- **Type Hash**: The type hash can be set at runtime if needed to enable static type checking.
- **Pure Adapter Interface**: The FB has neither event nor data inputs/outputs in the traditional sense, but communicates exclusively via adapters.

State Overview

Since the FB has no event inputs, it does not have an explicit state machine. Signal transmission occurs continuously and asynchronously as soon as the IN adapter is connected.

Application Scenarios

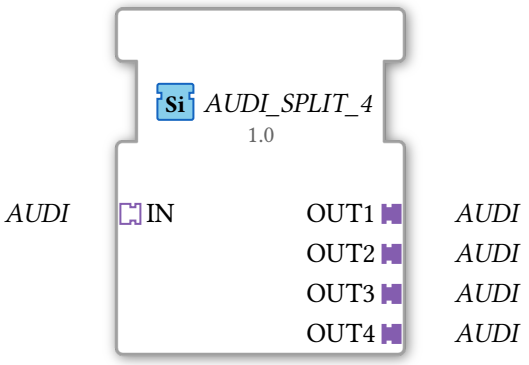
- **Signal Multiplication**: Distribution of a common control or measurement signal to different function blocks (e.g., parallel connection of several actuators or sensors).
- **Test and Simulation Environments**: Injecting a simulated audio signal into multiple independent analysis or monitoring paths.
- **Architecture Coupling**: Used in modular systems where a data stream needs to be passed to different subsystems without degrading the original signal.

Comparison with Similar Blocks

- **AUDI_MERGE** (counterpart): A combining element that merges multiple audio inputs into one output – unlike the split block.
- **AUDI_SPLIT_2**: A splitter reduced to two outputs; this block extends this to three outputs.
- **Generic Splitters**: Many libraries contain split variants for other adapter types (e.g., `DATA_SPLIT`), but these are data-type specific.
- `AUDI_SPLIT_3`: The gated variant – updates the output only on an actual value change.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.



Conclusion

The **AUDI_SPLIT_3_UNGATED** is a simple yet useful function block for distributing a unidirectional AUDI adapter signal to three outputs. Its generic nature and pure adapter interface allow it to integrate seamlessly into event-driven and data-stream-oriented IEC 61499 applications. It provides a clean, maintainable solution for architectural signal distribution and reduces the need for manual signal routing.

AUDI_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUDI_SPLIT_4** is used to distribute an incoming unidirectional **AUDI** adapter signal to four identical outputs. It functions as a simple signal distributor (fan-out) for the generic adapter type **AUDI**. The block is implemented as a generic function block (Generic FB) and can be adapted to different adapter types via the class `GEN_AUDI_SPLIT`.

Interface Structure

Event Inputs
No event inputs available.

Event Outputs
No event outputs available.

Data Inputs
No data inputs available.

Data Outputs
No data outputs available.

Adapters

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AUDI`	Input adapter that provides the signal to be distributed.
Plug	`OUT1`	`adapter::types::unidirectional::AUDI`	First output, identical to the input signal.
Plug	`OUT2`	`adapter::types::unidirectional::AUDI`	Second output, identical to the input signal.
Plug	`OUT3`	`adapter::types::unidirectional::AUDI`	Third output, identical to the input signal.
Plug	`OUT4`	`adapter::types::unidirectional::AUDI`	Fourth output, identical to the input signal.

Functionality
The module operates **eventlessly** and **continuously**:

As soon as socket `IN` is connected to an AUDI adapter, the data or signals transmitted via this adapter are forwarded unchanged to all four output adapters (`OUT1` to `OUT4`). No processing or conversion of the data takes place – the module functions solely as a passive distributor (splitter). Since no events or state changes are involved, the distribution occurs implicitly through the connection structure.

Technical Features
- **Generic Function Block**: The function block is declared as a generic type with the class name `'GEN_AUDI_SPLIT'`. This allows the specific adapter type (e.g., a specialized AUDI subtype) to be adapted at design time or through code generation.
- **Unidirectional Adapters**: All adapters used (`AUDI`) are unidirectional, meaning data flows only from the socket to the plugs.
- **No Event Control**: The function block has no event inputs or outputs. Signal distribution is data flow-driven and requires no explicit triggering.
- **Scalability**: The function block is specifically designed for 4 outputs. Variants exist for other numbers (e.g., `AUDI_SPLIT_2`, `AUDI_SPLIT_3`).

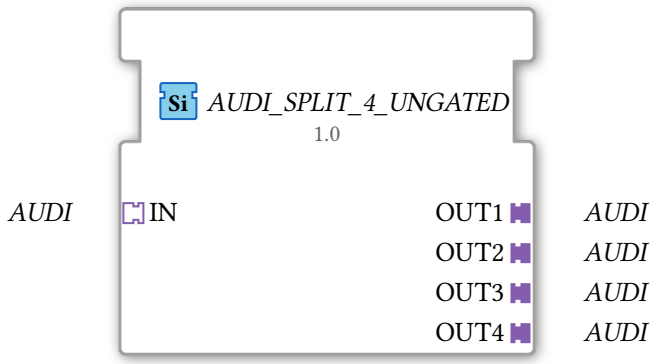
State Overview
This function block does **not have a state machine (ECC)**, as it does not process events or store an internal state. Its function is purely combinatorial: The outputs continuously reflect the input.

Application Scenarios
- **Signal Distribution in Control Systems**: An audio signal provided by a sensor or higher-level system is to be passed on in parallel to multiple consumers (actuators, visualizations, logic units).
- **Test and Simulation Environments**: A single test signal is split across multiple parallel test paths.
- **Prototypical Adapter Coupling**: When multiple downstream blocks require the same input signal without the need for logical replication.

Comparison with Similar Function Blocks

Function Block	Function	Special Feature
AUDI_SPLIT_2	Distributes an audio signal to two outputs.	Similar principle, but with two outputs.
AUDI_SPLIT_4`	Distributes an audio signal to four outputs.	This is a simple 1:4 splitter.
AUDI_MERGE`	Combines multiple audio inputs into one output.	Inverted splitter (1:1 mapping, but reversed).
Generic splitters	Can be applied to other adapters via type parameters.	Offer more flexibility than hardwired versions.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The AUDI_SPLIT_4 is a simple yet useful function block for multiplying a unidirectional audio adapter signal to four parallel outputs. Its generic nature allows for adaptation to various adapter types, and its eventless operation makes it particularly suitable for pure data distribution tasks without additional control logic. The component contributes to the structuring and reusability of signals in complex automation solutions.

AUDI_SPLIT_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AUDI_SPLIT_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUDI_SPLIT_4_UNGATED** is used to distribute an incoming unidirectional **AUDI** adapter signal to four identical outputs. It functions as a simple signal distributor (fan-out) for the generic adapter type **AUDI**. The block is implemented as a generic function block (Generic FB) and can be adapted to different adapter types via the class GEN_AUDI_SPLIT.

Interface Structure

Event Inputs
No event inputs available.

Event Outputs
No event outputs available.

Data Inputs
No data inputs available.

Data Outputs
No data outputs available.

Adapters

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AUDI`	Input adapter that provides the signal to be distributed.
Plug	`OUT1`	`adapter::types::unidirectional::AUDI`	First output, identical to the input signal.
Plug	`OUT2`	`adapter::types::unidirectional::AUDI`	Second output, identical to the input signal.
Plug	`OUT3`	`adapter::types::unidirectional::AUDI`	Third output, identical to the input signal.
Plug	`OUT4`	`adapter::types::unidirectional::AUDI`	Fourth output, identical to the input signal.

Functionality
The module operates **eventlessly** and **continuously**:

As soon as socket `IN` is connected to an AUDI adapter, the data or signals transmitted via this adapter are forwarded unchanged to all four output adapters (`OUT1` to `OUT4`). No processing or conversion of the data takes place – the module functions solely as a passive distributor (splitter). Since no events or state changes are involved, the distribution occurs implicitly through the connection structure.

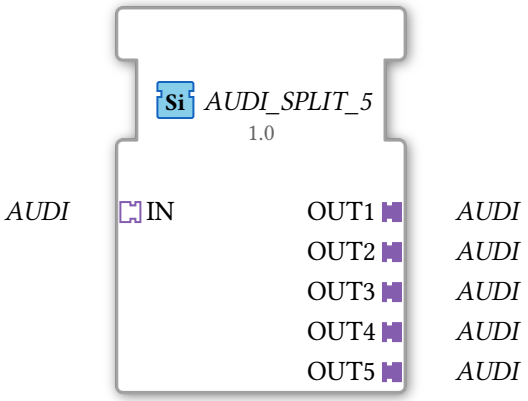
Technical Features
- **Generic Function Block**: The function block is declared as a generic type with the class name `'GEN_AUDI_SPLIT'`. This allows the specific adapter type (e.g., a specialized AUDI subtype) to be adapted at design time or through code generation.
- **Unidirectional Adapters**: All adapters used (`AUDI`) are unidirectional, meaning data flows only from the socket to the plugs.
- **No Event Control**: The function block has no event inputs or outputs. Signal distribution is data flow-driven and requires no explicit triggering.
- **Scalability**: The function block is specifically designed for 4 outputs. Variants exist for other numbers (e.g., `AUDI_SPLIT_2`, `AUDI_SPLIT_3`).

State Overview
This function block does **not have a state machine (ECC)**, as it does not process events or store an internal state. Its function is purely combinatorial: The outputs continuously reflect the input.

Application Scenarios
- **Signal Distribution in Control Systems**: An audio signal provided by a sensor or higher-level system is to be passed on in parallel to multiple consumers (actuators, visualizations, logic units).
- **Test and Simulation Environments**: A single test signal is split across multiple parallel test paths.
- **Prototypical Adapter Coupling**: When multiple downstream blocks require the same input signal without the need for logical replication.

Comparison with Similar Function Blocks

Function Block	Function	Special Feature
`AUDI_SPLIT_2`	Distributes an audio signal to two outputs.	Similar principle, but with two outputs.
AUDI_SPLIT_4_UNGATED`	Distributes an audio signal to four outputs.	This is a simple 1:4 splitter.
AUDI_MERGE`	Combines multiple audio inputs into one output.	Inverted splitter (1:1 mapping, but reversed).
Generic splitters	Can be applied to other adapters via type parameters.	Offer more flexibility than hard-wired versions.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AUDI_SPLIT_4_UNGATED` is a simple yet useful function block for multiplying a unidirectional audio adapter signal to four parallel outputs. Its generic nature allows for adaptation to various adapter types, and its eventless operation makes it particularly suitable for pure data distribution tasks without additional control logic. The component contributes to the structuring and reusability of signals in complex automation solutions.

AUDI_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUDI_SPLIT_5** is used to distribute a single incoming AUDI signal to five identical AUDI outputs. It is designed as a generic adapter module and allows for flexible further processing of the signal along multiple paths.

Interface Structure

Event Inputs

None available.

Event Outputs

None available.

Data Inputs

None available.

Data Outputs

None available.

Adapter

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AUDI`	Incoming AUDIO Signal
Plug	`OUT1`	`adapter::types::unidirectional::AUDI`	First Output
Plug	`OUT2`	`adapter::types::unidirectional::AUDI`	Second Output
Plug	`OUT3`	`adapter::types::unidirectional::AUDI`	Third Output
Plug	`OUT4`	`adapter::types::unidirectional::AUDI`	Fourth Output
Plug	`OUT5`	`adapter::types::unidirectional::AUDI`	Fifth Output

Functionality

This function block forwards the AUDI signal present at socket `IN` unchanged and simultaneously to all five plugs `OUT1` to `OUT5`. No signal processing, conversion, or buffering takes place – distribution occurs purely at the adapter level as soon as a connection to the outputs is established.

Technical Features

- **Generic Function Block**: The function block is implemented as a generic type (`GEN_AUDI_SPLIT`). It can be instantiated for various data types via appropriate runtime environment mechanisms, as long as these data types conform to the unidirectional AUDI adapter protocol.
- **No State Logic**: The function block contains no event or data processing and no internal state machine.
- **Simple and High-Performance Signal Distribution**: Due to its pure adapter structure, it is particularly suitable for scenarios where a signal needs to be duplicated without latency.

State Overview

The function block does not have an explicit state machine. Its behavior is deterministic: As long as the function block is in operation, every signal arriving at `IN` is immediately passed on to all outputs.

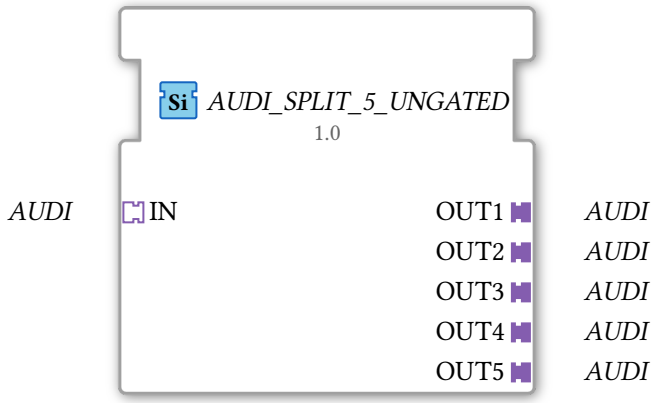
Application Scenarios

- **Distributing control signals** in industrial automation, e.g., a start/stop command that is intended to reach several identical modules.
- **Duplicating a measured value** for parallel evaluations or visualizations.
- **Establishing redundancy paths** by using the same signal multiple times.

Comparison with Similar Function Blocks

Unlike function blocks such as `AUDI_MERGE_5` (combining multiple signals) or `AUDI_SPLIT_2` (only two outputs), `AUDI_SPLIT_5` offers a specific distribution across exactly five outputs. Generic split function blocks for other numbers (e.g., `AUDI_SPLIT_N`) often exist as templates, while this function block covers a fixed, but frequently required, configuration.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AUDI_SPLIT_5` is a simple and efficient adapter function block for signal distribution. Its generic design and the absence of event/data logic make it lightweight and versatile. It is ideally suited for all applications where an audio signal needs to be split across five parallel paths.

AUDI_SPLIT_5_UNGATED

i UNGATED variant: This block is the ungated version of `AUDI_SPLIT_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Conclusion

AUDI_SPLIT_5_UNGATED` is a simple and efficient adapter function block for signal distribution. Its generic design and the absence of event/data logic make it lightweight and versatile. It is ideally suited for all applications where an audio signal needs to be split across five parallel paths.

AUDI_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUDI_SPLIT_6** serves as a generic splitter for a unidirectional AUDI adapter. It receives an incoming adapter data stream via a socket and forwards it unchanged to six separate output adapters (plugs). The block is designed generically, so the specific adapter type can be configured via the attribute `GenericClassName`.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Socket	**IN**	`adapter::types::unidirectional::AUDI`	Incoming adapter for the data stream to be distributed.
Plug	**OUT1**	`adapter::types::unidirectional::AUDI`	First output adapter (copy of the input).
Plug	**OUT2**	`adapter::types::unidirectional::AUDI`	Second output adapter.
Plug	**OUT3**	`adapter::types::unidirectional::AUDI`	Third output adapter.
Plug	**OUT4**	`adapter::types::unidirectional::AUDI`	Fourth output adapter.
Plug	**OUT5**	`adapter::types::unidirectional::AUDI`	Fifth output adapter.
Plug	**OUT6**	`adapter::types::unidirectional::AUDI`	Sixth output adapter.

Functionality

This function block acts as a pure distributor without any data processing. The data stream arriving via the **IN** socket is forwarded unchanged and in parallel to all six output adapters (OUT1–OUT6). Distribution occurs continuously as soon as the input adapter provides data. Since the function block is generic, it can be adapted to a specific adapter type (e.g., a custom derived type) by setting the attribute `eclipse4diac::core::GenericClassName`.

Technical Features

- **Generic Design:** The function block uses the 4diac generic mechanisms (`GenericClassName`). This allows the adapter type to be set at runtime or during instantiation without recompiling the function block.
- **Unidirectional:** Both the input and output adapters are unidirectional. No feedback from the outputs to the input is provided.
- **No Event Control:** The function block has no event interface and no ECC. Data transmission is purely data-driven (as soon as data is present at the IN socket).
- **No Internal State:** No state change occurs; the function block is stateless.

State Overview

No state machine (ECC) exists. The function block does not execute any sequential processes.

Application Scenarios

- **Data Distribution:** An audio data stream provided by a sensor or another function block is to be sent to several subsequent components simultaneously, e.g., to a visualization, a logging component, and control logic.
- **Parallel Processing:** When the same data stream needs to be processed in parallel in different path segments, e.g., filtering, conditioning, and storage.
- **Generic Use:** Thanks to its configurable type assignment, the function block (FB) can be used in various projects with different adapter definitions without having to modify the source code.

Comparison with Similar Function Blocks

Other split function blocks exist (e.g., `AUDI_SPLIT_2`, `AUDI_SPLIT_4`) that differ only in the number of outputs. With six outputs, `AUDI_SPLIT_6` offers a higher distribution density. Unlike pure data splitters for basic data types, this FB works exclusively with AUDI adapters and supports unidirectional coupling.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AUDI_SPLIT_6` is a simple yet flexible function block for multiplying adapter connections in a 4diac environment. Its generic nature and lean implementation without event overhead make it ideal for scenarios where an incoming data stream needs to be distributed to multiple independent receivers.

AUDI_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUDI_SPLIT_7` is used to distribute a single AUDI input signal to seven identical AUDI output signals. It is designed as a generic building block and is suitable for all unidirectional AUDI adapter types.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapter

Name	Type	Direction
IN	adapter::types::unidirectional::AUDI	Socket (Input)
OUT1	adapter::types::unidirectional::AUDI	Plug (Output)
OUT2	adapter::types::unidirectional::AUDI	Plug (Output)
OUT3	adapter::types::unidirectional::AUDI	Plug (Output)
OUT4	adapter::types::unidirectional::AUDI	Plug (Output)
OUT5	adapter::types::unidirectional::AUDI	Plug (Output)
OUT6	adapter::types::unidirectional::AUDI	Plug (Output)
OUT7	adapter::types::unidirectional::AUDI	Plug (Output)

All adapters are of the unidirectional type AUDI and transmit data exclusively from the socket to the plugs.

Functionality

The module copies the AUDIO data received via socket IN unchanged to all seven plug outputs OUT1 to OUT7. No processing or conversion of the data takes place – the function is limited to a simple 1-to-7 distribution (fan-out). Since there are no events or explicit data ports, the signal behavior is entirely defined by the connected adapters.

- **Generic Type**: The component is marked as generic via the attribute eclipse4diac::core::GenericClassName ('GEN_AUDI_SPLIT'). This allows it to be used for various specific implementations of the AUDI adapter without requiring a separate implementation.
- **No Runtime Dependency**: The component has no algorithm and no state diagram; signal transmission occurs purely structurally through the adapter wiring.
- **Type Hash**: The attribute eclipse4diac::core::TypeHash is empty, meaning that the type identity is not additionally secured at runtime.

State Overview

The component does not contain a state machine (ECC). Its behavior is completely deterministic and eventless – a state representation is therefore not required.

Application Scenarios

- **Signal Distribution**: An AUDI signal from a sensor or control unit must be forwarded in parallel to multiple consumers (actuators, displays, monitoring systems).
- **System Expansion**: Existing systems that provide a single AUDI signal are to be expanded with additional components without changing the source logic.
- **Test Setups**: A generated test signal is to be sent to multiple devices under test simultaneously.

Comparison with Similar Components

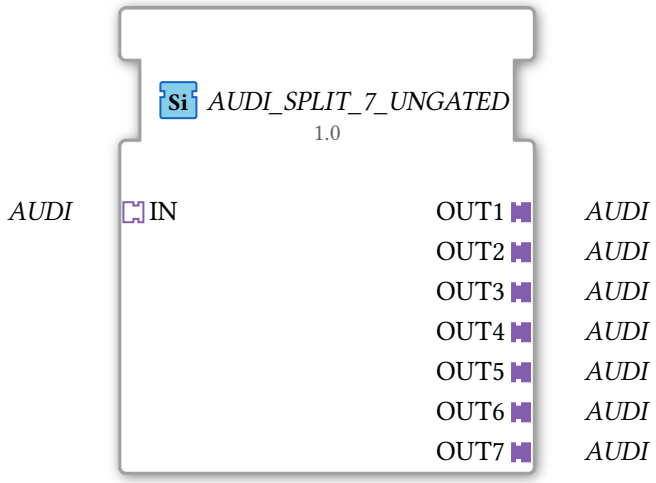
Component	Distribution	Adapter Type
AUDI_SPLIT_7	1 input ⟶ 7 outputs	Unidirectional AUDI
SPLIT_1_TO_2 (analog)	1 ⟶ 2	Any (generic)
AUDI_MERGE	Multiple Inputs ⟶ 1	Unidirectional AUDI

While AUDI_SPLIT_7 is designed for the specific AUDI adapter type, generic split modules exist for other data formats. Its limitation to a fixed number of seven outputs distinguishes it from flexible splitters with a configurable number of outputs.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion



AUDI_SPLIT_7` is a simple yet effective module for distributing an AUDI signal to seven identical paths. Its generic design allows it to be reused in various contexts. The absence of events and internal logic makes it lightweight and reliable for pure signal distribution tasks.

Adapter

Name	Type	Direction
IN	adapter::types::unidirectional::AUDI	Socket (Input)
OUT1	adapter::types::unidirectional::AUDI	Plug (Output)
OUT2	adapter::types::unidirectional::AUDI	Plug (Output)
OUT3	adapter::types::unidirectional::AUDI	Plug (Output)
OUT4	adapter::types::unidirectional::AUDI	Plug (Output)
OUT5	adapter::types::unidirectional::AUDI	Plug (Output)
OUT6	adapter::types::unidirectional::AUDI	Plug (Output)
OUT7	adapter::types::unidirectional::AUDI	Plug (Output)

All adapters are of the unidirectional type AUDI and transmit data exclusively from the socket to the plugs.

Functionality

The module copies the AUDIO data received via socket IN unchanged to all seven plug outputs OUT1 to OUT7. No processing or conversion of the data takes place – the function is limited to a simple 1-to-7 distribution (fan-out). Since there are no events or explicit data ports, the signal behavior is entirely defined by the connected adapters.

- **Generic Type**: The component is marked as generic via the attribute eclipse4diac::core::GenericClassName ('GEN_AUDI_SPLIT'). This allows it to be used for various specific implementations of the AUDI adapter without requiring a separate implementation.
- **No Runtime Dependency**: The component has no algorithm and no state diagram; signal transmission occurs purely structurally through the adapter wiring.
- **Type Hash**: The attribute eclipse4diac::core::TypeHash is empty, meaning that the type identity is not additionally secured at runtime.

State Overview

The component does not contain a state machine (ECC). Its behavior is completely deterministic and eventless – a state representation is therefore not required.

Application Scenarios

- **Signal Distribution**: An AUDI signal from a sensor or control unit must be forwarded in parallel to multiple consumers (actuators, displays, monitoring systems).
- **System Expansion**: Existing systems that provide a single AUDI signal are to be expanded with additional components without changing the source logic.
- **Test Setups**: A generated test signal is to be sent to multiple devices under test simultaneously.

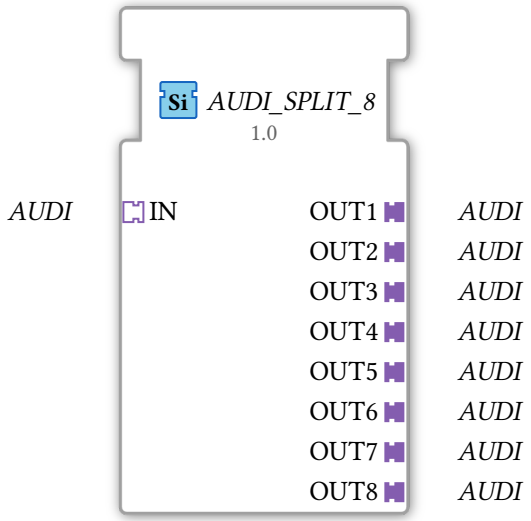
Comparison with Similar Components

Component	Distribution	Adapter Type
AUDI_SPLIT_7_UNGATED	1 input ⟶ 7 outputs	Unidirectional AUDI
SPLIT_1_TO_2 (analog)	1 ⟶ 2	Any (generic)
AUDI_MERGE	Multiple Inputs ⟶ 1	Unidirectional AUDI

While AUDI_SPLIT_7_UNGATED is designed for the specific AUDI adapter type, generic split modules exist for other data formats. Its limitation to a fixed number of seven outputs distinguishes it from flexible splitters with a configurable number of outputs.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.



Conclusion

AUDI_SPLIT_7_UNGATED` is a simple yet effective module for distributing an AUDI signal to seven identical paths. Its generic design allows it to be reused in various contexts. The absence of events and internal logic makes it lightweight and reliable for pure signal distribution tasks.

AUDI_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUDI_SPLIT_8** is used to distribute an incoming unidirectional **AUDI** adapter signal to eight parallel outputs. It is implemented as a generic function block (FB) and allows for the simple forwarding of an adapter signal to up to eight receivers.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Type	Direction	Name	Description
adapter::types::unidirectional::AUDI`	Socket (Input)	`IN`	Input adapter that receives the signal to be distributed.
adapter::types::unidirectional::AUDI`	Plug (Output)	`OUT1` .. `OUT8`	Eight output adapters, each providing the identical signal of the input.

Functionality

The module forwards the **AUDI** adapter signal present at socket `IN` unchanged to all eight plugs (`OUT1` to `OUT8`).

No processing, filtering, or buffering takes place – distribution is completely passive at the adapter level.

By using a generic type (see Technical Specifications), the function block can be flexibly used for various specific AUDI adapter implementations.

Technical Specifications

- **Generic Function Block**: The function block is declared as a generic type (`eclipse4diac::core::GenericClassName = 'GEN_AUDI_SPLIT'`).

This allows reuse for any AUDI adapter specialization without having to modify the function block itself.

- **No State Logic**: Since only adapters are used, the function block has neither events nor its own state machine.
- **Space Saving**: By combining eight outputs into a single function block, the network diagram becomes clearer than when using several simple split blocks.

State Overview

The function block has no internal state machine (no ECC).

The functionality is purely combinational: The signal at the input is permanently passed through to all outputs.

Application Scenarios

- **Signal broadcast** in control applications where a single AUDI adapter signal needs to be distributed to multiple independent receiver modules (e.g., smart sensors, actuators, or bus couplers).
- **Expanding the number of participants** in an existing AUDI wiring system without affecting the original signal.
- **Structured automation solutions** in agricultural machinery where adapters according to IEC 61499 are used for communication between components (e.g., in HR Agrartechnik GmbH systems).

Comparison with Similar Modules

- **Simple Split FB (e.g., SPLIT_2)**: Distributes a signal to two outputs – AUDI_SPLIT_8 offers eight outputs in a single module.
- **Data Distribution FB**: Some libraries provide generic distributors for data ports; this FB is specifically optimized for the AUDI adapter type and requires no additional data structure configuration.
- **Manual Parallel Connection**: Multiple AUDI socket-to-plug connections could achieve the same result, but are less organized and more prone to errors.

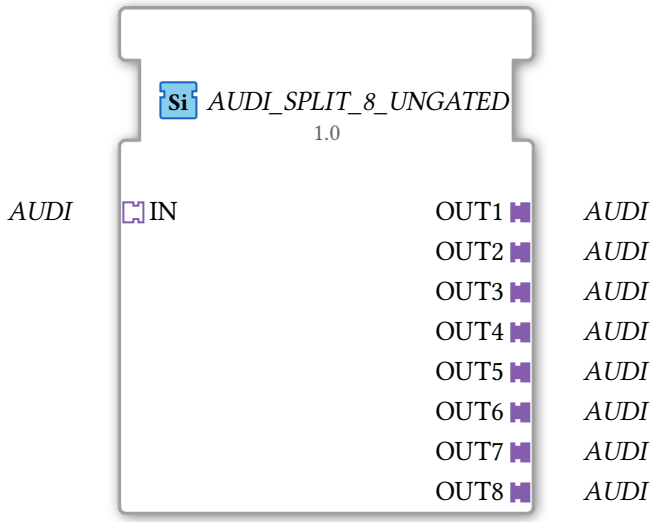
Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AUDI_SPLIT_8 is a compact, generic, specialized module for signal distribution at the adapter level.

It reduces modeling effort, improves the readability of control programs, and, due to its generic nature, can be flexibly deployed in various AUDI-based environments.



For applications requiring a 1:8 split of a unidirectional audio adapter, it represents an ideal and clean solution.

AUDI_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUDI_SPLIT_9` is used to distribute an incoming AUDI signal via a socket to nine identical AUDI plugs. It implements a 1-to-9 split functionality, where all outputs always carry the same value as the input. The block is defined as a generic FB (GenericClassName `GEN_AUDI_SPLIT`) and enables the easy duplication of AUDI data streams within a 4diac IDE application.

Interface Structure

Event Inputs

No event inputs are available. Data transmission occurs exclusively via the adapter interfaces.

Event Outputs

No event outputs are available. The output signals are provided directly via the adapter plugs.

Data Inputs

No direct data inputs are available. Input data is read via the socket adapter `IN`.

Data Outputs

No direct data outputs are available. Output data is provided via the nine plug adapters `OUT1` to `OUT9`.

Adapters

Adapter	Type	Direction	Description
`IN`	`adapter::types::unidirectional::AUDI`	Socket (Input)	Receives the AUDI signal to be distributed.
`OUT1` … `OUT9`	`adapter::types::unidirectional::AUDI`	Plug (Output)	Nine outputs that replicate the value of `IN`. Each output is identical and independent.

Functionality

This component establishes a passive coupling between the socket `IN` and the nine plugs `OUT1` to `OUT9`. Whenever the socket receives a valid AUDI data packet, it is forwarded unchanged to all nine plugs. No data modification, buffering, or time delay occurs. The component has no inherent behavior – it functions purely as a wiring aid for signal distribution.

Technical Features

- **Generic Implementation:** The function block (FB) carries the attribute `eclipse4diac::core::GenericClassName = 'GEN_AUDI_SPLIT'`, which allows it to be recognized as an instance of a generic split block and displayed correctly in tools with generic type support.
- **No Event Control:** Since no events are present, data transmission occurs purely via the adapter mechanisms of the target system (e.g., continuously or cyclically, depending on the runtime environment).
- **Scalability:** The number of outputs is fixed at nine. For other numbers, separate FB types (e.g., `AUDI_SPLIT_2`, `AUDI_SPLIT_4`, etc.) must be defined, or a parameterizable function block must be used.

State Overview

The function block has no internal state. Its behavior is completely static and defined solely by the forwarding of the signal. A state machine does not exist.

Application Scenarios

- **Distributing a measurement signal** to multiple parallel evaluation or control units.
- **Splitting a control command** to multiple actuators, provided they use the same AUDI protocol.
- **Test and simulation environments** where a generated signal needs to be sent to multiple observers (e.g., logging, visualization, control) simultaneously.
- **Replacing multiple copies** of a source function block when the source exists only once.

Comparison with Similar Function Blocks

Compared to a general-purpose `AUDI_MERGE` (which combines multiple inputs into one output) or a `AUDI_SELECT` (which switches between multiple inputs), the Split function block offers the exact opposite function: duplication instead of merging or selection. Compared to a custom, software-implemented split (e.g., by connecting an output multiple times in the application), the function block (FB) ensures a clean, typed, and reusable interface and avoids potential multiple connection errors in the editor.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AUDI_SPLIT_9` is a simple yet useful function block for duplicating audio signals. Its implementation as a generic type and the clear separation of input and nine outputs facilitate the development of modular automation solutions. Due to its static nature, it is particularly suitable for data flow-oriented applications where event control is not required.

AUI_CTD

• — ○ • — ○ • — ○ •

Introduction

The **AUI_CTD** is an event-driven down counter with adapter interfaces. It features **On-Change triggering**: The output signal **Q** is only updated when its logical state actually changes. This avoids unnecessary events and increases efficiency in event-driven systems.

Interface Structure

Event Inputs

Event	Description
CD	Count Down – reduces the counter value by 1.
LD	Load – loads the counter value **CV** with the preset value **PV**.

Event Outputs

Event	Description
CDO	Count Down Output – output after each CD step.
LDO	Load Output – output after a successful load.

Data Inputs

The FB has no direct data inputs. Instead, values are provided via the adapter interface **PV**.

Data Outputs

The FB has no direct data outputs. The current values of **CV** and **Q** are output via the respective adapter ports.

Adapter

Port	Type	Direction	Description

Q	`adapter::types::unidirectional::AX` (BOOL)	Plug	Status output: `TRUE`, if **CV** ≤ **0**.
CV	`adapter::types::unidirectional::AUI` (INT)	Plug	Current counter value.
PV	`adapter::types::unidirectional::AUI` (INT)	Socket	Preset value loaded into **CV** during the LD event.

Functionality

1. **Count Down (CD)**

Each **CD** event decrements **CV** by 1 and sets **Q** to `TRUE` if **CV** ≤ **0**. **CDO** is then output.

1. **Load (LD)**

An **LD** event copies the value from **PV** to **CV**. **Q** is updated accordingly (TRUE if **CV** ≤ **0**). Then, **LDO** is output.

1. **On-Change Triggering**

The function block (FB) compares the current **Q** value with the stored predecessor value **Q_OLD**. The adapter event **Q.E1** is only triggered if **Q** has changed. Otherwise, the FB returns directly to its initial state. This prevents repeated identical messages.

1. **PV Changes**

When the **PV** adapter reports (event **PV.E1**), **Q** is recalculated (using the **UPDATE** algorithm). Here too, **Q** is only output when there is a state change.

Technical Features

- **On-Change Triggering** – Reduces event load by activating the **Q** output only when changes actually occur.
- **Adapter Interface** – Enables loose coupling and reuse in complex control structures.
- **Initial Value** – **Q_OLD** is initialized with `FALSE`, so that a change is detected on the first iteration if **CV** is already ≤ 0.

State Overview

The process is controlled by the following ECC states:

State	Description	Actions
START	Waits for incoming events (CD, LD, PV.E1).	–
CD	Executes the countdown algorithm.	`CD (CV--, Q aktualisieren), CV.E1, CDO`
LD	Loads **PV** into **CV**.	`LOAD (CV:=PV; Q aktualisieren), CV.E1, LDO`
UPDATE_PV	Recalculates **Q** when **PV** changes.	`UPDATE (Q aus CV berechnen)`
EMIT_Q	Saves the current **Q** value and triggers **Q.E1**.	`SAVE_Q (Q_OLD:=Q), Q.E1`

Transitions:

- After **CD**, **LD**, or **UPDATE_PV**, the system only switches to **EMIT_Q** if `Q.D1 ≠ Q_OLD` is present.
- If the values are equal (`Q.D1 = Q_OLD`), the system immediately returns to **START** without triggering **Q.E1**.
- From **EMIT_Q**, the system always switches back to **START**.

Application Scenarios

- **Material Counter** in Conveyor Systems: **CD** is triggered for each part that leaves the station. As soon as **CV** ≤ **0**, a replenishment request is sent.

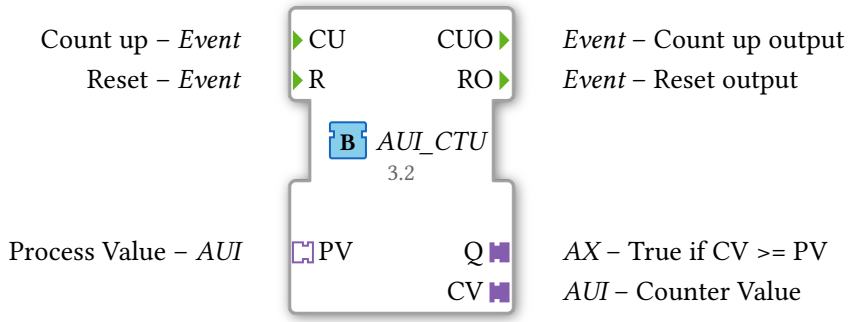
- **Cycle Control** for Repeated Processes: The counter runs from a starting value (loaded via **LD**) to zero and then triggers an action.
- **Event-optimized systems** with many parallel counters: Thanks to on-change triggering, only relevant status changes are reported.

Comparison with similar function blocks

Function block	Special feature	Difference to AUI_CTD
E_CTD	Standard down counter without adapters	Uses direct data inputs/outputs and no adapters. No on-change triggering.
E_CTUD	Up/down counter	Offers both counting directions, but without adapters and without on-change.
AUI_CTU	Up counter with adapters	Counts upwards, analog adapter structure, also on-change.

The **AUI_CTD** fills the gap of a specialized down counter with more modern adapter concepts and reduced event volume.

