridge:** Use in a toolchain that connects different data types via adapters without requiring the developer to perform the conversion manually.

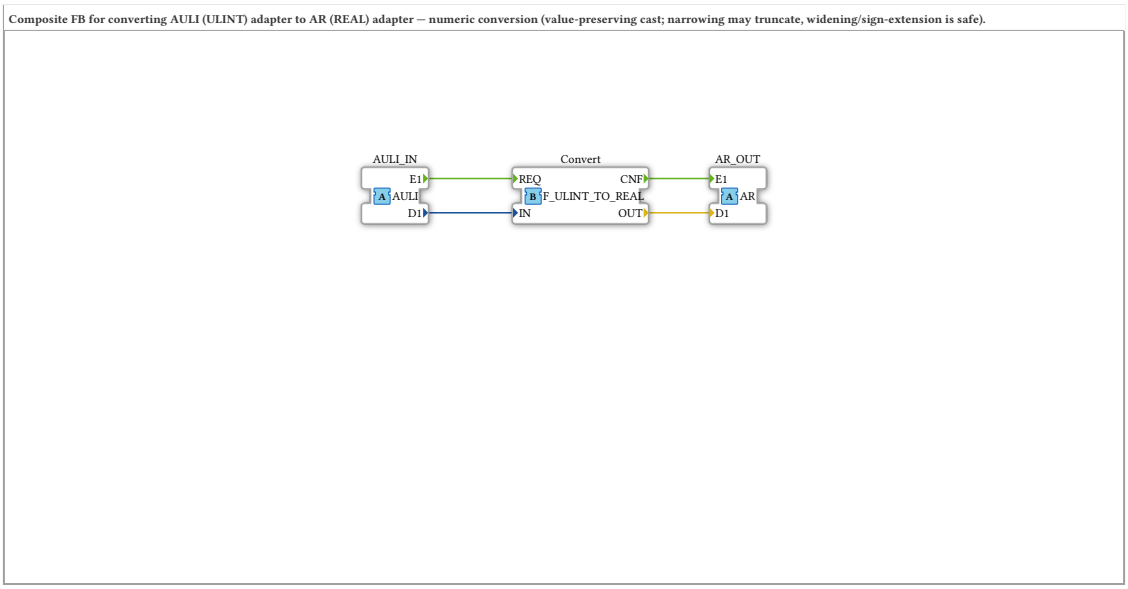
- **Data Integration:** Integrating REAL-based sensors or parameters into a system that internally uses ULINT (e.g., for status codes or cumulative values).

Comparison with Similar Function Blocks



- **F_REAL_TO_ULINT** – Basic function block without adapters; requires direct data and event connections. **AR_TO_AULI** is an encapsulated variant with adapters that simplifies integration into adapter-based architectures.
- AR_TO_ *blocks for other target types** – Corresponding composite blocks exist for conversions from REAL to LINT, DINT, etc. They follow the same pattern and each uses the appropriate IEC converter.
- **Direct conversion in the network** – Alternatively, the F_REAL_TO_ULINT block could be directly integrated into a function block network, but this requires more manual wiring. **AR_TO_AULI** reduces the effort and improves reusability.

Conclusion



The **AR_TO_AULI** block is a simple yet useful encapsulation of REAL-to-ULINT conversion in an adapter-based format. It extends IEC 61131 conversion with a plug-and-play interface for unidirectional adapters and enables a clean separation of conversion logic and application communication. This component is particularly suitable for modular systems that are based on adapter concepts.

AULI_TO_AR

ULINT Adapter Input – *AULI*

AR – REAL Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_TO_AR** serves as a converting composite block that transforms an **AULI** adapter (ULINT) into an **AR** adapter (REAL). It enables the easy integration of components that work with different data types and provides type conversion via standardized adapter interfaces.

Interface Structure

The function block has no direct event or data inputs/outputs, but communicates exclusively via two adapter interfaces.

Event Inputs

- **AULI_IN.E1** (event from socket AULI_IN) – triggers the conversion of the incoming ULINT value.

Event Outputs

- **AR_OUT.E1** (Event for plug AR_OUT) – signals that the converted REAL value is ready.

Data Inputs

- **AULI_IN.D1** (Data from socket AULI_IN) – the ULINT value to be converted.

Data Outputs

- **AR_OUT.D1** (Data for plug AR_OUT) – the converted REAL value.

Adapter

Name	Direction	Type	Description
AULI_IN	Socket	`adapter::types::unidirectional::AULI` (ULINT)	Input Value
AR_OUT	Plug	`adapter::types::unidirectional::AR` (REAL)	Output Value (Converted)

Functionality

The function block (FB) is implemented as a composite block and contains an instance of the conversion FB `F_ULINT_TO_REAL` from the IEC 61131 library.

Process:

1. An event on **AULI_IN.E1** triggers the execution of the internal conversion block `Convert`.
2. The current ULINT value from **AULI_IN.D1** is passed to input `Convert.IN`.
3. The internal FB performs the conversion from `ULINT` to `REAL` and stores the result at `Convert.OUT`. 4. After the conversion is complete, the event **AR_OUT.E1** is triggered, and the converted REAL value is available at **AR_OUT.D1**.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite structure** – enables reuse and encapsulation of the conversion logic.
- **Adapter-based** – no direct inputs/outputs; communication occurs via unidirectional adapters (socket/plug).
- **Use of the IEC 61131 standard function** `F_ULINT_TO_REAL` – guarantees platform-independent and correct type conversion.
- **Event-driven execution** – the conversion is only triggered by an input event when needed.
- **License** – Eclipse Public License 2.0 (see source code).

State Overview

The function block **does not have its own state machine**. The conversion is purely functional and event-driven via the internal function block. After each input event, the conversion is performed once, and the result is output.

Application Scenarios

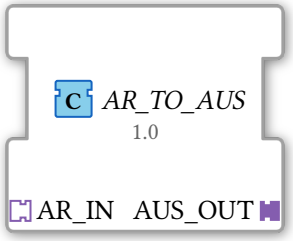
- **Adapter bridge** between components that supply ULINT and those that expect REAL.
- **Data preparation** in control systems when physical quantities (e.g., counter readings as ULINT) need to be converted into floating-point values for calculations.
- **Modular networking** in IEC 61499 applications, where adapters serve as standardized interfaces between function blocks.

Comparison with similar function blocks

- **AULI_TO_LREAL** – analog conversion to `LREAL` (double precision).

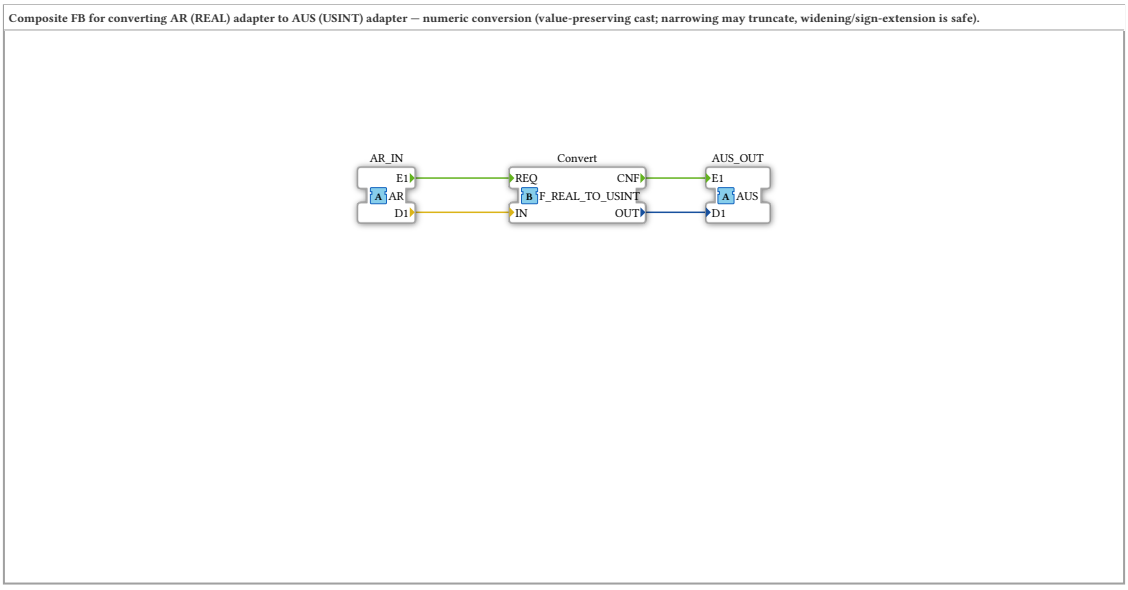
- **Direct conversion function blocks** (e.g., `F_ULINT_TO_REAL`): These operate at the data level but require manual wiring of events and data. The **AULI_TO_AR** encapsulates this wiring and provides a compact adapter interface.
- **Other Adapter Converters** – there are corresponding function blocks for other type combinations (e.g., `LINT_TO_AR`) that are similarly structured.

Conclusion



The **AULI_TO_AR** is a useful composite function block for simple and standardized type conversion from ULINT to REAL via adapter interfaces. Thanks to its event-driven execution and the use of an IEC 61131 standard function, it is reliable, reusable, and integrates seamlessly into IEC 61499 projects.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AR_TO_AUS

REAL Adapter Input – *AR*

AUS – USINT Adapter Output

• – ○ • – ○ • – ○ •

The AR_TO_AUS function block is a composite block for converting a REAL value to a USINT value via a unidirectional adapter interface. It encapsulates the conversion process and provides a standardized connection between a REAL adapter socket and a USINT adapter plug. The function block is designed for use in automation systems that require data type conversion.

- **AR_IN.E1** (via socket `AR_IN`): Event to start the conversion of the incoming REAL value.
- **AUS_OUT.E1** (via Plug `AUS_OUT`): Event triggered after successful conversion and output of the USINT value.
- **AR_IN.D1** (via Socket `AR_IN`, Type: REAL): Input value to be converted to USINT.
- **AUS_OUT.D1** (via Plug `AUS_OUT`, Type: USINT): Converted output value.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- **Socket AR_IN** (Type: `adapter::types::unidirectional::AR`): Unidirectional REAL input adapter.

Functionality

The FB AR_TO_AUS functions as a pure data converter without its own state logic. Internally, the predefined block `F_REAL_TO_USINT` from the IEC 61131 standard library is used.

Process:

1. An incoming event at `AR_IN.E1` triggers processing.
2. The current value of `AR_IN.D1` (REAL) is passed to the input `IN` of the internal converter.
3. After the conversion is complete, the result value (USINT) is forwarded to `AUS_OUT.D1`.
4. Simultaneously, the event `AUS_OUT.E1` is triggered to activate downstream function blocks.

The entire data and event flow is unidirectional from the input to the output adapter.

- The function block is implemented as a composite and uses the function block `iec61131::conversion::F_REAL_TO_USINT` from the library `adapter::conversion::unidirectional`.
- No range check is performed; the conversion follows the rules of IEC 61131 (REAL → USINT: decimal places are truncated, values outside the range 0…255 may lead to undefined behavior).
- The function block does not have its own state machine and operates in an event-driven manner.
- The use of adapters enables loose coupling of the interfaces and facilitates reuse in different project contexts.

The function block AR_TO_AUS does not have its own state machine. The runtime behavior is entirely determined by the internal function block `F_REAL_TO_USINT`, which operates statelessly by default. Event control occurs directly from `AR_IN.E1` to `AUS_OUT.E1` without intermediate states.

- **Sensor-Actuator Coupling**: A REAL value (e.g., from an analog sensor) must be transmitted as a USINT to a binary actuator (e.g., a motor controller with an 8-bit value).
- **Interface Adaptation**: When an adapter of type `AR` (REAL) needs to be connected to an adapter of type `AUS` (USINT).
- **Data Preprocessing**: Before transferring data to systems that only accept USINT values (e.g., diagnostic or visualization components).
- **AR_TO_INT** / **AR_TO_BYTE**: Analogous structure for converting to other data types (INT, BYTE). This function block is limited to converting REAL to USINT.
- **Direct Converter Function Blocks** (e.g., `F_REAL_TO_USINT`): These do not offer adapter interfaces but require direct wiring. AR_TO_AUS encapsulates this converter and provides an ad-hoc adapter connection.
- **Bidirectional Converters**: In contrast to these, AR_TO_AUS operates strictly unidirectionally, which increases the clarity of the data flow.