Conclusion



The **AUI_CTD** is a powerful down counter for IEC 61499-compliant controllers. Its combination of adapter interfaces and on-change triggering makes it particularly suitable for modular, resource-efficient automation solutions. Its behavior is deterministic and can be easily traced via the ECC. This makes it an ideal choice for applications requiring reliable and efficient counter functionality with minimized event communication.

]

AUI_CTU

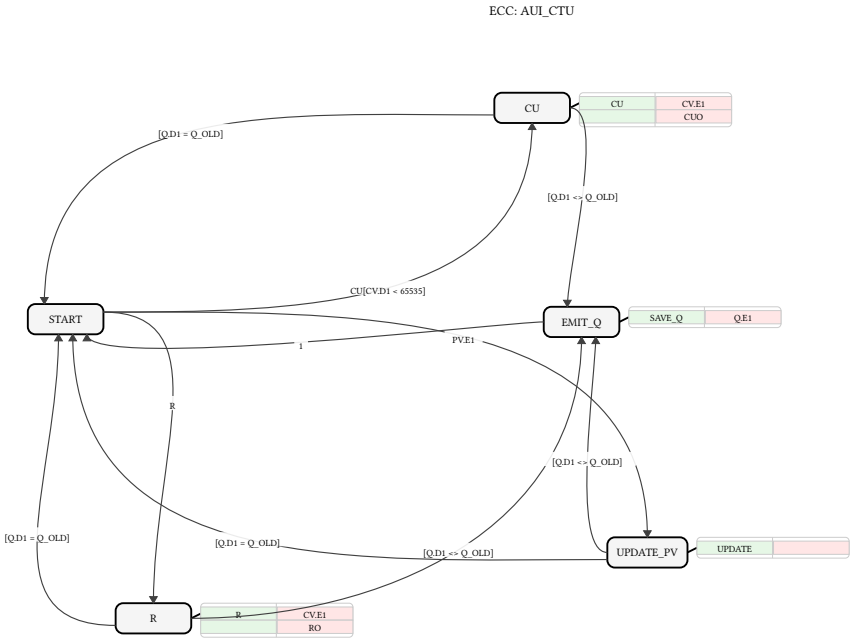

Image of function block not available

• — ○ • — ○ • — ○ •

Introduction

The AUI_CTU is an event-driven up counter with an adapter interface. It increments the counter on every positive edge event at input `CU` and outputs the count via adapter `CV`. The output `Q` indicates whether the counter value (`CV`) has reached or exceeded the set limit (`PV`). The special feature of this implementation is the “On-Change” triggering: The event on the adapter `Q.E1` is only triggered if the logical state of `Q` actually changes. This reduces unnecessary events in subsequent processing.

Interface Structure

Event Inputs

Name	Type	Comment
`CU`	Event	Count Up
`R`	Event	Reset

Event Outputs

Name	Type	Comment
`CUO`	Event	Output after successful increment
`RO`	Event	Output after successful reset

Data Inputs

Direct data inputs are not available. The limit value (`PV`) is provided via an adapter socket.

Data Outputs

Direct data outputs are not available. The current counter value (`CV`) and the comparison status (`Q`) are output via adapter plugs.

Adapters

Type	Direction	Name	Description
adapter::types::unidirectional::AX	Plug (Output)	Q	Outputs TRUE if CV >= PV, otherwise FALSE. The event Q.E1 is only sent on state changes.
adapter::types::unidirectional::AUI	Plug (Output)	CV	Returns the current counter value (unsigned integer). The event CV.E1 is triggered after each increment or reset.
adapter::types::unidirectional::AUI	Socket (Input)	PV	Receives the threshold value of type UINT. Changing this value automatically recalculates Q.

Functionality

This function block implements a finite state machine (ECC) with the following algorithms:

- **CU**: Increments the internal counter CV by 1 and then calculates Q := (CV >= PV).
- **R**: Sets CV to 0 and recalculates Q.
- **UPDATE**: Calculates Q from the current CV and the (modified) PV, without changing the counter.
- **SAVE_Q**: Stores the current value of Q in the internal variable Q_OLD for the next state change detection.

Process:

1. **Event CU** (and CV < 65535): Transition to state CU. The counter is incremented, Q is recalculated, and CV.E1 and the event CUO are output.

- If Q has changed compared to the last stored value (Q_OLD), the state changes to EMIT_Q.
- Otherwise, the function block returns to state START.

1. **Event R**: Transition to state R. The counter is reset, Q is recalculated, and CV.E1 and RO are output. Then, analogous to CU, a decision is made whether to reach EMIT_Q or return to START.
2. **Adapter event PV.E1** (limit change): Transition to state UPDATE_PV. The algorithm UPDATE recalculates Q. Here too, the state EMIT_Q is only traversed when Q changes.
3. **State EMIT_Q**: Executes the algorithm SAVE_Q (stores the new Q value in Q_OLD) and sends the event Q.E1. Afterward, the function block always returns to START.
4. **State EMIT_Q**: Executes the algorithm SAVE_Q (stores the new Q value in Q_OLD) and sends the event Q.E1.

The function block then always returns to START.

Technical Features

- **On-Change Triggering for Adapter Q**: The event Q.E1 is only triggered when the logical value of Q (true/false) changes. This is achieved through the internal status variable Q_OLD. This prevents unnecessary event flooding in the application.
- **Automatic Response to Threshold Change**: If the threshold value supplied via socket PV changes, Q is immediately recalculated and output upon change. The counter itself remains unaffected.
- **Overflow Protection**: The counter is only incremented if CV is less than 65535 (maximum value of UINT). Further incrementing beyond this value is not possible.
- **Adapter-Based**: Instead of classic direct inputs/outputs, all values are exchanged via standardized adapters. This allows for easy integration into existing 4diac adapter concepts.

State Overview

State	Description	Actions	Outgoing Transitions
START	Idle state, waiting for events	–	CU ⟶ CU, R ⟶ R, PV.E1 ⟶ UPDATE_PV
CU	Count up	CU algorithm, send CV.E1 and CUO	[Q != Q_OLD] ⟶ EMIT_Q, [Q == Q_OLD] ⟶ START

R	Reset	R algorithm, send CV.E1 and RO	[Q != Q_OLD] ⟶ EMIT_Q, [Q == Q_OLD] ⟶ START
UPDATE_PV	Recalculation after PV change	UPDATE algorithm	[Q != Q_OLD] ⟶ EMIT_Q, [Q == Q_OLD] ⟶ START
EMIT_Q	Emission of the Q event	SAVE_Q algorithm, send Q.E1	1 ⟶ START

The transitions are triggered by conditions:

- CU[CV.D1 < 65535]: CU event if the counter is not at its maximum.
- R: R event, always possible.
- PV.E1: Event from the PV adapter.
- [Q.D1 <> Q_OLD] / [Q.D1 = Q_OLD]Comparison of the current Q with the stored previous value.

Application Scenarios

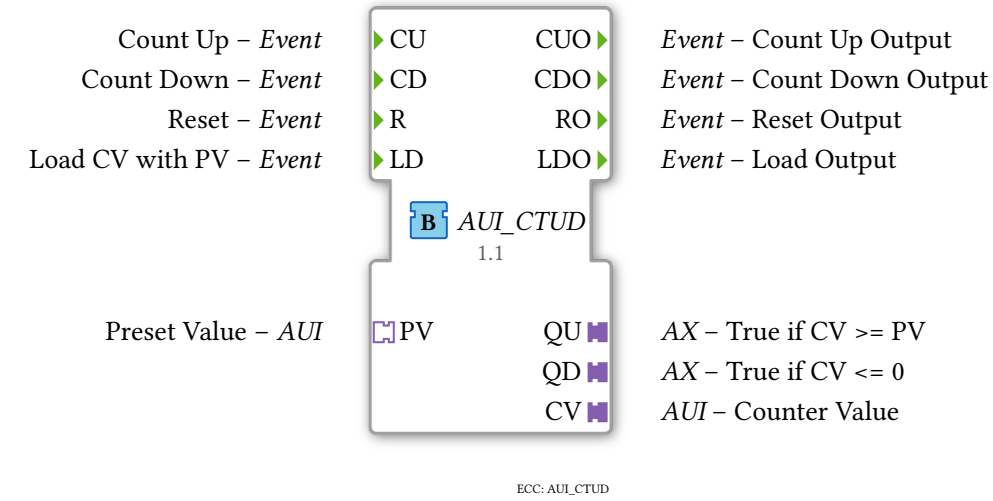
- **Event Counter with Threshold Monitoring**: Counting pulses (e.g., workpieces on a conveyor belt) and triggering an action as soon as a specific threshold is reached.
- **Level Monitoring**: Used as a limit switch that transmits a status when a setpoint is exceeded.
- **State-Dependent Controls**: E.g., in batch processing where a process step should be triggered after a certain number of steps.
- **Systems with Dynamic Threshold**: The threshold can be changed during operation via the adapter PV; the function block reacts automatically.

Comparison with Similar Function Blocks

Feature	AUI_CTU	Standard CTU (IEC 61131-3)	CTUD (Up/Down Counter)
Interface	Adapter-based	Direct Inputs/Outputs	Direct Inputs/Outputs
Event on Q Change	Yes (On-Change)	No (Always on Counting Event)	No
Response to PV Change	Automatic	Not Provided	Not Provided
Overflow Protection	Yes (max. 65535)	Yes, via configuration	Yes
Down Count	No	No	Yes

The AUI_CTU is specifically optimized for event-driven systems with an adapter concept. On-change triggering and automatic PV recalculation are key differences compared to traditional meters.

Conclusion



The AUI_CTU is a modern, adapter-based up-meter that stands out for its efficient event handling. Thanks to on-change triggering for the status Q, unnecessary messages in the system are avoided. Support for dynamic limits via the PV adapter increases flexibility in control applications. The module is robust against overflows and offers a clear, state-driven flow structure. It is particularly well-suited for distributed automation systems where loose coupling and event-driven communication are paramount.

AUI_CTUD

ECC: AUI_CTUD

• – ○ • – ○ • – ○ •

Introduction

The function block **AUI_CTUD** is an event-driven up/down counter in the adapter version. It is based on the standard function block E_CTUD and extends it with “On-Change” triggering for the output states. The counter value (CV), the preset value (PV), and the comparison results (QU, QD) are exchanged with other function blocks via the adapter interfaces. The function block is intended for use in IEC 61499 applications where loose coupling via adapters is desired.

Interface Structure

Event Inputs

Event	Description
CU	Increment counter by 1 (Count Up)
CD	Decrease counter by 1 (Count Down)

R	Reset counter to 0 (Reset)
LD	Load counter with preset value (PV) (Load)

Event Outputs

Event	Description
CUO	Acknowledgement of successful count-up operation
CDO	Acknowledgement of successful count-down operation
RO	Acknowledgement of successful reset
LDO	Acknowledgement of successful load operation

Data Inputs

This function block does not have direct data inputs. The preset value (PV) is provided via a **socket adapter**:

Adapter (Socket)	Type	Description
PV	`adapter::types::unidirectional::AUI`	Preset value (preselection) for the counter

Data Outputs

This function block does not have direct data outputs. The results are output via **Plug Adapters**:

Adapter (Plug)	Type	Description
QU	`adapter::types::unidirectional::AX`	True if the current counter value is ≥ PV
QD	`adapter::types::unidirectional::AX`	True if the current counter value is ≤ 0
CV	`adapter::types::unidirectional::AUI`	Current Counter Value (Unsigned Integer)

Adapters

This function block defines three plug adapters (QU, QD, CV) and one socket adapter (PV). The adapters are of type `adapter::types::unidirectional` and enable loose coupling between the function blocks – values are exchanged via events (e.g., `CV.E1`, `QU.E1`).

Functionality

This function block operates as an event-driven counter with a resolution of 0 to 65535 (maximum value for an unsigned 16-bit integer). The following sequence of steps is executed:

1. An **input event** (CU, CD, R, or LD) triggers a transition from the start state to the corresponding processing state.
2. **Calculation**: In each algorithm, the internal counter (`CV.D1`) is updated, and the output adapters QU and QD are recalculated:

- **CU**: `CV.D1 := CV.D1 + 1` (only if the previous value < 65535)
- **CD**: `CV.D1 := CV.D1 - 1` (nur, wenn der Wert vorher > was 0)
- **R**: `CV.D1 := 0`
- **LD**: `CV.D1 := PV.D1`
- Subsequently, `QU.D1 := (CV.D1 >= PV.D1)` and `QD.D1 := (CV.D1 <= 0)` are set.

1. **Counter Value Output**: After each value change, the event `CV.E1` is sent to propagate the new counter value via the adapter.

CU: ** ... 4. **On-Change Triggering**:

- After each counting operation or after a change to the PV (event from the PV adapter), the state of QU and QD is checked.

- The internal variables `QU_OLD` and `QD_OLD` store the previous state. Only if the value has changed is the corresponding adapter event (`QU.E1` or `QD.E1`) triggered.
- This behavior prevents unnecessary event flooding with constant threshold values.

1. **Processing of PV Changes**: An incoming event on the PV adapter (`PV.E1`) results in the state `UPDATE_PV`, in which only the comparison results are recalculated (without changing the counter). The on-change check is also performed afterward.

Technical Features

- **On-Change Triggering** (Change Detection): The module sends events to the output adapters only if the logical state has actually changed compared to the last iteration. This reduces the bus load and prevents infinite loops in cyclic systems.
- **Adapter-Based Communication**: All input and output values are exchanged via adapters (plug/socket), enabling flexible interconnection without fixed data connections. The counter value (CV) and the comparison results (QU, QD) are provided as plug adapters, while the preset value (PV) is supplied as a socket from external modules.
- **State Overflow Protection**: During count-up, the module checks whether the current value is less than 65535; during count-down, it checks whether it is greater than 0. This prevents overflows and underflows.
- **Two internal state variables**: `QU_OLD` and `QD_OLD` serve as shadow registers for change detection.
- **Extended ECC**: After each counting operation, the function block cycles through a sequential chain of states (e.g., CU → CHECK_QU → CHECK_QD → START) to ensure change detection.

State Overview

State	Description
START	Waiting for an input event (CU, CD, R, LD) or a PV change
CU	Increment counter and output new value via CV adapter
CD	Decrement counter and output new value via CV adapter
R	Reset counter to 0 and output new value via CV adapter
LD	Load meter with PV and output new value via CV adapter
UPDATE_PV	Recalculate QU and QD after PV change (without meter change)
CHECK_QU	Check if QU has changed (comparison with QU_OLD)
FIRE_QU	If QU has changed: Update QU_OLD and send event to QU adapter
CHECK_QD	Check if QD has changed (comparison with QD_OLD)
FIRE_QD	If QD has changed: Update QD_OLD and send event to QD adapter

The state transitions are controlled by the events and conditions `[QU.D1 <> QU_OLD]` and `[QD.D1 <> QD_OLD]`. After change detection is complete, the function block returns to the START state.

Application Scenarios

- **Counters with External Preset**: In a system, the preset value (PV) can be dynamically set by a higher-level system or an HMI via the PV adapter. The function block then counts events and reports when the thresholds are reached or fallen below via the QU and QD adapters.
- **Direction-Dependent Counters**: By using CU and CD, a forward/reverse counter can be implemented, e.g., for position detection or inventory counting.
- **Event-Driven Limit Monitoring**: The on-change triggering of QU and QD is ideally suited for sending a discrete signal (e.g., "fill level reached") only when a state changes – similar to an edge detector.

– **Modular Control Architecture**: Thanks to the adapter interface, the function block can be integrated into an existing IEC 61499 application without fixed data port wiring. The logical connection is established solely via the adapter runtime environment.

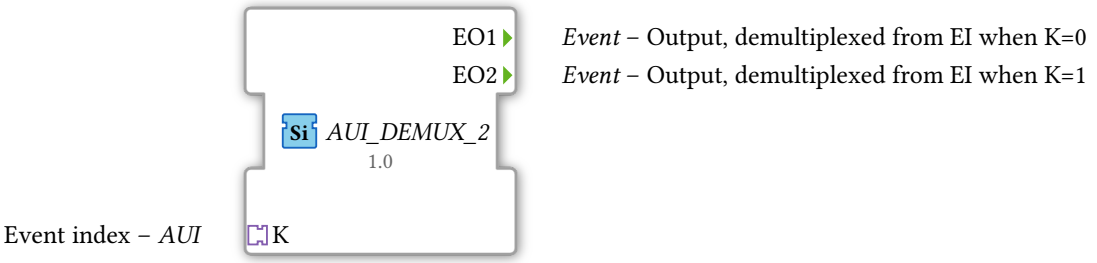
Comparison with Similar Function Blocks

The standard function block **E_CTUD** (from the IEC 61499 library) also offers an up/down counter with event control, but with the following features:

Feature	**E_CTUD** (Standard)	**AUI_CTUD** (Adapter Version)
Interface	Fixed event and data ports (e.g., CV as BOOL)	Loose coupling via adapter (plug/socket)
Output: Counter value	Data port: CV (INT/UDINT)	Adapter CV (Type AUI)
Limit output	Bool ports QU, QD	Adapter QU, QD (Type AX)
Event on change	No change detection; QU/QD are calculated with each count	On-change triggering: Event only on state change
Feedback on actions	No dedicated feedback events	CUO, CDO, RO, LDO as confirmation events

The AUI_CTUD is therefore more flexible in its interconnection and reduces the event load in distributed systems. For simple applications without adapters, however, the standard E_CTUD may suffice.

Conclusion



The **AUI_CTUD** function block represents a modern, adapter-based variant of an up/down counter. The on-change triggering of the limits and the feedback via dedicated event outputs are particularly noteworthy. The use of adapter interfaces enables loose coupling and reusability in a wide variety of control projects. Integrated overflow/underflow protection and the clean separation of counting and evaluation logic make it a robust component for industrial automation applications.

AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

AUI_DEMUX_2 is a generic event demultiplexer function block that routes an incoming event to one of two output event ports based on an index value received through an AUI (Adapter Unified Interface) adapter. It is the adapter-based variant of the standard E_DEMUX_2 block, replacing the conventional event input and data input pair with a single unidirectional AUI adapter. This design allows the event trigger and the selection index to be delivered together as a cohesive bundle, simplifying composition and promoting type-safe connections in IEC 61499 systems.

Interface Structure

The block features a minimal interface consisting solely of two event outputs and one adapter socket. No separate event inputs or data inputs/outputs are present, as all incoming information arrives via the AUI adapter.

Event Inputs

None. The triggering event is received through the AUI adapter socket “K”.

Event Outputs

Name	Type	Comment
EO1	Event	Output, demultiplexed from EI when K=0
EO2	Event	Output, demultiplexed from EI when K=1

Data Inputs

None. The selection value is conveyed through the adapter.

Data Outputs

None.

Adapters

Name	Type	Direction	Comment
K	adapter::types::unidirectional::AUI	Socket	Event index used for demultiplexing

Functionality

The block operates as a two-way event demultiplexer. When an event arrives through the AUI adapter K, the associated index value carried by the adapter is evaluated:

- If the index value equals 0, the event is propagated to output **EO1**.
- If the index value equals 1, the event is propagated to output **EO2**.

The AUI adapter bundles an event trigger with a data value, enabling the selection criterion to be delivered atomically with the event itself. This ensures that the demultiplexing decision is always based on the most current index value synchronized with the triggering event.

Technical Features

- **Generic FB**: Declared with the generic class name `GEN_E_DEMUX`, allowing the compiler/runtime to instantiate it with the appropriate underlying implementation.
- **Adapter-based input**: The single AUI socket replaces the traditional separate event input (EI) and data input (K) of the standard E_DEMUX_2 block.
- **Type-safe connections**: The adapter type enforces correct wiring at design time, preventing mismatched event/data pairs.
- **Two-way demultiplexing**: Supports exactly two distinct output paths based on a binary index.
- **Unidirectional adapter**: The AUI (adapter types::unidirectional::AUI) socket is of the unidirectional kind, meaning data flows in one direction only (into the FB).

State Overview

AUI_DEMUX_2 does not maintain internal state. It is a purely combinatorial event router:

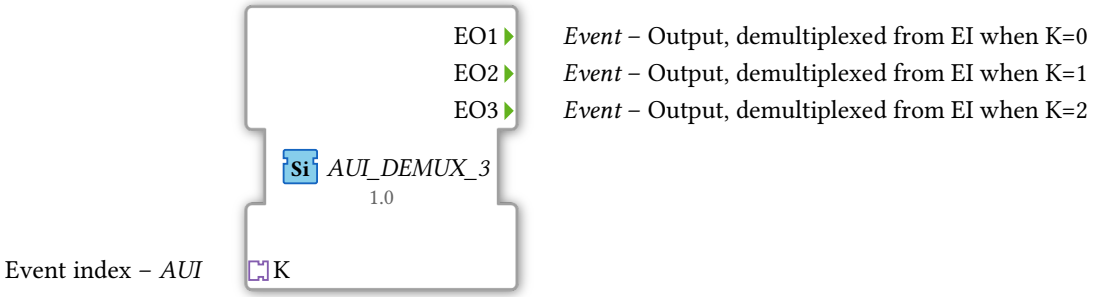
- On adapter event arrival with index = 0 ⟶ EO1 fires.
- On adapter event arrival with index = 1 ⟶ EO2 fires.

No internal variables, timers, or memory are used; the behavior is fully deterministic and stateless.

Application Scenarios

- **Event routing in automation chains**: Distributing a single trigger to different processing branches depending on a mode or selector value.
- **Mode switching**: Selecting between two alternative algorithms or control strategies based on a command index.
- **Multiplexed communication**: Demultiplexing incoming events from a unidirectional AUI-based communication channel into separate functional paths.
- **Structured composition**: Used in systems where adapters are preferred over raw event/data pairs for cleaner, more maintainable type-safe connections.

Comparison with Similar Blocks



Feature	AUI_DEMUX_2	E_DEMUX_2 (standard)
Input style	Single AUI adapter socket	Separate EI (event) + K (data)
Selector	Via adapter data	Via data input K
Outputs	EO1, EO2	EO1, EO2
Generic nature	Yes (GEN_E_DEMUX)	No (fixed type)
Wiring complexity	Reduced (one connection)	Higher (two connections)
Type safety	Enhanced via adapter contract	Manual, type-checked per pin

The primary advantage of AUI_DEMUX_2 over E_DEMUX_2 is the consolidation of event and selector into a single adapter interface, which reduces wiring overhead and enforces a consistent data/event pairing at the type level.

Conclusion

AUI_DEMUX_2 provides a clean, adapter-based solution for two-way event demultiplexing in IEC 61499 systems. By leveraging the AUI adapter pattern, it simplifies interface design, improves type safety, and reduces connection count compared to its classical counterpart. It is particularly well suited for modern, modular automation architectures where adapters are the preferred means of interconnecting function blocks.

AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

The `AUI_DEMUX_3` is an event demultiplexer function block that routes an incoming event to one of three possible event outputs based on a select index. Unlike a conventional demultiplexer (e.g., `E_DEMUX`), the selection information is not provided through a separate data input but via an AUI (Adapter for Unified Interaction) socket. This allows the select value and the triggering event to be delivered together through a single adapter interface, simplifying wiring and enabling a generic, reusable pattern for event routing.

This block is designed for use in IEC 61499-1 Annex A compliant systems and is intended for scenarios where an event needs to be distributed to different downstream function blocks depending on a runtime-available code or identifier.

Interface Structure

Event Inputs

None. The demultiplexing trigger is received via the AUI adapter socket `K`. The adapter encapsulates both the event that initiates the demultiplexing and the index value that determines which output is activated.

Event Outputs

Output	Type	Comment
`EO1`	Event	Output event when the select value `K` equals `0`

EO2	Event	Output event when the select value K equals 1
EO3	Event	Output event when the select value K equals 2

Data Inputs

None.

Data Outputs

None.

Adapters

Adapter	Type	Direction	Comment
K	adapter::types::unidirectional::AUI	Socket	Provides the select index and the triggering event. The AUI adapter typically carries an event and an integer data value that is used to select one of the three outputs.

Functionality

The AUI_DEMUX_3 block waits for an event to arrive through the adapter socket K. When that event occurs, the block reads the integer value associated with the adapter. The value is used as an index to determine which of the three event outputs shall be issued:

- If the value is 0, EO1 is triggered.
- If the value is 1, EO2 is triggered.
- If the value is 2, EO3 is triggered.

If the value is not one of these three valid indices, no output event is generated (the event is ignored). The block operates in a purely event-driven manner; it does not store any internal state or maintain the selection between invocations.

Because the select index and the triggering event are delivered together via the adapter, the block can be used as a building block for more complex event-routing networks without requiring additional data connections or manual synchronization.

Technical Features

- **Adapter-Based Input**: The select index and event are packaged into an AUI adapter, promoting a clean interface and reducing the number of separate pins.
- **Generic Implementation**: The block is annotated as a generic function block (eclipse4diac::core::GenericClassName = 'GEN_E_DEMUX'). This indicates that the same logic can be instantiated with different adapters or select ranges, although the current façade is fixed to three outputs.
- **No Internal State**: The block is stateless; each invocation is independent and does not depend on previous calls.
- **Standard Compliance**: Conforms to the IEC 61499-1 Annex A event-driven model.

State Overview

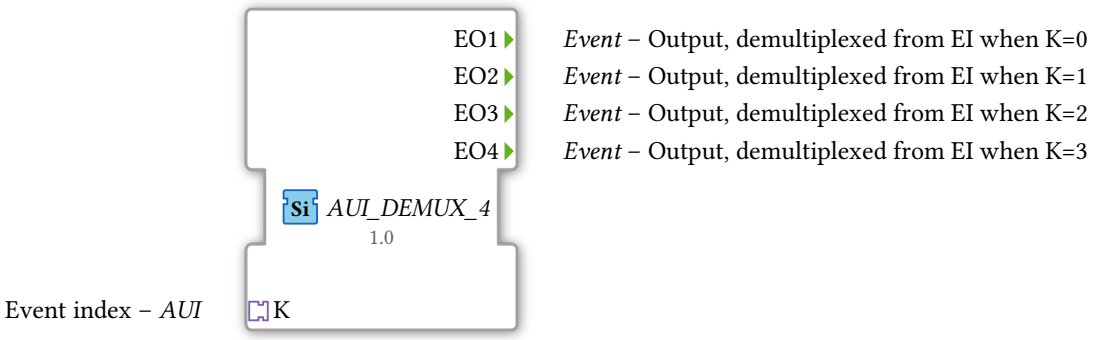
AUI_DEMUX_3 does not maintain any internal state machine. Its behavior is entirely combinational in the event domain: a single event arrives through the adapter, and based on the accompanying data value, exactly one of the three output events is emitted. There are no idle⟶active transitions or persistent memory elements. This makes the block easy to reason about and suitable for high-throughput event-handling applications.

Application Scenarios

- **Event Routing**: Distributing a single event to one of several processing units based on a runtime-selected channel ID.
- **Mode Selection**: Triggering different control actions depending on a mode number provided by a supervisor or a higher-level orchestration block.

- **Protocol Decoding**: In communication stacks, an incoming packet can be demultiplexed to the appropriate handler based on a header field.
- **Test and Simulation**: As a generic demultiplexer, it can be used to simulate different branches of an application by injecting events with configurable indices.

Comparison with Similar Blocks



Block	Input Type	Number of Outputs	Select Mechanism
`E_DEMUX`	Separate event input `EI` and data input `K`	Variable (2, 3, ...)	Standard data input
`AUI_DEMUX_3`	Adapter socket `K` (combines event + data)	Fixed to 3	AUI adapter

The primary difference is the interface. `AUI_DEMUX_3` consolidates the trigger and the selection into a single adapter, which can simplify system wiring and improve modularity. It also imposes a fixed number of outputs (here, three), whereas a generic `E_DEMUX` might be parameterized. However, the underlying demultiplexing behavior—selecting exactly one output based on an index—is identical.

Conclusion

The `AUI_DEMUX_3` function block provides a concise, adapter-based solution for event demultiplexing in IEC 61499 applications. By integrating the select index and the triggering event into a single AUI socket, it reduces connection complexity and enhances reusability. Its stateless, event-driven design fits well into modern automation and distributed control scenarios, and its generic annotation ensures that it can be adapted to various use cases. For systems requiring a clean separation between event triggering and routing logic, `AUI_DEMUX_3` is a recommended building block.

AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUI_DEMUX_4** function block is an event demultiplexer that routes incoming event triggers to one of four distinct output events based on an index value. Unlike the conventional E_DEMUX_4 block, which uses a separate plain event input and a data input for the selector index, this variant receives both the event trigger and the selector value through a single AUI adapter socket. This design reduces wiring complexity and improves interface encapsulation in distributed IEC 61499 applications. The block is implemented as a generic FB (GEN_E_DEMUX) and is part of the `adapter::events::unidirectional` package.

Interface Structure

The block provides a minimal interface that contains only event outputs and one adapter socket. There are no direct event inputs, data inputs, or data outputs — all incoming information is carried by the AUI adapter.

Event Inputs

None. The triggering event is delivered via the **K** adapter socket instead of a dedicated event input.

Event Outputs

Name	Description

EO1	Demultiplexed output, triggered when the index value K = 0
EO2	Demultiplexed output, triggered when the index value K = 1
EO3	Demultiplexed output, triggered when the index value K = 2
EO4	Demultiplexed output, triggered when the index value K = 3

Data Inputs

None.

Data Outputs

None.

Adapters

Name	Type	Description
K	`adapter::types::unidirectional::AUI` (Socket)	Event index adapter. Carries an event trigger together with the selector value (0–3) that determines which output is activated.

Functionality

The **AUI_DEMUX_4** block implements a 1-to-4 event demultiplexing function. The AUI adapter **K** encapsulates both an event signal and an index value. When an event arrives through the adapter, the block evaluates the accompanying index value and forwards the event to the corresponding output:

- Index **0** ⟶ event emitted on **EO1**
- Index **1** ⟶ event emitted on **EO2**
- Index **2** ⟶ event emitted on **EO3**
- Index **3** ⟶ event emitted on **EO4**

Only one output event is triggered per incoming event. The block acts as a pure event router — no data is transformed or stored, and no additional processing is performed.

Technical Features

- **Generic FB implementation**: Declared with `GenericClassName = 'GEN_E_DEMUX'`, making it a specialization of the generic E_DEMUX pattern within the 4diac framework.
- **Adapter-based event transport**: The combined event-and-index interface simplifies connections and improves reusability across different application contexts.
- **Unidirectional adapter**: The AUI adapter operates in one direction (socket side), suitable for producer-consumer event flows.
- **Deterministic routing**: The index-to-output mapping is fixed and immediate; no memory or state retention is involved in the routing decision.
- **Compliance**: Conforms to IEC 61499-1 Annex A identification and is distributed under the Eclipse Public License 2.0.

State Overview

The **AUI_DEMUX_4** block is essentially stateless in terms of routing logic. Its behavior can be described by a simple state model:

- **Idle State**: The block waits for an event to arrive on the **K** adapter.
- **Routing State**: Upon receiving an event, the index value is captured and the event is dispatched to the matching output (EO1–EO4). After emission, the block returns to the Idle State.

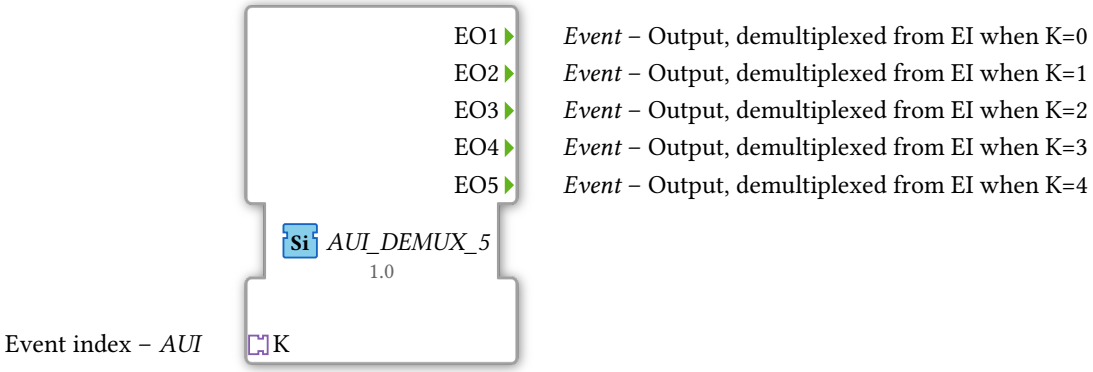
Since the block processes each event independently, there is no internal state that persists between activations.

Application Scenarios

- **Event distribution in modular control systems**: Use the block to route events from a single source to different consumers (e.g., state machines, processing stages) based on a dynamically changing selector.

- **Command dispatch**: In a machine control application, the AUI adapter can carry a command code (0–3) along with an execution trigger, directing the command to one of four sub-controllers.
- **Communication protocol handling**: When a received telegram contains a channel or service identifier, this block can forward the associated event to the appropriate protocol handler.
- **Reduced wiring in distributed setups**: By bundling event and index into a single adapter, connections between function blocks become cleaner and more maintainable, especially in large IEC 61499 system configurations.

Comparison with Similar Blocks



Feature	**AUI_DEMUX_4**	**E_DEMUX_4 (Standard)**
Event input	Via AUI adapter	Separate EI event input
Selector input	Part of adapter (index)	Separate K data input
Data inputs	None	1 (K)
Data outputs	None	None
Interface complexity	Reduced (fewer connections)	Higher (multiple separate pins)
Genericity	Generic FB (GEN_E_DEMUX)	Standard non-generic FB
Use case	Clean adapter-oriented designs	Classic flat wiring designs

The key advantage of the adapter variant is interface consolidation: event and index travel together, which improves modularity and reduces the risk of connection mismatches in complex applications.

Conclusion

The **AUI_DEMUX_4** function block provides a compact and elegant solution for event demultiplexing in IEC 61499-based systems. By integrating the event trigger and the selector index into a single AUI adapter, it simplifies the interface while preserving the deterministic routing behavior of a classic E_DEMUX. It is well suited for modular, adapter-centric control architectures where reducing wiring complexity and improving encapsulation are important design goals.

AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUI_DEMUX_5** function block is an event demultiplexer with a five-channel output structure. Instead of using a plain event input (EI) combined with a data selector (K), this block accepts its input through an **AUI adapter** (unidirectional application user interface). The block routes an incoming event to exactly one of five event outputs, based on the indexing value carried by the adapter. It is the adapter-based variant of the standard `E_DEMUX_5` block and is implemented as a generic FB (generic class name `GEN_E_DEMUX`).

Interface Structure

Event Inputs

There are no direct event inputs on this block. All event triggering and selection information is delivered through the **AUI adapter socket** named `K`. The adapter carries both the incoming event and the associated index value.

Event Outputs

Name	Type	Comment
EO1	Event	Output, demultiplexed from EI when K=0
EO2	Event	Output, demultiplexed from EI when K=1
EO3	Event	Output, demultiplexed from EI when K=2
EO4	Event	Output, demultiplexed from EI when K=3
EO5	Event	Output, demultiplexed from EI when K=4

Data Inputs

There are no direct data inputs. The selection value is embedded within the AUI adapter data channel.

Data Outputs

There are no data outputs.

Adapters

Name	Type	Direction	Comment
K	`adapter::types::unidirectional::AUI`	Socket	Event index (combines event input and selector data)

Functionality

The `AUI_DEMUX_5` block receives an event together with a selector index through the AUI adapter `K`. When an event arrives on the adapter's event channel, the block evaluates the accompanying index value and forwards the event to the corresponding output:

- If the index value is **0**, the event is emitted on `EO1`.
- If the index value is **1**, the event is emitted on `EO2`.
- If the index value is **2**, the event is emitted on `EO3`.
- If the index value is **3**, the event is emitted on `EO4`.
- If the index value is **4**, the event is emitted on `EO5`.

Exactly one output is triggered per incoming event; all other outputs remain inactive. This demultiplexing behavior enables the block to selectively activate different downstream logic branches based solely on the index provided through the adapter.

Technical Features

- **Adapter-based input:** Eliminates the need for a separate event input and data input pair, packaging both into a single `AUI` socket for cleaner interface design.
- **Unidirectional interface:** The adapter direction is unidirectional, meaning data and events flow only into the block.
- **Generic implementation:** Marked with the generic class name `GEN_E_DEMUX`, allowing the block to be instantiated with additional type information if required by the embedding application.
- **Five independent output channels:** Events are routed with a one-hot output pattern, which is straightforward to analyze and integrate into structured control logic.
- **No internal state:** The block operates purely combinatorially on the event transition; it retains no runtime data between events beyond the immediate routing decision.

State Overview

The AUI_DEMUX_5 block does not maintain any persistent internal states. Its behavior is instantaneous and deterministic:

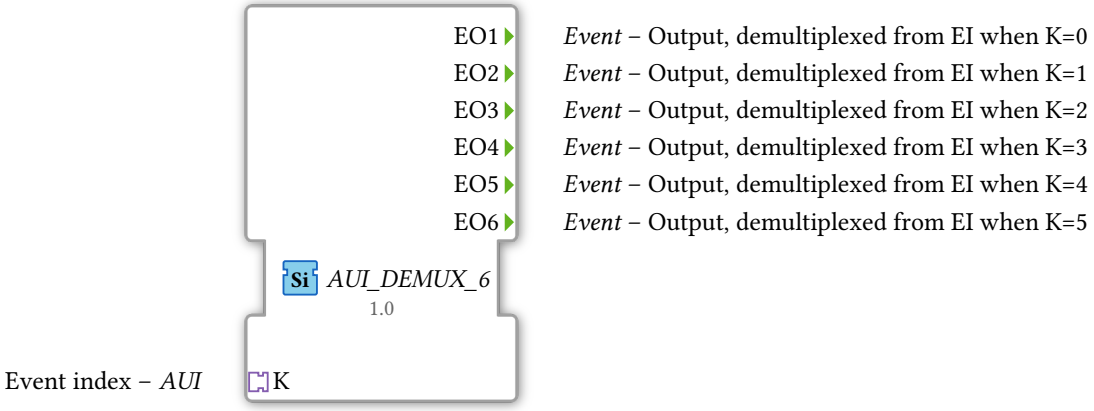
1. **Idle** – waiting for an event on the adapter.
2. **Routing** – upon event arrival, the index is evaluated and the matching output is triggered in the same execution cycle.

Because the block is stateless, it is inherently safe to use in multithreaded or event-driven IEC 61499 runtime environments without requiring synchronization measures.

Application Scenarios

- **Event stream splitting:** Distributing events from a single producer to one of several consumers based on a routing key.
- **Mode-based control:** Selecting between different operational modes (e.g., startup, normal, maintenance, shutdown) by routing the control event to the appropriate handler.
- **Protocol adaptation:** In communication stacks, demultiplexing incoming frames or messages to dedicated processing functions depending on the message type identifier carried in the adapter.
- **Test harnesses:** Building structured test sequences where a single test trigger can be directed to various test case blocks based on an index.

Comparison with Similar Blocks



Feature	AUI_DEMUX_5	E_DEMUX_5
Input interface	Single AUI adapter socket (event + index combined)	Separate event input (EI) and data input (K)
Interface complexity	Reduced – adapter encapsulates both signals	Explicit – requires two distinct connections
Suitability for structured models	Better for adapter-based design patterns	Simpler for flat FB networks
Index range	0–4 (five outputs)	0–4 (five outputs)
Event routing logic	Identical	Identical

The core demultiplexing logic is identical to that of E_DEMUX_5. The difference lies exclusively in the input packaging – the adapter approach promotes reusability and reduces wiring clutter when an AUI-based connection pattern is already established in the system architecture.

Conclusion

AUI_DEMUX_5 provides a clean, adapter-driven event demultiplexing solution with five outputs. Its integration of the event and index signal into a single AUI socket simplifies component interfaces and aligns well with modern, adapter-based IEC 61499 design practices. Being stateless and generic, it is a versatile building block for event routing in distributed automation and control applications.

AUI_DEMUX_6

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUI_DEMUX_6** is an event demultiplexer function block that routes an incoming event to one of six possible output channels based on a selector index. Unlike the conventional `E_DEMUX_6` block, which requires separate Event Input (`EI`) and control data input (`K`) pins, this variant encapsulates both the event trigger and the selector index within a single **AUI adapter socket**. The adapter delivers the activation event and the selector value together, making the block highly suitable for adapter-based composition patterns and hierarchical application design.

The block is implemented as a generic function block (`GEN_E_DEMUX`), allowing flexible reuse across different data types for the selector index.

Interface Structure

The block exposes six event outputs and one adapter socket. There are no direct event inputs, data inputs, or data outputs — all inbound information flows through the AUI adapter.

Event Inputs

No explicit event inputs are declared. The triggering event is received via the AUI adapter socket.

Event Outputs

Output	Description
`E01`	Demultiplexed output, activated when selector index = 0
`E02`	Demultiplexed output, activated when selector index = 1
`E03`	Demultiplexed output, activated when selector index = 2
`E04`	Demultiplexed output, activated when selector index = 3
`E05`	Demultiplexed output, activated when selector index = 4
`E06`	Demultiplexed output, activated when selector index = 5

Data Inputs

No data inputs are present. The selector value is supplied through the AUI adapter.

Data Outputs

No data outputs are present.

Adapters

Adapter	Type	Direction	Description
`K`	`adapter::types::unidirectional::AUI`	Socket	Provides the triggering event and the selector index used to determine the active output channel. The selector value is carried as data alongside the event within the adapter connection.

Functionality

The block operates as a 1-to-6 event demultiplexer. Upon receiving an event via the `K` AUI adapter socket, the block reads the accompanying selector value (the index carried by the adapter). The selector determines which of the six event outputs is fired:

- Index `0` ⟶ `E01`
- Index `1` ⟶ `E02`
- Index `2` ⟶ `E03`
- Index `3` ⟶ `E04`
- Index `4` ⟶ `E05`
- Index `5` ⟶ `E06`

Only one output event is generated per incoming event. If the selector value is outside the valid range `0..5`, no output is triggered. Since the selector and event arrive together via the adapter, the block guarantees synchronous handling of control and event data, eliminating the risk of race conditions between separate input pins.

Technical Features

- **Generic implementation**: Declared as a generic function block (`GEN_E_DEMUX`), allowing the selector data type to be instantiated appropriately for the application context.
- **Adapter-based interface**: Replaces the conventional separate event input and data input with a single AUI socket, simplifying connection diagrams and improving encapsulation.
- **Six-way demultiplexing**: Supports up to six distinct output channels.
- **Unidirectional AUI**: The adapter socket `K` is of unidirectional type, meaning the block acts purely as a sink for the event and selector data.
- **Deterministic behavior**: Exactly one output event is generated per incoming event, based on the current selector value.
- **Zero internal state retention**: The block does not store the selector value between events; each incoming event is evaluated independently.

State Overview

The block follows the typical demultiplexer state machine found in IEC 61499 event demultiplexers:

- **Start state**: The block is idle, waiting for an event to arrive on the AUI adapter.
- **Dispatch state**: Upon receiving the event, the selector value is evaluated and the corresponding output event is triggered.
- **Return state**: The block returns to the idle state, ready to process the next event.

There is no persistent internal state; the behaviour is fully event-driven and combinatorial with respect to the selector value.

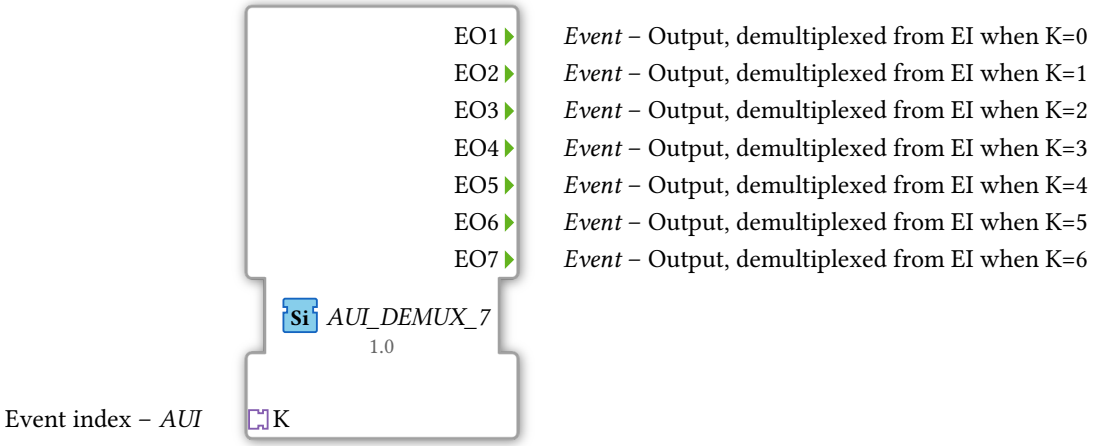
Application Scenarios

The `AUI_DEMUX_6` block is well suited for the following use cases:

- **Adapter-based control routing**: In applications where subsystems communicate through AUI adapters, this block can route events from one source to six different target components based on a control index carried in the same adapter connection.
- **Mode selection**: Selecting one of six operational modes by routing a “start” or “execute” event to the appropriate mode handler.
- **Data stream distribution**: Distributing data-triggered events (e.g. processing requests) to different processing units based on a priority or category index.
- **Hierarchical function block design**: Within composite FBs, the AUI socket keeps the internal interface clean and reduces the number of wires needed on the FB boundary.
- **Retrofitting existing designs**: The block provides a drop-in replacement for `E_DEMUX_6` in applications that already use AUI adapter architectures.

Comparison with Similar Blocks

Feature	`AUI_DEMUX_6`	`E_DEMUX_6`	`E_DEMUX` (generic)
Event input	Via AUI adapter	Separate `EI` pin	Separate `EI` pin
Selector input	Via AUI adapter (data channel)	Separate `K` data pin	Separate `K` data pin
Number of outputs	6 (`EO1`–`EO6`)	6 (`EO1`–`EO6`)	Configurable (3, 4, 6, etc.)
Adapter interface	Yes	No	No
Generic type	Yes (`GEN_E_DEMUX`)	No	Yes
Encapsulation	High — single connection	Low — two separate pins	Low — two separate pins



Suitability for adapter-based architectures	Excellent	Limited	Limited

Compared to the standard `E_DEMUX_6`, the AUI variant offers superior encapsulation by bundling event and selector data into a single connection. The trade-off is that it requires the surrounding system to support AUI adapter connections.

Conclusion

The **AUI_DEMUX_6** function block provides a clean, adapter-based approach to event demultiplexing in IEC 61499 applications. By integrating the event trigger and selector index into a single AUI socket, it simplifies interface design, enhances modularity, and supports generic instantiation. Its six output channels cover a wide range of routing and mode-selection use cases, making it a valuable building block for modern, adapter-oriented 4diac applications.

AUI_DEMUX_7

• – ◦ • – ◦ • – ◦ •

Introduction

AUI_DEMUX_7 is an event demultiplexer function block that routes a single incoming event to exactly one of seven mutually exclusive event outputs. It is an adapter-based variant of the standard `E_DEMUX_7` block: instead of exposing a separate event input (EI) and a data input (K), both the triggering event and the selector value are transported together through a unidirectional AUI adapter socket. This design reduces wiring complexity in modular IEC 61499 applications and enables clean encapsulation of event-triggered selection logic.

The block implements the generic class `GEN_E_DEMUX`, meaning that its behaviour follows the established demultiplexer pattern while its interface is expressed through the AUI adapter mechanism.

Interface Structure

The interface of AUI_DEMUX_7 consists exclusively of event outputs and one adapter socket. There are no plain data inputs or data outputs; all control information enters the block through the adapter.

Event Inputs

This block has no dedicated event inputs. The incoming event is carried by the AUI adapter `K`. The event arrives through the adapter's internal event channel and is demultiplexed internally.

Event Outputs

Name	Description
EO1	Output event, triggered when the selector K equals 0.
EO2	Output event, triggered when the selector K equals 1.
EO3	Output event, triggered when the selector K equals 2.

EO4	Output event, triggered when the selector K equals 3.
EO5	Output event, triggered when the selector K equals 4.
EO6	Output event, triggered when the selector K equals 5.
EO7	Output event, triggered when the selector K equals 6.

Data Inputs

None. All input data is encapsulated within the adapter.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Socket (Required)	K	`adapter::types::unidirectional::AUI`	Carries the input event and the demultiplexer selection value in one channel. The AUI adapter provides an event interface combined with associated data.

The adapter type `adapter::types::unidirectional::AUI` is part of the standard adapter library for unidirectional communication in 4diac. It bundles an event input together with the selector data, so the event and its associated select value arrive coherently.

Functionality

AUI_DEMUX_7 implements a 1-to-7 event demultiplexer. The functional behaviour is as follows:

1. An external module triggers an event on the AUI adapter connected to the socket `K`.
2. Simultaneously with that event, the adapter carries a selector value K (an integer in the range 0 to 6).
3. The block evaluates the selector value:
   - If K = 0 ⟶ the event is emitted on **EO1**.
   - If K = 1 ⟶ the event is emitted on **EO2**.
   - If K = 2 ⟶ the event is emitted on **EO3**.
   - If K = 3 ⟶ the event is emitted on **EO4**.
   - If K = 4 ⟶ the event is emitted on **EO5**.
   - If K = 5 ⟶ the event is emitted on **EO6**.
   - If K = 6 ⟶ the event is emitted on **EO7**.
4. Exactly one output is activated per input event. All other outputs remain inactive.

If the selector value is outside the valid range 0–6, no output is triggered (the event is dropped), or the behaviour follows the generic `GEN_E_DEMUX` specification.

The block is generic in the IEC 61499 sense: the attribute `eclipse4diac::core::GenericClassName` is set to `'GEN_E_DEMUX'`, which allows the 4diac runtime to treat this block as a specialisation of the generic demultiplexer implementation.

Technical Features

- **Adapter-based event transport:** The input event and selector travel together via a single AUI socket, avoiding the need for a separate event input and data input wiring.
- **Generic FB mechanism:** Declared as `GEN_E_DEMUX` through the `eclipse4diac::core::GenericClassName` attribute, enabling reuse of the generic demultiplexer behaviour.
- **Unidirectional adapter:** The AUI type is unidirectional, meaning the adapter only carries data from the plug to the socket (or vice versa, depending on orientation), simplifying the connection semantics.
- **Standard compliance:** The block is aligned with IEC 61499-1 (Annex A) identification and uses the standard 4diac adapter namespace `adapter::events::unidirectional`.
- **No external dependencies:** The block has no plain data outputs and no additional event outputs besides the seven demultiplexed channels.
- **License:** Distributed under the Eclipse Public License 2.0 (EPL-2.0).

State Overview

The internal execution control chart (ECC) of the generic `GEM_E_DEMUX` implementation follows a typical pattern for demultiplexers. Although this adapter variant does not expose its ECC in the Type definition (it relies on the generic class), the expected state behaviour is:

State	Description
IDLE	Waiting for an incoming event on the adapter's event channel. No output is active.
DECODE	The selector value K is read from the adapter and evaluated. This state is transient.
OUTPUT_1 … OUTPUT_7	One of these states is entered depending on the decoded K value. In each state, the corresponding event output (EO1 … EO7) is issued.

The transition from IDLE to DECODE is triggered by the adapter event. From DECODE, a conditional transition selects the matching output state based on K. After emitting the output event, the ECC returns to IDLE.

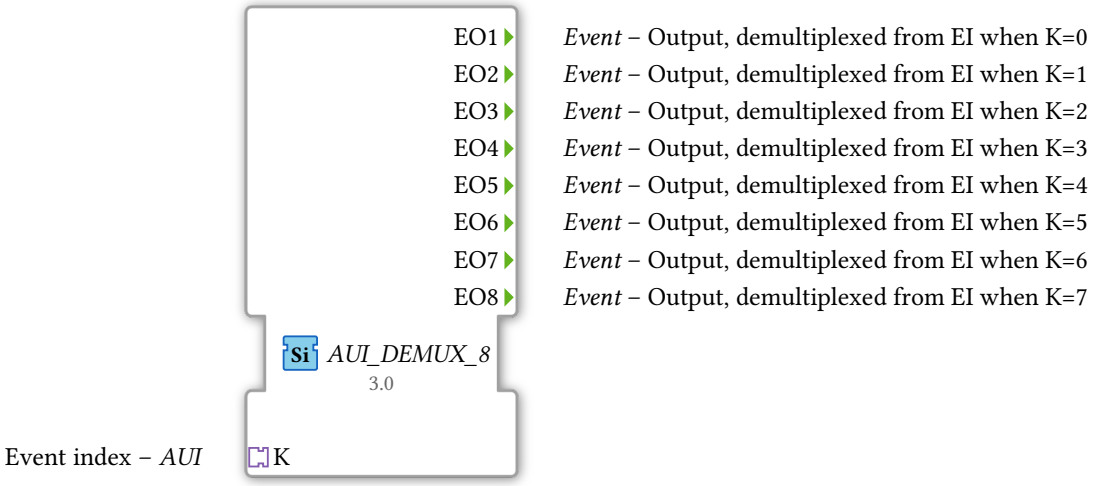
If K is outside the supported range, the ECC falls back to IDLE without emitting any event (or emits a default behaviour according to the generic implementation).

Application Scenarios

- **Event routing in modular automation systems:** When a single controller produces an event that must be forwarded to exactly one of seven downstream function blocks, AUI_DEMUX_7 provides a clean routing mechanism.
- **Mode-dependent processing chains:** The selector K can represent an operating mode (e.g., 0 = startup, 1 = normal, 2 = maintenance, …, 6 = error handling). The incoming event is then irrevocably channelled to the chain responsible for that mode.
- **Adapter-based subsystem interfaces:** In component-based designs where subsystems communicate via adapters, the AUI socket allows the demultiplexer to be plugged directly into a pre-existing adapter-based bus without additional event/data wiring.
- **Test and simulation environments:** Using the generic class mechanism, the block can be replaced or extended without changing its interface, which is useful for hardware-in-the-loop test benches.

Comparison with Similar Blocks

Feature	AUI_DEMUX_7	E_DEMUX_7 (standard)	E_DEMUX (generic, fewer outputs)
Input event	Via AUI adapter	Dedicated event input EI	Dedicated event input EI
Selector	Via AUI adapter (data channel)	Plain data input K	Plain data input K
Number of outputs	7	7	Variable (typically 2–N)
Interface style	Adapter-based, unidirectional	Event + data pins	Event + data pins
Wiring effort	Lower (single adapter connection)	Requires two connections (event + data)	Requires two connections
Reusability	High (generic mechanism)	Medium (fixed interface)	Medium (parameterised)



Compared to the classic `E_DEMUX_7`, the AUI variant reduces the external wiring footprint: only a single adapter connection is required at the input side. The disadvantage is that the selector value is no longer directly visible as a block pin, which can make debugging slightly less straightforward unless the adapter data is monitored.

Conclusion

AUI_DEMUX_7 is a compact and reusable event demultiplexer that combines an event input and a selector data input into a single AUI adapter connection. It is a generic, adapter-based specialisation of the well-

known E_DEMUX_7 and is suitable for IEC 61499 applications that favour modular, adapter-oriented design patterns. With seven mutually exclusive event outputs, it supports straightforward 1-to-N event routing, while its generic-class declaration ensures flexibility for different runtime implementations. The block is fully EPL-2.0 licensed and integrates seamlessly into the 4diac ecosystem.

AUI_DEMUX_8

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUI_DEMUX_8** is an event demultiplexer function block that routes an incoming event to one of eight possible output channels. Unlike a conventional E_DEMUX block, which requires a separate event input and a data input for the selection index, this block receives both the event trigger and the index value through a single unidirectional AUI adapter socket. This design simplifies wiring in distributed control applications by consolidating the event and its routing information into one adapter connection.

The block is implemented as a generic function block (GEN_E_DEMUX), allowing it to be parameterized and reused across different application contexts while maintaining a consistent demultiplexing behavior.

Interface Structure

Event Inputs

This function block has **no explicit event inputs**. The incoming event is received via the AUI adapter socket, which combines the event trigger and the routing index into a single connection.

Event Outputs

Name	Type	Comment
EO1	Event	Output, demultiplexed when K = 0
EO2	Event	Output, demultiplexed when K = 1
EO3	Event	Output, demultiplexed when K = 2
EO4	Event	Output, demultiplexed when K = 3
EO5	Event	Output, demultiplexed when K = 4
EO6	Event	Output, demultiplexed when K = 5
EO7	Event	Output, demultiplexed when K = 6
EO8	Event	Output, demultiplexed when K = 7

Each event output corresponds to one index value carried by the adapter, allowing the upstream event to be selectively forwarded to exactly one of the eight connected downstream blocks.

Data Inputs

This function block has **no data inputs**. The selection index is transmitted as part of the AUI adapter data, rather than through a standalone data port.

Data Outputs

This function block has **no data outputs**.

Adapters

Name	Type	Direction	Comment
K	adapter::types::unidirectional::AUI	Socket	Event index

The **K** socket is a unidirectional AUI adapter that provides the event trigger together with the index value (0–7). Because it is a socket, the block expects a matching plug from the partner component, typically an event source or a bus controller that supplies both the event and its destination index.

Functionality

The AUI_DEMUX_8 operates as a classic 1-to-N event demultiplexer, where N = 8. When the upstream component sends an event through the AUI adapter, the block extracts the accompanying index value and forwards the event to the corresponding output channel:

- If the index equals **0**, the event is emitted on **EO1**.
- If the index equals **1**, the event is emitted on **EO2**.
- ……
- If the index equals **7**, the event is emitted on **EO8**.

The demultiplexing decision is made solely from the index value carried by the adapter. The block requires no additional configuration parameters and does not retain state between events, making it a purely combinational routing element.

Because the block is a generic FB (GEN_E_DEMUX), the underlying implementation can be instantiated with different output counts or adapter variants depending on the application requirements, while the AUI_DEMUX_8 representation is fixed to eight outputs.

Technical Features

- **Eight output channels**: Supports routing to one of eight independent event destinations.
- **Adapter-based input**: The event and index are combined in a single unidirectional AUI adapter, reducing the number of connections and simplifying the interface.
- **Generic implementation**: The block is built on the GEN_E_DEMUX generic FB pattern, making it suitable for code generation and toolchain integration.
- **No internal state**: The routing decision is stateless, so the block does not require initialization or reset sequences.
- **Direct index mapping**: No ambiguity in routing — each index value has a dedicated output, and out-of-range indices are not generated by the upstream contract.

State Overview

The AUI_DEMUX_8 is a **stateless** function block. It does not contain an ECC (Execution Control Chart) state machine or maintain persistent internal variables. Every incoming event is processed independently:

1. An event arrives on the adapter K.
2. The index value is evaluated.
3. The corresponding output is triggered.
4. The block returns to its idle condition, ready for the next event.

This stateless behavior guarantees predictable and immediate response times, which is critical in time-sensitive control loops.

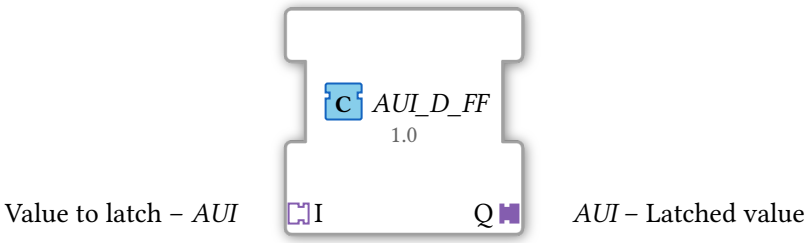
Application Scenarios

The AUI_DEMUX_8 is well suited for scenarios where a single event source must selectively activate one of several processing paths based on a routing index. Typical use cases include:

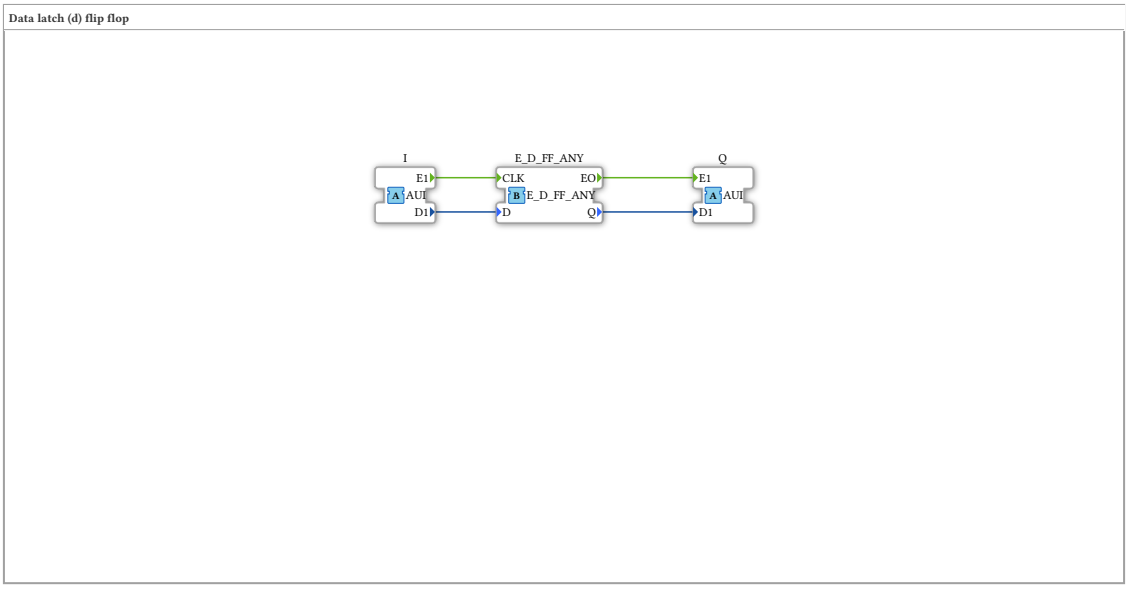
- **Multi-machine coordination**: Distributing a start command to one of eight machines or substations based on a machine identifier.

- **Mode-based routing**: Selecting one of eight operating modes, where the mode index determines which downstream FB receives the event.
- **Reconfigurable communication hubs**: Acting as a flexible event router in IEC 61499 distributed applications, especially when the index source is also an adapter-based block.
- **Reducing wiring complexity**: Replacing separate event and data connections with a single adapter link, which is particularly beneficial in modular or hot-pluggable systems.

Comparison with Similar Blocks



Feature	E_DEMUX (standard)	AUI_DEMUX_8
Event input	Separate EI port	Provided via AUI adapter
Selection index input	Separate K data port	Carried by AUI adapter
Number of outputs	Typically 2–8 (configurable)	Fixed to 8
Adapter-based connectivity	No	Yes (unidirectional AUI)
Genericity	Often generic	Generic (GEN_E_DEMUX)
Wiring complexity	Higher (two connections)	Reduced (one connection)



Compared to the traditional E_DEMUX, the AUI_DEMUX_8 provides a more compact interface by merging the event trigger and the routing index into one adapter. However, it requires both the source and sink to support the AUI adapter protocol, so it is most effective in systems already built around adapter-based communication.

Conclusion

The AUI_DEMUX_8 is a compact and efficient event demultiplexer that leverages a unidirectional AUI adapter to combine event triggering with index-based routing. Its eight outputs provide sufficient granularity for many industrial control and automation scenarios, while the stateless, generic implementation ensures reliable and predictable behavior. By reducing interface complexity and improving connection clarity, it is a valuable building block in modern IEC 61499-based distributed control systems.

AUI_D_FF

• – ○ • – ○ • – ○ •

Introduction

The function block **AUI_D_FF** implements a clock-controlled D flip-flop (data latch). It takes the value of a data input when an event occurs and outputs the stored value. The input and output interfaces are implemented as unidirectional **adapters**, enabling a flexible and standardized connection in the 4diac IDE.

Interface Structure

Event Inputs

None – event control is handled exclusively via the **I** adapter.

Event Outputs

None – event output is handled exclusively via the **Q** adapter.

Data Inputs

None – data transfer is handled exclusively via the **I** adapter.

Data Outputs

None – data output is exclusively via the **Q** adapter.

Adapters

Name	Type	Direction	Description
I	`adapter::types::unidirectional::AUI`	Socket (Input)	Input value (D) and clock event (CLK)
Q	`adapter::types::unidirectional::AUI`	Plug (Output)	Stored value (Q) and output event (EO)

The **AUI** adapter type provides a unidirectional channel that transmits exactly one event and one data value. Thus, the internal connections between the flip-flop and the outside world are implemented via adapters.

Functionality

The function block internally uses the function block `E_D_FF_ANY` from the IEC 61499 standard library.

- On each **clock event** on `I.E1`, the current data value is taken from `I.D1`.
- The taken value is made available at output `Q.D1`, and an **output event** is triggered simultaneously on `Q.E1`.
- The stored value is retained until a new clock event takes over a new data value.

Technical Features

- The interface consists exclusively of **adapters**, not separate event and data ports. This allows for loose coupling and reusability of the adapter type in different contexts.
- The adapter `AUI` is **unidirectional** – data and events flow in only one direction.
- The function block is type-safe: The data type is defined by the adapter (`ANY` by default).

State Overview

The function block has two logical states, corresponding to the internal flip-flop:

State	Description
Q = 0	Output value is LOW (logical 0).
Q = 1	Output value is HIGH (logical 1).

The state changes only on a rising edge of the clock event (provided the event is triggered in the adapter).

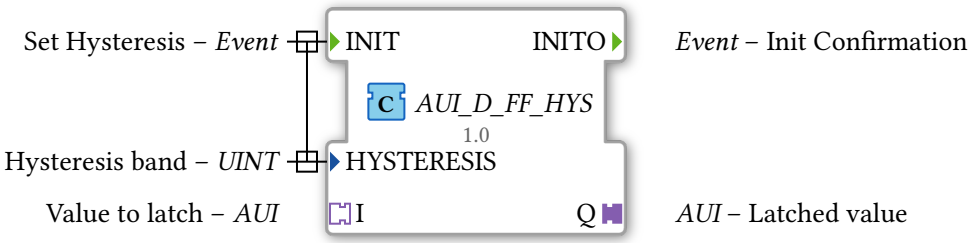
Application Scenarios

- **Synchronization**: Transfer of a data value at a precisely defined time (e.g., upon a sensor event).
- **Central Storage**: Buffering a value for further processing in subsequent components.
- **State Machines**: Storing states in discrete controllers when a simple D flip-flop function is sufficient.

Comparison with Similar Components

- **E_D_FF** (Standard IEC 61499): Offers the same flip-flop functionality, but with separate event and data ports. The `AUI_D_FF` encapsulates these ports in an adapter, enabling clean, adapter-based communication.
- **E_RS** or **E_SR** (Reset-Set Flip-Flops): Unlike the D flip-flop, these components require separate set/reset events and no clock signal. The `AUI_D_FF` is optimized for clock-driven applications.

Conclusion



The `AUI_D_FF` is a standards-compliant D flip-flop in the 4diac IDE that offers a modular and reusable interface through the use of **adapters**. It is particularly suitable for applications where a uniform, unidirectional connection structure is desired without having to forgo the proven flip-flop logic.

AUI_D_FF_HYS

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUI_D_FF_HYS` implements a data latch (D flip-flop) with a hysteresis function. It serves to reliably acquire an analog or digital value, suppressing small fluctuations (noise) through an adjustable hysteresis band. The block is designed for use in automation technology and complies with the IEC 61499-1 Annex A standard.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Sets the hysteresis width

Event Outputs

Event	Type	Comment
INITO	EInit	Initialization Confirmation

Data Inputs

Data	Type	Comment
HYSTERESIS	UINT	Hysteresis Band Width

Data Outputs

No dedicated data outputs; the latched value is provided via the `Q` adapter.

Adapters

Name	Type	Direction	Comment
I	adapter::types::unidirectional::AUI	Socket	Latch Value
Q	adapter::types::unidirectional::AUI	Plug	Latched Value

The adapters `I` and `Q` of type `AUI` (unidirectional) transport both data (e.g., `D1`) and associated events (e.g., `E1`).

Functionality

The component internally contains the instance `E_D_FF_ANY_HYS` (type `logiBUS::signalprocessing::hysteresis::E_D_FF_ANY_HYS`), which performs the actual latch with hysteresis. The signal flows are as follows:

- The event `I.E1` (from adapter `I`) is passed directly to the internal component as a clock signal (`CLK`).
- The data value `I.D1` is passed to the internal flip-flop as an input `D`.
- The hysteresis band is set via the parameter `HYSTERESIS`.
- The output of the internal component (`Q`) is routed to adapter `Q.D1`, and the output event (`EO`) is routed to `Q.E1`.
- The output of the internal component (`Q`) is routed to adapter `Q.D1`, and the output event (`EO`) is routed to adapter `Q.E1`.
- The data value `I.D1` is passed to the internal flip-flop as an input `D`.
- The output of the internal component (`Q`) is routed to adapter `EO`. - The event `INIT` is immediately passed through to `INITO` (no delay).

The hysteresis ensures that the latched value only jumps to the new input value if it differs from the currently stored value by more than the defined threshold (`HYSTERESIS`). This suppresses edge noise and unstable signal transitions.

Technical Features

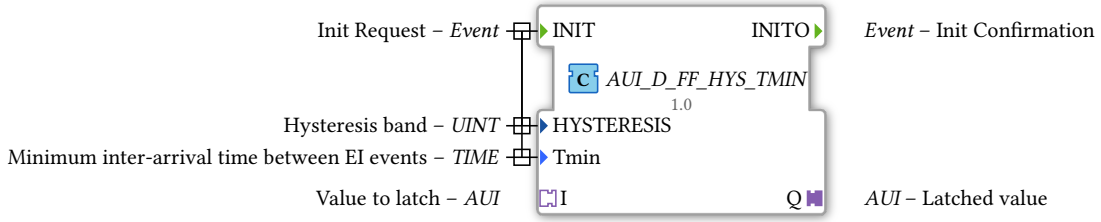
- The function block is a pure **composite function block** that delegates all logic to an internal instance.
- The hysteresis is passed as an unsigned integer (`UINT`).
- The adapters are unidirectional – data and events flow in only one direction (socket ⟶ plug).
- The function block does not contain its own state machine; the state is maintained in the internal flip-flop.

State Overview

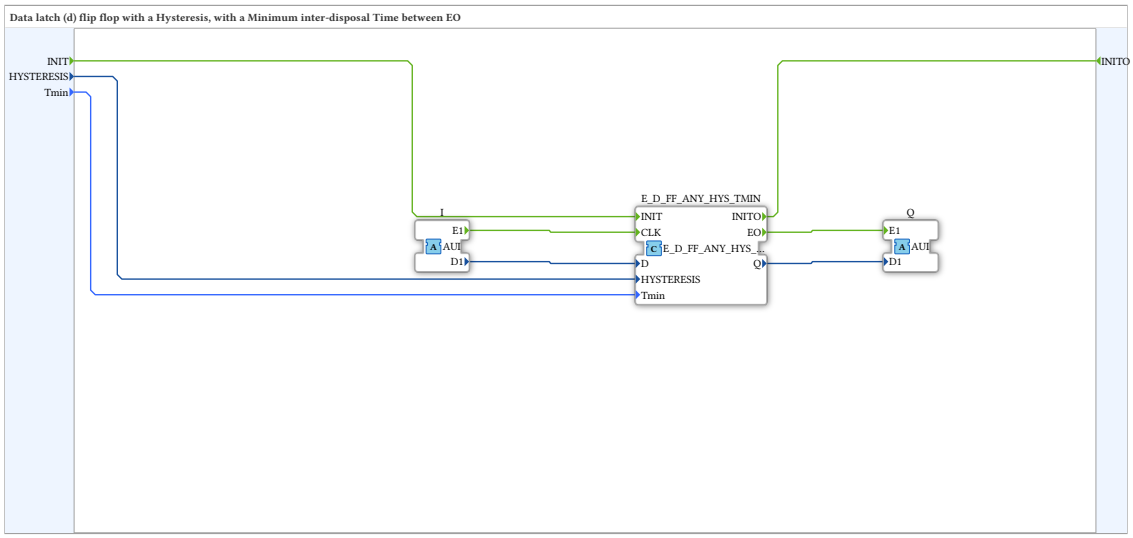
Since `AUI_D_FF_HYS` does not have its own ECC (Execution Control Chart), its behavior is determined solely by the internal component `E_D_FF_ANY_HYS`. A typical D flip-flop with hysteresis has two stable output states, which are switched by the applied clock signal and the hysteresis condition. A detailed state description can be found in the documentation for the internal component.

Application Scenarios

- **Sensor Data Debouncing**: Values from analog or digital sensors are stabilized with an adjustable hysteresis.
- **Threshold Switch**: The component can be used as a Schmitt trigger if an input value only changes its output above a defined upper threshold and below a defined lower threshold (determined by the hysteresis).
- **Signal Conditioning in Process Automation**: Noisy signals are smoothed before being passed to subsequent logic components.