The AR_TO_AUS function block offers a simple, modular solution for converting a REAL adapter to a USINT adapter. By using a standardized conversion block and encapsulating it as a composite function block, it can be easily integrated into existing 4diac projects. It is particularly suitable for scenarios requiring a clear separation of interfaces and unidirectional data transmission.

AUS_TO_AR

USINT Adapter Input – *AUS* *AR* – REAL Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUS_TO_AR** is a composite FB for converting an AUS adapter interface (based on USINT) to an AR adapter interface (based on REAL). According to its description, it serves to convert between these two adapter types. The current implementation (version 1.0) simply passes through event and data values without performing an explicit conversion – the actual type conversion must be implemented either through the adapter definitions themselves or through subsequent extensions.

Interface Structure

Event Inputs

No separate event inputs are available. Events are transmitted exclusively via the **AUS_IN** adapter.

Event Outputs

No separate event outputs are available. Events are output exclusively via the **AR_OUT** adapter.

Data Inputs

No separate data inputs are available. Data is transmitted exclusively via the **OFF_IN** adapter.

Data Outputs

No separate data outputs are available. Data is output exclusively via the **AR_OUT** adapter.

Adapters

Type	Name	Direction	Comment
`adapter::types::unidirectional::AUS`	OFF_IN	Socket (Input)	USINT-based adapter input
`adapter::types::unidirectional::AR`	AR_OUT	Plug (Output)	REAL-based adapter output

Functionality

This function block directly connects the event and data channels of the AUS_IN adapter to those of the AR_OUT adapter:

- **Event Forwarding**: The event arriving at socket `AUS_IN.E1` is forwarded without delay to plug `AR_OUT.E1`.
- **Data Forwarding**: The data value (type USINT) provided by socket `AUS_IN.D1` is passed directly to `AR_OUT.D1` (type REAL).

Since no type conversion or other processing is implemented in the network, the conversion from USINT to REAL is either implicitly handled by the 4diac runtime environment or must be implemented by adding a conversion function block (e.g., `CONV`) within an extension of the composite function block.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite without internal logic**: The function block network consists exclusively of two direct connections; it contains no other function blocks or state machines.
- **Adapter-based interface**: Instead of individual event/data inputs and outputs, all communication is handled via standardized unidirectional adapters. This facilitates reuse in modular adapter hierarchies.
- **Incomplete implementation**: The block's name and comment suggest active conversion, which is not implemented in the current version (1.0). This can lead to runtime errors if the runtime environment does not support implicit type conversion.

State overview

The block does not contain any state machines (ECCs). Its behavior is purely combinatorial and limited to the immediate forwarding of events and data.

Application Scenarios

- **Replacement for legacy systems**: An existing AUS adapter interface (USINT) needs to be connected to a component that expects an AR adapter interface (REAL).
- **Placeholder during the development phase**: The function block serves as a temporary connection until actual conversion logic is implemented.
- **Test environments**: Fast coupling of two adapter types without data modification for simulations or tests.

Comparison with similar function blocks

Typical conversion function blocks (e.g., `CONV` from the standard library) perform explicit value conversion using arithmetic or logical operations. `AUS_TO_AR`, on the other hand, delegates the conversion to the adapter level and does not perform any transformation itself. It is more of a **structural adaptation** than a true converter.

Conclusion

The function block `AUS_TO_AR` is a simple adapter-to-adapter through-pass block. Its usefulness depends heavily on whether the target system supports automatic type conversions between USINT and REAL.

If not, the function block must be extended with explicit conversion logic. It is therefore suitable as a temporary solution or as a foundation for a complete implementation.

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AR_TO_AX

REAL Adapter Input – *AR*

AX – BOOL Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The AR_TO_AX function block converts a REAL value received via an AR adapter into a BOOL value and outputs it via an AX adapter. The conversion is performed by comparing the REAL value with 0.0. If the value is not zero, TRUE is output; otherwise, FALSE. The block serves as a bridge between analog and digital adapter interfaces.

Interface Structure

Event Inputs

No direct event inputs at the FB level. The event input is contained in the AR adapter (`AR_IN.E1`).

Event Outputs

No direct event outputs at the FB level. The event output is included in the AX adapter (`AX_OUT.E1`).

Data Inputs

No direct data inputs at the FB level. The data input is included in the AR adapter (`AR_IN.D1`).

Data Outputs

No direct data outputs at the FB level. The data output is included in the AX adapter (`AX_OUT.D1`).

Adapters

- **AR_IN** (Socket) – Adapter of type `adapter::types::unidirectional::AR`. Accepts a REAL value and an event to start processing.
- **AX_OUT** (Plug) – Adapter of type `adapter::types::unidirectional::AX`. Provides the BOOL result value and an event to confirm processing.

Functionality

The function block processes incoming REAL values as follows:

1. An event at `AR_IN.E1` triggers the internal comparison function block `F_NE` (not equal).
2. The REAL value received via `AR_IN.D1` is compared to the constant value 0.0.
3. The result of the comparison (BOOL) is forwarded via `F_NE.OUT` to `AX_OUT.D1`.
4. An event at output `F_NE.CNF` is sent to `AX_OUT.E1` to signal the availability of the BOOL value.

The internal function block `F_NE` is an IEC 61131-3 compliant comparator block and outputs TRUE if the input `IN1` is not equal to `IN2` (here 0,0).

Technical Features

- **Bit-reinterpretation**: extracts the IEEE754 bit pattern of the source value (intentional, e.g. for serialization), not its numeric value.
- Uses a composite function block approach, where the logic consists of a single comparator block and adapter connections.
- All inputs and outputs are implemented via standardized unidirectional adapters (`AR`, `AX`), enabling a modular and interchangeable interface definition.
- The comparator value (0,0) is fixed in the function block and cannot be changed at runtime.
- Execution is event-driven: A conversion is only performed when an event occurs at `AR_IN.E1`.

State Overview

Since the function block (FB) is implemented as a composition (network of basic building blocks), it does not have its own state machine. Its function is determined by the sequential processing of event and data flows in the internal network:

- **Waiting State**: No event at `AR_IN.E1`. The output value remains unchanged.
- **Processing State**: An event at `AR_IN.E1` triggers the comparison and generates an event at `AX_OUT.E1` as soon as the BOOL value is available.

Application Scenarios

- **Threshold Switch**: An analog sensor (e.g., a pressure sensor) provides REAL values. The FB outputs TRUE as soon as the value deviates from 0.0 (e.g., when a threshold is exceeded, if the zero point is calibrated).
- **Digitization of Analog Signals**: For connecting analog adapters to digital logic in control engineering.
- **Simple Plausibility Check**: Checks whether a REAL value is non-zero (e.g., a valid measured value).

Comparison with Similar Function Blocks

Unlike a generic `AR_TO_BOOL` function block, which uses direct data without an adapter, AR_TO_AX is specifically designed for use with adapter interfaces. A comparison block with an adjustable threshold (e.g., `F_GT`, `F_LT`) would offer more flexibility but would also require additional configuration effort. This function block provides a simple, fixed conversion: non-zero → TRUE.

Conclusion

The AR_TO_AX function block offers a compact solution for converting a REAL adapter value to a BOOL adapter value using zero comparison. Thanks to the use of adapters and a standardized comparison module, it can be easily integrated into existing 4diac projects and is well-suited for fast, unidirectional signal conversions.

]

AX_TO_AR

BOOL Adapter Input – *AX*

AR – REAL Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **AX_TO_AR** function block is a composite function block that converts a Boolean signal from an AX adapter (type `adapter::types::unidirectional::AX`) into a REAL value (0.0 or 1.0) and outputs it via an AR adapter (type `adapter::types::unidirectional::AR`). The conversion is performed using the IEC 61131 function block **F_SEL**.

Interface Structure

Event Inputs

The function block does not have its own event inputs at the FB level. The internal process is controlled exclusively via the event of the AX_IN adapter, which is connected to the REQ input of the F_SEL.

Event Outputs

There are no event outputs at the FB level. The output event of F_SEL (CNF) is directly forwarded to the event input of the AR_OUT adapter.

Data Inputs

There are no direct data inputs at the FB level. The only data input is provided via the AX_IN adapter:

- **D1** (BOOL) – the Boolean signal to be converted.

Data Outputs

There are no direct data outputs at the FB level. The converted value is output via the AR_OUT adapter:

- **D1** (REAL) – the resulting REAL value (0.0 or 1.0).

Adapters

- **AX_IN** (Socket):
- Type: `adapter::types::unidirectional::AX`
- Provides a Boolean signal and an event pulse.
- **AR_OUT** (Plug):
- Type: `adapter::types::unidirectional::AR`
- Outputs the converted REAL value.

Functionality

The function block operates in an event-driven manner:

1. An incoming event at the AX_IN adapter (E1) triggers the internal F_SEL function block via its REQ input.
2. Simultaneously, the Boolean signal (AX_IN.D1) is applied to the G input of F_SEL.
3. F_SEL selects the following depending on G:

- For `G = FALSE` => Output of **IN0** (value `REAL#0.0`).
- For `G = TRUE` => Output of **IN1** (value `REAL#1.0`).

1. The result is passed via output OUT to data input D1 of the AR_OUT adapter.
2. The CNF event of F_SEL triggers output event E1 of the AR_OUT adapter, allowing the connected logic to accept the new data.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Reusability**: The function block is implemented as a composite function block and uses the standardized IEC 61131 function block `F_SEL` from the library `iec61131::selection`.
- **Adapter Coupling**: All communication takes place via unidirectional adapters (`adapter::types::unidirectional::AX` and `adapter::types::unidirectional::AR`), enabling loose coupling and easy reuse in different contexts.
- **Configuration**: The limit values (IN0=0.0, IN1=1.0) are fixed and can be changed as needed by adjusting the parameters of the internal F_SEL.

State Overview

The function block does not have an internal state machine. It reacts **event-driven** and performs a one-time selection for each event at the AX_IN adapter. There are no stored states – the behavior is purely combinatorial.

Application Scenarios

- Conversion of a binary sensor signal (e.g., switch, limit switch) into a numerical value for further processing in REAL-based control loops or visualizations.
- Integration of Boolean adapter signals into systems that operate entirely with REAL values.
- Simple mapping of digital inputs/outputs to analog values (0/1) in adapter-based automation solutions.

Comparison with Similar Function Blocks

- **Standard conversion function blocks** such as `BOOL_TO_REAL` from IEC libraries offer direct data-level conversion, but without adapter interfaces.
- **`SELECT`** (IEC 61131) can also use a Boolean signal to select between two REAL values, but requires manual wiring.
- **AX_TO_AR** encapsulates the complete adapter conversion in a reusable composite function block, thus significantly reducing the wiring effort in adapter network-based 4diac applications.

Conclusion

The **AX_TO_AR** function block provides a compact and robust solution for converting Boolean adapter signals into real values. By utilizing `F_SEL` and encapsulating it as a composite function block, it is easy to integrate, extensible, and ideally suited for adapter-oriented automation architectures.

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AS_TO_AUDI

SINT Adapter Input – *AS*

AUDI – UDINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The AS_TO_AUDI function block is a composite function block that performs a conversion from a SINT adapter (AS) to a UDINT adapter (AUDI). It serves as a bridge between two different adapter types and enables the seamless integration of components that use different data types.

Interface Structure

Event Inputs

Not present. Event control is handled via the adapter socket **AS_IN**.

Event Outputs

Not present. Event output is handled via the adapter plug **AUDI_OUT**.

Data Inputs

Not present. Data acquisition is handled via the adapter socket **AS_IN**.

Data Outputs

Not present. Data output is provided via the adapter plug **AUDI_OUT**.

Adapter

Name	Type	Direction	Description
AS_IN	`adapter::types::unidirectional::AS`	Socket (Input)	SINT adapter that provides an input value (SINT) and a corresponding event.
AUDI_OUT	`adapter::types::unidirectional::AUDI`	Plug (Output)	UDINT adapter that outputs the converted value (UDINT) and an event.

The adapters each contain one data element and one event element:

- **AS_IN**: Data `D1` (SINT), Event `E1`.
- **AUDI_OUT**: Data `D1` (UDINT), Event `E1`.