Comparison with Similar Components



- **E_D_FF**: A pure D flip-flop without hysteresis. It adopts the input value on every clock edge, regardless of minimal fluctuations. `AUI_D_FF_HYS` offers improved noise immunity.
- **E_RS_BISTABLE**: A set-reset flip-flop without hysteresis and limited to binary states. `AUI_D_FF_HYS` operates with analog/integer values and allows for a dynamic threshold.
- **E_SPLIT_HYS**: A component that splits a signal with a fixed hysteresis. In contrast, the hysteresis in `AUI_D_FF_HYS` can be changed at runtime via the input `HYSTERESIS`.

Conclusion

The `AUI_D_FF_HYS` is a useful component for stable latching of values in environments with noise or signal instability. It combines the functionality of a D flip-flop with an adjustable hysteresis threshold and can be easily integrated into modular IEC 61499 controllers using adapters.

AUI_D_FF_HYS_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **AUI_D_FF_HYS_TMIN** is a data storage device (D flip-flop) with adjustable hysteresis and a minimum intermediate event time (`Tmin`). It is connected to other function blocks via adapter interfaces (socket `I` and plug `Q`). The internal core corresponds to function block `E_D_FF_ANY_HYS_TMIN` from the library `logiBUS::signalprocessing::hysteresis`. The initialization defines the parameters. Afterward, for each incoming event at input `I.E1`, the current value from `I.D1` is taken, filtered, and output via `Q.D1`.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization Request

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Acknowledgement

Data Inputs

Name	Type	Comment
HYSTERESIS	UINT	Hysteresis Band
Tmin	TIME	Minimum Intermediate Arrival Time of EI Events

Data Outputs

No standalone data outputs – the output value is transmitted via the `Q` adapter.

Adapter

Type	Name	Comment
`adapter::types::unidirectional::AUI` (Socket)	I	Value to be stored
`adapter::types::unidirectional::AUI` (Plug)	Q	Stored Value

The adapter `AUI` is a unidirectional type that bundles an event and a data value (`E1` and `D1`).

Functionality

1. **Initialization**

Upon the event `INIT`, the parameters `HYSTERESIS` (as UINT) and `Tmin` (as TIME) are passed to the internal module. After successful initialization, `INITO` is triggered.

1. **Operation**

The internal function block `E_D_FF_ANY_HYS_TMIN` operates as a clocked D flip-flop with hysteresis and a time limit:

- An event at `I.E1` (Clock) takes the current data value from `I.D1`.
- The taken value is only passed on as a valid output `Q.D1` if the interval to the last valid event is greater than or equal to `Tmin`.
- Additionally, the value is smoothed with a hysteresis (band `HYSTERESIS`): Small changes below the hysteresis threshold are suppressed.
- The output is signaled via the event `Q.E1`.

1. **Result**

The output adapter `Q` returns the last assumed, filtered value.

Technical Features

- **Hysteresis** in conjunction with a **minimum time between two events** prevents both noise and excessively rapid state changes.
- The function block is implemented as an **adapter wrapper** – it uses standardized unidirectional AUI adapters for input and output.
- The implementation delegates all logic to the function block `E_D_FF_ANY_HYS_TMIN`, which is universally designed for any data type. Here, it is used in the context of the AUI adapter.

State Overview

The function block does not have an explicit internal state machine. The behavior is represented by the internal function block:

- **Idle:** Waits for the next event on `I.E1`.
- **Sampling:** The data value is captured upon arrival of `I.E1`.
- **Filtering:** Checks against hysteresis and minimum time.
- **Output:** If successful, `Q.E1` is triggered and the new value is assigned to `Q.D1`.

Application Scenarios

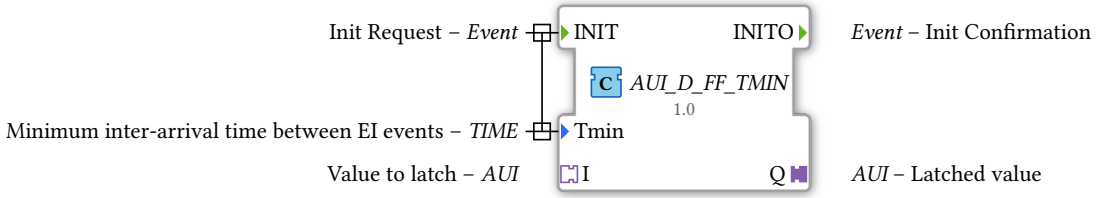
- **Sensor Value Acquisition** in agricultural technology (see Copyright HR Agrartechnik GmbH): Processing of analog or digital signals with debouncing and minimum sampling rate.
- **Control Components** in automation systems where noise suppression and a minimum pulse duration are required.
- **Data Logic** in distributed systems that must respond to asynchronous events with stability requirements.

Comparison with Similar Components

Component	Property
`E_D_FF`	Simple D flip-flop without hysteresis or time limit

`E_D_FF_HYS`	D flip-flop with hysteresis, but without `Tmin`
`E_D_FF_HYS_TMIN` (this FB)	Combines hysteresis *and* minimal time interval → more robust against noise and burst events

Conclusion



The `AUI_D_FF_HYS_TMIN` offers a compact and reliable solution for signal-processing data acquisition, suppressing unwanted interference pulses through hysteresis and time limiting. The adapter interface facilitates integration into existing 4diac projects using standardized, unidirectional AUI connections.

AUI_D_FF_TMIN

• – ○ • – ○ • – ○ • –

Introduction

The function block **AUI_D_FF_TMIN** implements a data-locking D flip-flop (data latch) with a minimum inter-disposal time between two consecutive output events. It serves to receive values via the unidirectional **AUI** adapter and pass them on with a defined minimum delay to prevent an excessively rapid sequence of events at the output.

Interface Structure

Event Inputs

Event	Comment
INIT	Initialization request; configures the block with the parameter `Tmin`.

Event Outputs

Event	Comment
INITO	Confirmation of successful initialization.

Data Inputs

Variable	Type	Comment
Tmin	TIME	Minimum time that must elapse between two output events (`EO`).

Data Outputs

No direct data outputs – the output values are provided via the `Q` adapter.

Adapter

Direction	Name	Type	Comment
Plug (Output)	**Q**	`adapter::types::unidirectional::AUI`	Provides the locked data value (event and data line).
Socket (Input)	**I**	`adapter::types::unidirectional::AUI`	Receives the data value to be locked (event and data line).

Functionality

1. **Initialization**

The block is initialized via the event input `INIT`, and the minimum time is set via `Tmin`.

1. **Data Transfer**

Every event arriving at the adapter input `I` via the event line `I.E1` transfers the corresponding data value `I.D1` to the flip-flop. The transferred value is immediately stored internally.

1. **Output with Minimum Time Delay**

The stored value is only output as an event on `Q.E1` and as a data value on `Q.D1` if at least `Tmin` of time has elapsed since the last output event. If a new transfer event occurs before this time has elapsed, the new value is stored, and the output is further delayed until the minimum time has been met.

1. **Output with Minimum Time Delay**

The output of the stored value occurs only as an event on `Q.E1` and as a data value on `Q.D1` if at least `Tmin` of time has passed since the last output event. If a new transfer event occurs before this time has elapsed, the new value is stored, and the output is further delayed until the minimum time has been met.

1. **State Protection**

The block behaves like an edge-triggered D flip-flop, where each valid clock cycle (event on `I.E1`) takes over the current data value, but the actual transmission is time-limited.

Technical Features

- **Adapter-Based Input/Output** – The block uses only the standardized unidirectional **AUI** adapter. This makes it easy to integrate into existing adapter-oriented architectures.
- **Reuse of Basic Components** – Internally, the IEC 61499 component `E_D_FF_ANY_TMIN` is used, which implements the time-limited throttling. This block encapsulates it and simplifies connection via adapters.
- **No Dedicated State Machines** – The behavior is entirely determined by the internal component; The outer function block is purely configurable and connective.

State Overview

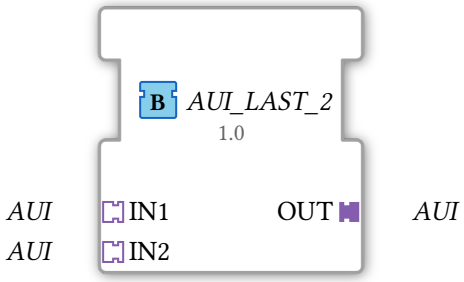
The function block does not have an externally visible state machine (ECC). Internally, the used `E_D_FF_ANY_TMIN` can have the following implicit states:

State	Description
Idle	Waiting for an event at input `I`.
Timed	Data has been received; output is held back until `Tmin` expires.
Output	Minimum time has been met – output event is sent.

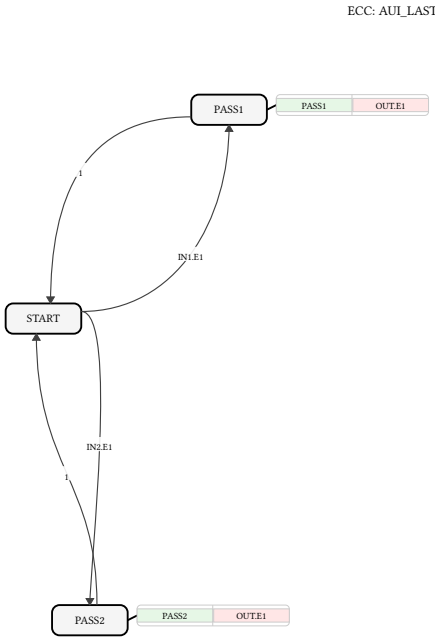
These states are transparent to the user.

Application Scenarios

- **Sensor Value Smoothing** – Prevents a sensor that delivers measurements at short intervals from flooding the subsequent processing block with events.
- **Actuator Control with Minimum Switching Time** – Ensures that an actuator (e.g., a valve) can only be switched after a defined minimum pause to reduce wear.
- **Data Flow Limiting in Communication Lines** – Throttles the output rate of a data stream to prevent overloading the receiver.



Comparison with Similar Components



Component	Feature
E_D_FF (Standard D Flip-Flop)	No time limit; each event is output immediately.
E_D_FF_ANY_TMIN	Same behavior, but without adapter encapsulation; Direct event-/ data-based connection.
AUI_D_FF_TMIN (this block)	Combines D flip-flop functionality with time-based throttling and provides an adapter-based interface.

Conclusion

The **AUI_D_FF_TMIN** is a useful function block when data needs to be passed at time-controlled intervals. It simplifies the implementation of throttling logic in adapter-based IEC 61499 systems and is particularly suitable for applications in agricultural engineering and other time-critical control environments.

AUI_LAST_2

Introduction

The AUI_LAST_2 function block merges two same-type UINT adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: UINT adapter (unidirectional) - first signal source
- **IN2**: UINT adapter (unidirectional) - second signal source

Output adapter (Plug):

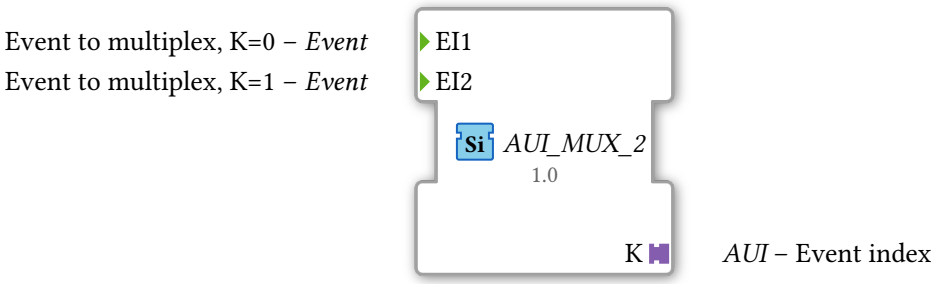
- **OUT**: UINT adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid UINT signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same UINT value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AUI_LAST_2 is the inverse of AUI_SPLIT_2: AUI_SPLIT_2 distributes 1 input to 2 outputs, AUI_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use AX_AE_MERGE instead, which merges only the event without altering the data value.

AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

AUI_MUX_2 is an event multiplexer function block that forwards one of two incoming events (EI1 or EI2) based on an index value supplied through an AUI (Adapter User Interface) adapter. It is a specialized variant of the standard E_MUX_2 block, replacing the conventional combination of a data input K and a plain event output EO with a unidirectional AUI adapter connection. This design integrates the event-index selection and the multiplexed event delivery into a single adapter-based interface, making it suitable for architectures where adapter-based communication is preferred over direct event/data ports.

Interface Structure

Event Inputs

Name	Type	Description
EI1	Event	Event to be multiplexed when the index K selects channel 0.
EI2	Event	Event to be multiplexed when the index K selects channel 1.

Event Outputs

The block has no explicit event output ports. The multiplexed event is delivered through the AUI adapter connection (see Adapters below).

Data Inputs

No data inputs are provided. All selection information is carried via the adapter.

Data Outputs

No data outputs are provided. The adapter serves as the data and event output mechanism.

Adapters

Name	Type	Direction	Description
K	adapter::types::unidirectional::AUI	Plug (required)	Provides the event selection index and carries the multiplexed event output to a connected socket.

Functionality

The AUI_MUX_2 operates as a two-channel event selector. When an event arrives on EI1 or EI2, the block evaluates the current index value transmitted through the K adapter. If the index selects channel 0, the incoming event on EI1 is forwarded via the AUI adapter to the connected partner FB. If the index

selects channel 1, the event on EI2 is forwarded instead. Events arriving on a non-selected channel are ignored.

The adapter-based design encapsulates both the index value and the event output in one interface. This means the consuming logic does not need to observe a separate K data input or a dedicated event output; instead, it receives the selection context and the event through the same AUI connection. This reduces port clutter and enforces a cleaner separation between the multiplexing logic and the consuming application.

The block is declared as a generic FB (GEN_E_MUX) within the 4diac framework, meaning its behavior can be instantiated with a configurable number of inputs, although the fixed AUI_MUX_2 variant presented here exposes exactly two event input channels.

Technical Features

- **Adapter-based I/O:** All selection and output communication occur through a unidirectional AUI adapter, eliminating dedicated data input and event output ports.
- **Generic background:** Built on the generic GEN_E_MUX core, allowing conceptual extension to more than two channels in adapted versions.
- **Combinational event logic:** No internal storage or state machine is required; the routing decision is made purely based on the current adapter index value at the time an input event occurs.
- **Deterministic selection:** Each input event channel is strictly associated with one index value (EI1 ↔ index 0, EI2 ↔ index 1).
- **Standard compliance:** Developed according to IEC 61499-1 Annex A, ensuring interoperability within 4diac-based automation systems.

State Overview

This function block does not maintain persistent internal states. Its behavior is purely event-driven and combinational:

- When EI1 fires and the adapter-index is 0 ⟶ the selected event is emitted through the AUI adapter.
- When EI1 fires and the adapter-index is not 0 ⟶ the event is discarded.
- When EI2 fires and the adapter-index is 1 ⟶ the selected event is emitted through the AUI adapter.
- When EI2 fires and the adapter-index is not 1 ⟶ the event is discarded.

The block's reaction is instantaneous and does not depend on prior events, making it a deterministic routing element within a larger IEC 61499 application.

Application Scenarios

AUI_MUX_2 is particularly useful in system designs that already rely on AUI adapter connections for unidirectional communication between FBs. Typical use cases include:

- **Event routing in adapter-based architectures:** When a framework or application layer mandates that all event exchange between components occurs via adapters, AUI_MUX_2 allows event selection without breaking that convention.
- **Reducing port complexity:** In large FB networks, replacing multiple separate K data inputs and EO outputs with a single adapter simplifies wiring and improves readability.
- **Modular consumer integration:** The AUI socket on the consumer side can be designed to automatically interpret the multiplexed events with the accompanying index, enabling polymorphic event handling.
- **Migration of E_MUX_2 logic:** Applications previously built with E_MUX_2 but moving toward adapter-based communication can be migrated by swapping the plain output/data ports with the AUI adapter.

Comparison with Similar Blocks

Feature	E_MUX_2	AUI_MUX_2
Event inputs	EI1, EI2	EI1, EI2
Selection mechanism	Data input K (INT)	AUI adapter K
Event output	Plain event output EO	Via AUI adapter
Port count	3 (2 events + 1 data) + 1 event output	2 events + 1 adapter

Adapter support	None	Unidirectional AUI
Generic base	GEN_E_MUX	GEN_E_MUX

The key distinction is that AUI_MUX_2 consolidates the index selection and event output into one adapter interface. This makes it more suitable for adapter-oriented designs but requires that the connected consumer FB exposes a matching AUI socket. In contrast, E_MUX_2 uses the more traditional separate data input and event output, which is simpler to use in classic IEC 61499 applications.

Conclusion

AUI_MUX_2 provides a clean, adapter-based alternative to the classical E_MUX_2 event multiplexer. By routing the selection index and the multiplexed event through a single unidirectional AUI adapter, it aligns with modern IEC 61499 communication patterns that favor adapter encapsulation. It is ideal for systems where adapter-based event propagation is a design requirement, and it retains the deterministic, combinational behavior expected from a multiplexing element. While slightly more constrained than its plain counterpart due to the dependency on a matching AUI socket, it offers significant advantages in modularity and interface clarity for appropriate application contexts.

AUI_MUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

The AUI_MUX_3 is an event multiplexer function block designed for selecting and forwarding one of three incoming event signals based on an index provided through an AUI (Adapter Unit Interface) adapter. Unlike conventional multiplexers that use separate event output and index data inputs, this block integrates the selector and output channel into a single unidirectional AUI adapter. This design reduces the number of interface elements and simplifies the connection to downstream components that expect a standardized adapter-based event interface.

As a generic function block (based on the GEN_E_MUX template), it can be instantiated with different numbers of inputs or adapted to various use cases, but the provided configuration supports exactly three event inputs (EI1, EI2, EI3). The block is particularly useful in event-driven systems where multiple sources need to be routed to a common destination, with the selection logic controlled by an external entity via the AUI adapter.

Interface Structure

Event Inputs

Name	Type	Comment
EI1	Event	Event to multiplex, K=0
EI2	Event	Event to multiplex, K=1
EI3	Event	Event to multiplex, K=2

These three event inputs represent the sources to be multiplexed. Only one of them is passed through to the output, depending on the value of the index provided through the AUI adapter.

Event Outputs

There are no explicit event outputs in this block. The selected event is transmitted via the AUI adapter connection, which acts as the output channel. This is a deliberate design choice to integrate the output event and the selection logic in a single adapter interface.

Data Inputs

There are no data inputs in this block. The multiplexer index is not provided as a separate data input but is instead carried within the AUI adapter connection.

Data Outputs

There are no data outputs in this block.

Adapters

Name	Type	Direction	Comment
K	adapter::types::unidirectional::AUI	Output (Plug)	Event index and output channel

The adapter `K` is a **plug** (output adapter) of type `adapter::types::unidirectional::AUI` (Adapter Unit Interface). It provides two functions:

- **Output for the selected event**: The multiplexed event is sent through this adapter to a connected socket.
- **Selector input**: The index value (0, 1, or 2) is supplied from the connected socket, indicating which of the three event inputs should be forwarded.

The AUI adapter encapsulates the index and the event output in a single connection, simplifying the wiring between the multiplexer and the receiving function block.

Functionality

The AUI_MUX_3 operates as a three-input event router. Whenever an event occurs on any of its inputs (EI1, EI2, EI3), the block checks the current value of the index available on the AUI adapter. Only if the index matches the input number (i.e., EI1 with index 0, EI2 with index 1, EI3 with index 2) will the event be forwarded through the AUI adapter to the connected downstream block. Events arriving on non-selected inputs are ignored.

The index value is continuously monitored and can be updated at any time via the AUI adapter. This allows dynamic switching between sources without needing to preconfigure the selection externally. The block does not have internal states; it simply reacts to incoming events based on the current index.

In a typical scenario, the AUI adapter is connected to a socket of another function block that both provides the selection index (e.g., from a controller) and receives the multiplexed event. This creates a bidirectional (or unidirectional, depending on the adapter definition) communication channel where the upstream block supplies the selection, and the downstream block receives the event.

Technical Features

- **Generic Implementation**: The block is based on the `GEN_E_MUX` generic template, allowing instantiation with different numbers of event inputs if needed, though the default configuration is fixed to three inputs.
- **AUI Adapter Integration**: Minimizes the number of separate interface points by combining the output event and the selector index into a single adapter connection. This reduces wiring complexity and improves modularity.
- **Unidirectional Adapter**: The `AUI` adapter is defined as unidirectional, meaning data and events flow only in one direction (from the multiplexer to the connected block). The index value is supplied externally to the adapter's socket and is read by the multiplexer.
- **No Internal State**: The block is stateless and reacts purely to input events and the current index value. This makes it suitable for time-critical applications where deterministic behavior is required.
- **Event Prioritization**: In case multiple events occur simultaneously, the block does not prioritize them; the first event processed according to the runtime order will be evaluated. This is consistent with the behavior of standard event multiplexers.

State Overview

This function block does not maintain any internal state. It has no state diagram because it does not store information between executions. The behavior is purely combinatorial:

- **Idle**: No event is present on any input.
- **Event Reception**: When an event arrives on one of the inputs, the block evaluates the current index from the AUI adapter.
- **Forwarding**: If the index matches the arriving input, the event is emitted through the adapter. Otherwise, the event is discarded.

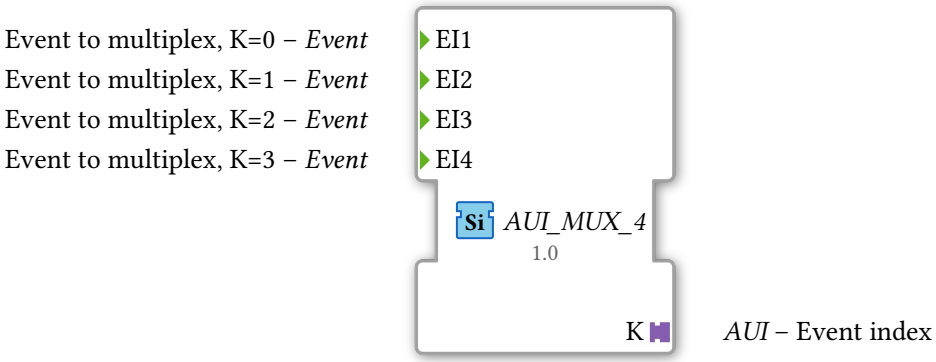
The block is always ready to process the next event, and there is no transition delay except for the propagation of the adapter's index value (which may change independently).

Application Scenarios

- **Selective Event Routing**: In a system where multiple sensors or components generate events but only one should be processed at a time, AUI_MUX_3 can direct events from the currently active source to a central processing unit.
- **Configurable Input Selection**: When a control unit needs to switch between different data sources (e.g., different operating modes), the AUI adapter can be used to set the selection index dynamically, allowing the multiplexer to forward the appropriate event stream.
- **Adapter-Based Architectures**: In 4diac applications that heavily use adapters for decoupling and reusability, this block integrates seamlessly into a chain of adapters, avoiding the need for separate event and data lines.
- **Test and Simulation**: The block can be used in test harnesses to inject events from different input channels into a single output line, controlled by a test script that updates the adapter index.

Comparison with Similar Blocks

The AUI_MUX_3 is a variant of the standard `E_MUX` event multiplexer. The key differences are:



- **Interface Structure**: `E_MUX` typically has separate event output (EO) and a data input (K) of type INT to specify the active input. AUI_MUX_3 instead uses an AUI adapter that combines the index and the output event into one connection.
- **Flexibility**: The `E_MUX` may allow configuration of the number of inputs via a generic parameter, while AUI_MUX_3 is fixed to three inputs in this version, but can be extended following the same pattern.
- **Integration**: AUI_MUX_3 is more suited for adapter-based designs where the output is expected to be an adapter socket. It reduces the number of connections and can simplify the visual layout of the application.
- **Standard-Tool Compatibility**: While `E_MUX` is a well-known block in many IEC 61499 implementations, AUI_MUX_3 is a specialized adaptation that may be used in environments where adapter-based event communication is preferred.

Other multiplexers like `E_MUX2` or `E_MUX4` share the same concept but differ in input count. AUI_MUX_3 is unique in that it encapsulates the selector channel into an adapter, which is not typical in standard libraries.

Conclusion

AUI_MUX_3 provides a compact and elegant solution for event multiplexing in IEC 61499 applications that leverage adapter-based communication. By integrating the selection index and the output event into a single AUI adapter, it reduces interface clutter and promotes a cleaner system structure. Its stateless, event-driven nature ensures predictable behavior and easy integration into existing event processing chains. While it may not replace the standard `E_MUX` in all scenarios, it offers a valuable alternative for modern, adapter-centric designs. The block is a clear demonstration of how generic event processing can be adapted to meet the needs of evolving industrial automation architectures.

AUI_MUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUI_MUX_4** is an event multiplexer function block that selects one of four event inputs and forwards the received event through an **AUI adapter** interface. This is an adapter-based variant of the standard `E_MUX_4` block, replacing the plain event output plus data selector with a unidirectional AUI adapter plug. The block is configured as a generic function block (`GEN_E_MUX`), allowing the number of inputs to be adapted as needed.

Interface Structure

The AUI_MUX_4 features four event inputs and one AUI adapter plug. There are no conventional event outputs, data inputs, or data outputs; all selection and output functionality is carried through the adapter.

Event Inputs

Name	Type	Comment
EI1	Event	Event to multiplex, K=0
EI2	Event	Event to multiplex, K=1
EI3	Event	Event to multiplex, K=2
EI4	Event	Event to multiplex, K=3

Event Outputs

None. The multiplexed event is delivered via the AUI adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Name	Type	Direction	Comment
K	`adapter::types::unidirectional::AUI`	Plug (output)	Event index and event forwarding interface

The adapter `K` is of type `AUI` (unidirectional), carrying both the selection index and the event signal to the connected partner FB.

Functionality

The AUI_MUX_4 operates as an event selector. When an event occurs on one of the four inputs (EI1–EI4), the block recognizes the corresponding index (0–3) and forwards an event through the AUI adapter plug

K. The adapter carries the index value along with the event trigger, enabling the connected downstream block to identify which input caused the event.

The behavior is analogous to a classic multiplexer: exactly one input is selected and its event is propagated. The selection is implicit—based on which input fired—rather than set via a separate data input. This makes the block suitable for scenarios where event sources are known and need to be routed to a single consumer.

Technical Features

- **Generic FB instantiation**: Marked with `eclipse4diac::core::GenericClassName = 'GEN_E_MUX'`, enabling flexible adaptation of the number of event inputs.
- **Adapter-based output**: Uses the `AUI` adapter type (`adapter::types::unidirectional::AUI`) instead of a standard event output plus data output, offering a clean interface for unidirectional event communication.
- **Four input channels**: Supports multiplexing of up to four independent event sources.
- **No data handling**: Pure event-based operation; no data inputs or outputs are involved.
- **Package classification**: Belongs to the `adapter::events::unidirectional` package, reflecting its unidirectional event-oriented architecture.

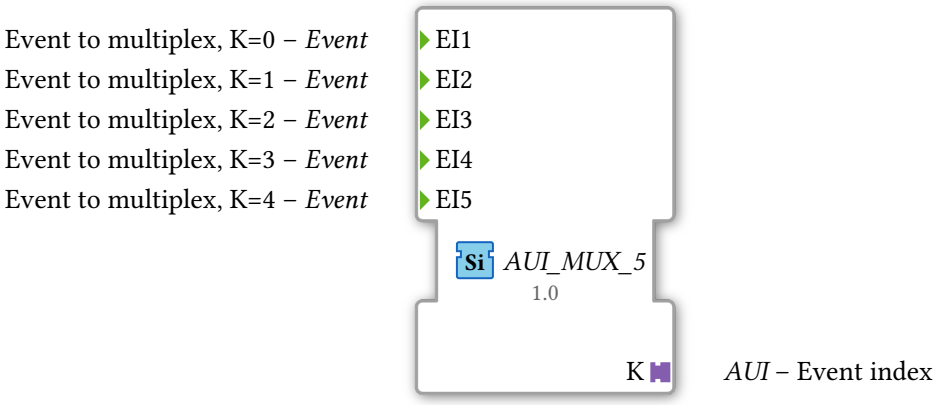
State Overview

The block does not maintain internal state machines or persistent states. It operates purely combinatorially in response to incoming events. Each event on an input is immediately forwarded through the adapter without internal buffering or state retention. There are no ECC (Execution Control Chart) states to consider for this FB.

Application Scenarios

- **Event consolidation**: Merging multiple event sources into a single event stream where the adapter carries the origin index.
- **Inter-module event routing**: Connecting multiple sensors or controllers to a common processing unit via an AUI adapter, preserving the identity of the event source.
- **Generic event demultiplexing**: When used with a matching AUI recipient block, the index can be used to reconstruct the original event distribution on the consumer side.
- **Adapter-based system design**: Ideal for modular IEC 61499 systems that rely on adapter connections for clean, decoupled communication between function blocks.

Comparison with Similar Blocks



Feature	AUI_MUX_4	E_MUX_4 (standard)
Output type	AUI adapter plug	Event output (EO) + data output (K)
Selection mechanism	Implicit via fired input, index via adapter	Explicit via data input K
Event count	4 inputs	4 inputs
Data handling	None	Carries selector value K
Use case	Adapter-based architectures	Traditional ECC/event chains

The key difference is the output interface: AUI_MUX_4 delivers the event and selector via an adapter, promoting loose coupling and reusability, whereas E_MUX_4 uses traditional event and data outputs.

Conclusion

The AUI_MUX_4 is a specialized event multiplexer designed for adapter-centric IEC 61499 applications. By utilizing a unidirectional AUI adapter for both event forwarding and index signaling, it simplifies wiring in complex systems and enables clean separation of concerns. Its generic nature allows scaling to different input counts, making it a flexible building block for event routing in distributed automation systems.

AUI_MUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

AUI_MUX_5 is an event multiplexer with five event inputs. It is the adapter-based variant of a classic `E_MUX_5` block. Instead of providing a plain event output `EO` and a data output `K`, this block uses a unidirectional AUI adapter output called `K` that carries both the generated event and the selected event index.

The block belongs to the `adapter::events::unidirectional` package and is implemented using the generic event multiplexer class `GEN_E_MUX`.

Interface Structure

Event Inputs

Name	Type	Comment
`EI1`	Event	Event to multiplex, K=0
`EI2`	Event	Event to multiplex, K=1
`EI3`	Event	Event to multiplex, K=2
`EI4`	Event	Event to multiplex, K=3
`EI5`	Event	Event to multiplex, K=4

Event Outputs

None. The event output is embedded in the AUI adapter `K`.

Data Inputs

None.

Data Outputs

None. The data output is embedded in the AUI adapter `K`.

Adapters

Name	Direction	Type	Comment
`K`	Plug	`adapter::types::unidirectional::AUI`	Event index

The adapter plug `K` is the output side of the block. It provides a unidirectional connection to a consuming FB that has a matching AUI socket.

Functionality

AUI_MUX_5 works as an event selector. When one of the five event inputs `EI1` to `EI5` is triggered, the block:

1. Recognizes which event input received the event.
2. Maps that input to the corresponding zero-based index:
   - `EI1` ⟶ `K = 0`
   - `EI2` ⟶ `K = 1`
   - `EI3` ⟶ `K = 2`
   - `EI4` ⟶ `K = 3`
   - `EI5` ⟶ `K = 4`
3. Forwards the event through the AUI adapter `K`.
4. Provides the index value through the same adapter connection.

The consumer connected to the AUI socket receives both the event and the associated channel index in one structured interface.

Technical Features

- Five event inputs: `EI1` to `EI5`.
- One unidirectional AUI adapter plug named `K`.
- Generic implementation based on `GEN_E_MUX`.
- Uses the adapter type `adapter::types::unidirectional::AUI`.
- Replaces the separate `EO` and `K` outputs of a conventional event multiplexer.
- The adapter output is unidirectional, meaning events and index data flow from this block to the connected consumer.
- No separate event output, data input, or data output is exposed on the outer interface.

State Overview

AUI_MUX_5 does not expose an application-visible state machine. It behaves as an event-driven selector. After an event is processed, the selected index is available on the AUI adapter and the event is propagated to the connected socket.

The block is stateless between event occurrences from the user's perspective. No internal event history is required for normal operation.

Application Scenarios

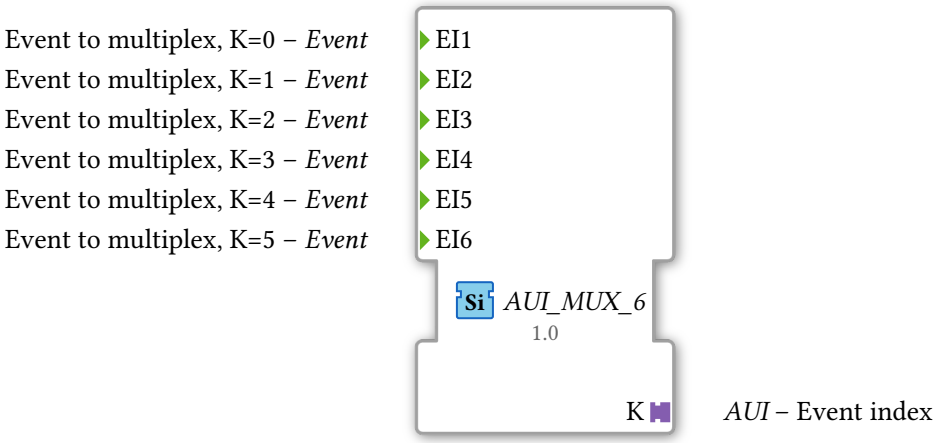
AUI_MUX_5 is suitable for applications where several event sources need to be combined into one adapter-based output channel.

Typical use cases include:

- Merging event signals from multiple sensors into one common event handling path.
- Selecting one of several alarm or status sources and forwarding it to a central monitoring block.
- Connecting an event multiplexer to an AUI-compatible consumer without manually wiring an event output and an index data output.
- Replacing a conventional `E_MUX_5` in systems that already use unidirectional AUI adapters for communication between FBs.

Comparison with Similar Blocks

Compared with `E_MUX_5`, AUI_MUX_5 provides the same event multiplexing behavior but uses an AUI adapter output instead of a separate event output `EO` and data output `K`. This groups the related output information together and reduces connection clutter.



Compared with other `AUI_MUX_n` variants, AUI_MUX_5 is specialized for exactly five event inputs. The index mapping starts at `0` and ends at `4`.

Compared with the generic `GEN_E_MUX` block, AUI_MUX_5 is a concrete typed specialization with a fixed number of five event inputs and a predefined AUI adapter interface.

Conclusion

AUI_MUX_5 is a compact, adapter-based event multiplexer for five event inputs. It combines event selection and index information in one unidirectional AUI adapter connection. This makes it especially useful in component-oriented IEC 61499 applications where standardized AUI adapters are used for event and data exchange between function blocks.

AUI_MUX_6

• – ◦ • – ◦ • – ◦ •

Introduction

`AUI_MUX_6` is an event multiplexer function block with six event inputs. Instead of exposing a separate event output and a plain `K` data connection, it uses a unidirectional AUI adapter as its output interface. This combines the delivered event and the associated event index in a single adapter connection.

The block is a concrete configuration of the generic event multiplexer `GEN_E_MUX` and is intended for applications where multiple event sources must be merged into one unidirectional adapter-based event channel while preserving the identity of the triggering event source.

Interface Structure

The block provides six event inputs and one AUI adapter plug. It has no conventional event outputs, data inputs, or data outputs.

Event Inputs

Name	Type	Comment
`EI1`	Event	Event to multiplex, K=0
`EI2`	Event	Event to multiplex, K=1
`EI3`	Event	Event to multiplex, K=2
`EI4`	Event	Event to multiplex, K=3
`EI5`	Event	Event to multiplex, K=4
`EI6`	Event	Event to multiplex, K=5

**Event Outputs

None. The output event is carried through the AUI adapter `K`.

Data Inputs

None.

Data Outputs

None.

Adapters

Name	Type	Direction	Comment
`K`	`adapter::types::unidirectional::AUI`	Plug	Event index

The adapter K bundles the outgoing event with the corresponding event index. The index is zero-based and identifies which event input caused the output event.

Functionality

AUI_MUX_6 monitors its six event inputs and forwards a triggering event through the AUI adapter output. The event index carried by the adapter is derived from the input that was activated:

- An event on EI1 produces an adapter event with index 0.
- An event on EI2 produces an adapter event with index 1.
- An event on EI3 produces an adapter event with index 2.
- An event on EI4 produces an adapter event with index 3.
- An event on EI5 produces an adapter event with index 4.
- An event on EI6 produces an adapter event with index 5.