Functionality

The module internally uses the IEC 61131 function `F_SINT_TO_UDINT` to convert the incoming SINT value into a UDINT value. The process is event-driven:

1. An event at element `E1` of socket **AS_IN** (e.g., from an upstream function block) is forwarded to input `REQ` of the internal conversion function block `Convert`.
2. The conversion function block reads the current value of `AS_IN.D1` and converts it into a UDINT value.
3. After successful conversion, the converter's output event `CNF` is triggered, which in turn activates the event at element `E1` of plug **AUDI_OUT**. ...3. The output event is triggered by the converter, which in turn activates the event at element `E1` of plug **AUDI_OUT**.
4. The output event is triggered by an event at element `E1` of plug **AUDI_OUT**.
5. The output event is triggered by an event at element `E1` of plug **AUDI_OUT**.
6. The event is forwarded to the input `Convert` of the internal conversion function block `Convert`.
7. The event at element qzmsdocs00008qz of socket **AS_IN** (e 4. Simultaneously, the converted value is written from `Convert.OUT` to `AUDI_OUT.D1`.

This ensures that the converted UDINT value is only available at the output when the corresponding event is signaled.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Pattern**: The function block is implemented as a composite (composed functional block) that encapsulates a single conversion function block. This results in a reusable and encapsulated unit.
- **Use of IEC 61131 Function Blocks**: The conversion utilizes the standardized function `F_SINT_TO_UDINT`, which promotes portability and traceability.
- **Unidirectional Adapters**: Both the input and output adapters are unidirectional (no feedback). This simplifies the data flow direction.

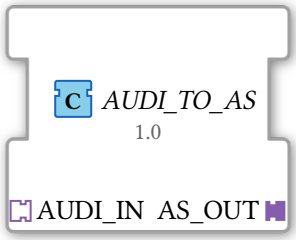
State Overview

The composite block does not have its own state machine (ECC). The entire sequence control is defined by the event chaining of the internal network. Therefore, there are no defined states or state transitions.

Application Scenarios

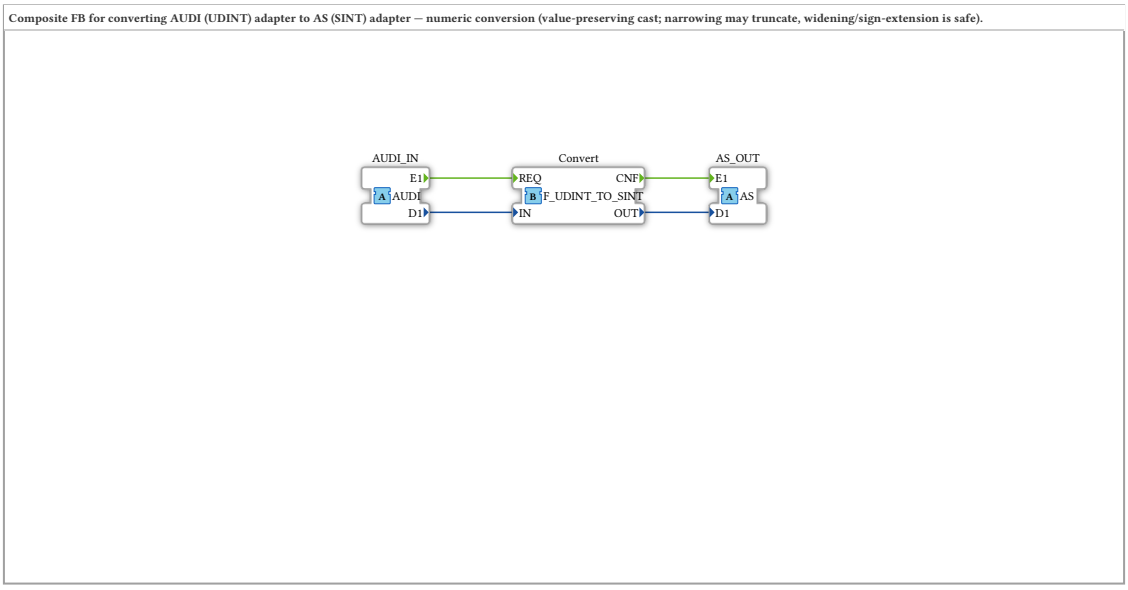
- **System Integration**: When a subsystem provides data in SINT format via an adapter, but a subsequent subsystem expects UDINT data via an adapter.
- **Protocol Adaptation**: In heterogeneous automation systems where different data types are exchanged via adapters, this block can serve as a universal converter.
- **Network Structure Simplification**: Instead of performing the conversion directly in the application blocks, it is encapsulated in a separate composite, which improves maintainability.

Comparison with Similar Blocks



Similar blocks exist for other data type conversions, e.g.,... For example, `AS_TO_ABOOL` (SINT to BOOL) or `AUINT_TO_AUDI` (UINT to UDINT). The present function block differs in its specific combination of SINT input and UDINT output. It adds another conversion option to the library and follows the same design pattern (composite with an internal IEC 61131 converter).

Conclusion



The function block `AS_TO_AUDI` offers an elegant solution for converting SINT adapter data to UDINT adapter data. Encapsulating it in a composite function block improves the reusability and clarity of the overall system. The use of standardized conversion functions ensures that the conversion is correct and efficient.

AUDI_TO_AS

UDINT Adapter Input – *AUDI*

AS – SINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUDI_TO_AS** is a composite block that converts an AUDI adapter (data type `UDINT`) into an AS adapter (data type `SINT`). It serves as a bridge between two different adapter interfaces and enables the lossy conversion of an unsigned 32-bit value into a signed 8-bit value. The conversion is event-driven using the internal conversion function `F_UDINT_TO_SINT`.

Interface Structure

Event Inputs

The function block does not have its own dedicated event inputs. Event control is handled via the **socket adapter `AUDI_IN`**, which provides an event `E1`.

Event Outputs

The function block (FB) does not have its own independent event outputs. The result event is output via the **plug adapter `AS_OUT`** using the event `E1`.

Data Inputs

Data inputs are available exclusively via the **socket adapter `AUDI_IN`**:

- **`D1`** (data type `UDINT`): The 32-bit value to be converted.

Data Outputs

Data outputs are provided via the **`AS_OUT`** plug adapter:

- **`D1`** (data type `SINT`): The converted 8-bit value (value range −128…127).

> Note: A `UDINT` value greater than 127 is either truncated or interpreted during conversion (depending on the implementation of `F_UDINT_TO_SINT`).

Adapter

Name	Type	Direction	Description
`AUDI_IN`	`adapter::types::unidirectional::AUDI`	Socket	Input adapter (UDINT)
`AS_OUT`	`adapter::types::unidirectional::AS`	Plug	Output adapter (SINT)

Functionality

This function block acts as a transparent conversion stage between two unidirectional adapters. An incoming event on `AUDI_IN.E1` triggers the internal function block `F_UDINT_TO_SINT`, which converts the `UDINT` value at `AUDI_IN.D1` into a `SINT` value. After the conversion is complete, an event is output to `AS_OUT.E1`, and the converted value is made available to `AS_OUT.D1`.

The internal process is purely causal and requires no separate states or timings – the response occurs immediately after the input event.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Adapter-based interface**: The function block communicates exclusively via special adapters, enabling loose coupling and reusability in different environments.
- **Data loss possible**: Since `SINT` only contains 8 bits, over 127 bits of information are lost with a `UDINT` input value. The exact mapping (e.g., clipping or modular reduction) depends on the internal conversion function.
- **No Internal Logic**: The function block consists entirely of the interconnection of the existing conversion function block and two adapters – a pure composition type.

State Overview

The function block does not have its own state machine. It behaves statelessly: Each incoming event at the socket triggers exactly one output at the plug. Processing is deterministic and event-synchronous.

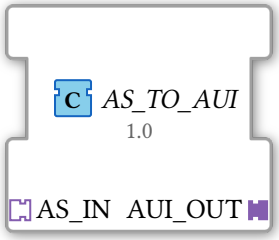
Application Scenarios

- **Protocol Adaptation**: When a subsystem delivers data as `UDINT` via an AUDI adapter, but the target system only accepts `SINT` via an AS adapter (e.g., with 8-bit actuator controllers).
- **Value Range Reduction**: Explicitly restricting a large number range to a smaller one to ensure compatibility with older or resource-constrained components.
- **Testing and Simulation**: Use in test environments where adapter interfaces of different data types interact.

Comparison with similar function blocks

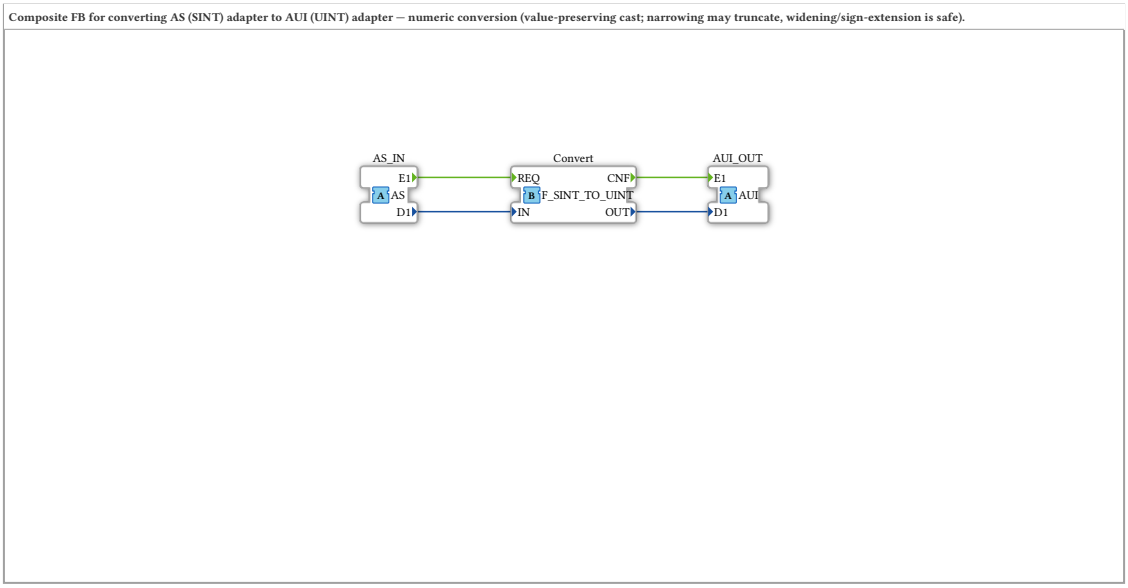
- **`UDINT_TO_SINT` (direct)**: The pure conversion function block without adapter integration. `AUDI_TO_AS` encapsulates this function block and adds the specific adapters.
- Other adapter converters (e.g., `DINT_TO_AS`, `AUDI_TO_INT`) handle different data type combinations. This function block is specifically optimized for the combination `AUDI` ↔ `AS`.

Conclusion



The composite function block `AUDI_TO_AS` provides a simple yet effective way to convert a `UDINT`-based adapter to a `SINT`-based adapter. Thanks to its clear event control and the use of a proven conversion function, it is suitable for all scenarios where lossy data type conversion between these two adapter standards is required.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AS_TO_AUI

SINT Adapter Input – *AS*

AUI – UINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block `AS_TO_AUI` is a composite function block (FB) that converts a SINT adapter input (`AS`) into a UINT adapter output (`AUI`). It encapsulates the type conversion and enables a clean, adapter-based interface between components that use different data types.

Interface Structure

Event Inputs

Name	Data Type	Description
`E1` (via `AS_IN`)	EVENT	Starts the conversion of the incoming SINT value.

Event Outputs

Name	Data Type	Description
`E1` (via `AUI_OUT`)	EVENT	Confirms the completion of the conversion and output of the UINT value.

Data Inputs

Name	Data Type	Description
D1 (via AS_IN)	SINT	The signed 8-bit value to be converted.

Data Outputs

Label	Data Type	Description
D1 (via AUI_OUT)	UINT	The converted unsigned 16-bit value.

Adapters

Label	Type	Direction	Description
AS_IN	adapter::types::unidirectional::AS	Socket (Input)	Provides the SINT value and the triggering event.
AUI_OUT	adapter::types::unidirectional::AUI	Plug (Output)	Outputs the converted UINT value and the acknowledgment event.

Functionality

The function block operates in an event-driven manner:

1. When the event E1 arrives at the AS_IN adapter, the incoming SINT data value (D1) is forwarded to the internal conversion function block F_SINT_TO_UINT.
2. The F_SINT_TO_UINT function block performs the data type conversion according to IEC 61131 (SINT → UINT).
3. Once the conversion is complete, the resulting UINT value is passed to the AUI_OUT adapter, and the event E1 is triggered on AUI_OUT.

The entire process is atomic within an event cycle: event in, data conversion, event out.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- The function block internally uses the IEC 61131 conversion function F_SINT_TO_UINT, which is derived from the iec61131::conversion library.
- The adapters are designed as **unidirectional** types (AS for input, AUI for output), which clearly defines the data flow direction and avoids misunderstandings.
- There are no internal states or timing behaviors – the conversion is purely combinatorial, controlled by the event.
- The function block is licensed under the Eclipse Public License 2.0.

State Overview

Since this is a composite function block without its own state machine, there is no internal state machine. The function block is completely event-driven and executes the conversion immediately upon each trigger.

•

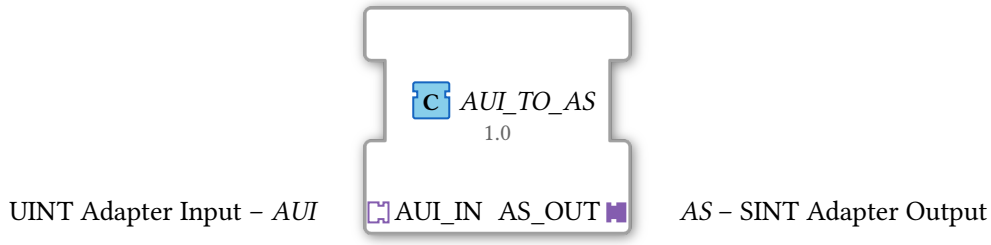
Application Scenarios

- **Connecting Different Bus Systems**: If a sensor (e.g., AS-Interface) delivers SINT values, but the controller expects UINT values, this function block can handle the translation.
- **Protocol or Adapter Compatibility**: Use in heterogeneous automation systems where different fieldbuses or components operate with different data types.
- **Data Preparation**: Preparation of SINT data for further processing that only supports UINT.

Comparison with Similar Function Blocks

- **Direct Conversion Function Blocks** (e.g., `F_SINT_TO_UINT`): These operate at the level of individual signals without adapter encapsulation. `AS_TO_AUI` integrates the adapter interface and is therefore easier to integrate into adapter-based architectures.
- **Bidirectional Adapter Converters**: If conversion in both directions is required, a separate module (e.g., `AUI_TO_AS`) must be used. `AS_TO_AUI` is strictly unidirectional.

Conclusion



The `AS_TO_AUI` module provides a simple, reliable, and standardized method for converting SINT adapter data to a UINT adapter format. Thanks to the use of IEC 61131 modules and unidirectional adapters, it is robust, easy to understand, and integrates well into existing 4diac projects.

]

AUI_TO_AS

• – ○ • – ○ • – ○ •

Introduction

The function block `AUI_TO_AS` is a composite block that enables the conversion of an **AUI (UINT)** adapter to an **AS (SINT)** adapter. It encapsulates the necessary signal and data conversion in a reusable unit and provides the converted values via a single adapter output.

Interface Structure

Event Inputs

The block has **no direct event inputs** at its top level.

The triggering event is provided via socket `AUI_IN` (adapter `adapter::types::unidirectional::AUI`). This event (labeled `E1`) starts the conversion internally.

Event Outputs

At the top level, there are **no direct event outputs**.

The conversion completion event is output externally via plug `AS_OUT` (adapter `adapter::types::unidirectional::AS`) as event `E1`.

Data Inputs

There are **no direct data inputs**.

The input data (data type `UINT`) is fed into the function block via socket `AUI_IN` (channel `D1`).

Data Outputs

There are also **no direct data outputs**. The converted data (data type `SINT`) exits the module via plug `AS_OUT` (channel `D1`).

Adapter

Direction	Name	Type	Description
Socket	AUI_IN	`adapter::types::unidirectional::AUI`	Input adapter (UINT data)
Plug	AS_OUT	`adapter::types::unidirectional::AS`	Output adapter (SINT data)

Functionality

The function block functions as a pure encapsulation of a conversion process:

1. An incoming event via `AUI_IN.E1` triggers the internal function block `Convert` (of type `iec61131::conversion::F_UINT_TO_SINT`).
2. Simultaneously, the data value from `AUI_IN.D1` (of type `UINT`) is forwarded to the input `Convert.IN`.
3. After the conversion is complete, `Convert.CNF` sends an event to `AS_OUT.E1`.
4. The converted value (`SINT`) is transferred from `Convert.OUT` to `AS_OUT.D1`.

This enables end-to-end, event-driven conversion from a UINT adapter to a SINT adapter, without requiring the user to implement the conversion details themselves.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block:** All connections are encapsulated within a network. The internal logic remains hidden from the calling environment.
- **Use of the Standard Conversion Function:** The actual conversion is performed by the IEC 61131 block `F_UINT_TO_SINT`. This block is externally referenced and imported as a library block.
- **Unidirectional Adapters:** Both the input and output adapters are unidirectional, meaning data flows in only one direction (from input to output).
- **No Own States:** Because this is a composite device, it does not have its own Execution Control Chart (ECC). Its behavior is determined solely by its internal connections.

State Overview

This device does **not have its own state machine**.

Its operation is purely data flow and event-driven through the interconnection of its constituent elements. There are no defined states such as IDLE, BUSY, or ERROR.

Application Scenarios

- **Adapter Bridging:** If an application uses adapters with different data types (e.g., AUI with `UINT` and AS with `SINT`), this device can be used as a converter between the adapter interfaces.
- **System Integration:** In heterogeneous control systems where components use different data types, this function block facilitates integration without manual type conversion.

- **Reuse:** The composite function block can be used multiple times in different projects or networks to always provide the same conversion logic.

Comparison with Similar Function Blocks

- **Other Conversion Adapters:** Similar function blocks exist, such as `SINT_TO_UINT_AS` or generic type converters. The difference lies in the specific type combination (UINT → SINT) and the use of adapters instead of direct event/data inputs.
- **Direct Conversion Without Adapters:** Instead of an adapter-based function block, one could also use the function `F_UINT_TO_SINT` directly and wire the adapter interfaces separately. The composite function block simplifies this through encapsulation.

Conclusion

The function block `AUI_TO_AS` offers a simple, encapsulated solution for converting a unidirectional UINT adapter to a SINT adapter. By utilizing a standardized IEC 61131 conversion function and clear event handling, it integrates seamlessly into 4diac IDE projects. It is particularly suitable for scenarios where adapters of different data types need to be connected without requiring the user to implement the conversion logic themselves.

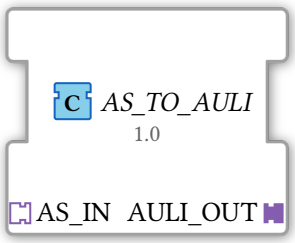
Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AS_TO_AULI

Introduction

SINT Adapter Input – *AS*

AULI – ULINT Adapter Output

The composite function block `AS_TO_AULI` converts an **AS (SINT) adapter** to an **AULI (ULINT) adapter**. Internally, it uses the IEC 61131 conversion block `F_SINT_TO_ULINT` to perform the actual type conversion

from SINT to ULINT. The block is designed as part of a unidirectional adapter library for communication between different data types

---

Interface Structure

Event Inputs

The block has **no direct event inputs**. Events are received via the **Socket adapter `AS_IN`**:

- **`AS_IN.E1`** – Event input via the AS adapter, which triggers the data conversion.

Event Outputs

This function block has **no direct event outputs**. Events are output via the **Plug adapter `AULI_OUT`**:

- **`AULI_OUT.E1`** – Event output via the AULI adapter, which is activated after the conversion is complete.

Data Inputs

This function block has **no direct data inputs**. Data input is via the **Socket adapter `AS_IN`**:

- **`AS_IN.D1`** – Data input of type **SINT**, which provides the value to be converted.

Data Outputs

The module has **no direct data outputs**. Data output is via the **Plug adapter `AULI_OUT`**:

- **`AULI_OUT.D1`** – Data output of type **ULINT**, which provides the converted value.

Adapters

Adapter	Type	Direction	Description
`AS_IN`	`adapter::types::unidirectional::AS` (Socket)	Input	Receives SINT values and trigger event `E1`.
`AULI_OUT`	`adapter::types::unidirectional::AULI` (Plug)	Output	Sends ULINT values and acknowledgment event `E1`.

Functionality

1. The function block expects an event at the socket adapter `AS_IN.E1`. Simultaneously, the data value `AS_IN.D1` (type SINT) must be present. ... 2. The event is forwarded to the internal function block `F_SINT_TO_ULINT` (as `REQ`).
2. The internal function block performs the conversion **SINT → ULINT**.
3. After successful conversion, `F_SINT_TO_ULINT` sends an acknowledgment event (`CNF`) to the plug adapter `AULI_OUT.E1`.
4. The converted value (type ULINT) is output via `AULI_OUT.D1`.

The conversion is performed according to the IEC 61131-3 standard: The SINT value (8-bit signed) is converted into an unsigned 64-bit value (ULINT). Negative SINT values result in a negative ULINT representation (two's complement conversion to 64 bits).

Technical Specifications

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Standard Compliance**: The component is specified according to IEC 61499-2.
- **License**: Eclipse Public License 2.0 (EPL-2.0).
- **Dependency**: Imports the IEC 61131 component `F_SINT_TO_ULINT` from the package `iec61131::conversion`.
- **Type Safety**: The adapters `AS` and `AULI` ensure type-safe connections; direct cabling from SINT to ULINT without conversion is not possible.

- **Unidirectional Data Flow**: The function block operates purely unidirectionally – it receives data and events and outputs converted data and acknowledgments.

State Overview

The function block does **not have its own state machine**. It functions purely as an interconnect for the inner `F_SINT_TO_ULINT` function block. Its behavior is strictly event-driven:

- **Waiting** (Initial State) ⟶ Event sent to `AS_IN.E1` ⟶ Transition to **Conversion**.
- **Conversion** ⟶ Internal function block operates asynchronously ⟶ After completion ⟶ Event sent to `AULI_OUT.E1` ⟶ Return to **Waiting**.

Error handling is not explicitly modeled; the inner function block outputs a defined result (e.g., 0) for invalid inputs (e.g., outside the value range).

Application Scenarios

- **Integration into Adapter Chains**: If an upstream function block provides a SINT value, but subsequent components only process ULINT, `AS_TO_AULI` can be used as an intermediate adapter.
- **Sensor Connection**: Sensors with 8-bit output (e.g., rotary encoders, simple switches) can be connected to a 64-bit bus.
- **Legacy Systems**: This adapter makes legacy systems with SINT interfaces compatible with modern ULINT-based controllers.

–

Comparison with Similar Function Blocks

Function Block	Target Type	Source Type	Special Feature
`AS_TO_AULI`	ULINT	SINT	SINT to ULINT conversion
AS_TO_AUDI`	UDINT	SINT	SINT to UDINT conversion (32-bit)
AS_TO_AWORD`	WORD	SINT	SINT to WORD conversion (16-bit)
AULI_TO_AS`	SINT	ULINT	ULINT to SINT conversion (with overflow limitation)

This function block covers the conversion from an 8-bit signed type to a 64-bit unsigned type and is particularly suitable for applications requiring a large output range.

Conclusion

AS_TO_AULI` is a simple yet important composite module for type conversion between SINT and ULINT adapters. It encapsulates the IEC 61131 conversion and enables type-safe, event-driven integration into automation systems. Its clear interface structure and use of standard libraries make it maintainable, reusable, and easily integrated into existing 4diac IDE projects.

AULI_TO_AS

ULINT Adapter Input – *AULI*

AS – SINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AULI_TO_AS** function block is a composite module for converting a unidirectional **AULI** adapter (ULINT) to a unidirectional **AS** adapter (SINT). It encapsulates the type conversion of unsigned 64-bit integers to signed 8-bit integers and provides seamless connectivity between components with different data type requirements in the 4diac framework.

Interface Structure

The module does not have separate event or data ports at the top level. All communication takes place exclusively via two adapters.

Adapters

Adapter	Direction	Type	Description
`AULI_IN`	Socket (Input)	`adapter::types::unidirectional::AULI`	Provides an event `E1` and a data value `D1` of type `ULINT`.
`AS_OUT`	Plug (Output)	`adapter::types::unidirectional::AS`	Provides an event `E1` and a data value `D1` of type `SINT`.