The adapter output is therefore both the multiplexed event signal and the source-identification signal. The receiving FB, connected through an AUI socket, can use the event to trigger its logic and the K value to determine which of the six original event inputs originated the event.

Technical Features

- Six fixed event input channels with zero-based indices.
- Single unidirectional AUI adapter output K.
- Compact interface: replaces separate event output and data output connections with one adapter.
- No external data inputs are required for multiplexing.
- The K value is delivered together with the output event, guaranteeing that the event and its index are observed consistently.
- Uses the generic implementation class GEN_E_MUX, allowing tooling and runtime environments to treat it as a generic event multiplexer.

State Overview

AUI_MUX_6 does not define a persistent internal state machine. It behaves statelessly from the application viewpoint: each event input is handled independently and immediately produces the corresponding adapter output event. After the event is emitted, the block returns to its idle condition and waits for the next input event.

There is no enabling, disabling, or selection state. All six event inputs are always ready to be forwarded.

Application Scenarios

- **Event source aggregation**: Combine multiple event sources into one adapter-based connection while preserving the source index.
- **Modular subapplication communication**: Transport events from several components of a subapplication to a central coordinator through a single unidirectional adapter.
- **Reduction of interface wiring**: Replace separate event and data lines with one AUI adapter connection, simplifying the interface of reusable FBs.
- **Source identification**: Use the K value on the receiving side to distinguish which of the six event inputs triggered the received event.
- **Generic event multiplexing**: Use the GEN_E_MUX generic behavior to build similar multiplexer variants with different numbers of event inputs.

Comparison with Similar Blocks

Block / Variant	Output Approach	Typical Use
Classic E_MUX style	Separate event output and K connection	Standard event multiplexing with direct event and data wiring
AUI_MUX_6	Event and index bundled in a unidirectional AUI adapter	Adapter-based multiplexing with source identification
Event demultiplexer	One input event routed to one of several outputs	Opposite operation: distributing one event stream to multiple destinations

The main advantage of AUI_MUX_6 over classic multiplexing blocks is the use of a single adapter connection instead of physically separate event and data interfaces. This keeps the event and its index together and simplifies the interface of the containing function block or subapplication.

Conclusion

AUI_MUX_6 provides a clean, adapter-based solution for multiplexing six event inputs into one unidirectional event channel. By combining the output event with a zero-based event index in the K AUI adapter, it preserves source information while reducing interface complexity. It is especially useful in modular 4diac applications where adapter-based communication is preferred over individual event and data connections.

AUI_MUX_7

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUI_MUX_7** is a generic event multiplexer function block that selects one out of seven incoming event inputs and routes it to an event output provided through an **AUI (Adapter Usage Interface)** adapter. This block is a variant of the standard **E_MUX_7**, where the selection index and the output event are bundled into a single unidirectional AUI adapter, making it suitable for modular, adapter-based communication patterns in distributed control applications.

Interface Structure

Event Inputs

Name	Type	Description
EI1	Event	Event to multiplex; selected when K = 0
EI2	Event	Event to multiplex; selected when K = 1
EI3	Event	Event to multiplex; selected when K = 2
EI4	Event	Event to multiplex; selected when K = 3
EI5	Event	Event to multiplex; selected when K = 4
EI6	Event	Event to multiplex; selected when K = 5
EI7	Event	Event to multiplex; selected when K = 6

Event Outputs

None. The multiplexed event is delivered through the AUI adapter's event channel.

Data Inputs

None. The selection index is provided via the AUI adapter.

Data Outputs

None.

Adapters

Name	Type	Direction	Description
K adapter	`::types::unidirectional::AUI`	Plug (output side)	Carries the event index (selection value) and provides the multiplexed event output to the connected socket.

Functionality

The **AUI_MUX_7** operates as a single-selection multiplexer controlled by the index value `K` supplied through the AUI adapter. When an event occurs on one of the seven inputs (EI1–EI7), the block checks the current value of `K`:

- If `K` matches the index associated with the triggered input, the event is forwarded to the output event channel of the AUI adapter.
- If `K` does not match, the event is discarded.

Only one event input is forwarded at a time, determined by the most recent value of `K`. This behavior allows a single consumer connected via the AUI socket to receive events from exactly one source (selected dynamically at runtime) without requiring separate event connections.

Technical Features

- **Generic FB implementation** – The block is based on the generic class `GEN_E_MUX`, allowing instantiation with a configurable number of inputs (here fixed to 7).
- **Adapter-based output** – The output event and selection index are encapsulated in a unidirectional AUI adapter, promoting loose coupling between producer and consumer.
- **Event-index correlation** – Each event input is mapped to a fixed index (EI1⟶0, EI2⟶1, ..., EI7⟶6), directly corresponding to the `K` value.
- **No data processing** – The block performs purely event-based routing; it does not manipulate or generate data values.
- **SPDX-Licensed** – Distributed under Eclipse Public License 2.0.

State Overview

The **AUI_MUX_7** is a stateless, combinational event router. It does not maintain internal state variables or sequential logic. The behavior can be summarized as:

Condition	Action
Event on EIn and K == (n-1)	Forward event to AUI output
Event on EIn and K != (n-1)	Drop event (no output)
No event on any input	No action

Since there is no state, the block is always ready to react to the next incoming event.

Application Scenarios

- **Dynamic source selection** – In systems where multiple sensors or controllers generate events but only one should be active at a time, the AUI_MUX_7 can route the active source's events to a downstream processing unit.
- **Adapter-based modular architectures** – When using AUI adapters to standardize connections between components, this block integrates seamlessly with unidirectional event-driven communication patterns.
- **Mode-switchable control panels** – A control application can switch between different operational modes (e.g., manual, automatic, emergency) by changing `K`, thereby selecting which event source (button, PLC signal, safety circuit) drives the output.
- **HMI and event aggregation** – In visualization systems, the block can multiplex multiple user-interface events to a single rendering engine, with the active widget determined by the index.

Comparison with Similar Blocks

Feature	AUI_MUX_7	E_MUX_7 (standard)
Output event	Via AUI adapter	Plain Event Output (EO)
Selection index	Via AUI adapter (K)	Separate data input (K)
Interface style	Adapter-based (unidirectional)	Direct event/data pins
Coupling	Loose (decoupled via adapter)	Tight (direct wiring)
Reusability	Higher – can connect to any matching AUI socket	Lower – requires explicit event and data connections
Typical use	Modular, distributed IEC 61499 systems	Simple, monolithic function block networks

The AUI_MUX_7 is essentially the adapter-wrapped equivalent of the standard E_MUX_7, trading a direct interface for greater modularity and interchangeability.

Conclusion

The **AUI_MUX_7** provides a clean, adapter-based solution for multiplexing seven event sources into a single output. By integrating the selection index and the output event into one unidirectional AUI adapter, it simplifies wiring, improves component interchangeability, and fits naturally into modern IEC 61499 distributed control architectures that rely on adapter-based communication. Its stateless nature and generic implementation make it a robust and flexible building block for event-driven applications.

AUI_MUX_8

• – ◦ • – ◦ • – ◦ •

Introduction

AUI_MUX_8 is an event multiplexer function block with a unidirectional AUI adapter output. It concentrates up to eight incoming event inputs on a single AUI adapter connection. Instead of forwarding the selected event through a plain event output and a separate index value, the block emits the event and the associated event index through the adapter `K`. It is a concrete specialization of the generic event multiplexer `GEN_E_MUX` and is intended for use in event-driven 4diac applications.

Interface Structure

The FB has eight event inputs and one AUI adapter Plug. There are no conventional event outputs, data inputs, or data outputs. All outgoing event and index information is transported through the `K` adapter.

Event Inputs

Input	Description
EI1	Event to multiplex, K = 0
EI2	Event to multiplex, K = 1
EI3	Event to multiplex, K = 2
EI4	Event to multiplex, K = 3
EI5	Event to multiplex, K = 4
EI6	Event to multiplex, K = 5
EI7	Event to multiplex, K = 6
EI8	Event to multiplex, K = 7

Event Outputs

None. The multiplexed event is sent through the AUI adapter `K`.

Data Inputs

None.

Data Outputs

None.

Adapters

Adapter	Type	Direction	Description
K	`adapter::types::unidirectional::AUI`	Plug	Output adapter carrying the multiplexed event and the index of the active event input (0–7).

Functionality

When an event occurs at one of the event inputs, the FB produces an event on the `K` adapter. The index value attached to this adapter output corresponds to the triggered input:

- EI1 ⟶ K = 0
- EI2 ⟶ K = 1
- EI3 ⟶ K = 2
- EI4 ⟶ K = 3
- EI5 ⟶ K = 4
- EI6 ⟶ K = 5
- EI7 ⟶ K = 6
- EI8 ⟶ K = 7

The receiving FB on the other side of the AUI adapter can use the event to trigger processing and the index to identify the source. Because the index is determined by the event input and not by an external selector, the block can be used as a compact event-source encoder.

Technical Features

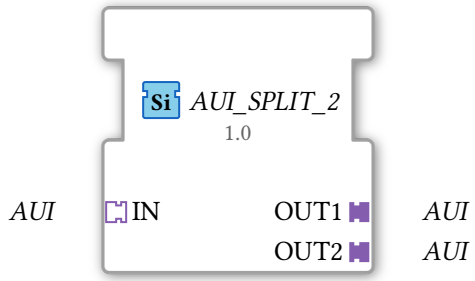
- Supports up to eight event inputs with a fixed 0-based index mapping.
- Provides an AUI plug `K` using adapter type `adapter::types::unidirectional::AUI`.
- No separate event outputs or data pins; the AUI adapter encapsulates the output interface.
- Declared as a generic FB specialization with `GenericClassName = 'GEN_E_MUX'`.
- Stateless operation with no internal data persistence.
- Simplifies wiring by replacing explicit EO + K connections with an adapter-based connection.

State Overview

The type description does not define an explicit ECC state machine. AUI_MUX_8 is a stateless, event-activated block. At runtime, it remains in its ready state until an event input occurs; then it immediately emits the event and index through K and returns to the ready state. No state information is stored between invocations.

Application Scenarios

- Consolidating multiple event sources such as buttons, sensors, diagnostic flags, or mode triggers into one AUI-based connection to a central event handler.
- Supplying an event index to a processing block so the receiver can distinguish which source triggered the event.
- Reducing wiring complexity in 4diac applications by using AUI adapters instead of separate event output and index data connections.
- Serving as an eight-input specialization of a generic event multiplexer in modular automation logic.



Comparison with Similar Blocks

- **Standard E_MUX:** Uses a plain event output and an external selector input. AUI_MUX_8 replaces this interface with an AUI adapter and derives the index directly from the triggering event input.
- **E_DEMUX:** Performs the inverse operation, routing one incoming event to one of several outputs according to a selector. AUI_MUX_8 merges several inputs into one adapter output.
- **Other AUI_MUX variants:** AUI_MUX_2, AUI_MUX_4, AUI_MUX_16, etc. follow the same principle with a different number of inputs and index range; AUI_MUX_8 is the eight-channel version.

Conclusion

AUI_MUX_8 is a practical event multiplexing block for applications that use AUI adapter connections. It combines event concentration and source identification in one interface, allowing up to eight event inputs to be forwarded as a single adapter-based event with a clear index. Its stateless behavior and generic design make it suitable for modular, event-driven control systems based on 4diac.

AUI_SPLIT_2

Introduction

The function block **AUI_SPLIT_2** distributes a signal received from one AUI adapter (socket) unchanged to two identical AUI adapters (plugs). It is delivered as a generic function block (GenericClassName = `'GEN_AUI_SPLIT'`) and enables the simple splitting of a unidirectional AUI data stream to two independent sinks.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No direct data inputs available. Data is transported exclusively via the adapters.

Data Outputs

No direct data outputs available. Data is transmitted exclusively via the adapters.

Adapters

Name	Type	Direction / Role
`IN`	`adapter::types::unidirectional::AUI`	Socket (Input)
`OUT1`	`adapter::types::unidirectional::AUI`	Plug (Output 1)
`OUT2`	`adapter::types::unidirectional::AUI`	Plug (Output 2)

All three adapters are of type **AUI** and operate unidirectionally. Socket `IN` receives data, and plugs `OUT1` and `OUT2` forward the same data.

Functionality

This component forwards every incoming AUI signal at socket `IN` simultaneously to both plugs `OUT1` and `OUT2`. No processing, filtering, or buffering of the data takes place—the data is copied and sent **1:1**. The distribution is strictly deterministic and without any additional delay (apart from the propagation time of the internal connection).

Technical Features

- **Generic Type**: The function block is identified by the attribute `GenericClassName` as `'GEN_AUI_SPLIT'` and can be instantiated at runtime using type-hash mechanisms (`TypeHash` is currently empty).
- **No ECC (Execution Control Chart)**: Since there is no event-driven logic, the function block does not have a state machine. The routing is purely data-driven.
- **EPL 2.0 Licensed**: The function block is provided under the Eclipse Public License 2.0.

State Overview

The AUI_SPLIT_2 function block has **no state machine**. There are no internal states or transitions – the signal is continuously routed without clocking.

Application Scenarios

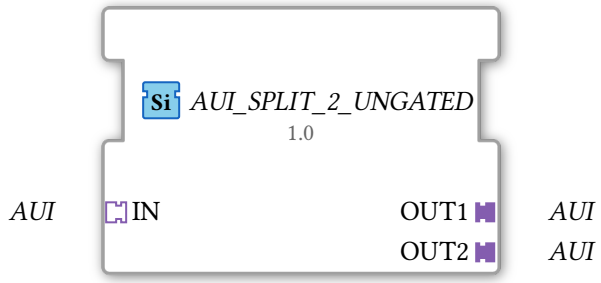
- **Signal Distribution**: An AUI data stream needs to be transmitted in parallel to two independent receivers or subsystems (e.g., two controllers, displays, or actuators).
- **Redundancy**: Identical data should be provided on two paths to support failover mechanisms.
- **Protocol Multicasting**: A unidirectional AUI stream is distributed to multiple consumers without requiring the sender to be addressed multiple times.

Comparison with Similar Components

- **AUI_SPLIT_N**: An extended variant that splits one input into N outputs (e.g., 1:3, 1:4). The AUI_SPLIT_2 is the simplest member of this family.
- **AUI_MERGE_2**: Combines two AUI inputs into one output (optionally with arbitration). The splitter operates in the opposite direction.
- **AUI_PASS**: A pure 1:1 pass-through adapter without branching.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.



Conclusion

The **AUI_SPLIT_2** is a minimalist yet useful function block for splitting a unidirectional AUI signal into two outputs. Thanks to its generic implementation and the absence of complex logic, it is ideally suited for scenarios requiring clean, lossless duplication of data streams.

AUI_SPLIT_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_SPLIT_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change.

This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUI_SPLIT_2_UNGATED** distributes a signal received from one AUI adapter (socket) unchanged to two identical AUI adapters (plugs). It is delivered as a generic function block (GenericClassName = `'GEN_AUI_SPLIT'`) and enables the simple splitting of a unidirectional AUI data stream to two independent sinks.

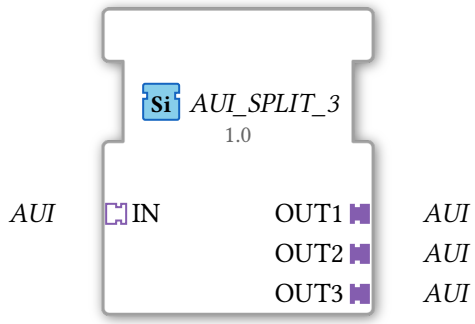
- **AUI_MERGE_2**: Combines two AUI inputs into one output (optionally with arbitration). The splitter operates in the opposite direction.
- **AUI_PASS**: A pure 1:1 pass-through adapter without branching.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The **AUI_SPLIT_2_UNGATED** is a minimalist yet useful function block for splitting a unidirectional AUI signal into two outputs. Thanks to its generic implementation and the absence of complex logic, it is ideally suited for scenarios requiring clean, lossless duplication of data streams.

AUI_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUI_SPLIT_3** serves as a generic splitter that distributes a single incoming AUI interface to three identical outgoing AUI interfaces. It allows for the simple duplication of a unidirectional adapter (of type `adapter::types::unidirectional::AUI`) without altering the events or data it carries.

Interface Structure

Event Inputs

None – the function block has no independent event inputs. Event forwarding occurs exclusively via the AUI adapters.

Event Outputs

None – the function block has no independent event outputs. Event forwarding occurs exclusively via the AUI adapters.

Data Inputs

None – the FB has no independent data inputs. Data is transmitted via the AUI adapters.

Data Outputs

None – the FB has no independent data outputs. Data is transmitted via the AUI adapters.

Adapters

Direction	Name	Type	Description
Socket (Input)	IN	adapter::types::unidirectional::AUI	Incoming AUI interface distributed across three outputs.
Plug (Output)	OUT1	adapter::types::unidirectional::AUI	First outgoing AUI output (identical to the input signal).
Plug (Output)	OUT2	adapter::types::unidirectional::AUI	Second outgoing AUI output (identical to the input signal).
Plug (Output)	OUT3	adapter::types::unidirectional::AUI	Third outgoing AUI output (identical to the input signal).

Functionality

The module functions purely as a signal distributor. It receives an AUI interface via socket `IN` and forwards all incoming events and data unchanged to the three plugs `OUT1`, `OUT2`, and `OUT3`. No processing, delay, or state change takes place. The function block (FB) is therefore **stateless** and behaves like a simple replication of wiring.

Technical Features

- **Generic Structure**: The function block is labeled as a generic FB (`GEN_AUI_SPLIT`), allowing it to be used with various AUI adapter variants (with different event/data signatures).
- **Unidirectional**: The adapter type `unidirectional` means that data and event flows are only in one direction (from the socket to the plugs). Backward communication is not supported.
- **No Latency**: Due to the absence of internal logic, no measurable delay occurs.
- **No Configuration**: The FB requires no parameters – the number of outputs is fixed at three.

State Overview

The function block does not have an internal state machine. There is only one continuous operating state in which the input interface is permanently mirrored to the three output interfaces.

Application Scenarios

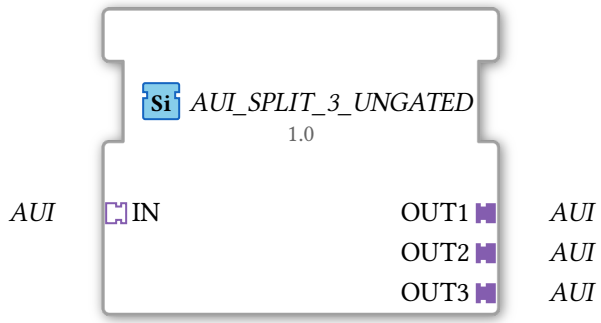
- **Signal Multiplication**: An AUI signal from a sensor or controller is to be forwarded to multiple independent receivers (e.g., actuators, displays, other controllers).
- **Monitoring**: An existing AUI data stream is copied to a monitoring unit without affecting the original signal paths.
- **Test and Simulation Environments**: A test stimulus is to be distributed in parallel to multiple components under test.

Comparison with Similar Components

Component	Outputs	Properties
`AUI_SPLIT_2`	2	Same functionality, but only two outputs.
`AUI_SPLIT_4`	4	Extended version with four outputs.
`AUI_MERGE`	–	Combines multiple AUI inputs into one output (opposite function).

The `AUI_SPLIT_3` represents a specific configuration that provides exactly three identical outputs. It can be replaced by other splitter variants if needed.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AUI_SPLIT_3` is a simple yet useful generic function block for multiplying a unidirectional AUI interface. Thanks to its pure pass-through function and lack of state logic, it is reliable, performant, and easily integrated into existing automation solutions. It is particularly suitable for applications where a signal needs to be split across multiple paths.

AUI_SPLIT_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_SPLIT_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

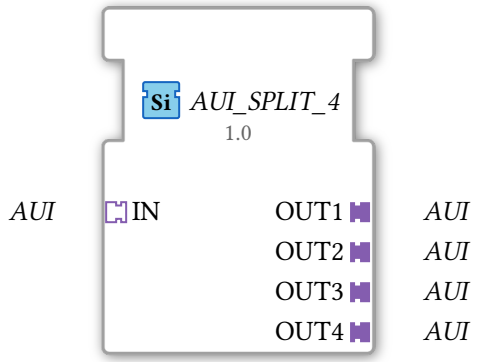
`AUI_SPLIT_2`	2	Same functionality, but only two outputs.
`AUI_SPLIT_4`	4	Extended version with four outputs.
`AUI_MERGE`	–	Combines multiple AUI inputs into one output (opposite function).

The `AUI_SPLIT_3_UNGATED` represents a specific configuration that provides exactly three identical outputs. It can be replaced by other splitter variants if needed.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AUI_SPLIT_3_UNGATED` is a simple yet useful generic function block for multiplying a unidirectional AUI interface. Thanks to its pure pass-through function and lack of state logic, it is reliable, performant, and easily integrated into existing automation solutions. It is particularly suitable for applications where a signal needs to be split across multiple paths.

AUI_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUI_SPLIT_4** serves as a generic distributor for AUI signals. It accepts a single AUI input (socket) and routes it to four separate AUI outputs (plugs). This block is typically used in automation technology when a unidirectional signal is required multiple times in parallel.

Interface Structure

Event Inputs

None available.

Event Outputs

None available.

Data Inputs

None available.

Data Outputs

None available.

Adapters

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AUI`	Input signal (AUI)
Plug	`OUT1`	`adapter::types::unidirectional::AUI`	First output (identical to IN)
Plug	`OUT2`	`adapter::types::unidirectional::AUI`	Second output (identical to IN)
Plug	`OUT3`	`adapter::types::unidirectional::AUI`	Third output (identical to IN)
Plug	`OUT4`	`adapter::types::unidirectional::AUI`	Fourth output (identical to IN)

Functionality

This function block does not perform any data manipulation. It acts as a passive distribution unit: As soon as a signal is present via adapter `IN`, it is passed on to all four output adapters `OUT1`–`OUT4` without delay or modification. The signal direction is unidirectional, from the socket to the plugs.

Technical Features

- **Generic Type:** The function block is declared as a generic function block (`GenericClassName = 'GEN_AUI_SPLIT'`). It can therefore be used with various implementations of the AUI adapter type.
- **No States:** Since there are no events or algorithms, the function block does not have an internal state machine.
- **License:** The source code is available under the **Eclipse Public License 2.0**.

State Overview

This function block has no event inputs or outputs and does not execute any algorithm. There is no explicit state machine. The function block behaves like a simple signal distributor (wire connection).

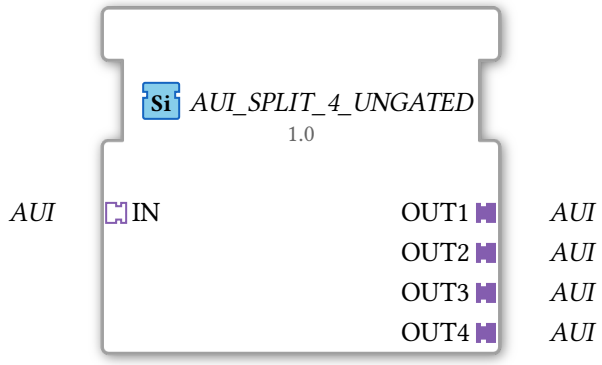
Application Scenarios

- **Signal Cascading:** A sensor signal (e.g., an AUI-based clock signal) needs to be distributed to multiple actuators.
- **Test Environments:** A test signal is to be routed in parallel to multiple devices under test.
- **Redundancy:** A signal is split across multiple parallel paths to ensure fault tolerance.
- **Bus Extension:** As a passive splitter in an AUI communication system.

Comparison with Similar Function Blocks

- **AUI_SPLIT_2** – Splits one input into two outputs (analog principle, fewer outputs).
- **AUI_MERGE** – Combines multiple AUI inputs into a single output (counterpart).
- **AUI_SELECT** – Selects one of several inputs using a control signal (with selection function).
- Unlike these function blocks, `AUI_SPLIT_4` offers a pure 1:4 distribution without selection logic or merging.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AUI_SPLIT_4** function block is a simple yet useful component for passively multiplying AUI signals. Its generic nature and clear interface make it a flexible tool in automation development, especially when multiple identical receivers need to be supplied with the same signal.

AUI_SPLIT_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_SPLIT_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Conclusion

The **AUI_SPLIT_4_UNGATED** function block is a simple yet useful component for passively multiplying AUI signals. Its generic nature and clear interface make it a flexible tool in automation development, especially when multiple identical receivers need to be supplied with the same signal.

AUI_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUI_SPLIT_5** is a generic building block for splitting an incoming AUI adapter (Automation Unit Interface) into five separate, identical AUI outputs. It implements a 1:5 distribution in a unidirectional data direction. Designed for use in automation technology, it enables the redundant or distributed forwarding of AUI signals.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available. Signals are transmitted exclusively via the adapter interfaces.

Data Outputs

No data outputs available.

Adapters

The module features six adapter interfaces of type `adapter::types::unidirectional::AUI`:

- **IN** (Socket) – Input adapter for the AUI signal to be distributed.
- **OUT1** to **OUT5** (Plugs) – Five output adapters that mirror the incoming signal.

All adapters are unidirectional and transmit data and, optionally, associated events according to the AUI specification.

Functionality

The module functions as a pure splitter without logic or buffering. An AUI signal present at socket **IN** is copied in parallel and unchanged to all five plugs **OUT1** to **OUT5**. The forwarding is instantaneous, i.e., without delay due to internal processing. The individual outputs are not galvanically or logically isolated – a change at the input immediately affects all outputs.

Technical Features

- **Generic Type**: The function block (FB) is declared as a generic block (attribute `eclipse4diac::core::GenericClassName = 'GEN_AUI_SPLIT'`). This allows for later type adaptation or instantiation with a specific AUI type.
- **No State Maintenance**: Since there are no events or data that react to changes, the FB is stateless. A state machine is not required.
- **Full Bandwidth**: The outputs provide the input signal without restriction – all data and event channels of the AUI adapter are copied 1:1.

State Overview

The function block does not have its own states or state machines. It behaves like passive wiring. A state overview is therefore not applicable.

Application Scenarios

- **Signal Distribution**: Splitting a central AUI data stream to multiple parallel consumers (e.g., displays, monitoring units, controllers).
- **Test and Diagnostic Setups**: Used in test benches to simultaneously send a signal to multiple measuring devices or logging systems.
- **Redundancy**: Provides identical signals for failover systems when AUI communication is unidirectional.
- **Bus Coupling**: Used as a passive splitter in AUI-based line or star topologies.

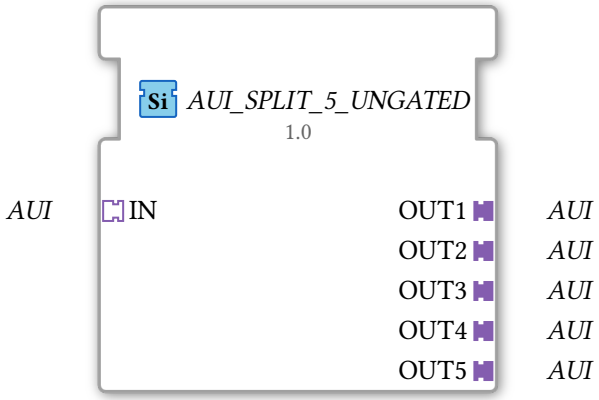
Comparison with Similar Components

- **AUI_SPLIT_2 / AUI_SPLIT_3 / AUI_SPLIT_4**: Analog components with fewer outputs; scaling is achieved solely by selecting the appropriate split type.
- **AUI_MERGE (e.g., AUI_MERGE_5)**: Combines multiple AUI inputs into a single output – the opposite function.
- **Pure Event Splitters (E_SPLIT)**: Share only events, not data adapters. The AUI_SPLIT_5, however, distributes complete adapter interfaces.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion



The **AUI_SPLIT_5** is a simple yet essential component for multiplying AUI signals. Its generic design and the adapter's complete passthrough make it highly versatile. It represents an optimal solution for applications requiring unidirectional 1:5 distribution while minimizing latency.

AUI_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUI_SPLIT_6** is used to split an incoming **AUI adapter** (Application Universal Interface) into six outgoing AUI adapters. It is designed as a generic function block capable of distributing the incoming AUI signal to all six outputs without any data processing or logic.

Interface Structure

Event Inputs
No event inputs available.

Event Outputs
No event outputs available.

Data Inputs
No data inputs available.

Data Outputs
No data outputs available.

Adapters
The function block uses adapters exclusively for communication:

Direction	Name	Type	Description
Input	**IN**	`adapter::types::unidirectional::AUI`	Incoming AUI adapter being split.
Output	**OUT1**	`adapter::types::unidirectional::AUI`	First outgoing AUI adapter.
Output	**OUT2**	`adapter::types::unidirectional::AUI`	Second outgoing AUI adapter.
Output	**OUT3**	`adapter::types::unidirectional::AUI`	Third outgoing AUI adapter.
Output	**OUT4**	`adapter::types::unidirectional::AUI`	Fourth outgoing AUI adapter.
Output	**OUT5**	`adapter::types::unidirectional::AUI`	Fifth outgoing AUI adapter.
Output	**OUT6**	`adapter::types::unidirectional::AUI`	Sixth outgoing AUI adapter.

Functionality
The function block forwards the AUI signal arriving at the adapter input **IN** to all six adapter outputs (**OUT1** to **OUT6**) without any delay or processing. No data manipulation takes place – the function block acts purely as a splitter for AUI signals.

Technical Features
- The function block is declared as a **generic function block**: The attribute `eclipse4diac::core::GenericClassName` is set to `'GEN_AUI_SPLIT'`.
- There is no state management or event logic – the function block is purely combinatorial.
- The outputs are independent of each other; A fault at one output does not affect the others.
- By using AUI adapters, the function block is optimized for unidirectional signal transmission.

State Overview
The function block has **no states**. It operates continuously without an internal state machine. The input signal is immediately and continuously mirrored to all outputs.

Application Scenarios
- **Signal Distribution in Control Engineering**: When an AUI signal (e.g., a measured value or control command) needs to be passed on to multiple devices.
- **Redundancy or Parallel Processing**: Distribution of a signal to multiple identical downstream functional units.
- **Test and Simulation Setups**: Splitting an AUI signal for simultaneous monitoring and processing.

Comparison with Similar Function Blocks
- **AUI_SPLIT_2 / AUI_SPLIT_4**: These function blocks split a signal across two or four outputs, respectively. **AUI_SPLIT_6** offers the largest number (6) of outputs, thus covering applications with many parallel destinations.
- **AUI_MERGE_***: Unlike splitters, merge blocks combine multiple AUI signals into one.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AUI_SPLIT_6** is a simple yet effective distribution block for AUI signals. It enables the star-shaped routing of an input signal to up to six independent outputs. Due to its generic nature and lack of logic, it is ideally suited for flexible and expandable automation solutions.

AUI_SPLIT_6_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_SPLIT_6`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUI_SPLIT_6_UNGATED** is used to split an incoming **AUI adapter** (Application Universal Interface) into six outgoing AUI adapters. It is designed as a generic function block capable of distributing the incoming AUI signal to all six outputs without any data processing or logic.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

The function block uses adapters exclusively for communication:

Direction	Name	Type	Description
Input	**IN**	`adapter::types::unidirectional::AUI`	Incoming AUI adapter being split.
Output	**OUT1**	`adapter::types::unidirectional::AUI`	First outgoing AUI adapter.
Output	**OUT2**	`adapter::types::unidirectional::AUI`	Second outgoing AUI adapter.
Output	**OUT3**	`adapter::types::unidirectional::AUI`	Third outgoing AUI adapter.
Output	**OUT4**	`adapter::types::unidirectional::AUI`	Fourth outgoing AUI adapter.
Output	**OUT5**	`adapter::types::unidirectional::AUI`	Fifth outgoing AUI adapter.
Output	**OUT6**	`adapter::types::unidirectional::AUI`	Sixth outgoing AUI adapter.

Functionality

The function block forwards the AUI signal arriving at the adapter input **IN** to all six adapter outputs (**OUT1** to **OUT6**) without any delay or processing. No data manipulation takes place – the function block acts purely as a splitter for AUI signals.

Technical Features

- The function block is declared as a **generic function block**: The attribute `eclipse4diac::core::GenericClassName` is set to `'GEN_AUI_SPLIT'`.
- There is no state management or event logic – the function block is purely combinatorial.
- The outputs are independent of each other; A fault at one output does not affect the others.
- By using AUI adapters, the function block is optimized for unidirectional signal transmission.

State Overview

The function block has **no states**. It operates continuously without an internal state machine. The input signal is immediately and continuously mirrored to all outputs.

Application Scenarios

- **Signal Distribution in Control Engineering**: When an AUI signal (e.g., a measured value or control command) needs to be passed on to multiple devices.
- **Redundancy or Parallel Processing**: Distribution of a signal to multiple identical downstream functional units.
- **Test and Simulation Setups**: Splitting an AUI signal for simultaneous monitoring and processing.

Comparison with Similar Function Blocks

- **AUI_SPLIT_2 / AUI_SPLIT_4**: These function blocks split a signal across two or four outputs, respectively. **AUI_SPLIT_6_UNGATED** offers the largest number (6) of outputs, thus covering applications with many parallel destinations.
- **AUI_MERGE_***: Unlike splitters, merge blocks combine multiple AUI signals into one.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The **AUI_SPLIT_6_UNGATED** is a simple yet effective distribution block for AUI signals. It enables the star-shaped routing of an input signal to up to six independent outputs. Due to its generic nature and lack of logic, it is ideally suited for flexible and expandable automation solutions.

AUI_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUI_SPLIT_7` is used to distribute an incoming AUI (Application User Interface) signal to up to seven identical outputs. It is designed as a generic block and operates exclusively via adapter interfaces – without event or data inputs/outputs in the traditional sense. This makes it particularly suitable for pure signal distribution in adapter-based architectures.

Interface Structure

Event Inputs

None available.

Event Outputs

None available.

Data Inputs

None available.

Data Outputs

None available.

Adapter

Type	Direction	Name
Socket (adapter::types::unidirectional::AUI)	Input	IN
Plug (adapter::types::unidirectional::AUI)	Output	OUT1
Plug (adapter::types::unidirectional::AUI)	Output	OUT2
Plug (adapter::types::unidirectional::AUI)	Output	OUT3
Plug (adapter::types::unidirectional::AUI)	Output	OUT4
Plug (adapter::types::unidirectional::AUI)	Output	OUT5
Plug (adapter::types::unidirectional::AUI)	Output	OUT6

Plug (adapter::types::unidirectional::AUI)	Output	OUT7

Functionality

This module represents a 1-to-7 distribution logic for AUI adapters. The signal received via socket `IN` is replicated to all seven plugs (`OUT1` … `OUT7`) without further processing or logical conditions. The forwarding is purely passive: each received signal is simultaneously made available at every output.

Technical Features

- **Pure Adapter Module**: The module contains neither event nor data inputs/outputs – all communication takes place via the AUI adapters.
- **Unidirectional**: The adapters are of type `unidirectional`, meaning that data flows only from the input (socket) to the outputs (plugs).
- **Generic Type**: The function block (FB) is implemented as a generic block (`GenericClassName = 'GEN_AUI_SPLIT'`) and can be reused for various AUI subtypes.
- **No State Logic**: Due to its pure distribution function, the block has no internal state machine – it operates continuously and without delay.

State Overview

There is no state machine. The block is purely data flow controlled and has only one static operating state.

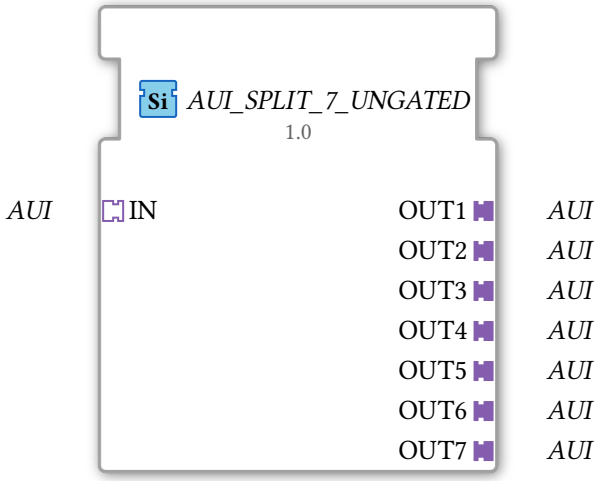
Application Scenarios

- **Signal Distribution in Field Automation**: An AUI signal (e.g., sensor data or control commands) coming from a central controller is forwarded to several parallel actuators or display units.
- **Test and Simulation Environments**: Used as a splitter to simultaneously output an input signal to multiple simulation or diagnostic units.
- **Modular Systems**: In adapter-based architectures (e.g., according to IEC 61499), this function block is used to distribute a single interface across multiple downstream function blocks.

Comparison with Similar Function Blocks

- **AUI_SPLIT_2, AUI_SPLIT_4** – Function blocks with the same functionality, but reduced to 2 or 4 outputs, respectively. The `AUI_SPLIT_7` offers the largest number of outputs and thus covers more extensive distribution requirements.
- **AUI_MERGE** – the counterpart that combines multiple AUI inputs into a single output. In contrast, the `SPLIT` is purely passive and does not aggregate any data.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AUI_SPLIT_7` is a simple yet essential function block for unidirectional signal distribution in adapter-based control systems. Thanks to its generic design and clear 1-to-N structure, it can be flexibly integrated into any AUI-based architecture. For applications requiring broad parallel distribution without side effects, it represents a robust and maintainable solution.

AUI_SPLIT_7_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_SPLIT_7`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Conclusion

The `AUI_SPLIT_7_UNGATED` is a simple yet essential function block for unidirectional signal distribution in adapter-based control systems. Thanks to its generic design and clear 1-to-N structure, it can be flexibly integrated into any AUI-based architecture. For applications requiring broad parallel distribution without side effects, it represents a robust and maintainable solution.

AUI_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUI_SPLIT_8` is used to distribute an incoming AUI adapter signal (unidirectional) to eight identical output adapters. It functions as a passive splitter and enables the simple distribution of a signal path to multiple downstream components. The function block is generic and uses the adapter pattern of IEC 61499.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

Adapters

Adapter	Type	Direction
IN	`adapter::types::unidirectional::AUI`	Socket (Input)
OUT1	`adapter::types::unidirectional::AUI`	Plug (Output)
OUT2	`adapter::types::unidirectional::AUI`	Plug (Output)
OUT3	`adapter::types::unidirectional::AUI`	Plug (Output)
OUT4	`adapter::types::unidirectional::AUI`	Plug (Output)
OUT5	`adapter::types::unidirectional::AUI`	Plug (Output)
OUT6	`adapter::types::unidirectional::AUI`	Plug (Output)
OUT7	`adapter::types::unidirectional::AUI`	Plug (Output)
OUT8	`adapter::types::unidirectional::AUI`	Plug (Output)

Functionality

This module forwards all data and events received via the `IN` socket of the unidirectional AUI adapter to all eight `OUT` adapters. No logical or temporal processing takes place; the forwarding is one-to-one and without latency. The adapters are of the same type (`AUI`), so the complete signature (data, events, and included interfaces) is passed through unchanged.

Technical Features

- **Generic Type**: The component is declared as generic using `GenericClassName` (`GEN_AUI_SPLIT`). It can therefore be used for various AUI adapter variants (e.g., different data widths), provided the underlying type is `adapter::types::unidirectional::AUI`.
- **Unidirectional**: The adapters are unidirectional – data transmission is only possible in one direction (from IN to OUT). Return channels are not included.
- **No State Logic**: The component has no internal states, algorithms, or event processing. It is purely structural (passive wiring).

State Overview

The component has no states. It behaves statically and always passes through all incoming signals.

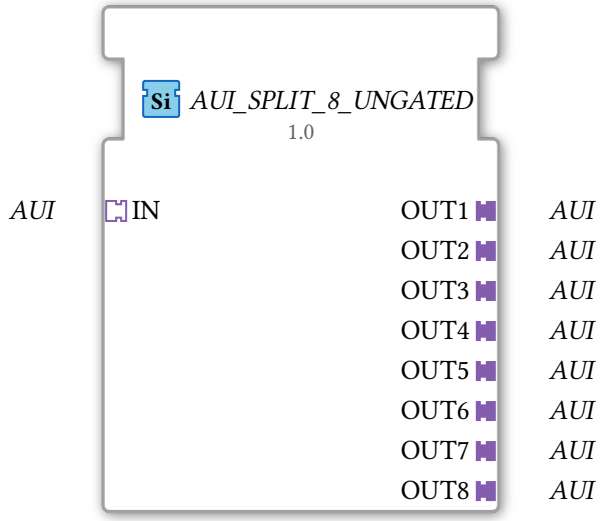
Application Scenarios

- **Signal Distribution in Automation Networks**: A sensor or controller provides an AUI-compliant signal that needs to be distributed to multiple actuators or subsystems.
- **Test and Simulation Environments**: Distributing a test signal across multiple parallel test paths.
- **Redundant Signal Paths**: Simultaneously supplying multiple independent controllers with the same information.

Comparison with Similar Components

- **`AUI_MERGE_8`** (counterpart): Combines eight AUI inputs into one output (inverse operator).
- **`AUI_SPLIT_2`, `AUI_SPLIT_4`**: Same functionality with fewer outputs.
- **Event Splitters (e.g., `E_SPLIT`)**: Distribute only events without the accompanying data from an adapter. `AUI_SPLIT_8`, on the other hand, replicates the entire adapter content.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AUI_SPLIT_8` is a simple yet essential component for replicating a unidirectional AUI signal path. Due to its generic design and purely passive structure, it is suitable for any AUI-based application where a signal needs to be distributed to up to eight receivers. The implementation is lean, error-free, and requires no configuration.

AUI_SPLIT_8_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_SPLIT_8`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. - **Redundant Signal Paths**: Simultaneously supplying multiple independent controllers with the same information.

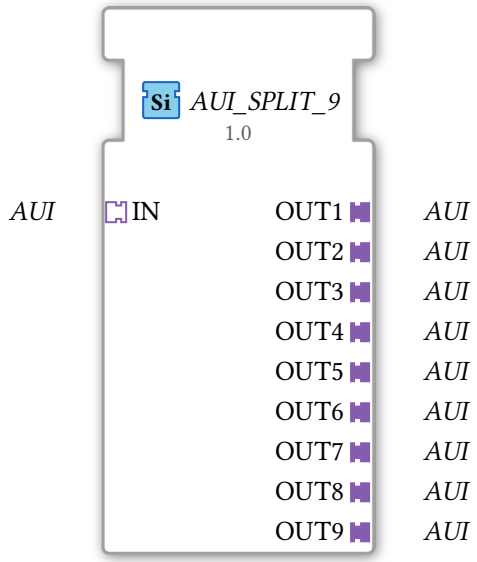
Comparison with Similar Components

- **`AUI_MERGE_8`** (counterpart): Combines eight AUI inputs into one output (inverse operator).
- **`AUI_SPLIT_2`, `AUI_SPLIT_4`**: Same functionality with fewer outputs.
- **Event Splitters (e.g., `E_SPLIT`)**: Distribute only events without the accompanying data from an adapter. `AUI_SPLIT_8_UNGATED`, on the other hand, replicates the entire adapter content.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AUI_SPLIT_8_UNGATED` is a simple yet essential component for replicating a unidirectional AUI signal path. Due to its generic design and purely passive structure, it is suitable for any AUI-based application where a signal needs to be distributed to up to eight receivers. The implementation is lean, error-free, and requires no configuration.

AUI_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUI_SPLIT_9** serves as a generic splitter for unidirectional AUI adapter connections. It receives an incoming AUI signal via socket `IN` and distributes it identically to nine separate output plugs (`OUT1` to `OUT9`). The block is typed as a generic function block (`GEN_AUI_SPLIT`) and can be used in various automation environments where an AUI signal needs to be passed on to multiple downstream components.

Interface Structure

Event Inputs

Not present. The function block operates purely on an adapter basis without event control.

Event Outputs

Not available.

Data Inputs

Not available.

Data Outputs

Not available.

Adapters

Socket (Input):

- `IN` – Type: `adapter::types::unidirectional::AUI` Receives the AUI signal to be distributed.

Plugs (Outputs):

- `OUT1` to `OUT9` – each Type: `adapter::types::unidirectional::AUI` Nine identical outputs that forward the incoming AUI signal unchanged.

The FB is a pure adapter splitter without additional logic and operates unidirectionally. All plugs are of the same type as the socket.

Functionality

The function block copies the AUI signal present at socket `IN` to all nine output plugs. No signal conditioning, delay, or filtering takes place – the outputs are exact replicas of the input. Distribution occurs in parallel and without data buffering. Since it is a generic function block, the specific signal type (e.g.,

fieldbus data, measured values, control commands) is not defined; it is determined by the AUI adapter definition.

Technical Features

- **Generic Type**: The function block is attributed as `GEN_AUI_SPLIT` with a type hash, which supports the dynamic creation of instances at runtime in the 4diac IDE.
- **No State Dependency**: The function block has no internal states or timing behavior – the outputs are always a direct switching of the input.
- **Extensibility**: The unidirectional adapter interface allows the FB to be integrated into any AUI-based communication chain.
- **Compatibility**: Requires the imports `eclipse4diac::core::GenericClassName` and `eclipse4diac::core::TypeHash`, which must be available in the target 4diac environment.

State Overview

The FB does not have a state machine. Sequential processing does not occur; signal transmission is static and continuous. There is no explicit state.

Application Scenarios

- **Signal Distribution in Fieldbus Systems**: Splitting an AUI-based bus signal to multiple subsystems or actuators.
- **Test and Debugging Environments**: Connected downstream of a signal generator to supply multiple test points in parallel.
- **Redundancy or Parallel Operation**: When a signal needs to be sent to multiple controllers or monitoring units simultaneously.
- **Prototype Development**: Serves as a placeholder for later branching in the adapter logic.

Comparison with Similar Function Blocks

- **AUI_SPLIT_4 / AUI_SPLIT_16**: These function blocks offer the same functionality with 4 or 16 outputs, respectively. The choice depends on the required number of branches.
- **AUI_MERGE_***: A merger combines multiple AUI inputs into one output – the opposite function. A splitter, on the other hand, distributes the output.
- **Generic Splitters of Other Adapter Types (e.g., Data-Based)**: Unlike data-event splitters, AUI_SPLIT_9 operates purely at the adapter level and requires no event control, thus reducing implementation effort.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AUI_SPLIT_9** is a simple yet effective function block for distributing multiple unidirectional AUI signals. Its generic nature allows for flexible reuse in various projects. Due to its lack of inherent logic, this building block is resource-efficient and easy to understand. It is particularly well-suited for the rapid implementation of one-to-many connections in adapter-based automation architectures.

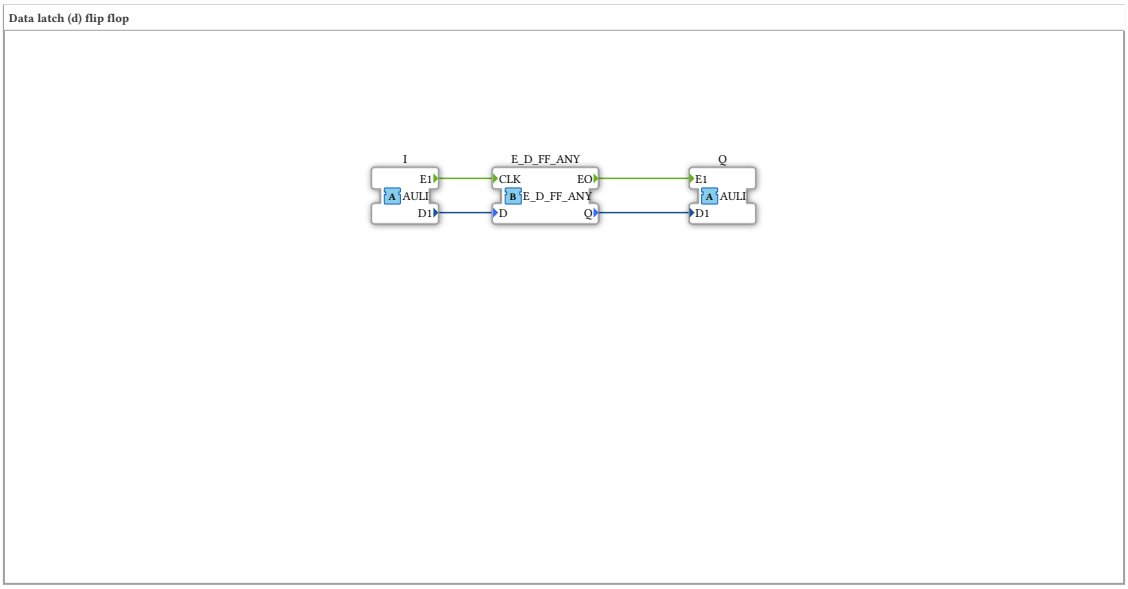
Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AULI_D_FF

Value to latch – *AULI*

AULI – Latched value

• – ◦ • – ◦ • – ◦ •

Introduction

The AULI_D_FF function block implements a clock-edge-triggered D flip-flop (data latch). Upon receiving an event, it accepts the incoming data value and holds it until the next clock cycle. Input and output are handled via standardized unidirectional adapters, allowing for easy integration of the block into modular control architectures.

Interface Structure

Event Inputs

- **I.E1** – Clock event (rising edge): triggers the transfer of the data value

Event Outputs

- **Q.E1** – Output event: sent after successful transfer of the value

Data Inputs

- **I.D1** – Data value to be latched (any type, as the internal function block `E_D_FF_ANY` is used)

Data Outputs

- **Q.D1** – Latched data value (corresponds to the last value transferred from I.D1)

Adapters

The function block has two unidirectional adapters of type `adapter::types::unidirectional::AULI`:

- **Socket I** (input): receives the clock event and the data value.
- **Plug Q** (Output): Passes on the acknowledgment event and the stored data value.

Functionality

As soon as an event arrives at **I.E1** on input adapter I, the current value of **I.D1** is transferred to the internal flip-flop. Immediately afterward, the event **Q.E1** is sent at output adapter Q, and the new value is output to **Q.D1**. The stored value is retained until another clock event transfers a new value.

The function block operates as **clocked memory** and is particularly suitable for synchronizing data flows in event-driven automation systems.

Technical Features

- The function block is implemented as a **composition** and internally uses the standard function block `iec61499::events::E_D_FF_ANY`, which provides the actual flip-flop functionality.
- The use of adapters enables **uniform connectivity** to a wide variety of components that support the same adapter type.
- No further configuration parameters or initializations are required – the function block operates deterministically after the first clock edge.

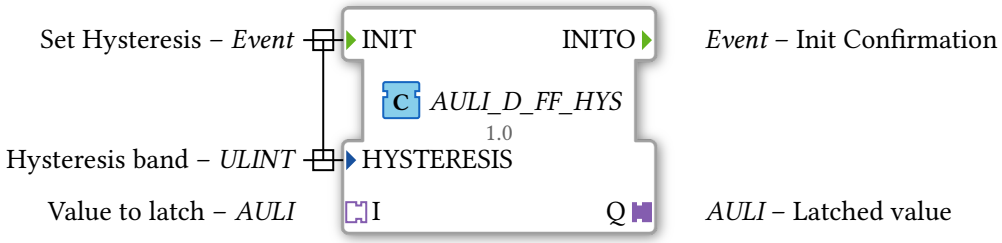
State Overview

The internal state of the D flip-flop can be logical 0 or 1. Since the data value can be arbitrary, the state corresponds to the last latched value. An explicit state diagram is not required, as the behavior is fully described by the simple edge triggering.

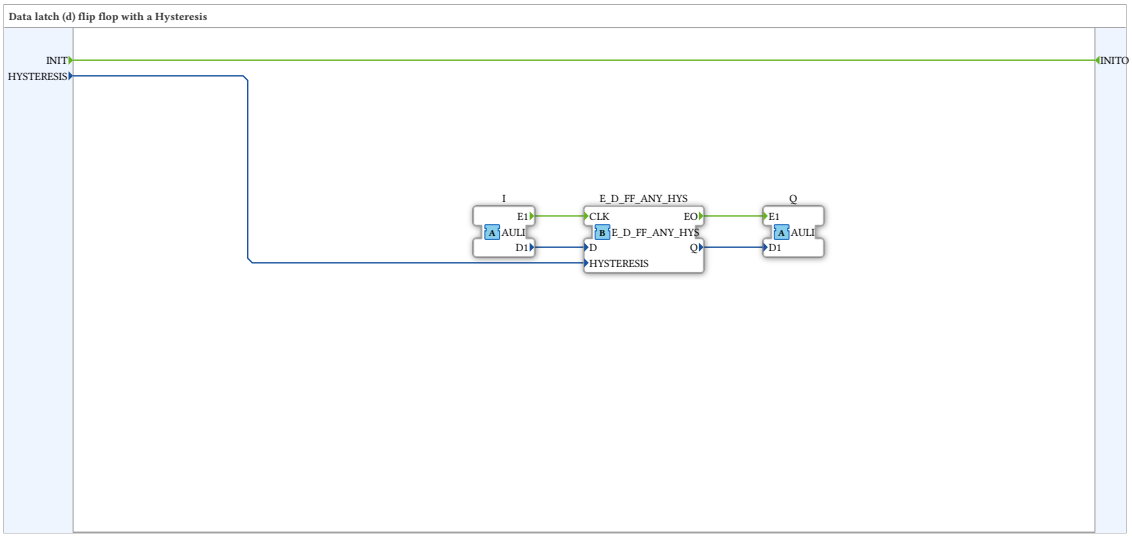
Clock (I.E1)	Previous Q value	New Q value
Event	arbitrary	Value of I.D1
no event	unchanged	unchanged

Application Scenarios

- **Data Buffering** in production lines: A sensor value is acquired and buffered at each clock cycle.
- **State Machines**: Implementation of memory cells for step sequences where the next state depends on the current output.
- **Synchronization**: Adapting asynchronous data streams to a uniform clock in distributed control systems.
- **Signal Processing**: Holding a digital signal for the duration of a clock cycle.



Comparison with Similar Components



Component	Description	Difference from AULI_D_FF
SR-FF	Set-Reset Flip-Flop	Requires two separate inputs; can have illegal states.
JK-FF	Universal Flip-Flop	More complex, with toggle functionality; not needed here.
T-FF	Toggle Flip-Flop	Changes the state on each clock cycle; no data input.
AULI_D_FF	D Flip-Flop	Simple, no toggle, no illegal states, ideal for storing a value.

Conclusion

The AULI_D_FF is a compact, event-driven D flip-flop component that communicates via standardized adapters. It is ideally suited for intermediate data storage in discrete-event control environments. Its internal use of a proven standard function block ensures robust and deterministic behavior. The modular adapter interface facilitates integration into complex automation projects.

AULI_D_FF_HYS

• – ○ • – ○ • – ○ •

Introduction

The function block `AULI_D_FF_HYS` implements a data latch (D flip-flop) with adjustable hysteresis. It encapsulates the logic of such a flip-flop in an adapter-based interface and allows the transmission of data and events via unidirectional adapters of type `AULI`.

Interface Structure

Event Inputs

- `INIT` (EInit): Sets the hysteresis value and initializes the function block.

Event Outputs

- `INITO` (EInit): Confirms the successful initialization process (passed-through INIT).

Data Inputs

- `HYSTERESIS` (ULINT): Sets the hysteresis width. The value is taken during the INIT event.

Data Outputs

No direct data outputs are available; the output data is provided via the `Q` adapter.

Adapters

- **Socket `I`** (Type `adapter::types::unidirectional::AULI`): Receives the value to be latched and the associated clock signal.
- **Plug `Q`** (Type `adapter::types::unidirectional::AULI`): Passes on the latched value and the output event.

Functionality

The module internally uses the sub-module `E_D_FF_ANY_HYS`. The clock signal (`I.E1`) is fed to the CLK input and the data value (`I.D1`) to the D input of the sub-module via socket `I`. The data input `HYSTERESIS` is directly connected to the corresponding input of the sub-module. The output `Q` of the sub-module is

transferred to the data output of the plug `Q` (`Q.D1`), and the event `E0` of the sub-module is mapped to the output event of the plug `Q` (`Q.E1`).

The INIT event is passed through unchanged as INITO. The actual hysteresis initialization is performed by the sub-module upon receiving INIT, adopting the current value of `HYSTERESIS`.

The hysteresis prevents the output from switching immediately in response to small fluctuations in the input signal. Only when the input value exceeds or falls below the latched value by more than the hysteresis band is a new value adopted.

Technical Features

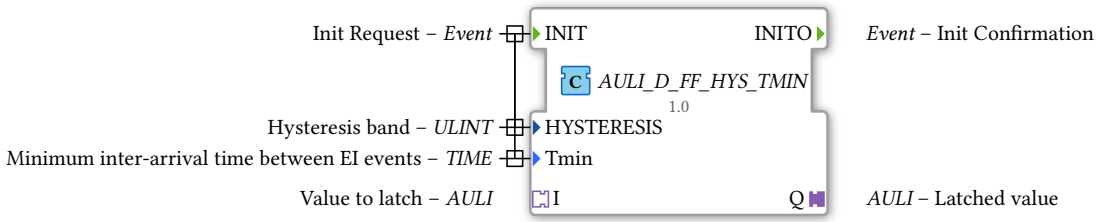
- The function block is defined as a pure interaction of adapters and a sub-function block (no dedicated ECC or SIFB logic).
- The use of the adapter type `AULI` (unidirectional) allows for a clear separation of data and events in a standardized interface.
- Hysteresis is set only during the INIT event; thereafter, the value remains constant for the duration of operation.
- The function block is available under the Eclipse Public License 2.0 and is defined in the IEC 61499 Annex A standard structure.

State Overview

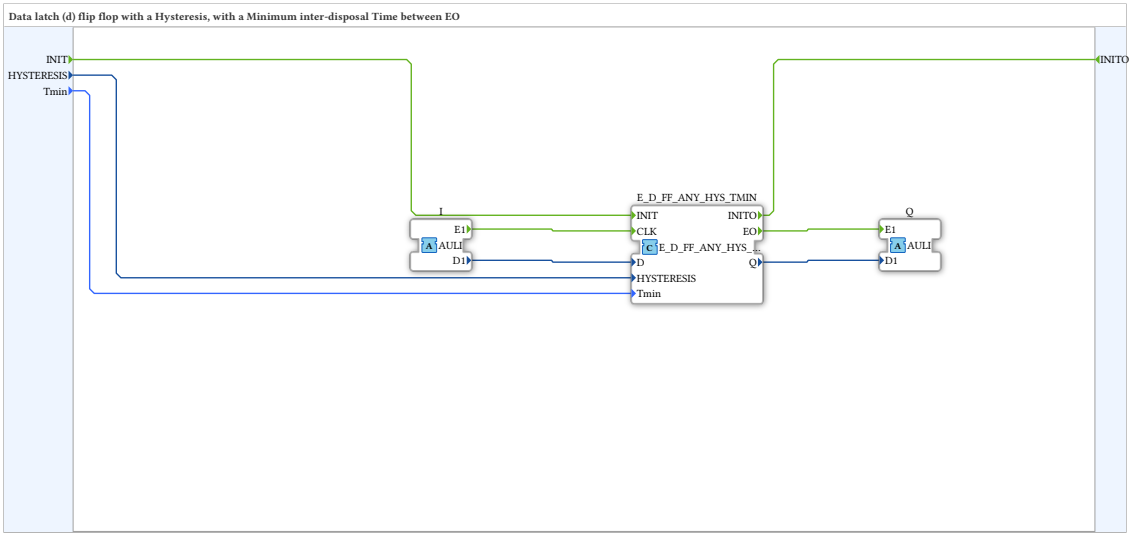
The function block does not have its own state machine. The entire state logic is implemented in the sub-function block `E_D_FF_ANY_HYS`, which presumably implements two states (setting the latch, checking hysteresis).

Application Scenarios

- **Debouncing of Sensors or Switches**: A noisy digital signal is only accepted as a stable value if it exceeds the hysteresis band.
- **Signal Smoothing**: Small fluctuations in a measured value are suppressed, while significant changes are immediately passed through.
- **Data Backup in Asynchronous Systems**: The function block serves as a reliable buffer between a signal source and a subsequent processing unit.



Comparison with Similar Function Blocks



- A simple D flip-flop (e.g., `E_D_FF`) accepts the input value on every rising edge without hysteresis. The `AULI_D_FF_HYS` extends this functionality with a configurable switching threshold.
- Compared to a Schmitt trigger IC, the focus here is on the latching behavior with added hysteresis, not on level conversion.

Conclusion

The `AULI_D_FF_HYS` is a compact, adapter-based functional IC for reliable signal conditioning with hysteresis. By delegating the logic to a specialized sub-IC, the design remains maintainable and expandable. It is particularly suitable for applications where noise or unstable input signals need to be filtered without having to forgo a simple flip-flop.

AULI_D_FF_HYS_TMIN

• – ◦ • – ◦ • – ◦ •

The function block **AULI_D_FF_HYS_TMIN** implements a clock-edge-triggered D flip-flop (data latch) with hysteresis and a minimum dwell time between successive events. It is typically used to smooth noisy or fluctuating input signals and suppress unwanted rapid switching. The block communicates via standardized unidirectional adapters.

Event	Type	Comment
`INIT`	`EInit`	Initialization request. Sets the parameters hysteresis and minimum time.
Event	Type	Comment
`_____`	`__`	`____`
`INITO`	`EInit`	Confirmation of successful initialization.
Variable	Type	Comment
`_____`	`__`	`____`
`HYSTERESIS`	`ULINT`	Hysteresis band as an unsigned integer. The output only changes its value when the input exceeds the band.
`Tmin`	`TIME`	Minimum time between two triggered events at the output. Prevents excessively fast switching.

No direct data outputs. The latched information is provided via the `Q` adapter.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

Adapter	Direction	Type	Comment

`I` (Socket)	**Input**	`adapter::types::unidirectional::AULI`	Receiving adapter that provides the signal to be latched. Contains the event and data signals `E1` and `D1`.
`Q` (Plug)	**Output**	`adapter::types::unidirectional::AULI`	Output adapter that provides the currently held value. Signal `E1` indicates a value change, `D1` contains the value.

Functionality

The function block internally uses the function block `E_D_FF_ANY_HYS_TMIN`, which implements the actual logic. The operation is as follows:

1. **Initialization:** An event `INIT` transfers the parameters `HYSTERESIS` and `Tmin` into the internal function block.
2. **Hysteresis:** The new output value is only adopted if the difference between the current input `D1` and the last valid output exceeds the hysteresis value.
3. **Minimum Time:** After each adoption (output of an event on `Q.E1`), no further adoption is permitted for the duration `Tmin`.
4. **Output:** On a valid edge, the new value is output via `Q.D1`, and an event is generated on `Q.E1`.

- **Hysteresis:** Suppresses noise or small fluctuations at the input by defining a deadband. The output only changes in the case of significant deviations.
- **Minimum Dwell Time (`Tmin`):** Enforces a pause between successive output events. This ensures compliance with minimum switching times due to mechanical or system requirements.
- **Adapter Interface:** The use of a unidirectional adapter type enables loose coupling and reusability in different environments.
- **Internal Function Block:** The actual logic is outsourced to a typed function block, which improves testability and maintainability.

The function block does not have its own explicit states, but delegates to the internal function block. However, the essential behaviors can be described as follows:

Phase	Description
Initial	After power-on, `HYSTERESIS` and `Tmin` are not yet applied. A `INIT` event must set the parameters.
Ready	After successful initialization, the function block waits for clock events at input `I.E1`.
Lock (Tmin active)	After an output event, any further takeover is blocked for the duration `Tmin`.
Takeover (on valid edge)	If the hysteresis is exceeded and no lock is present, the current input value is adopted and output.

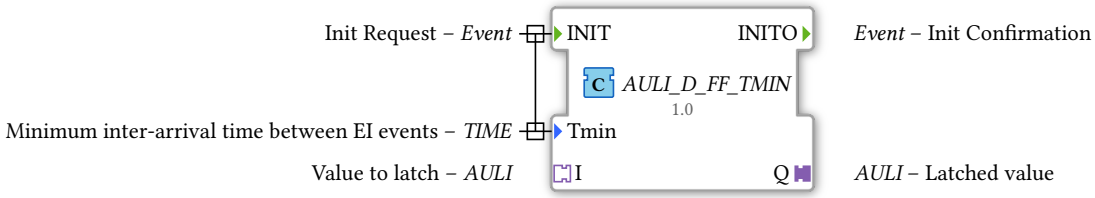
- **Sensor Signal Debouncing:** A push button or proximity switch delivers a fluctuating signal. Hysteresis and a minimum time ensure a clean switching edge.
- **Data Logic with Signal Conditioning:** In automation technology, where a digital input value can be acquired but distorted by noise or bounce.
- **Time-Controlled Actuators:** If an actuator requires a minimum switching time (e.g., valves), `Tmin` prevents excessively fast actuation.

Function Block	Properties
Simple D-FF	No hysteresis, no delay – instantly responds to every clock edge.
D-FF with Hysteresis	Contains only the hysteresis band, no time limit between outputs.
D-FF with Tmin	Minimum dwell time only, without hysteresis – can still switch quickly in noisy environments.

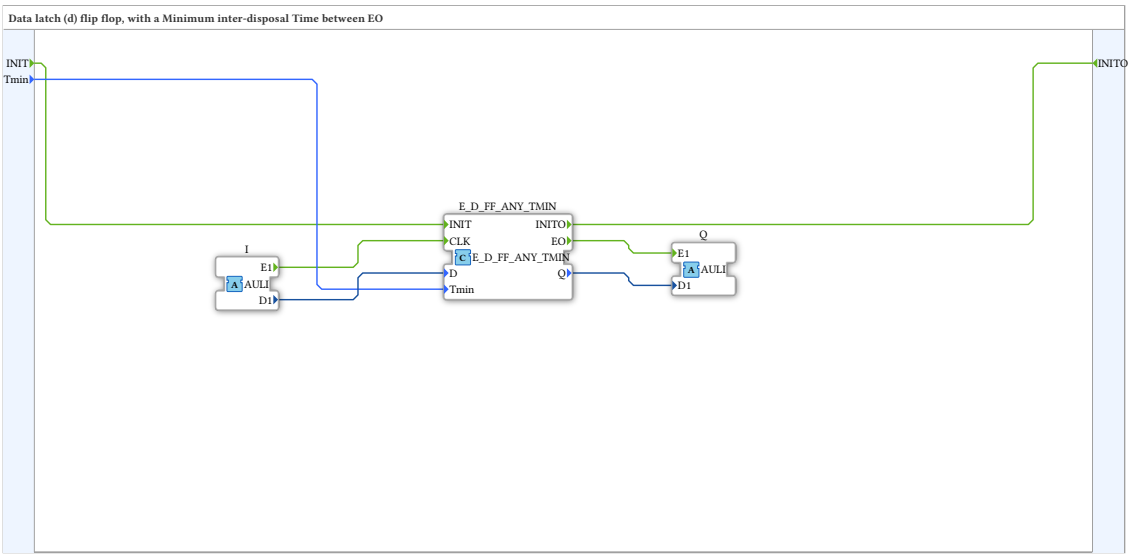
AULI_D_FF_HYS_TMIN	Combines hysteresis and minimum dwell time – more robust against noise and protects downstream components from excessively fast switching.

The **AULI_D_FF_HYS_TMIN** offers a reliable combination of hysteresis and time limiting for clock-controlled signal takeovers. It is particularly suitable for industrial control systems where interference must be suppressed and actuators protected. The modular adapter interface facilitates integration into existing IEC 61499 applications.

Technical Features



State Overview



Application Scenarios

Comparison with Similar Function Blocks

Conclusion

AULI_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_D_FF_TMIN** implements a data latch (D flip-flop) with an adjustable minimum delay time between successive event outputs. It serves as a memory element for asynchronous event/data interfaces and ensures that a defined time interval elapses after a data transfer before another event is triggered. The block operates exclusively via adapter interfaces of type `AULI` (unidirectional) and is therefore particularly suitable for modular and distributed control architectures.

Interface Structure

Event Inputs

Name	Type	Comment

INIT	EInit	Initialization request; synchronized with `Tmin`

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization confirmation

Data Inputs

Name	Type	Comment
Tmin	TIME	Minimum time between two event outputs (EO) at the output adapter

Data Outputs

None

Adapters

Name	Role	Type	Comment
I	Socket	AULI	Input: value to latch (event E1, data D1)
Q	Plug	AULI	Output: latching value (event E1, data D1)

Functionality

This function block encapsulates an internal `E_D_FF_ANY_TMIN` function block from the IEC 61499 library. It operates as an edge-triggered D flip-flop with the following sequence:

1. **Initialization** – An event at the `INIT` input resets the internal state and assigns the parameter `Tmin`. The output `INITO` acknowledges the initialization.
2. **Event-driven data transfer** –

- An event at the adapter input `I.E1` (as a clock signal) transfers the current data value `I.D1` to the internal flip-flop.
- Simultaneously, the minimum time `Tmin` is started.
- After `Tmin` has elapsed, an event is triggered at the adapter output `Q.E1`, and the transferred data value `Q.D1` is output.

1. **Lockout time** – While `Tmin` is still active, a subsequent input event is ignored or buffered (depending on the internal implementation). Only after the specified time has elapsed can the next value be processed.

Technical Features

- **Unidirectional Adapters** – The function block exclusively uses the standardized adapter type `AULI` for events and data, enabling easy integration with other AULI-compatible function blocks.
- **Minimum Time (`Tmin`)** – Enforces a minimum pause between two consecutive output events. This prevents data loss or overloads in downstream components with limited processing speed.
- **No Dedicated Data Outputs** – Output data is provided exclusively via the plugin adapter `Q`, increasing modularity.

State Overview

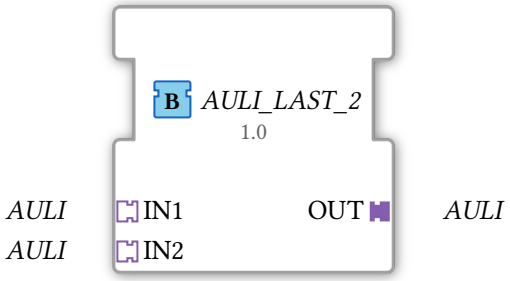
The internal function block `E_D_FF_ANY_TMIN` can be simplified to three states:

- **IDLE** – Waiting for a clock event at input `I.E1`.
- **LATCHED** – Data has been transferred and the `Tmin` timer is running. No further transfer is possible.
- **OUTPUT** – `Tmin` has expired; the output event is triggered and the block returns to the IDLE state.

Initialization (`INIT`) resets the function block to the IDLE state.

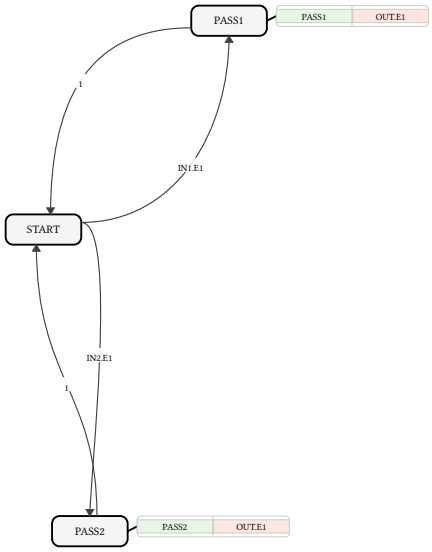
Application Scenarios

- **Data synchronization** in time-critical control loops where a sensor value may only be sampled at a minimum interval.
- **Buffering** of asynchronous events to smooth out peak loads in the data stream.
- **Cascading** of flip-flops with different minimum times to implement time-staggered signal processing.
- **Interface between fast and slow components** (e.g., between fast logic and a slow actuator).



Comparison with similar components

- **E_D_FF** – Simple D flip-flop without timing; takes data immediately on every clock edge. The `AULI_D_FF_TMIN` extends this with an adjustable minimum time.
- **E_D_FF_TMIN** – Same internal core, but with direct event/data interfaces instead of adapters. The adapter version `AULI_D_FF_TMIN` is designed for systems that rely on standardized, reusable interfaces.
- **E_D_FF_ANY_TMIN** (directly used) – Offers the same functionality but is designed for arbitrary data types. `AULI_D_FF_TMIN` is specifically tailored for the AULI adapter.



Conclusion

The `AULI_D_FF_TMIN` is a specialized D flip-flop device for event/data adapter interfaces. Its integrated minimum time (`Tmin`) ensures reliable and predictable data transfer in time-critical environments. Its modular design and compliance with IEC 61499 Annex A make it a robust component for industrial control applications.