Event Inputs (via adapter)

- `AULI_IN.E1` – Starts the conversion of the incoming ULINT value.

Event Outputs (via adapter)

- `AS_OUT.E1` – Confirms completion of the conversion and indicates that the new SINT value is valid.

Data Inputs (via adapter)

- `AULI_IN.D1` – ULINT value to be converted (value range 0 … 2^{24-1}).

Data Outputs (via adapter)

- `AS_OUT.D1` – Conversion result as a SINT value (value range −128 … 127).

Functionality

The module internally uses the IEC 61131 conversion function `F_ULINT_TO_SINT`. When the input adapter receives the event `E1`, the current value of `AULI_IN.D1` is read and converted. The result is then passed to `AS_OUT.D1`, simultaneously triggering the event `AS_OUT.E1`.

The processing is purely event-driven and occurs without intermediate storage of internal states.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Value Range Loss:** Since `ULINT` covers a very large range of values (0 … 2^{64}−1), while `SINT` can only represent −128 … 127, conversion for values outside the SINT range leads to overflow or saturation (according to the IEC 61131 definition). This should be taken into account during application.
- **Unidirectional Adapters:** The block is designed for data flow in one direction – from the input to the output adapter. It cannot be used for bidirectional communication.
- **License:** The block is provided under the Eclipse Public License 2.0.

State Overview

The block does not have an explicit state machine or internal state registers. It behaves like a purely combinatorial function triggered by an event. There is no persistent storage of values or processing states.

Application Scenarios

- **Sensor Integration:** A sensor delivers data in ULINT format, but a downstream module expects SINT values (e.g., for a simple display or threshold logic).
- **Protocol Adaptation:** Heterogeneous automation systems where adapters use different data types can be connected using this function block in a type-compatible manner.
- **Data Reduction:** Targeted conversion of large numerical ranges into smaller formats to save memory or bus bandwidth (at the expense of accuracy).
- **Sensor Integration:**

Comparison with Similar Function Blocks

- **`AULI_TO_INT`** – Converts to `INT` (16-bit, −32768 … 32767), larger value range than SINT, but still lossy with large numbers.
- **`AULI_TO_DINT`** – Converts to `DINT` (32-bit, -2^{31} … $2^{31}-1$), covers a significantly larger portion of the ULINT range and is the better choice for many applications.
- **`ULINT_TO_SINT` (direct)** – A simple function block without adapter encapsulation; `AULI_TO_AS` provides the same service in an adapter-based environment.

Conclusion

The **AULI_TO_AS** is a lean, purpose-built converter for unidirectional adapters. It enables the easy integration of components based on the SINT data type into a ULINT-dominated system. However, due to the large difference in value ranges, users must consider potential overflow or saturation effects and, if necessary, switch to wider data types.

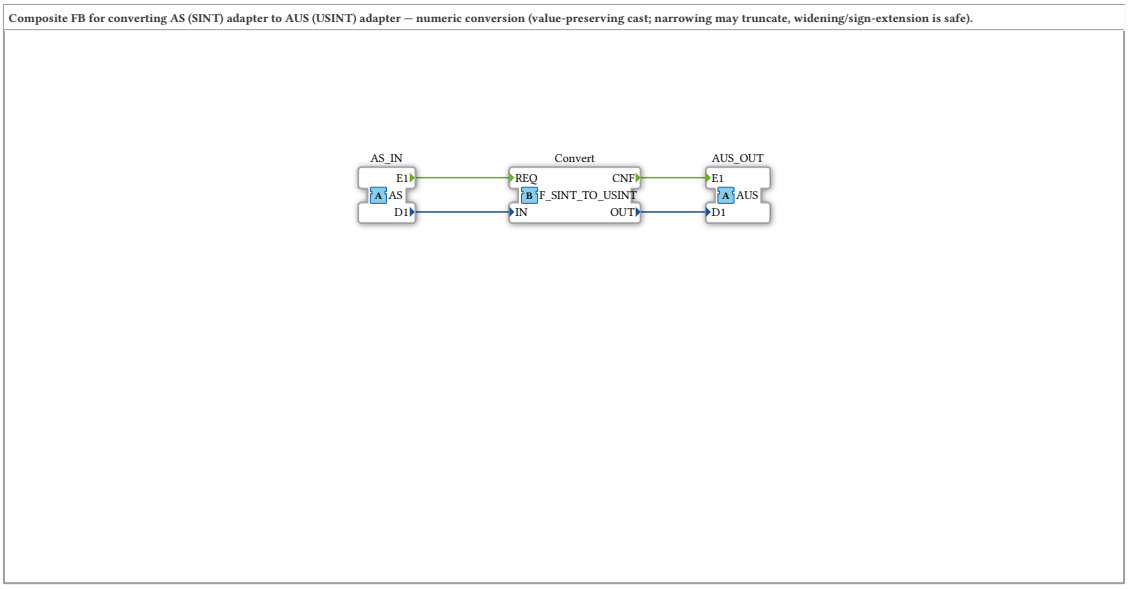
Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AS_TO_AUS

SINT Adapter Input – *AS*

AUS – USINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The function block **AS_TO_AUS** is a composite block that connects an AS adapter (type `adapter::types::unidirectional::AS`) to an AUS adapter (type `adapter::types::unidirectional::AUS`) and converts the data values contained within from `SINT` (signed 8-bit) to `USINT` (unsigned 8-bit). The conversion is performed by the embedded standard function block `F_SINT_TO_USINT` from the IEC 61131 library. This function block enables simple, adapter-based data type conversion in industrial control applications.

Interface Structure

Event Inputs

No direct event inputs. Event control is handled exclusively via the `AS_IN` adapter (socket).

Event Outputs

No direct event outputs. Event transmission is handled exclusively via the `AUS_OUT` adapter (plug).

Data Inputs

No direct data inputs. Data acquisition is handled exclusively via the `AS_IN` adapter.

Data Outputs

No direct data outputs. Data output is handled exclusively via the `AUS_OUT` adapter.

Adapters

Adapter	Type	Direction	Description
`AS_IN`	`adapter::types::unidirectional::AS`	Socket (Input)	Receives a SINT value and an event (E1).
`AUS_OUT`	`adapter::types::unidirectional::AUS`	Plug (Output)	Outputs the converted USINT value and an event (E1).

Functionality

The function block operates as a pure data flow converter:

1. An external event at socket `AS_IN.E1` triggers the conversion.
2. Simultaneously, the corresponding data value `AS_IN.D1` (SINT) is passed to the input `IN` of the internal block `F_SINT_TO_USINT`.

3. The conversion block converts the SINT value to the corresponding USINT value and places it at its output `OUT`.
4. The converter's completion event (`CNF`) triggers the event `AUS_OUT.E1` and passes the converted value to `AUS_OUT.D1`.
5. The output adapter makes the result available to the calling environment.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block**: The function block (FB) does not contain its own state logic but combines the existing standard converter with the predefined adapter interfaces.
- **Unidirectional Adapters**: Both the input and output adapters are unidirectional – data and events flow in only one direction.
- **Type Conversion**: The conversion from SINT to USINT is lossless, as the value range of USINT (0…255) completely covers the positive part of SINT (–128…127). However, negative SINT values are interpreted as follows: e.g., –1 becomes 255 (two's complement). This behavior corresponds to the IEC 61131 function `SINT_TO_USINT`.

State Overview

The FB does not have an internal state machine (ECC). The entire sequence control is implemented through event chaining in the network.

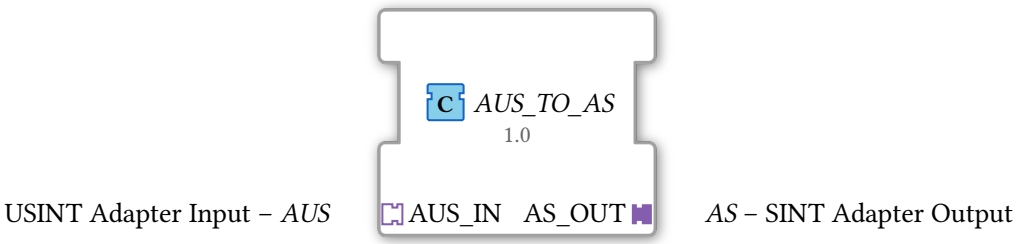
Application Scenarios

- **Sensor Integration**: A sensor delivers a SINT value (e.g., temperature as a signed value), but the subsequent module expects USINT (e.g., for displays or logic with unsigned types).
- **System Coupling**: Between different control components that communicate via adapters, a signed representation must be converted to an unsigned representation.
- **Protocol Adaptation**: In fieldbus or OPC UA connections where the data formats are predefined.

Comparison with Similar Function Blocks

- **F_SINT_TO_USINT**: This standard function block performs pure type conversion without an adapter. This function block encapsulates it in an adapter interface so that it can be directly integrated into adapter-based architectures.
- **Other Converters** (e.g., `F_INT_TO_DINT`): These work analogously, but for different data types. The advantage of `AS_TO_AUS` lies in its specific adapter adaptation for the AS and AUS types.

Conclusion



The function block `AS_TO_AUS` is a practical tool for type conversion in adapter-based 4diac applications. It simplifies the integration of components that use different signed and unsigned 8-bit data types and enables a clean separation of the adapter interfaces. Thanks to the use of the established IEC converter, the functionality is reliable and standards-compliant.

AUS_TO_AS

USINT Adapter Input – *AUS* — *AS* – SINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The function block **AUS_TO_AS** is a composite function block (FB) for converting a unidirectional OFF adapter (based on the USINT data type) into a unidirectional AS adapter (based on the SINT data type). It serves as a standardized interface between components that use different unsigned/signed integer types.

Interface Structure

The FB has no direct event or data inputs/outputs, but only two adapter interfaces:

Event Inputs

No directly visible event inputs. Event control is handled via the socket adapter `AUS_IN`.

Event Outputs

No directly visible event outputs. Event feedback is provided via the plug adapter `AS_OUT`.

Data Inputs

No directly visible data inputs. The data is provided via the socket adapter `AUS_IN`.

Data Outputs

No directly visible data outputs. The data is output via the plug adapter `AS_OUT`.

Adapters

Name	Type	Direction	Comment
`AUS_IN`	`adapter::types::unidirectional::AUS` (Socket)	Input	USINT Adapter Input
`AS_OUT`	`adapter::types::unidirectional::AS` (Plug)	Output	SINT Adapter Output

The interface of the adapters themselves contains:

- `AUS_IN.E1` (Event), `AUS_IN.D1` (USINT)
- `AS_OUT.E1` (Event), `AS_OUT.D1` (SINT)

Functionality

The function block is implemented as a composite and contains an internal function block `Convert` of type `iec61131::conversion::F_USINT_TO_SINT`, which performs the actual value conversion.

1. **Data Acquisition:** An incoming USINT value is provided via socket `AUS_IN.D1`.
2. **Triggering:** An event at output `AUS_IN.E1` triggers input `REQ` of the conversion block.

3. **Conversion:** The internal function block `F_USINT_TO_SINT` converts the USINT value into a corresponding SINT value (value range 0..255 ⟶ −128..127; if this range is exceeded, a range limitation according to IEC 61131 applies).
4. **Feedback:** After the conversion is complete, the internal function block signals an event to plug `AS_OUT.E1` via its output `CNF`.
5. **Data Transfer:** The converted SINT value is output to the connected plug via `AS_OUT.D1`.

The connections in the FBNetwork are:

- Event: `AUS_IN.E1` ⟶ `Convert.REQ`
- Event: `Convert.CNF` ⟶ `AS_OUT.E1`
- Data: `AUS_IN.D1` ⟶ `Convert.IN`
- Data: `Convert.OUT` ⟶ `AS_OUT.D1`

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Adapter-Based:** The module functions as a pure adapter converter and can be seamlessly integrated into existing adapter-oriented systems.
- Event: `AUS_IN.D1` ⟶ `Convert.IN`
- Data: `Convert.OUT` ⟶ `AS_OUT.D1`
- **Adapter-Based:** The module functions as a pure adapter converter and can be seamlessly integrated into existing adapter-oriented systems.
- Event: `AUS_IN.E1` ⟶ `Convert.IN`
- Event: `Convert.OUT` ⟶ `AS_OUT.D1`
- **Adapter-Based:** - **Composite Structure:** Conversion is performed by an internal, standardized IEC 61131 converter, ensuring reliable and certified conversion.
- **Unidirectional Interface:** Data and event flows are strictly unidirectional (from input to output).
- **No Explicit State Machine:** Control is purely event-driven via adapter events. There are no internal states.