AULI_LAST_2

ECC: AULI_LAST_2

Introduction

The AULI_LAST_2 function block merges two same-type ULINT adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: ULINT adapter (unidirectional) - first signal source
- **IN2**: ULINT adapter (unidirectional) - second signal source

Output adapter (Plug):

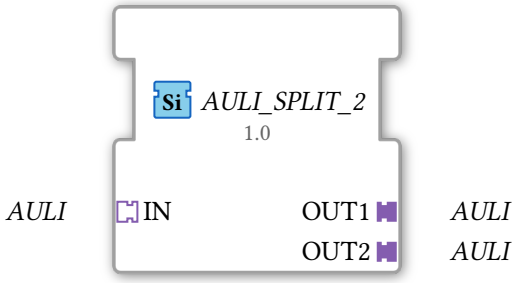
- **OUT**: ULINT adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid ULINT signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same ULINT value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AULI_LAST_2 is the inverse of `AULI_SPLIT_2`: AULI_SPLIT_2 distributes 1 input to 2 outputs, AULI_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

AULI_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AULI_SPLIT_2** is used to distribute an incoming AULI adapter (unidirectional) to two identical outputs. It is implemented as a generic function block and enables simple signal multiplication in IEC 61499-based systems.

Interface Structure

Event Inputs
None.

Event Outputs
None.

Data Inputs
None.

Data Outputs
None.

Adapter

Direction	Name	Type	Description
Socket (Input)	IN	AULI (unidirectional)	Incoming AULI data stream
Plug (Output)	OUT1	AULI (unidirectional)	First output, identical copy of IN
Plug (Output)	OUT2	AULI (unidirectional)	Second output, identical copy of IN

Functionality
The module forwards the AULI data received via the **IN** socket unchanged to both outputs, **OUT1** and **OUT2**. No data manipulation, buffering, or protocol conversion takes place. The distribution is passive and instantaneous.

Technical Features
- **Generic Type**: The function block is declared as `'GEN_AULI_SPLIT'` via the attribute `eclipse4diac::core::GenericClassName`, enabling flexible reuse in various engineering environments.
- **No State Management**: The function block has no internal state machine (ECC) and no memory behavior. It is completely passive.
- **Pure Adapter Interface**: Only adapters (`Plugs` and `Sockets`) are used; there are no data or event inputs.

State Overview
Since the function block contains no internal logic or state machine, there is no state description. Its behavior is limited to the constant forwarding of the incoming signal.

Application Scenarios
- **Signal Distribution**: Splitting an AULI data stream to two subsequent function blocks, e.g., for parallel processing or control.
- **Redundant Transmission**: Providing a second, identical data path for monitoring or security purposes.
- **Point-to-Multipoint Communication**: Enabling simple 1-to-2 wiring in adapter-based architectures.

Comparison with Similar Components

Component	Function
AULI_SPLIT_2	Split to two outputs (identical to IN)
AULI_SPLIT_N	Generalized variant with a configurable number of outputs
AULI_MERGE	Merging multiple inputs into one output

While **AULI_SPLIT_2** performs a fixed 1:2 split, generic splitters allow for a flexible number of outputs. Mergers like **AULI_MERGE** accomplish the opposite.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AULI_SPLIT_2** is a minimal and efficient component for multiplying signals from unidirectional AULI adapters. Due to its passive, stateless nature, it is ideally suited for real-time applications where copies of a data stream are needed without additional latency or logic. Its generic implementation facilitates its use in various development tools and libraries.

AULI_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AULI_SPLIT_3** is used to distribute a single AULI adapter signal to three identical outputs. It acts as a simple splitter for unidirectional AULI connections and enables the broadcast of a signal to multiple downstream components. The block is designed generically and can be instantiated for various AULI types.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Name	Type	Description
IN	AULI (unidirectional)	Input adapter – receives the signal to be distributed.
OUT1	AULI (unidirectional)	First output adapter.
OUT2	AULI (unidirectional)	Second output adapter.
OUT3	AULI (unidirectional)	Third output adapter.

Functionality

The function block forwards all AULI information (both events and associated data) arriving at the input adapter **IN** directly and without delay to all three output adapters **OUT1**, **OUT2**, and **OUT3**. No filtering, transformation, or buffering takes place. The outputs are identical and operate in parallel, so the input signal is sent to three independent receivers simultaneously.

Technical Features

- **Generic Type:** The function block is declared as a generic function block (GenericClassName `'GEN_AULI_SPLIT'`). It can be used with various specific AULI adapter types, provided they conform to the unidirectional AULI interface.
- **Latency:** Due to the pure forwarding without internal logic, latency is minimal and limited to the runtime of the runtime system.
- **Copyright:** This function block is subject to the Eclipse Public License 2.0 (SPDX License Identifier: EPL-2.0).

State Overview

The function block does not have an internal state machine. Its functionality is purely combinational and continuously active – as soon as a signal is present at the input, it is passed on to all outputs.

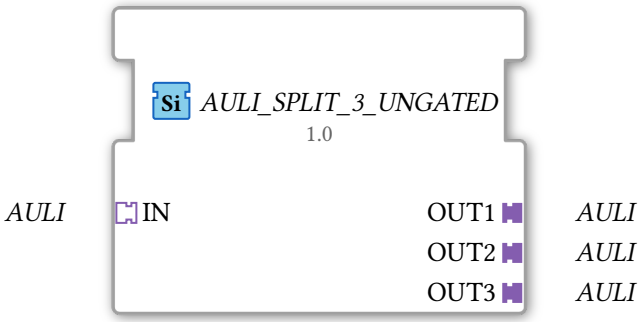
Application Scenarios

- **Signal Distribution:** An AULI signal (e.g., control commands, measured values) is to be sent to several independent actuators or subsystems.
- **Test and Simulation Setups:** A test signal is recorded or sent from a source and distributed in parallel to several monitoring or analysis blocks.
- **Redundant Processing:** The same input value is required simultaneously by several parallel logic circuits.

Comparison with Similar Function Blocks

Unlike an **AULI_MERGE** (which combines multiple inputs into one output) or an **AULI_SELECT** (which selectively passes through one of several inputs), **AULI_SPLIT_3** offers a pure fan-out function. There is no decision mechanism, no prioritization, and no data modification. Similar splitters with a different number of outputs (e.g., SPLIT_2) differ only in the number of outputs.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AULI_SPLIT_3 is a simple yet essential function block for multiplying unidirectional AULI signals. Its generic design and delay-free transmission make it particularly suitable for broadcast scenarios in automation technology, where a signal must be transmitted to multiple devices simultaneously.

AULI_SPLIT_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AULI_SPLIT_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Its generic design and delay-free transmission make it particularly suitable for broadcast scenarios in automation technology, where a signal must be transmitted to multiple devices simultaneously.

AULI_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AULI_SPLIT_4** is used to split an incoming **AULI** adapter into four separate, identical outputs. It is designed as a generic function block (Generic FB) and is distributed under the Eclipse Public License 2.0. It was developed for use in automation technology, particularly within the HR Agrartechnik GmbH environment.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::AULI`	`IN`	Socket	Input adapter for the AULI signal to be distributed
`adapter::types::unidirectional::AULI`	`OUT1`	Plug	First output adapter (identical to the input)
`adapter::types::unidirectional::AULI`	`OUT2`	Plug	Second output adapter
`adapter::types::unidirectional::AULI`	`OUT3`	Plug	Third output adapter
`adapter::types::unidirectional::AULI`	`OUT4`	Plug	Fourth Output Adapter

Functionality

This function block operates as a passive distribution structure. The AULI adapter connected to `IN` is internally routed to the four outputs `OUT1` to `OUT4`. Since no active logic, processing, or buffering takes place, the data present at the input (e.g., signals, values, states) is passed on unchanged to all four outputs. The connection is unidirectional – changes to the outputs do not affect the input.

Technical Features

- **Generic Function Block**: The function block is declared as a generic function block with the generic class name `GEN_AULI_SPLIT`. This allows for flexible adaptation and reuse in various contexts (e.g., through parameterization during instantiation).
- **Unidirectional Adapters**: All adapters used are of type `adapter::types::unidirectional::AULI`, meaning they only support data flow in one direction.
- **License**: The block is licensed under the Eclipse Public License 2.0 and may be used and modified in accordance with the terms of this license.
- **No Own Events or Data**: All functionality is implemented exclusively via adapters. This reduces overhead and simplifies integration into existing 4diac architectures.

State Overview

The block does not have its own state machine (no ECC states). It behaves stateless: The outputs always reflect the current state of the input. Initialization or special state transitions are not required.

Application Scenarios

- **Signal Distribution**: An AULI-based signal (e.g., control command, measured value) is to be forwarded to multiple consumers or downstream function blocks.
- **Redundancy or Parallel Processing**: Several independent instances of a component require the same input value – the split enables simple distribution without additional logic.
- **Test and Simulation Environments**: In test setups, an AULI signal can be distributed to multiple observers or loggers.

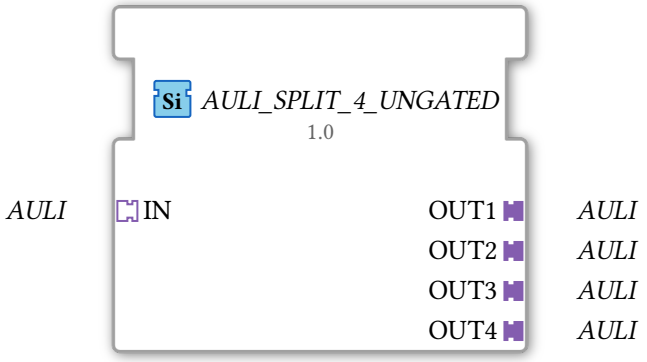
Comparison with Similar Function Blocks

The **AULI_SPLIT_4** is a specialized split function block exclusively for the unidirectional AULI adapter type. Unlike general split function blocks (e.g., `SPLIT` for various data types), it is fixed to exactly one adapter interface, which increases type clarity and prevents misconfigurations. It differs from active distributors (e.g., `MUX` or `DEMUX`) in its passive, lossless distribution without switching logic or addressing.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion



The **AULI_SPLIT_4** is a simple yet useful function block for multiplying an AULI adapter to four outputs. Its generic design and the absence of unnecessary logic allow it to integrate seamlessly into modular 4diac projects. It is particularly suitable for applications where a signal needs to be passed on to multiple receivers without requiring further processing or selection.

AULI_SPLIT_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AULI_SPLIT_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AULI_SPLIT_4_UNGATED** is used to split an incoming **AULI** adapter into four separate, identical outputs. It is designed as a generic function block (Generic FB) and is distributed under the Eclipse Public License 2.0. It was developed for use in automation technology, particularly within the HR Agrartechnik GmbH environment.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::AULI`	`IN`	Socket	Input adapter for the AULI signal to be distributed
`adapter::types::unidirectional::AULI`	`OUT1`	Plug	First output adapter (identical to the input)
`adapter::types::unidirectional::AULI`	`OUT2`	Plug	Second output adapter
`adapter::types::unidirectional::AULI`	`OUT3`	Plug	Third output adapter
`adapter::types::unidirectional::AULI`	`OUT4`	Plug	Fourth Output Adapter

Functionality

This function block operates as a passive distribution structure. The AULI adapter connected to `IN` is internally routed to the four outputs `OUT1` to `OUT4`. Since no active logic, processing, or buffering takes place, the data present at the input (e.g., signals, values, states) is passed on unchanged to all four outputs. The connection is unidirectional – changes to the outputs do not affect the input.

Technical Features

- **Generic Function Block**: The function block is declared as a generic function block with the generic class name `GEN_AULI_SPLIT`. This allows for flexible adaptation and reuse in various contexts (e.g., through parameterization during instantiation).

- **Unidirectional Adapters**: All adapters used are of type `adapter::types::unidirectional::AULI`, meaning they only support data flow in one direction.
- **License**: The block is licensed under the Eclipse Public License 2.0 and may be used and modified in accordance with the terms of this license.
- **No Own Events or Data**: All functionality is implemented exclusively via adapters. This reduces overhead and simplifies integration into existing 4diac architectures.

State Overview

The block does not have its own state machine (no ECC states). It behaves stateless: The outputs always reflect the current state of the input. Initialization or special state transitions are not required.

Application Scenarios

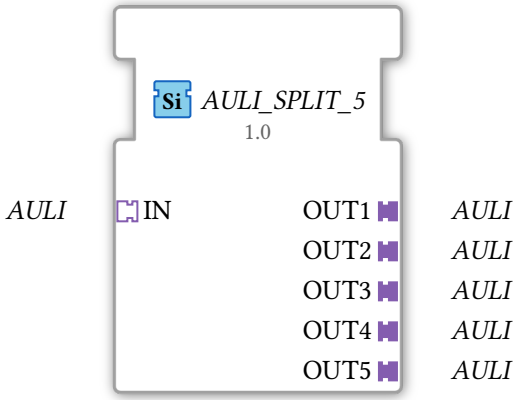
- **Signal Distribution**: An AULI-based signal (e.g., control command, measured value) is to be forwarded to multiple consumers or downstream function blocks.
- **Redundancy or Parallel Processing**: Several independent instances of a component require the same input value – the split enables simple distribution without additional logic.
- **Test and Simulation Environments**: In test setups, an AULI signal can be distributed to multiple observers or loggers.

Comparison with Similar Function Blocks

The **AULI_SPLIT_4_UNGATED** is a specialized split function block exclusively for the unidirectional AULI adapter type. Unlike general split function blocks (e.g., `SPLIT` for various data types), it is fixed to exactly one adapter interface, which increases type clarity and prevents misconfigurations. It differs from active distributors (e.g., `MUX` or `DEMUX`) in its passive, lossless distribution without switching logic or addressing.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.



Conclusion

The **AULI_SPLIT_4_UNGATED** is a simple yet useful function block for multiplying an AULI adapter to four outputs. Its generic design and the absence of unnecessary logic allow it to integrate seamlessly into modular 4diac projects. It is particularly suitable for applications where a signal needs to be passed on to multiple receivers without requiring further processing or selection.

AULI_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AULI_SPLIT_5** serves as a generic splitter for the unidirectional AULI adapter type. It generates five identical output signals from a single incoming AULI signal, which can then be distributed to separate devices. The block is implemented as a generic FB and is parameterized for the Eclipse 4diac Core Framework using the attributes `GenericClassName` and `TypeHash`.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AULI`	Incoming AULI adapter (source)
Plug	`OUT1`	`adapter::types::unidirectional::AULI`	First outgoing AULI adapter
Plug	`OUT2`	`adapter::types::unidirectional::AULI`	Second outgoing AULI adapter
Plug	`OUT3`	`adapter::types::unidirectional::AULI`	Third outgoing AULI adapter
Plug	`OUT4`	`adapter::types::unidirectional::AULI`	Fourth outgoing AULI adapter
Plug	`OUT5`	`adapter::types::unidirectional::AULI`	Fifth outgoing AULI adapter

The interface consists solely of one socket and five plugs of the same type. All adapters are unidirectional.

Functionality

The FB forwards the AULI signal arriving at socket `IN` to all five plugs (`OUT1` … `OUT5`) without delay or processing. A simple **1:5 replication** takes place. The function block has no logic, no states, and no internal buffer. Data is passed passively: As soon as the source adapter sends data, it is replicated to all outputs.

Technical Features

- **Generic Function Block**: The function block is declared as a generic type (`GenericClassName = 'GEN_AULI_SPLIT'`). The specific type used is only resolved at runtime by the Eclipse 4diac Core Framework.
- **Unidirectional Adapters**: All adapters use the type `adapter::types::unidirectional::AULI`, which allows data flow in only one direction, from the source to the destinations.
- **No Conditions or Filters**: The input signal is distributed to all outputs without quality control, conversion, or synchronization.
- **Compatibility**: The function block (FB) is designed for use in IEC 61499-2 compliant systems and requires the import of the packages `eclipse4diac::core::GenericClassName` and `eclipse4diac::core::TypeHash`.

State Overview

The FB has **no internal state machine**. There are no states, no transitions, and no actions. Its functionality is limited to passive signal distribution.

Application Scenarios

- **Signal Distribution**: A sensor value or a control signal (e.g., an AULI-based data source) must be sent to multiple parallel processing units or actuators.
- **Test Environments**: In simulation or test systems, the same input signal can be applied simultaneously to multiple analysis blocks or log functions.
- **Redundant Outputs**: When multiple subsystems require the same value, but cascaded chaining is not desired.

Comparison with Similar Components

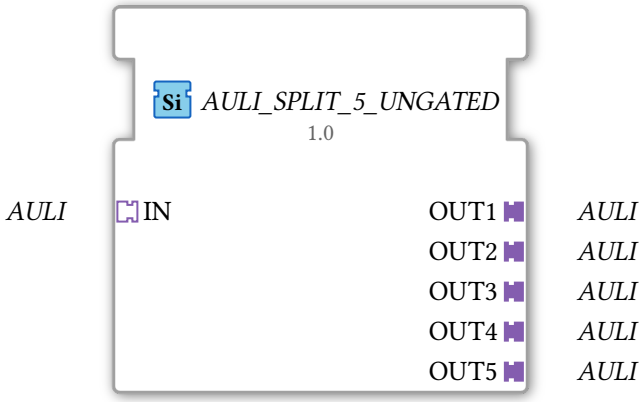
Component	Type	Outputs	Special Feature
`AULI_SPLIT_5`	Generic splitter	5	Specific to AULI adapters
`SPLIT_2` (non-standardized)	Generic splitter	2	Mostly for data types such as INT or BOOL
`F_SPLIT` (from IEC 61499 libraries)	Functional splitter	Variable	Based on ECC and events

The `AULI_SPLIT_5`, unlike event-based splitters, is **eventless** and purely adapter-based. It is therefore particularly suitable for use in data flow systems without a clock signal.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion



The `AULI_SPLIT_5` is a minimalist yet useful function block for multiplying a unidirectional AULI signal to five outputs. Its generic nature allows for flexible parameterization within the Eclipse 4diac framework. Due to the absence of a state machine and its simple pass-through functionality, it is extremely resource-efficient and suitable for high-speed data distribution.

AULI_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AULI_SPLIT_6** is used to distribute a single AULI adapter input (unidirectional) to six identical AULI outputs. It provides a generic solution for forwarding an AULI signal to multiple subsequent blocks without compromising signal integrity.

Interface Structure

Event Inputs
None.

Event Outputs
None.

Data Inputs
None.

Data Outputs
None.

Adapters

Adapter	Direction	Type	Description
IN	Socket (Input)	adapter::types::unidirectional::AULI	Receives the AULI signal to be distributed.
OUT1	Plug (Output)	adapter::types::unidirectional::AULI	First identical output of the distributed signal.
OUT2	Plug (Output)	adapter::types::unidirectional::AULI	Second identical output.
OUT3	Plug (Output)	adapter::types::unidirectional::AULI	Third identical output.
OUT4	Plug (Output)	adapter::types::unidirectional::AULI	Fourth identical output.
OUT5	Plug (Output)	adapter::types::unidirectional::AULI	Fifth identical output.
OUT6	Plug (Output)	adapter::types::unidirectional::AULI	Sixth identical output.

Functionality
This component functions as a pure signal distributor (splitter). An AULI signal applied to **IN** is duplicated to all six output adapters (**OUT1** to **OUT6**) without delay or data loss. No active processing or filtering takes place – data transmission occurs exclusively via the unidirectional AULI adapters.

Since there are no events or data inputs/outputs, communication is based entirely on the adapter interface. The component is event-free and is activated solely by connecting the adapters.

Technical Features
- **Generic Type:** The function block is implemented as a generic function block (`GEN_AULI_SPLIT`), allowing it to be reused for various AULI variants.
- **Unidirectional Adapters:** The adapters used are declared as unidirectional interfaces – they only support one direction of data flow (from the socket to the plugs).
- **No Data or Event Processing:** The function block contains no internal algorithms or states; it functions solely as a passive splitter.
- **Simple Scaling:** With a fixed number of six outputs, the function block is optimized for typical applications in agricultural technology (e.g., HR agricultural technology).

State Overview
Since the function block has no event control and manages no internal states, there is no state machine. The function block is purely combinational and passes the input signals unchanged to all outputs.

Application Scenarios

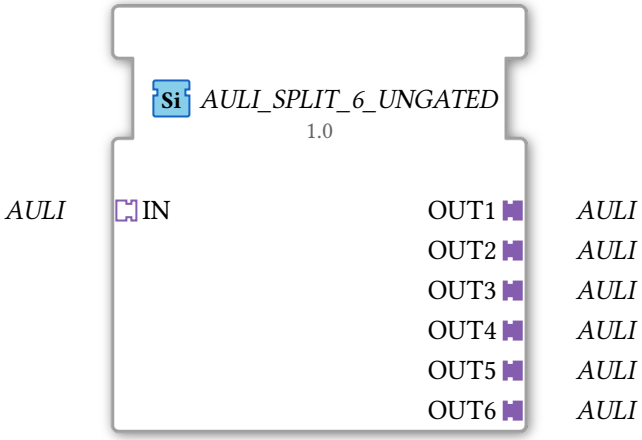
- **Distributing a Sensor Signal:** In agricultural control systems, a single AULI sensor (e.g., for crop flow) can be connected to multiple downstream evaluation modules.
- **Parallel Actuator Controls:** A control command (e.g., for hydraulic valves) is to be simultaneously forwarded to six identical actuators.
- **Redundancy Setup:** In safety-critical applications, the same signal can be routed multiple times to redundant control units.

Comparison with Similar Modules

Module	Number of Outputs	Special Feature
AULI_SPLIT_6	6	Fixed splitter for AULI adapter
AULI_SPLIT_2	2	Smaller version for two outputs
AULI_SPLIT_4	4	Medium-sized version for four outputs

Compared to smaller splitters, the **AULI_SPLIT_6** offers a higher number of outputs, reducing wiring complexity in complex systems while maintaining a clean signal structure.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AULI_SPLIT_6** is a simple yet effective function block for distributing an AULI adapter signal to six parallel outputs. Thanks to its generic implementation and pure adapter interface, it can be easily integrated into IEC 61499 applications in agricultural and automation technology. It is particularly suitable for scenarios where a signal is required multiple times without additional logic or state management.

Thanks to its generic implementation and pure adapter interface, it can be easily integrated into IEC 61499 applications in agricultural and automation technology. It is particularly suitable for scenarios where a signal is required multiple times without additional logic or state management.

AULI_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The **AULI_SPLIT_7** function block serves as a generic splitter that distributes an incoming AULI adapter signal (unidirectional) to seven separate AULI outputs. It is specifically designed for splitting a command or data stream (AULI protocol) and allows multiple downstream components to be supplied with the same signal simultaneously.

Interface Structure

Event Inputs
No event inputs available.

Event Outputs
No event outputs available.

Data Inputs
No data inputs available.

Data Outputs
No data outputs available.

Adapter

Direction	Name	Type	Description
Socket (Input)	IN	adapter::types::unidirectional::AULI	Receives the AULI signal to be split
Plug (Output)	OUT1	adapter::types::unidirectional::AULI	First output for the AULI signal
Plug (Output)	OUT2	adapter::types::unidirectional::AULI	Second output
Plug (Output)	OUT3	adapter::types::unidirectional::AULI	Third output
Plug (Output)	OUT4	adapter::types::unidirectional::AULI	Fourth output
Plug (Output)	OUT5	adapter::types::unidirectional::AULI	Fifth Output
Plug (Output)	OUT6	adapter::types::unidirectional::AULI	Sixth Output
Plug (Output)	OUT7	adapter::types::unidirectional::AULI	Seventh Output

Functionality
This module forwards the AULI signal present at socket **IN** unchanged to all seven plugs **OUT1** through **OUT7**. No signal processing, filtering, or delay takes place. Each output receives the same signal sequence simultaneously as the input. The distribution is handled purely by the circuitry and signal processing within the 4diac IDE; no calculations or state changes are required.

Technical Features
- **Generic Function Block:** The function block is declared as a generic type (`GEN_AULI_SPLIT`) and uses the attribute `eclipse4diac::core::GenericClassName` for type-safe adapter assignment.
- **Unidirectional Adapter:** Both input and output are based on the adapter type `adapter::types::unidirectional::AULI`, which supports only one direction of data flow.
- **No Event Control:** The function block does not require trigger events; signal propagation occurs automatically when the input signal changes.
- **No Internal States:** There is no state machine or memory behavior – the function block is purely combinational.

State Overview
Since there is no state machine (ECC), the function block has no internal states. The output signal follows the input signal immediately without delay or logic.

Application Scenarios
- **Parallel Supply of Multiple Actuators**: A common control signal (e.g., via an AULI adapter) is to be distributed simultaneously to multiple actuators or subsystems.
- **Signal Multicasting**: Distribution of a sensor signal or configuration message to multiple receivers in the automation system.
- **Test and Simulation Setups**: Splitting an input signal for simultaneous monitoring at different measuring points.

Comparison with Similar Function Blocks

The 4diac library contains splitter blocks for various output numbers, e.g., `AULI_SPLIT_3` or `AULI_SPLIT_5`. The `AULI_SPLIT_7` differs only in the number of outputs (7). Function blocks for splitting other adapter types (e.g., `BOOL_SPLIT`, `INT_SPLIT`) have similar logic but work with different data and adapter formats.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AULI_SPLIT_7` is a simple yet essential function block for signal distribution within the AULI adapter landscape. It allows for the clean and type-safe splitting of a unidirectional signal across up to seven paths without additional logic or delays. Thanks to its generic design, it can be flexibly used in IEC 61499-based automation projects.

AULI_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AULI_SPLIT_8` is used to split an incoming unidirectional AULI adapter (socket `IN`) into eight identical AULI output adapters (`OUT1` to `OUT8`). It operates as a simple distributor – the incoming signal is passed on to all outputs without delay or logic modification. The block is designed generically and can be used with various AULI types (see attribute `GenericClassName`).

Interface Structure

Event Inputs

No event inputs are available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

Direction	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::AULI`	Incoming AULI adapter, distributed to the eight outputs.
Plug (Output)	`OUT1` – `OUT8`	`adapter::types::unidirectional::AULI`	Eight parallel outputs that forward the identical signal of the input.

Functionality

The function block has no integrated control logic (no ECC) and no data processing algorithms. It connects the incoming adapter `IN` directly to all eight output adapters `OUT1` to `OUT8`. Any data exchange that occurs via the adapter `IN` (e.g., events, value changes) is passed on to all output adapters without modification. The distribution is combinatorial – there is no intermediate storage or time staggering.

Technical Features

- **Generic Structure:** The function block is declared as a generic function block with `eclipse4diac::core::GenericClassName = 'GEN_AULI_SPLIT'`. This allows it to be parameterized for different AULI adapter types (e.g., with different data types).
- **Pure Adapter Connection:** Neither event inputs/outputs nor data elements are required at the FB level – all communication takes place via the AULI adapters.
- **No State Logic:** The FB has no ECC; its behavior is entirely determined by the adapter wiring.

State Overview

The function block does not contain an internal state machine. There are no distinguishable operating modes or state changes – the behavior is purely combinatorial.

Application Scenarios

- **Signal Distribution:** An AULI sensor (e.g., temperature, pressure) should forward its signal to several independent devices (controllers, displays, data loggers) simultaneously.
- **Redundancy / Broadcasting:** A command or configuration is distributed from a central instance to up to eight actuators or subsystems.
- **Test Environments:** A simulated AULI value is sent in parallel to several FB instances for validation.

Comparison with Similar Blocks

The 4diac IDE often includes blocks such as `SPLIT_2`, `SPLIT_4`, or generic split blocks for event/data lines. `AULI_SPLIT_8` specializes in this for the AULI adapter and offers a compact 1:8 distribution without additional data type conversion. Compared to manually chaining simpler split blocks, it reduces wiring complexity and improves clarity.

- `AULI_SPLIT_8_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AULI_SPLIT_8` is a simple yet useful distribution block for unidirectional AULI adapters. It enables clean, generic signal distribution across up to eight outputs and is particularly suitable for broadcasting scenarios where multiple receivers require the same adapter value. Its generic nature makes it versatile and facilitates reuse in various projects.

AULI_SPLIT_8_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AULI_SPLIT_8`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AULI_SPLIT_8_UNGATED` is used to split an incoming unidirectional AULI adapter (socket `IN`) into eight identical AULI output adapters (`OUT1` to `OUT8`). It operates as a simple distributor – the incoming signal is passed on to all outputs without delay or logic modification. The block is designed generically and can be used with various AULI types (see attribute `GenericClassName`).

Interface Structure

Event Inputs

No event inputs are available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

Direction	Name	Type	Description

Socket (Input)	IN	adapter::types::unidirectional::AULI	Incoming AULI adapter, distributed to the eight outputs.
Plug (Output)	OUT1 – OUT8	adapter::types::unidirectional::AULI	Eight parallel outputs that forward the identical signal of the input.

Functionality

The function block has no integrated control logic (no ECC) and no data processing algorithms. It connects the incoming adapter `IN` directly to all eight output adapters `OUT1` to `OUT8`. Any data exchange that occurs via the adapter `IN` (e.g., events, value changes) is passed on to all output adapters without modification. The distribution is combinatorial – there is no intermediate storage or time staggering.

Technical Features

- **Generic Structure:** The function block is declared as a generic function block with `eclipse4diac::core::GenericClassName = 'GEN_AULI_SPLIT'`. This allows it to be parameterized for different AULI adapter types (e.g., with different data types).
- **Pure Adapter Connection:** Neither event inputs/outputs nor data elements are required at the FB level – all communication takes place via the AULI adapters.
- **No State Logic:** The FB has no ECC; its behavior is entirely determined by the adapter wiring.

State Overview

The function block does not contain an internal state machine. There are no distinguishable operating modes or state changes – the behavior is purely combinatorial.

Application Scenarios

- **Signal Distribution:** An AULI sensor (e.g., temperature, pressure) should forward its signal to several independent devices (controllers, displays, data loggers) simultaneously.
- **Redundancy / Broadcasting:** A command or configuration is distributed from a central instance to up to eight actuators or subsystems.
- **Test Environments:** A simulated AULI value is sent in parallel to several FB instances for validation.

Comparison with Similar Blocks

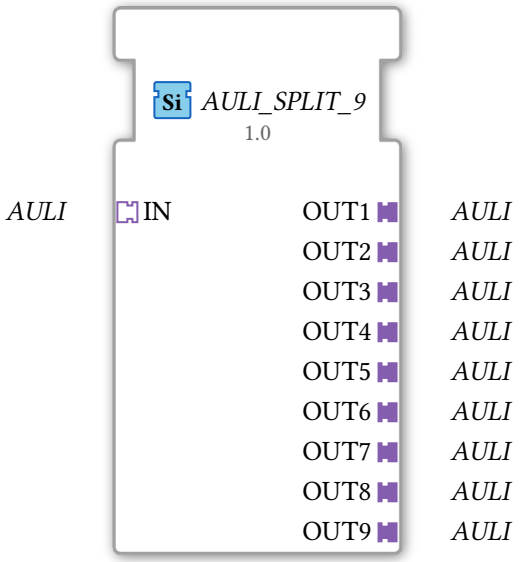
The 4diac IDE often includes blocks such as `SPLIT_2`, `SPLIT_4`, or generic split blocks for event/data lines. `AULI_SPLIT_8_UNGATED` specializes in this for the AULI adapter and offers a compact 1:8 distribution without additional data type conversion. Compared to manually chaining simpler split blocks, it reduces wiring complexity and improves clarity.

- **`AULI_SPLIT_8`**: The gated variant – updates the output only on an actual value change.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The `AULI_SPLIT_8_UNGATED` is a simple yet useful distribution block for unidirectional AULI adapters. It enables clean, generic signal distribution across up to eight outputs and is particularly suitable for broadcasting scenarios where multiple receivers require the same adapter value. Its generic nature makes it versatile and facilitates reuse in various projects.

AULI_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AULI_SPLIT_9** serves as a distributor for the unidirectional AULI adapter. It receives an incoming AULI data set via the **IN** socket and forwards it unchanged to all nine output adapters (**OUT1** to **OUT9**). The block is designed as a generic splitter and is suitable for applications where an AULI signal needs to be split among multiple devices.

Interface Structure

Event Inputs

No event inputs available.
The forwarding is purely data-driven.

Event Outputs

No event outputs available.
The block does not generate any control events.

Data Inputs

No data inputs available.
All data exchange occurs via the **IN** adapter.

Data Outputs

No data outputs are available.
Data output occurs exclusively via the **OUT1** to **OUT9** adapters.

Adapters

Type	Direction	Name	Description
Socket	Input	**IN**	Unidirectional AULI adapter – receives the data set to be distributed.
Plug	Output	**OUT1** ... **OUT9**	Nine unidirectional AULI adapters – output the identical input data set.

Functionality

The module operates as a pure 1:9 distribution stage. As soon as a data set is present at the **IN** socket, this data set is copied unchanged to all nine plugs **OUT1** to **OUT9**. Since there are no event-driven activations

or processing steps, the pass-through occurs implicitly through the runtime environment as soon as the input data record changes. The function block has no internal logic or state memory.

Technical Features

- **Generic Structure**: The function block is registered under the generic class name `GEN_AULI_SPLIT` and can be adapted depending on the runtime environment configuration.
- **Unidirectional Data Flow**: All involved adapters are of type `adapter::types::unidirectional::AULI`, which defines a clear data flow direction – from the socket IN to the plugs. No feedback is intended.
- **No State Maintenance**: The function block is stateless and requires no initialization or special control.

State Overview

The function block does not have an explicit state machine. It is always in active pass-through mode. The only "state" is the identity of the input data record being passed through.

Application Scenarios

- **Multiplication of a control/measurement signal** in automation technology, e.g., in agricultural or farm engineering (the origin of the function block indicates corresponding environments).
- **Division of an AULI-based protocol channel** across multiple parallel receivers without requiring active copying or signal amplification.
- **Simple star distribution** within a 4diac application when multiple subsequent function blocks require the same AULI data set.

Comparison with Similar Function Blocks

- **AULI_SPLIT_4 / AULI_SPLIT_8**: These variants differ only in the number of output channels. The function block described here offers a particularly high distribution density with 9 outputs.
- **Generic splitter function blocks for other adapter types**: In principle, analog splitters exist for... B. `AULI` adapter with a lower output count. All of them share stateless 1:n duplication.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AULI_SPLIT_9** is a simple yet effective distribution block for the unidirectional AULI adapter. Thanks to its generic nature and complete signal passthrough without latency or processing delay, it is ideally suited for scenarios where a single data set needs to be distributed to many receivers. The lack of event control and the pure adapter approach make it particularly lightweight and performant.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AUS_D_FF

• – ○ • – ○ • – ○ •

The function block **AUS_D_FF** implements a data latch (D flip-flop) for the data type `AUS`. Upon receiving an event, it stores the incoming data value and outputs this stored value via an adapter output. Communication occurs exclusively via unidirectional adapters. No direct event inputs. Event-driven data transfer occurs via the adapter input **I** (see section Adapters).

No direct event outputs. The output of the stored value is signaled via the adapter output **Q** (see section Adapters).

No direct data inputs. The data to be stored is provided via the adapter input **I**.

No direct data outputs. The stored value is output via the adapter output **Q**.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

Adapter	Direction	Type	Description
I	Socket	`adapter::types::unidirectional::AUS`	Provides the signal to be latched (event E1 and data D1).
Q	Plug	`adapter::types::unidirectional::AUS`	Outputs the latched value (event E1 and data D1).

The internally used module `E_D_FF_ANY` expects an event (inherited from **I.E1**) at its **CLK** input and the corresponding data value (from **I.D1**) at **D**. The output event **EO** is forwarded to **Q.E1**, and the stored data value **Q** to **Q.D1**.

Functionality

As soon as an event arrives at the adapter input **I** (pin **E1**), the simultaneously present data value (pin **D1**) is transferred to the internal memory. After successful transfer, an event is triggered at the adapter output **Q** (pin **E1**), and the stored value is available at **Q.D1**. The stored value is retained until a new event at **I.E1** transfers a new value.

- **Adapter-based interface:** The component uses only unidirectional adapters, enabling loose coupling and flexible interconnection.
- **No dedicated event/data pins:** All input and output is handled via the **I** and **Q** adapters.
- **Internal standard flip-flop:** The actual latch functionality is provided by the IEC 61499 component `E_D_FF_ANY`, which is specified to operate on any data type template.

The component has an implicit internal state – the stored data value (`Q` output). This only changes when an event occurs at **I.E1**. There is no explicit state machine in the FBNet; The state is managed by the internal `E_D_FF_ANY`.