State Overview

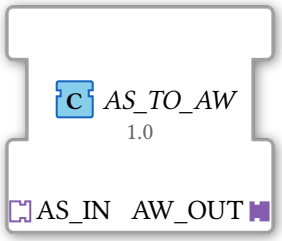
The function block (FB) has no visible state machine. It behaves like a transparent gateway that triggers the conversion upon each input event and provides the result at the output.

Application Scenarios

- **Integration of components** with different data types, e.g., when a sensor delivers USINT data, but a subsequent controller expects SINT values.
- **Adapter Conversion** in modular control systems based on unidirectional adapters (e.g., according to IEC 61499).
- **Safety-critical systems** where precise type conversion (without overflow) is essential – the internal function block `F_USINT_TO_SINT` is specification-compliant.

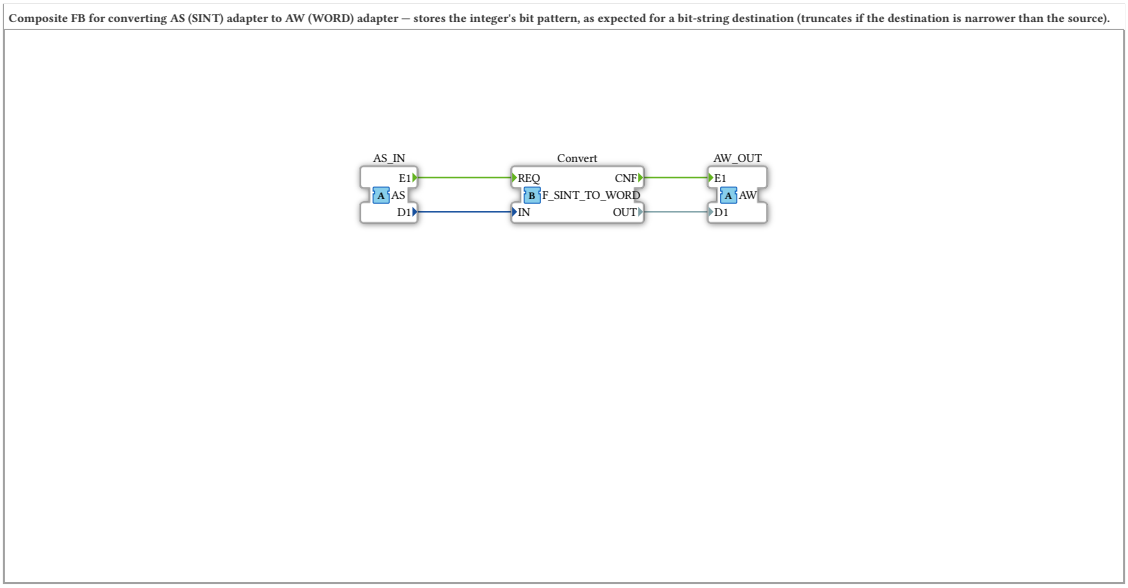
Comparison with similar function blocks

- **Simple converters like `F_USINT_TO_SINT`:** Only convert scalar values but do not use adapters. `AUS_TO_AS` encapsulates this conversion in an adapter-based function block.
- **`INT_TO_DINT` adapter:** Other type conversions (e.g., INT to DINT) follow the same pattern but differ in bit width and sign handling.
- **Bidirectional adapters:** Unlike bidirectional variants, this function block is designed for only one data flow, which reduces complexity.



Conclusion

The **AUS_TO_AS** function block offers a clean, adapter-based solution for converting USINT to SINT values. Thanks to its composite structure and the use of a standardized IEC 61131 converter, it is easy to maintain, reliable, and readily integrated into industrial control networks. It is particularly suitable for systems that rely on unidirectional adapters and require explicit type conversion.



Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AS_TO_AW

SINT Adapter Input – *AS* *AW* – WORD Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AS_TO_AW** is a composite block that converts a unidirectional **SINT** adapter (AS) into a unidirectional **WORD** adapter (AW). It serves as a bridge between different adapter types and enables the further processing of SINT signals as WORD data in a 4diac environment.

Interface Structure

Event Inputs

No direct event inputs.

The block has a **socket** of type `AS`, which indirectly provides an event input:

- **AS_IN.E1** – Event input via the socket; an incoming event triggers the conversion.

Event Outputs

No direct event outputs.

The function block has a **plug** of type `AW`, which indirectly provides an event output:

- **AW_OUT.E1** – Event output via the plug; an event is sent after successful conversion.

Data Inputs

- **AS_IN.D1** (`SINT`) – Input data value of the AS socket; the SINT value to be converted.

Data Outputs

- **AW_OUT.D1** (`WORD`) – Output data value of the AW plug; the converted WORD value.

Adapter

Type	Name	Direction	Comment
`AS` (unidirectional)	**AS_IN**	Socket (input)	SINT Adapter input
`AW` (unidirectional)	**AW_OUT**	Plug (output)	WORD Adapter output

Functionality

The function block contains an internal instance of the conversion function block `iec61131::conversion::F_SINT_TO_WORD`.

Processing is event-driven:

1. An event at **AS_IN.E1** (socket) triggers the internal function block via its `REQ` input.
2. Simultaneously, the value of **AS_IN.D1** (`SINT`) is forwarded to the `IN` input of the converter.
3. The converter `F_SINT_TO_WORD` performs the type conversion and signals its completion via its `CNF` output.
4. This event is passed to **AW_OUT.E1** (Plug), and the converted `WORD` value is available at **AW_OUT.D1**.

Thus, a reliable, one-time conversion is performed upon each event arrival.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite FB**: The function block utilizes 4diac's composite functionality to integrate an existing conversion function block (`F_SINT_TO_WORD`) into an adapter package.
- **Unidirectional Adapters**: Both the input and output adapters are unidirectional, meaning only one data and event direction is supported.
- **IEC 61131-3 Conversion**: The actual type conversion is performed according to the IEC 61131-3 standard, which facilitates compatibility with other systems.
- **Copyright Notice**: The function block includes a copyright notice (EPL 2.0) that governs its use and distribution.

State Overview

Since the function block consists of an internal FB with REQ/CNF handshake, the process can be described as follows:

| State | Description | ** |---|---|---| | **Idle** | Waiting for an event at AS_IN.E1 | | **Busy** | Conversion in progress (internal FB active) | | **Done** | Conversion complete, event sent to AW_OUT.E1 |

The function block is not stateful in the sense of a state machine – the internal FB implements the state logic.

Application Scenarios

- **Signal Conversion**: A sensor delivers data as a SINT (e.g., an 8-bit value), but the downstream system expects a WORD (16-bit). The AS_TO_AW function block handles the conversion.
- **Adapter Integration**: In a heterogeneous control system, different adapter types must be connected. The function block acts as a "translator" between AS and AW interfaces.
- **Test and Simulation Environments**: For bridging adapter incompatibilities during development or when testing function blocks.

Comparison with Similar Blocks

Block	Function	Difference
AS_TO_AW	SINT → WORD	Specific conversion for unidirectional adapters
General Converters (e.g., `F_SINT_TO_WORD`)	Pure data conversion without adapter encapsulation	AS_TO_AW provides a ready-made adapter interface and can be used directly in adapter-based networks

Other Adapter Converters (e.g., `BOOL_TO_BYTE`)	Other data types	AS_TO_AW specializes in SINT ↔ WORD

Conclusion

The **AS_TO_AW** is a useful, compact conversion module that seamlessly integrates the conversion from a SINT adapter (AS) to a WORD adapter (AW) into the 4diac IDE. By using the standardized IEC 61131-3 converter and unidirectional adapter technology, it enables flexible and reliable signal conversion in automation projects.

AW_TO_AS

WORD Adapter Input – *AW*

AS – SINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block `AW_TO_AS` is a composite block that converts a WORD-based adapter (AW) into a SINT-based adapter (AS). It encapsulates the necessary type conversion, thus enabling the easy integration of different adapter interfaces in automation technology.

Interface Structure

Event Inputs

- `AW_IN.E1` – Starts the conversion of the incoming data value.

Event Outputs

- `AS_OUT.E1` – Signals that the converted value is available at the data output.

Data Inputs

- `AW_IN.D1` (WORD) – The 16-bit value to be converted to a SINT value.

Data Outputs

- `AS_OUT.D1` (SINT) – The converted 8-bit value (signed, range –128 … 127).

Adapter

- **Socket (Input)**: `AW_IN` of type `adapter::types::unidirectional::AW`
- **Plug (Output)**: `AS_OUT` of type `adapter::types::unidirectional::AS`

Functionality

The module is implemented as a composite and internally uses the IEC 61131 function block `F_WORD_TO_SINT`. An incoming event at `AW_IN.E1` triggers the conversion: The data value from `AW_IN.D1` is passed to the input `IN` of the internal converter. After successful conversion, this generates an acknowledgment event at `CNF`, which is forwarded to the output adapter `AS_OUT.E1`. Simultaneously, the converted SINT value is output to `AS_OUT.D1`.

Technical Features

- **Bit-reinterpretation**, value-preserving only if the source value fits the narrower destination width (otherwise the upper bits are silently dropped).
- The conversion follows the IEC 61131 function `WORD_TO_SINT`. An overflow occurs if the incoming WORD value is outside the valid SINT range (-128 … 127) – this must be taken into account in the application.
- The function block operates purely event-driven: Conversion only occurs when an event is present at the input.
- The adapters are unidirectional; conversion back from SINT to WORD is not supported.

State Overview

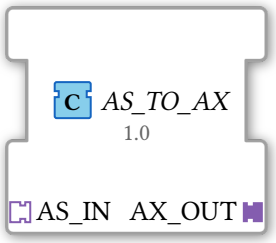
Since this is a simple composite function block (FB) without its own state machine, there is no explicit state machine. The FB waits for an event, performs the conversion, and outputs the result synchronously. A state table is not required.

Application Scenarios

- Adapting sensor data supplied as WORD (e.g., via an analog input) to a system that processes SINT values.
- Converting fieldbus data formats when coupling different automation components.
- Use in heterogeneous control environments where adapters use different data types.

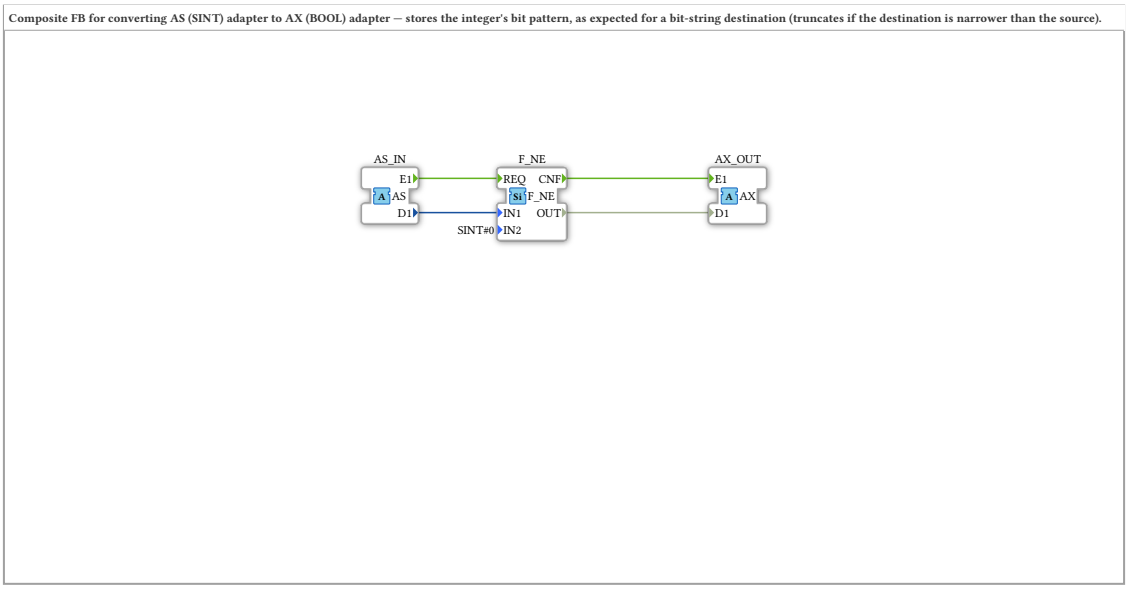
Comparison with Similar Function Blocks

Analogously structured converters such as `AW_TO_BY` (WORD ⟶ BYTE) or `AINT_TO_AUDINT` (INT ⟶ UDINT) follow the same principle. The `AW_TO_AS` function block stands out due to its specific adapter combination, which enables direct integration into adapter-based architectures. Unlike simple data-level type conversions, this block utilizes an event-driven adapter interface, thus increasing reusability and interchangeability.



Conclusion

The composite function block `AW_TO_AS` offers a compact and clear solution for converting a WORD adapter to a SINT adapter. Encapsulating the conversion in a separate function block improves the readability and maintainability of the application. This function block is particularly suitable for environments where different data types are handled at the adapter level.



Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AS_TO_AX

SINT Adapter Input – *AS* *AX* – BOOL Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AS_TO_AX** function block is a composite function block that converts a SINT adapter (AS) into a BOOL adapter (AX). It checks the incoming SINT value for inequality to zero and outputs the result as a BOOL signal. The function block is suitable for simple signal conversion in an IEC 61499 application.

Interface Structure

Event Inputs

Name	Type	Description
AS_IN.E1	Event	Receives the trigger signal from the connected AS adapter for data processing.

Event Outputs

Name	Type	Description
AX_OUT.E1	Event	Sent after successful conversion; indicates that the BOOL value is present at the AX adapter.

Data Inputs

Name	Type	Description
AS_IN.D1	SINT	Receives the SINT value, which is checked for inequality to zero.

Data Outputs

Name	Type	Description
AX_OUT.D1	BOOL	Outputs the result of the comparison: `TRUE` if the input value is not zero, otherwise `FALSE`.

Adapter

Name	Type	Direction	Description
AS_IN	adapter::types::unidirectional::AS	Socket (Input)	SINT adapter for the input value and its associated event.
AX_OUT	adapter::types::unidirectional::AX	Plug (Output)	BOOL adapter for the output value and its associated event.

Functionality

The function block internally uses the function block `iec61131::comparison::F_NE` (inequality check).

- When an event is received at input `AS_IN.E1`, processing of `F_NE` (input `REQ`) is started.
- `F_NE` compares the SINT value received via `AS_IN.D1` with the constant parameter `IN2` (fixed to `SINT#0`).
- The result of the comparison (`OUT`) – `TRUE` if inequality, `FALSE` if equality – is forwarded to the data output `AX_OUT.D1`.
- After the calculation is complete, the event `AX_OUT.E1` is triggered via `F_NE.CNF`, signaling the new BOOL value at the AX adapter.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Type Conversion**: The function block implicitly converts a SINT adapter to a BOOL adapter without requiring the user to write direct type conversion logic.
- **Use of Standard Function Blocks**: Internally, the existing IEC 61131 function block `F_NE` is used, increasing reusability and testability.
- **Fixed Comparison Value**: The parameter `IN2` is preset to `SINT#0` – a change is only possible by modifying the composite function block.

State Overview

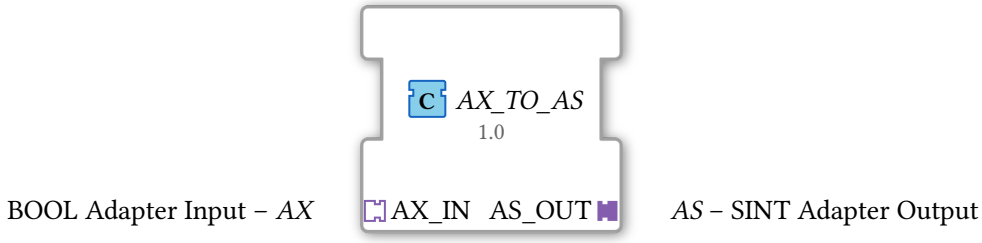
Since this is a composite function block without its own state machine, its behavior is limited to the data and event flow according to the internal interconnection. The states result from the processing function block `F_NE`:

- **Idle**: No event is pending.
- **Processing**: An event is being processed (comparison in progress).
- **Completed**: The comparison is complete, and the result is available at the output.

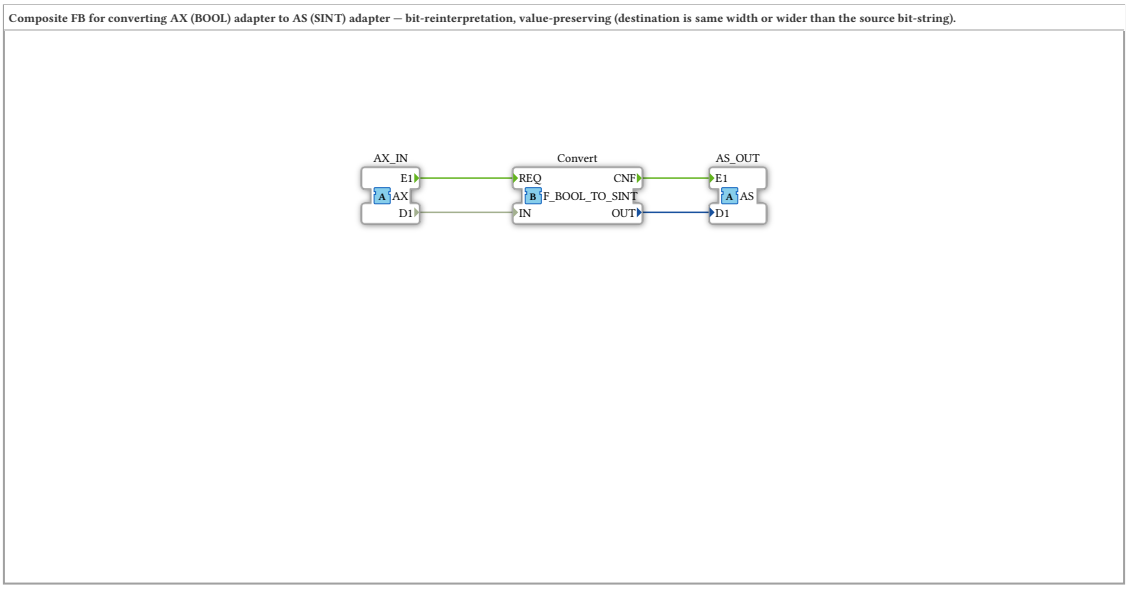
Application Scenarios

- **Threshold Check**: Conversion of a SINT counter value into a BOOL signal that indicates whether the value deviates from zero (e.g., "Motor running").
- **Adapter Bridge**: Connection of a component with an AS interface to a component with an AX interface without manual conversion.
- **Simple Status Indication**: Signal transmission indicating whether a data record exists (non-zero) or not.

Comparison with Similar Function Blocks



- **Direct Conversion Function Blocks** (e.g., `SINT_TO_BOOL`): Convert the data type without adapter logic, but do not provide event-driven behavior via adapters.
- **Custom Composite Solution**: Offers flexibility, but requires more effort; `AS_TO_AX` cleanly encapsulates the conversion and is reusable.



- **Adapter Wrappers**: Other function blocks may use different comparison operations (e.g., `F_EQ`), specifically checking for inequality to zero.

Conclusion

The **AS_TO_AX** function block provides a compact and reliable solution for converting a SINT adapter signal to a BOOL adapter signal. By utilizing the IEC 61131 standard function block `F_NE`, its behavior is deterministic and easily traceable. This function block is particularly suitable for applications requiring simple zero checks across adapter boundaries.

AX_TO_AS

• – ○ • – ○ • – ○ •

Introduction

The function block `AX_TO_AS` is a composite function block that converts a BOOL adapter (type AX) into a SINT adapter (type AS). It encapsulates the conversion of a binary signal into a signed 8-bit value and provides this via a standardized adapter interface.

Interface Structure

Event Inputs

No separate event inputs; event control is handled via the AX_IN adapter (see Adapters).

Event Outputs

No separate event outputs; event output is handled via the AS_OUT adapter (see Adapters).

Data Inputs

No separate data inputs; Data is transferred via the AX_IN adapter (see Adapters).

Data Outputs

No separate data outputs; data is output via the AS_OUT adapter (see Adapters).

Adapters

- **AX_IN** (Socket):

Type `adapter::types::unidirectional::AX` (BOOL).
Provides the binary input signal via the event port `E1` and the data port `D1`.

- **AS_OUT** (Plug):

Type `adapter::types::unidirectional::AS` (SINT).
Outputs the converted SINT signal via the event port `E1` and the data port `D1`.

Functionality

The function block (FB) has an internal network consisting of an instance of the standard function block `F_BOOL_TO_SINT`.

1. An incoming event at the AX_IN adapter (`E1`) triggers the conversion.
2. The data value of `AX_IN.D1` (BOOL) is passed to the input `IN` of the conversion function block.
3. The conversion function block converts the BOOL value into a SINT value (`TRUE` ⟶ 1, `FALSE` ⟶ 0).
4. The result is provided at output `OUT` and forwarded to the AS_OUT adapter (`D1`).
5. An acknowledgment event is output via `AS_OUT.E1`.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Composite Structure**: The function block (FB) is implemented as a composition, making the internal logic transparent and reusable.
- **Standard Conversion**: Uses the standardized FB `iec61131::conversion::F_BOOL_TO_SINT` from the IEC 61131 library.
- **Adapter Interface**: Input and output are exclusively via unidirectional adapters (sockets/plugs), enabling modular connections in adapter-based architectures.

State Overview

The FB does not have any explicitly modeled states. The behavior is purely event-driven: Every event at the input adapter triggers a conversion, after which an output event is sent.

Application Scenarios

- **Binary Sensor Connection**: A binary sensor (e.g., limit switch) is read via an AX adapter and passed to a controller as a SINT value.
- **Protocol Adaptation**: In systems requiring SINT-based adapters, existing BOOL adapters can be connected without additional coding.
- **Test Environments**: Easy switching between BOOL and SINT signals to verify adapter communication paths.

Comparison with Similar Components

- **Direct Conversions (`F_BOOL_TO_SINT`)**: These operate at the data level without adapters. The `AX_TO_AS` encapsulates the conversion in an adapter-based interface and is therefore easier to integrate into adapter networks.
- **Other adapter converters (e.g., `AS_TO_AX`)**: These represent the reverse direction; `AX_TO_AS` complements them as a counterpart.

Conclusion

The `AX_TO_AS` is a simple yet useful composite function block for converting BOOL adapter signals to SINT adapter signals. By using a standardized conversion block and adapter technology, it can be flexibly integrated into existing 4diac projects and contributes to the clean separation of signal types.

AUDI_TO_AUI

UDINT Adapter Input – *AUDI*

AUI – UINT Adapter Output

No image available.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUDI_TO_AUI` is a composite block that converts an AUDI adapter (data type UDINT) into an AUI adapter (data type UINT). It serves as a simple interface adapter between components that use different integer data types for their unidirectional adapters. The block encapsulates the conversion and enables seamless integration into IEC 61499 networks.

Interface Structure

Event Inputs

The function block does not have a direct event input at the top level. Events are received via socket `AUDI_IN`:

- **E1** – Trigger for the conversion of a new data value.

Event Outputs

The FB does not have a direct event output at the top level. Events are sent via the plug `AUI_OUT`:

- **E1** – Confirmation that the converted value is present at the output.

Data Inputs

The FB does not have a direct data input at the top level. Data is received via the socket `AUDI_IN`:

- **D1** (`UDINT`) – The input value to be converted.

Data Outputs

The FB does not have a direct data output at the top level. Data is output via the plug `AUI_OUT`:

- **D1** (`UINT`) – The converted output value.

Adapters

- **Socket `AUDI_IN`** – Unidirectional input adapter of type `adapter::types::unidirectional::AUDI`. It returns an event `E1` and a data value `D1` (type `UDINT`).
- **Plug `AUI_OUT`** – Unidirectional output adapter of type `adapter::types::unidirectional::AUI`. It expects an event `E1` and outputs a data value `D1` (type `UINT`).

Functionality

The module is implemented as a composite and internally contains the function block `iec61131::conversion::F_UDINT_TO_UINT`. The sequence is event-driven:

1. An event at socket `AUDI_IN.E1` triggers the input `REQ` of the internal conversion module.
2. Simultaneously, the data value `AUDI_IN.D1` is transferred to the input `IN` of the converter.
3. The converter performs the conversion from `UDINT` to `UINT`.
4. Upon completion, the converter sends an event at its output `CNF`, which is forwarded to plug `AUI_OUT.E1`.
5. The converted value at the converter's output `OUT` is placed on the data output `AUI_OUT.D1`.

The entire conversion takes place within a single event pass (synchronously).

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Architecture:** The function block is designed as a composite, meaning its functionality is entirely determined by the internal network. This facilitates reuse and adaptation.
- **Standard Conversion Block:** The actual type conversion uses the IEC 61131 block `F_UDINT_TO_UINT`, which provides a platform-independent and tested implementation.
- **License:** The block is licensed under the Eclipse Public License 2.0 (EPL-2.0).
- **Version:** 1.0, released on February 17, 2026.

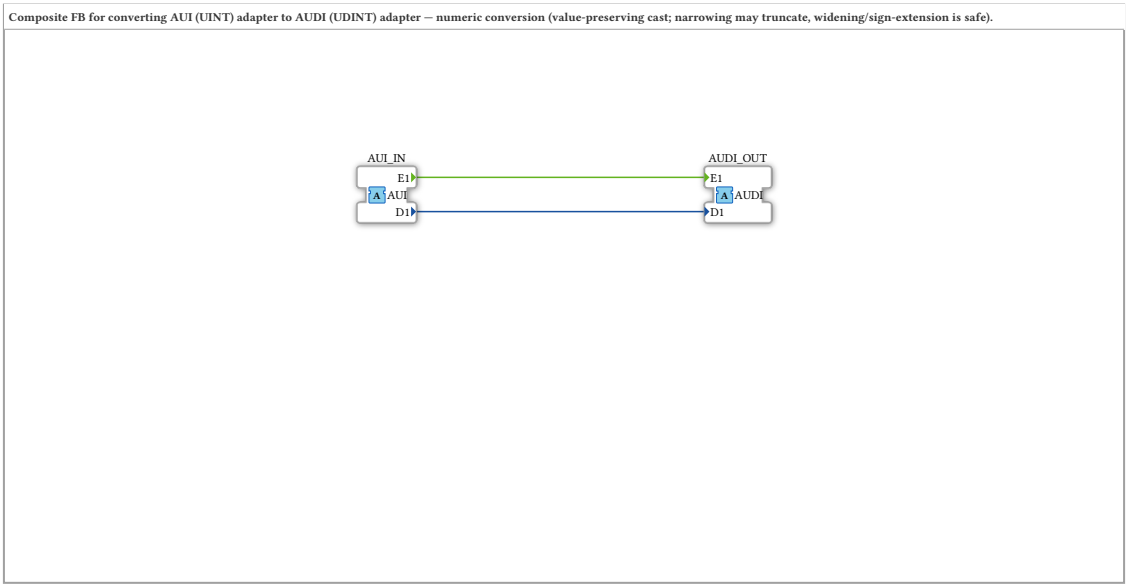
State Overview

The FB (Function Block) has no states of its own. Since the composite network consists of only a single functional block, which itself operates without state, `AUDI_TO_AUI` also behaves without state. Each event pulse immediately triggers a one-time conversion.

Application Scenarios

- **Connecting Sensors/Actuators:** A sensor delivers values as `UDINT` via an AUDI adapter, while the subsequent processing chain expects `UINT` via AUI.
- **System Integration:** Different data types often occur in heterogeneous automation systems. The block serves as an adapter to connect components from different manufacturers or libraries.
- **Prototype Development:** Simple and quick adaptation of interfaces without manual conversion logic.

Comparison with Similar Function Blocks



- **`AUDI_TO_XXX` Function Blocks:** Analogous function blocks exist for other target types (e.g., `AUDI_TO_DINT`, `AUDI_TO_SINT`). `AUDI_TO_AUI` is specific for conversion to `UINT`.
- **Direct Adapter Coupling:** Without a conversion block, type conversion would have to be performed in the application itself or via a generic function block. `AUDI_TO_AUI` offers an encapsulated, reusable solution.

Conclusion

The `AUDI_TO_AUI` function block provides a compact and reliable way to mediate between two unidirectional adapters with different data types. Thanks to its composite structure and the use of a standardized conversion module, it requires little maintenance and can be easily integrated into existing IEC 61499 projects.

AUI_TO_AUDI

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUI_TO_AUDI** function block is a composite function block that converts an AUI adapter (UINT) into an AUDI adapter (UDINT). It serves to transfer data and events from one adapter type to another, where the underlying data types differ (UINT ⟶ UDINT). The conversion is performed by simply passing the signals through, without any additional logic.

Interface Structure

Event Inputs

No dedicated event inputs: The function block has no direct event inputs. Events are received via the connected socket adapter **AUI_IN**.

Event Outputs

No dedicated event outputs: The function block has no direct event outputs. Events are sent via the connected plug adapter **AUDI_OUT**.

Data Inputs

No dedicated data inputs: This function block has no direct data inputs. Data is received via the connected socket adapter **AUI_IN**.

Data Outputs

No dedicated data outputs: This function block has no direct data outputs. Data is sent via the connected plug adapter **AUDI_OUT**.

Adapters

Name	Type	Direction	Comment

AUI_IN	adapter::types::unidirectional::AUI	Socket (Input)	Receives UINT data and associated event
AUDI_OUT	adapter::types::unidirectional::AUDI	Plug (Output)	Sends UINT data and associated event

Functionality

The function block internally connects the interfaces of the incoming AUI adapter with those of the outgoing AUDI adapter:

- **Event Connection**: The event `E1` of the AUI adapter is directly forwarded to the event `E1` of the AUDI adapter.
- **Data Connection**: The data value `D1` of the AUI adapter (type UINT) is directly transferred to the data value `D1` of the AUDI adapter (type UDINT). This involves an implicit type conversion from UINT (16 bits) to UDINT (32 bits).

The function block does not perform any logic or conversion of its own; it simply acts as a pass-through for adapters with different data types.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Unidirectional Adapters**: Both the input and output adapters are unidirectional, meaning data and events flow only in one direction (from the socket to the plug).
- **Composite FB**: The function block is implemented as a composite function block (FB) that maps the adapter connections in the FBNetwork.
- **Implicit Type Conversion**: The conversion from UINT to UDINT occurs automatically within the data connection, based on the IEC 61499 data type rules.
- **Package Structure**: The function block belongs to the package `adapter::conversion::unidirectional`.

State Overview

The function block does not have its own states or state machines. Its behavior results solely from the forwarding connection of the adapter interfaces.

Application Scenarios

- **Adapter Adaptation**: If a system uses an AUI adapter (UINT) but expects an AUDI adapter (UDINT), this function block can be used as an intermediary converter.
- **Signal Forwarding**: Used in hierarchical systems where a unidirectional data flow from a smaller to a larger data type needs to be mapped.
- **Prototypical Integration**: Rapid coupling of components with different adapter types without additional logic.

Comparison with Similar Function Blocks

- **AUI_TO_AUDI** performs pure type conversion without further processing.
- Similar function blocks like `AUDI_TO_AUI` would map the reverse direction (UDINT ⟶ UINT), possibly with data overflow handling.
- Other adapter converters (e.g., `BOOL_TO_BYTE`) follow the same pattern but differ in the data types used and the direction.

Conclusion

The **AUI_TO_AUDI** block is a simple yet useful composite function block for converting a UINT-based AUI adapter to a UDINT-based AUDI adapter. It is particularly suitable for situations requiring unidirectional signal forwarding with implicit data type conversion, without the need for custom processing logic. Thanks to its clear structure, it can be easily integrated into existing 4diac projects.

AUDI_TO_AULI

UDINT Adapter Input – *AUDI* *AULI* – ULINT Adapter Output

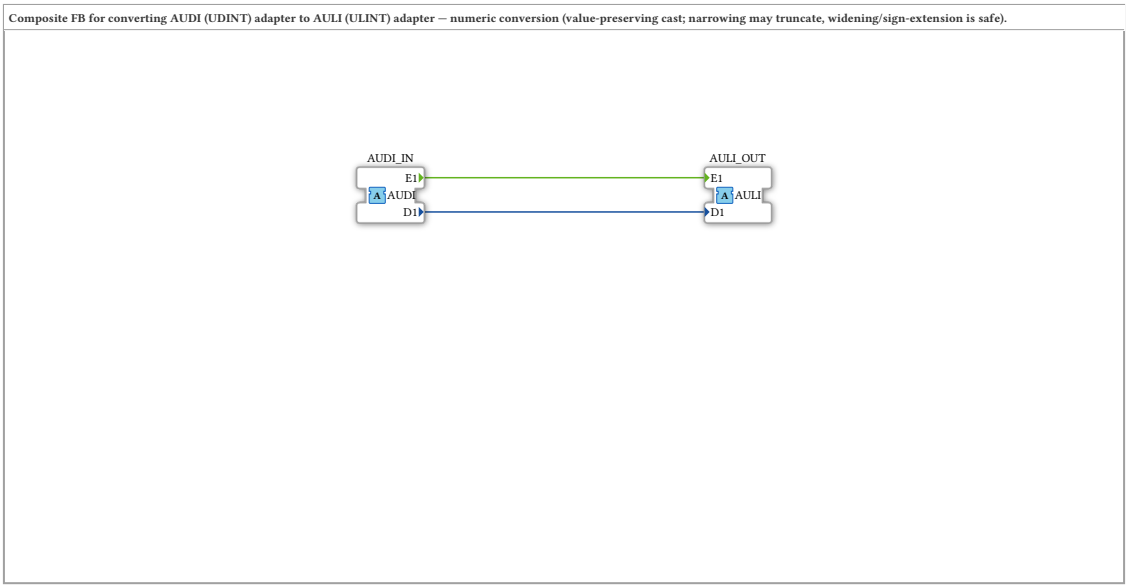

Image not available

• – ○ • – ○ • – ○ •

Introduction

This composite function block converts an AUDI adapter (UDINT) to an AULI adapter (ULINT). It serves as an interface between components that use different adapter types for unsigned integers. The function block is licensed under the Eclipse Public License 2.0 (EPL 2.0) and is provided by HR Agrartechnik GmbH.

Interface Structure

Event Inputs

None (events are received via the AUDI_IN adapter).

Event Outputs

None (events are sent via the AULI_OUT adapter).

Data Inputs

None (data is received via the AUDI_IN adapter).

Data Outputs

None (data is sent via the AULI_OUT adapter).

Adapters

- **AUDI_IN** (Socket): Receives an AUDI adapter (type: `adapter::types::unidirectional::AUDI`). Contains one event input (E1) and one data input (D1) of type UDINT.
- **AULI_OUT** (Plug): Sends an AULI adapter (type: `adapter::types::unidirectional::AULI`). Contains one event output (E1) and one data output (D1) of type ULINT.

Functionality

The function block forwards incoming events and data from the AUDI_IN adapter directly to the AULI_OUT adapter:

- The event `E1` from `AUDI_IN` is transferred to `E1` from `AULI_OUT`.
- The data value `D1` (UDINT) from `AUDI_IN` is transferred to `D1` (ULINT) from `AULI_OUT`. The 32-bit UDINT value is implicitly converted to the 64-bit ULINT value (null extension). No additional logic is performed.

...

Technical Features

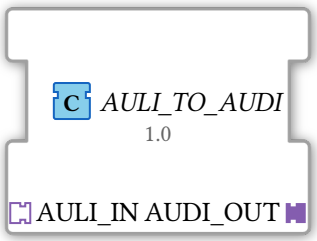
- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite FB**: Contains no function block logic or state machine, but merely wiring between two adapters.
- **Package**: `adapter::conversion::unidirectional`
- **Version**: 1.0, created on 2026-02-17.
- **License**: EPL 2.0.

State Overview

The FB has no internal state or algorithm. It operates strictly in a flow-oriented manner and reacts immediately to every incoming event.

Application Scenarios

- **System Integration**: If one system component provides data via an AUDI adapter (UDINT), but another component expects an AULI adapter (ULINT), this FB acts as a bridge.
- **Protocol Adaptation**: Use in control systems that use different integer widths for buses or interfaces (e.g., 32-bit to 64-bit).



Comparison with Similar Function Blocks

- **Simple Data Type Converters** (e.g., `UDINT_TO_ULINT`): These only convert data without adapters. This function block operates at the adapter level and also forwards events.
- **Adapter Transceivers**: Other function blocks could perform more complex conversions (e.g., scaling, offsetting). This function block is minimal.