- **Cache Storage:** A signal (value + event) is to be cached for later processing, e.g., in a control sequence where a sensor value is only to be acquired at a specific clock cycle.
- **Data Synchronization:** An asynchronously arriving data value is latched synchronously with an event and then used in the subsequent program flow.
- **State Maintenance:** The function block remembers the last valid value until a new value is explicitly acquired.
- **SR Flip-Flop:** Sets or resets the output via separate set/reset inputs; stores only Boolean or binary states. `AUS_D_FF`, on the other hand, stores general data values of type `AUS`.
- **Toggle Flip-Flop (T-FF):** Toggles the output on every clock cycle. `AUS_D_FF` takes the current data value and outputs it unchanged.
- **MUX-based Latch:** A multiplexer could also store a value, but requires additional reset logic. `AUS_D_FF` already encapsulates this logic.

The **AUS_D_FF** is an easy-to-use latching device that uses adapters to take a stored data-event pair and pass it on. Due to its adapter interface and the use of a standardized internal flip-flop, it is suitable for modular and reusable control designs in the IEC 61499 environment.

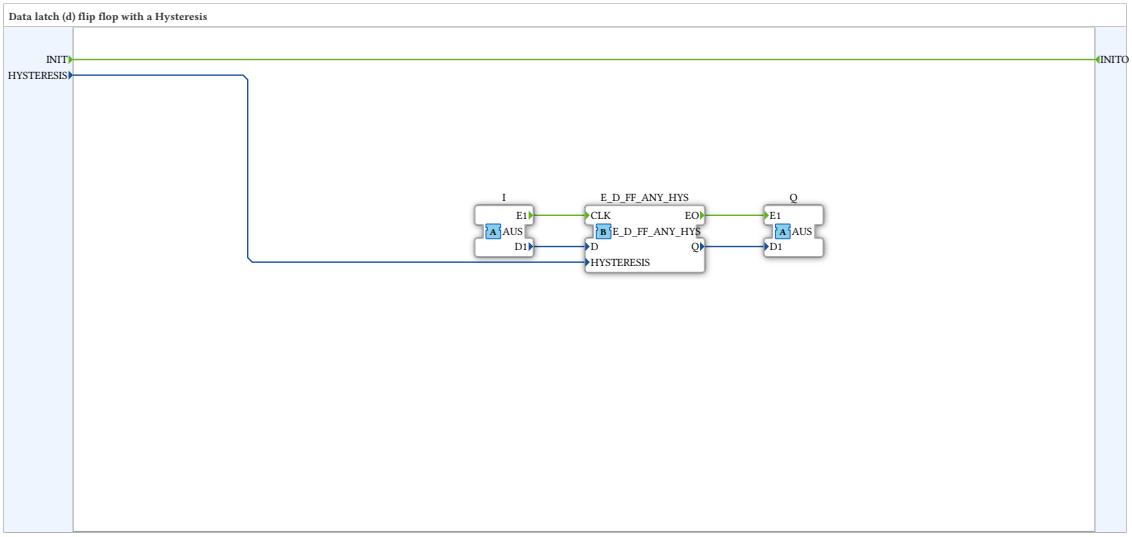
State Overview



Application Scenarios

Comparison with Similar Function Blocks

Conclusion

AUS_D_FF_HYS

• – ○ • – ○ • – ○ •

Introduction

The function block `AUS_D_FF_HYS` implements a data latch (D flip-flop) with hysteresis (threshold band). It serves to receive an incoming data value on an edge-triggered basis and make it available at the output. The hysteresis ensures stable switching behavior even with noisy or fluctuating input signals. The block uses generic adapters (`AUS`) that enable unidirectional data transmission with event-driven control, making it usable with any data type.

Interface Structure

Event Inputs

Event	Type	Comment	With Parameter
`INIT`	EInit	Set Hysteresis	`HYSTERESIS`

Event Outputs

Event	Type	Comment
`INITO`	EInit	Init Confirmation

Data Inputs

Name	Type	Comment
`HYSTERESIS`	USINT	Hysteresis band

Data Outputs

The FB has no direct data outputs. The latched value is provided via the adapter output `Q`.

Adapters

Name	Type	Direction	Comment
`I`	`adapter::types::unidirectional::AUS`	Socket	Value to latch
`Q`	`adapter::types::unidirectional::AUS`	Plug	Latched value

The adapters are unidirectional and each contains an event (`E1`) and a data value (`D1`). The input value and its acceptance event are received via `I`, and the output value and an acknowledgment event are sent via `Q`.

Functionality

The function block encapsulates an internal block, `E_D_FF_ANY_HYS`, which implements the actual D flip-flop with hysteresis.

- **Initialization:** The hysteresis value (`HYSTERESIS`) is passed to the internal block via the event `INIT`. The initialization is acknowledged via the event `INITO`.

The FB encapsulates an internal block, `E_D_FF_ANY_HYS`, which implements the actual D flip-flop with hysteresis. - **Data Transfer:** An event on `I.E1` causes the internal component to take the current data value from `I.D1` and pass the latched value to `Q.D1`. Simultaneously, `Q.E1` is triggered.

- **Hysteresis Function:** The flip-flop output changes its state only when the input value exceeds an upper or lower threshold defined by the hysteresis value. This suppresses bounce or noise in the input signal (Schmitt trigger behavior).

The exact switching threshold depends on the data type used by the adapter (the `AUS` adapter supports any type). The hysteresis value (`USINT`) is internally scaled or interpreted to the corresponding numerical range.

Technical Features

- **Generic Adapter:** The use of the unidirectional adapter `AUS` allows the use of a wide variety of data types (e.g., `INT`, `REAL`, `BOOL`) without requiring the function block itself to be typed. Type conversion is handled by the internal function block.
- **Hysteresis as USINT:** Hysteresis is specified as an unsigned 8-bit value. The specific interpretation (e.g., as an absolute difference or percentage) depends on the implementation and is defined in the internal function block.
- **Event Passthrough:** The INIT event is passed directly to the INITO event. This enables a simple initialization chain in the network.
- **Event Passthrough:** - **No visible state machine:** The function block (FB) does not have its own Execution Control Chart (ECC); the logic is implemented entirely by the internal FB.

State Overview

Since the FB does not explicitly expose a state machine, its behavior is determined by the internal D flip-flop with hysteresis. This flip-flop has two stable output states:

- **State 0:** The output value corresponds to the logical “low” level (or the lower limit of the data range).
- **State 1:** The output value corresponds to the logical “high” level (or the upper limit).

State transitions occur only when the respective hysteresis thresholds are exceeded:

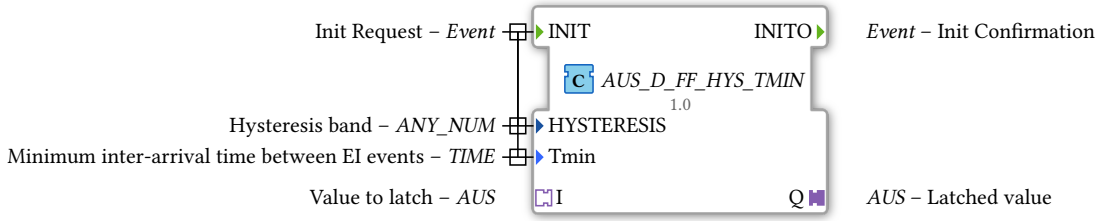
Transition	Condition (Input Value)
$0 \longrightarrow 1$	Input exceeds upper threshold
$1 \longrightarrow 0$	Input falls below lower threshold

The thresholds are offset by the hysteresis value relative to a mean or reference value (typically upper threshold = reference + hysteresis/2, lower threshold = reference - hysteresis/2).

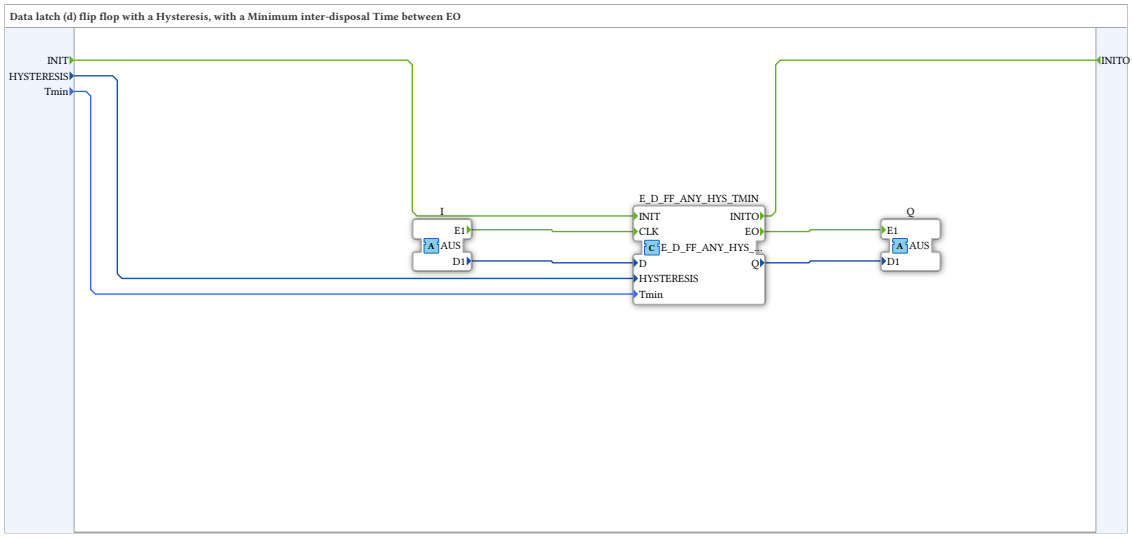
Application Scenarios

- **Sensor Debouncing:** A digital or analog sensor delivers fluctuating values (e.g., due to mechanical bouncing). The function block smooths the signal and provides a stable output.
- **Threshold Switch with Reset Delay:** Monitoring of a process value that triggers a signal when an upper limit is exceeded and is only reset when a lower limit is undershot.
- **Signal Conditioning in Building Automation:** Suppression of short interference pulses from temperature, brightness, or level sensors.
- **Hysteresis in Position Controllers:** Prevents rapid switching on and off of actuators near a setpoint limit.

Comparison with Similar Function Blocks



Function Block	Properties	Difference to `AUS_D_FF_HYS`



Standard D flip-flop (`E_D_FF`)	Transfers data on clock edge, no hysteresis	No noise suppression; state changes on every edge.
Schmitt trigger (`E_D_FF_ANY_HYS`)	Flip-flop with hysteresis, but usually data-type specific	`AUS_D_FF_HYS` encapsulates the generic adapter and provides a uniform interface for arbitrary types.
SR flip-flop (`E_SR_FF`)	Set/reset function without clock	No edge-triggered data transfer; Hysteresis not directly integrated.

Conclusion

AUS_D_FF_HYSis a versatile function block for applications requiring robust, edge-triggered data acquisition with hysteresis. The use of generic adapters makes it independent of the specific data type and facilitates reuse in different contexts. Particularly in automation technology, signal processing, and sensor evaluation, it offers reliable signal conditioning through noise and bounce suppression. Initialization viaINIT` and direct event pass-through simplify integration into existing control networks.

AUS_D_FF_HYS_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **AUS_D_FF_HYS_TMIN** implements a data-triggered flip-flop (D flip-flop) with hysteresis and a minimum inter-event time. It is structured as a sub-application (FB network) that delegates the actual logic to the inner block `logiBUS::signalprocessing::hysteresis::E_D_FF_ANY_HYS_TMIN`. This block serves to latch an analog or discrete value with a predefined hysteresis band and simultaneously limit the event rate (via the adapter input) to a configurable minimum interval.

Interface Structure

Event Inputs

Event	Type	With Variables	Description
INIT	EInit	HYSTERESIS, Tmin	Initialization request; sets hysteresis and minimum time.

Event Outputs

Event	Type	With Variables	Description
INITO	EInit	–	Confirmation of completed initialization.

Data Inputs

Name	Type	Description
HYSTERESIS	ANY_NUM	Hysteresis band – Threshold difference that must be exceeded/fallen below for a new value to be latched.
Tmin	TIME	Minimum time interval between two incoming events (inter-arrival time).

Data Outputs

– No direct data outputs are available. The latched value is output via the adapter plug Q.

Adapters

Adapter	Direction	Type	Description
I	Socket (In)	adapter::types::unidirectional::AUS	Receives the event to be latched and the corresponding data value.
Q	Plug (Out)	adapter::types::unidirectional::AUS	Outputs the processed event and the latched data value.

Functionality

This function block operates as a pure encapsulation of an internal flip-flop. After starting, INIT must first be called with the parameters HYSTERESIS and Tmin. Afterwards, events (via I.E1) and associated data values (via I.D1) can be received via the adapter socket I.

- Each event at input I.E1 is forwarded to the internal function block E_D_FF_ANY_HYS_TMIN.
- The data I.D1 is compared with the hysteresis band: The flip-flop is only updated if the new value lies outside the deadband defined by the hysteresis around the last latched value.
- Additionally, the time since the last valid event is monitored (Tmin). If an event occurs too soon (shorter than Tmin) after the previous one, it is ignored.
- A valid, latched event is output via the adapter plug Q as Q.E1, and the corresponding data value as Q.D1.

The internal function block handles all the logic; the outer block serves as an interface wrapper that connects the events and data accordingly.

Technical Features

- **Adapter Interface:** Communication takes place via the unidirectional adapters adapter::types::unidirectional::AUS. This enables a clear separation of event and data flow and easy reuse in different contexts.
- **Hysteresis:** Prevents constant switching due to noisy signals. The latched value only changes when the input leaves the hysteresis band.
- **Minimum Inter-Event Time (Tmin):** Debounces events and prevents bursts. Only events with a minimum interval of Tmin are accepted.

- **Compact Encapsulation:** The function block (FB) contains no independent behavior but forms a logical unit comprising initialization, event processing, and output – ideal for modular control architectures.

State Overview

Since the function block does not have its own state diagram (the logic resides within the internal FB), the state behavior results from the interaction of event control and the parameters:

1. **Initialization (`INIT` – `INITO`)**: After startup, the internal FB is configured. Only then can events be processed.
2. **Waiting for Incoming Event**: The function block is passive until an event arrives via `I.E1`.
3. **Event Check** (internal):

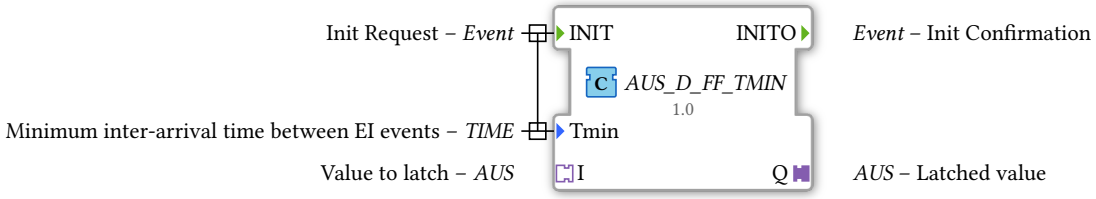
- Time Check: Is the interval to the last event ≥ `Tmin`?
- Hysteresis Check: Does the new value exceed the old value by more than `HYSTERESIS`?

1. **Output**: If the check is successful, `Q.E1` is triggered and the new data value is passed to `Q.D1`.
2. **Return to Waiting State**.

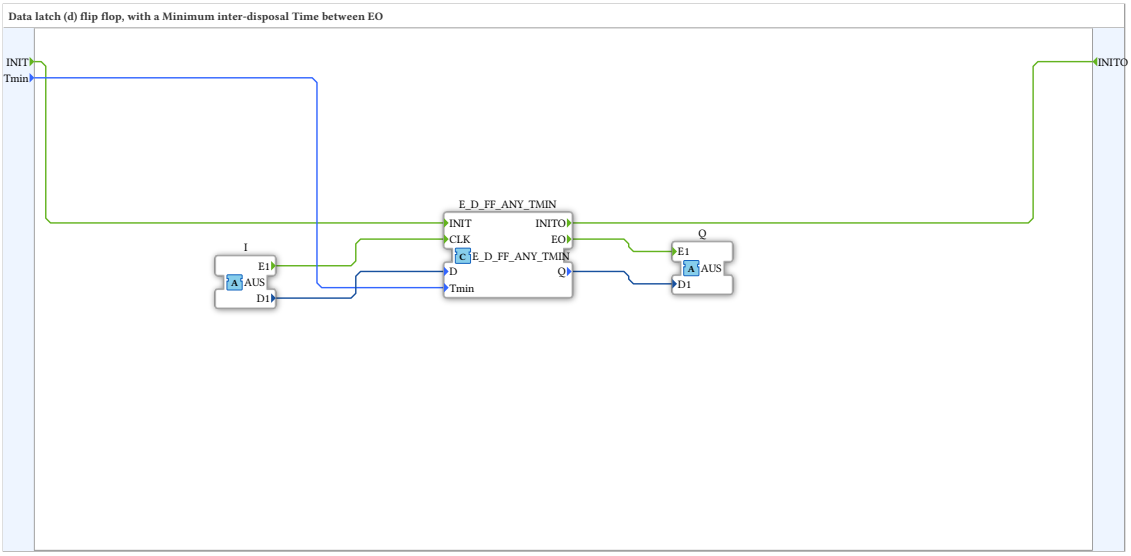
Application Scenarios

- **Sensor Evaluation with Noise:** An analog value (e.g., temperature, pressure) should only trigger a switching operation if it shows a significant change (hysteresis) and does not occur too rapidly (debouncing).
- **Frequency Limiting:** In communication protocols where an event must not be processed more frequently than a certain rate.
- **Safety-Critical Applications:** Preventing false triggers caused by short-duration interference pulses (minimum time between two edges).

Comparison with Similar Components



Component	Properties
Standard D Flip-Flop	Latches on every rising edge without hysteresis or time limit.
`E_D_FF_HYS` (without Tmin)	Hysteresis only, no time debouncing.
E_D_FF_TMIN` (without Hys)	Minimum time only, no hysteresis.
AUS_D_FF_HYS_TMIN`	Combines hysteresis **and** minimum time – more robust against noise and bursts.



This component is therefore particularly suitable when both effects (signal tolerance and time limiting) are required simultaneously.

Conclusion

AUS_D_FF_HYS_TMINThis is a specialized D-flip-flop wrapper that offers reliable, debounced data latching through a combination of hysteresis and minimal event interval time. Its encapsulation as a sub-application with adapter interfaces makes it easy to integrate into larger control networks. Initialization via INIT` ensures a defined startup configuration. This component is an ideal solution for applications requiring robust threshold detection with noise suppression and frequency limiting.

AUS_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **AUS_D_FF_TMIN** implements a clock-controlled D-latch (data flip-flop) with a minimum inter-disposal time between two consecutive output events (EO). It is particularly suitable for applications where an incoming value (via an adapter socket) is received and may only be output again after a configurable minimum time has elapsed. Initialization is performed via the standard event input **INIT**.

Interface Structure

Event Inputs

Name	Type	Comment	With Variable
INIT	EInit	Init Request	Tmin

Event Outputs

Name	Type	Comment
INITO	EInit	Init Confirmation

Data Inputs

Name	Type	Comment
HYSTERESIS	ANY_NUM	Hysteresis band (currently not connected to the internal network)
Tmin	TIME	Minimum time interval between two EO events

Data Outputs

No direct data outputs – output data is provided exclusively via the **Adapter Plug Q**.

Adapter

Direction	Name	Type	Comment
Socket	I	adapter::types::unidirectional::OFF	Value to be transferred (contains event E1 and data D1)
Plug	Q	adapter::types::unidirectional::OFF	Transferred output value (contains event E1 and data D1)

Functionality

The function block internally contains a pre-built FB **E_D_FF_ANY_TMIN** (from the library `iec61499::events`). This function block takes the current data value from the Clock input upon each incoming event and passes it on to the output – but only if the time elapsed since the last output event is at least **Tmin**.

- During the **INIT** event, the parameter *Tmin* is passed to the internal function block.
- An event on **I.E1** (adapter socket) acts as the clock for the internal flip-flop.
- The latched data value appears on **Q.D1** (adapter plug) and is simultaneously acknowledged with an event on **Q.E1** – provided the timing condition is met.
- The **HYSTERESIS** parameter is declared but is not used in the current network. It can be used for future expansions or for manual wiring.

Technical Features

- **Minimum time between outputs**: The output of the latched value is only enabled when the time elapsed since the last **EO** is ≥ *Tmin*. This prevents an excessively high event rate at the output.
- **Adapter Interface**: Input and output are implemented as unidirectional adapters of type **OFF**, allowing the module to be easily integrated into existing adapter-based architectures.
- **Hysteresis Parameter**: Although not directly wired, the *HYSTERESIS* input is available – for example, to implement Schmitt-trigger-like behavior in later versions.

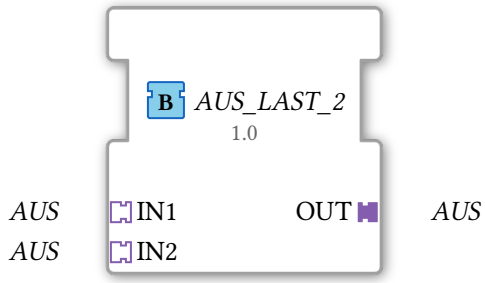
State Overview

The internal FB **E_D_FF_ANY_TMIN** has a memory for the last acquired data value. This state is updated with each clock event (I.E1). An explicit state machine is not present at the top level; the behavior results from the logic of the underlying flip-flop.

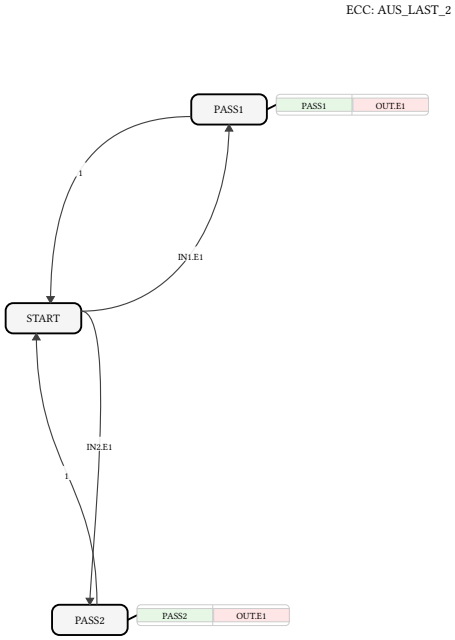
Application Scenarios

- **Sensor Value Debouncing**: On and off thresholds with a minimum repetition rate.
- **Data Buffer with Output Limit**: Prevents downstream consumers from being flooded with too many updates.
- **Timed Latch Function**: A value is only transferred if the last output was longer than *Tmin*.

Comparison with Similar Components



Component	Properties
E_D_FF (Simple D Flip-Flop)	Transfers a value immediately at each clock cycle, no time control.
AUS_D_FF_TMIN	Like **E_D_FF**, but with an additional minimum time between output events.
R_TRIG / F_TRIG	Detect edges, but do not store a data value.



The **AUS_D_FF_TMIN** is therefore particularly suitable for time-critical applications where a minimum sampling or update rate must be maintained.

Conclusion

The **AUS_D_FF_TMIN** is a useful extension module for the D flip-flop, providing time-decoupling of the output. Thanks to its adapter interface and simple configuration via **Tmin**, it can be flexibly integrated into IEC 61499 systems. The existing but unused **HYSTERESIS** input offers potential for future functional extensions.

AUS_LAST_2

Introduction

The AUS_LAST_2 function block merges two same-type USINT adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: USINT adapter (unidirectional) - first signal source
- **IN2**: USINT adapter (unidirectional) - second signal source

Output adapter (Plug):

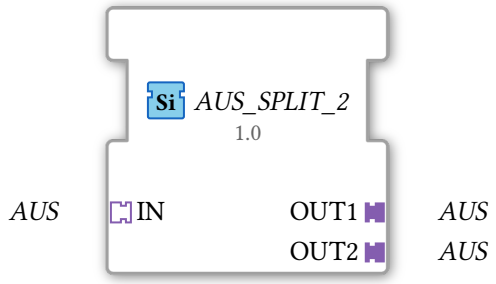
- **OUT**: USINT adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid USINT signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same USINT value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AUS_LAST_2 is the inverse of `AUS_SPLIT_2`: AUS_SPLIT_2 distributes 1 input to 2 outputs, AUS_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

OFF_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **OFF_SPLIT_2** is used to distribute an incoming OFF signal to two identical outputs. It is implemented as a generic function block (FB) and is suitable for applications where a universal control signal is required multiple times. The block operates purely on an adapter basis and has no event or data inputs of its own.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Direction	Name	Type	Description
Sockets	IN	OFF (unidirectional)	Input adapter that receives the signal to be distributed
Plugs	OUT1	OFF (unidirectional)	First output adapter, identical to the input signal
Plugs	OUT2	OFF (unidirectional)	Second output adapter, identical to the input signal

Functionality

The module forwards the OFF signal present at socket **IN** unchanged to both plugs **OUT1** and **OUT2**. No processing or buffering takes place – the distribution is purely topological. The input signal is available at both outputs simultaneously and without delay. The connection is only activated when the socket is connected to a corresponding adapter.

Technical Features

- **Generic Type**: The function block is declared as `GEN_AUS_SPLIT` with the attribute `eclipse4diac::core::GenericClassName`. This allows it to be reused in different projects without type modification.
- **No State Dependency**: The function block operates statelessly – there is no internal behavior controlled by a state machine.
- **Adapter-Based**: All interfaces are implemented as adapters of type `adapter::types::unidirectional::AUS`. This enables flexible cabling in directional communication.
- **Copyright**: The function block originates from HR Agrartechnik GmbH and is subject to the Eclipse Public License 2.0.

State Overview

Since the function block has no state logic, there is no state machine. Its functionality is limited to simple signal transmission.

Application Scenarios

- **Signal Distribution in Control Engineering**: When a bus signal or a universal control signal needs to be distributed to multiple parallel modules.
- **Test and Simulation Setups**: To split a single test signal across two parallel paths.
- **Redundant Connection**: When a signal needs to be sent to two independent receivers for availability reasons.

Comparison with Similar Components

- **OFF_SPLIT_3 / OFF_SPLIT_N**: Analog components with three or more outputs. `AUS_SPLIT_2` is the simplest option for splitting a signal across two channels.
- **Event-Based Splitters**: Unlike components with event inputs (e.g., `E_SPLIT`), `AUS_SPLIT_2` operates exclusively via adapters and is therefore suitable for pure signal distribution without control logic.
- **Merge Blocks**: While splitters duplicate signals, merge blocks combine multiple signals into one (e.g., `AUS_MERGE_2`).

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AUS_SPLIT_2` is a minimalist yet useful function block for decentralized signal distribution in 4diac applications. Its generic nature and simple adapter interface make it universally applicable, especially when only unidirectional signal copying is required. More complex tasks involving control or processing logic require extended versions.

OFF_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **OFF_SPLIT_3** serves as a universal distributor for incoming adapter signals of type `adapter::types::unidirectional::AUS`. It receives such a signal and forwards it unchanged to three identical output adapters. This allows control, alarm, or status information to be easily distributed across multiple subsequent blocks.

Interface Structure

Event Inputs

None – signal transmission occurs via the adapter IN.

Event Outputs

None – output occurs via the adapter OUTs.

Data Inputs

None – the block has no dedicated data inputs; all data is transmitted via the adapter `IN`.

Data Outputs

None – the data is output via the adapters `OUT1`, `OUT2`, and `OUT3`.

Adapters

Name	Type	Direction	Description
`IN` ad	`apter::types::unidirectional::AUS`	Socket (incoming)	Receives an OFF signal.
`OUT1` ad	`apter::types::unidirectional::AUS`	Plug (outgoing)	First output of the incoming signal.
`OUT2` ad	`apter::types::unidirectional::AUS`	Plug (outgoing)	Second output of the incoming signal.
`OUT3` ad	`apter::types::unidirectional::AUS`	Plug (outgoing)	Third output of the incoming signal.

Functionality

The FB operates as a pure signal distributor. As soon as an OFF signal (consisting of an event and associated data) is active at socket `IN`, it is passed on identically to all three plugs `OUT1`, `OUT2`, and `OUT3` without delay or transformation. Each output receives the same event and the same data. No buffering, filtering, or logical processing takes place.

Technical Features

- **Generic Type**: The function block is declared as a generic FB (`eclipse4diac::core::GenericClassName = 'GEN_AUS_SPLIT'`). This allows it to be adapted to different OFF adapter types, provided they have the same interface structure.
- **Stateless**: The FB has no internal state diagram (ECC). Its response is purely data flow-driven and requires no initialization or reset logic.
- **License Notice**: The function block is provided under the Eclipse Public License 2.0.

State Overview

Since **AUS_SPLIT_3** has no sequence control or explicit states, a state machine is not required. The behavior is deterministic and immediate: One input signal synchronously generates three identical output signals.

Application Scenarios

- **Distribution of alarm signals** to multiple display or logic units.
- **Multiple use of a sensor signal** in different automation branches.
- **Splitting a control command** (e.g., “Shut down”) across multiple actuators or subsystems.
- **Signal cascading** in modular 4diac applications.

Comparison with similar function blocks

- **EVENT_SPLIT**: Distributes only events (without data). **AUS_SPLIT_3**, on the other hand, distributes complete adapter signals including all associated data.
- **DATA_SPLIT**: Distributes pure data channels and requires separate event control. The OFF splitter encapsulates the event and data together in the adapter.
- **Manual implementation**: Without this function block, each output would have to be connected to its own copy of the source adapter. **AUS_SPLIT_3** simplifies wiring and improves clarity.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AUS_SPLIT_3** is a simple yet useful function block for multiplying OFF adapter signals. Due to its generic design and stateless nature, it is ideally suited for the modular and maintainable structuring of 4diac applications.

AUS_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUS_SPLIT_4` distributes an incoming **OFF** signal (typically a binary control signal for "Off") to four identical output signals. It serves as a generic splitter and allows a single command or state to be forwarded to multiple downstream components without requiring separate branching logic.

Interface Structure

Event Inputs

No direct event inputs are available. Control is integrated into the input adapter.

Event Outputs

No direct event outputs are available. Control is integrated into the output adapters.

Data Inputs

No direct data inputs are available. Data is received via the input adapter.

Data Outputs

No direct data outputs are available. Data is provided via the output adapters.

Adapters

The function block communicates exclusively via adapters of type `adapter::types::unidirectional::AUS`. This is a unidirectional adapter that transmits a Boolean signal (OFF command).

Direction	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::AUS`	Receives the original OFF signal.
Plug (Output)	`OUT1`	`adapter::types::unidirectional::AUS`	First outgoing OFF path.
Plug (Output)	`OUT2`	`adapter::types::unidirectional::AUS`	Second outgoing OFF path.
Plug (Output)	`OUT3`	`adapter::types::unidirectional::AUS`	Third outgoing OFF path.
Plug (Output)	`OUT4`	`adapter::types::unidirectional::AUS`	Fourth outgoing OFF path.

Functionality

The module operates as a pure signal distributor: As soon as an OFF signal is present at socket `IN`, it is passed on unchanged to all four plugs (`OUT1` to `OUT4`). No logical processing, delay, or state change takes place. The distribution occurs in parallel and immediately.

- **License**: The source code is subject to the **Eclipse Public License 2.0** (EPL-2.0).
- **Author**: Developed by **HR Agrartechnik GmbH**, Version 1.0, January 24, 2025.

- **Generic Implementation**: The function block is declared as a generic FB (`GenericClassName = 'GEN_AUS_SPLIT'`), which allows for easy adaptation to different signal types or configurations.
- **Adapter-Based**: Communication takes place exclusively via adapters, not via traditional event or data ports. This allows the function block to be seamlessly integrated into an adapter-based architecture.
- **No State Machine**: There is no internal state logic – the distribution is purely combinatorial.

Technical Features

The module does not have a state machine. The output signals follow the input signal directly. Therefore, a graphical state overview is not available.

State Overview

- **Feedback of OFF Signals**: A central "off" command from a controller should simultaneously switch off multiple actuators or subsystems.
- **Redundant Monitoring**: Distributing an OFF signal to multiple monitoring units that must react to the command independently.
- **Modular Machine Structure**: In a modular system, an OFF signal, once detected, is routed to multiple modules via buses or coupling elements. `AUS_SPLIT_4` replaces complex wiring or logical OR operations.
- **Testing and Simulation**: For simultaneously controlling multiple simulated components with the same signal.

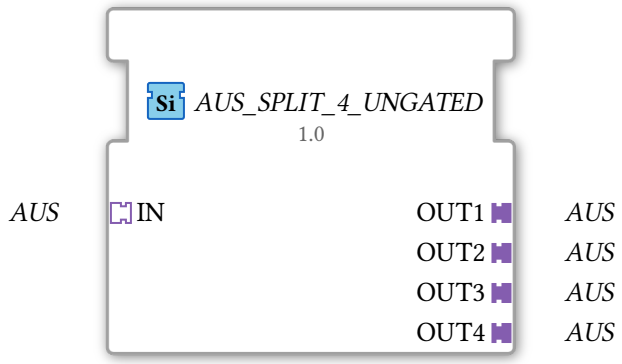
Application Scenarios

Function Block	Function	Special Feature
`AUS_SPLIT_2`	Distributes an OFF signal to two outputs	Fewer ports, more compact.
`AUS_SPLIT_4`	Distributes to four outputs	This function block.
`AUS_SPLIT_N`	Configurable splitter (e.g., via generic adapter lists)	More flexible number, but more complex to configure.
`AUS_MERGE`	Combines multiple OFF inputs into one output	Counterpart to the splitter.

Comparison with Similar Function Blocks

The `AUS_SPLIT_4` sits between a simple 2-way splitter and a fully configurable splitter. It is ideal when exactly four outputs are needed – without any additional configuration.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AUS_SPLIT_4` is a simple yet useful generic function block for distributing an OFF signal to four parallel paths. Its adapter-based interface and clear separation of logic and signal transmission make it a robust component in IEC 61499-based automation. Thanks to its generic declaration, it can be easily integrated into various projects and, if necessary, adapted to custom signal types.

AUS_SPLIT_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUS_SPLIT_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

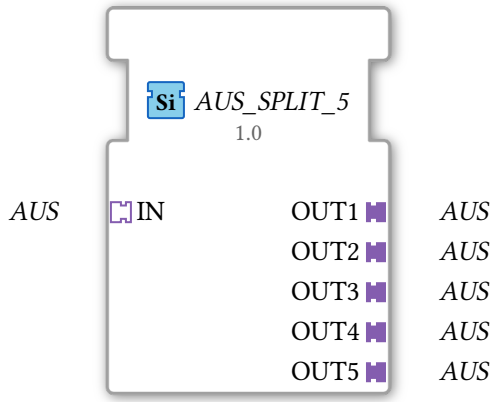
Function Block	Function	Special Feature
`AUS_SPLIT_2`	Distributes an OFF signal to two outputs	Fewer ports, more compact.
`AUS_SPLIT_4_UNGATED`	Distributes to four outputs	This function block.
`AUS_SPLIT_N`	Configurable splitter (e.g., via generic adapter lists)	More flexible number, but more complex to configure.
`AUS_MERGE`	Combines multiple OFF inputs into one output	Counterpart to the splitter.

Comparison with Similar Function Blocks

The `AUS_SPLIT_4_UNGATED` sits between a simple 2-way splitter and a fully configurable splitter. It is ideal when exactly four outputs are needed – without any additional configuration.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AUS_SPLIT_4_UNGATED` is a simple yet useful generic function block for distributing an OFF signal to four parallel paths. Its adapter-based interface and clear separation of logic and signal transmission make it a robust component in IEC 61499-based automation. Thanks to its generic declaration, it can be easily integrated into various projects and, if necessary, adapted to custom signal types.

OFF_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUS_SPLIT_5` distributes an incoming OFF event (e.g., a signal or a message) to five identical outputs. It is a generic function block that serves as a placeholder for an application-specific type (`GEN_AUS_SPLIT`) in the 4diac IDE.

Interface Structure

Event Inputs

None (signal exchange occurs exclusively via adapters).

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type
Socket (Input)	`IN`	`adapter::types::unidirectional::AUS`
Plug (Output)	`OUT1`	`adapter::types::unidirectional::AUS`
Plug (Output)	`OUT2`	`adapter::types::unidirectional::AUS`
Plug (Output)	`OUT3`	`adapter::types::unidirectional::AUS`
Plug (Output)	`OUT4`	`adapter::types::unidirectional::AUS`
Plug (Output)	`OUT5`	`adapter::types::unidirectional::AUS`

Functionality

The function block receives a unidirectional OFF event (e.g., a pulse or a logic 1) via socket `IN` and forwards it without delay or processing to all five connected plugs (`OUT1` to `OUT5`). Each outgoing event is an exact copy of the incoming event.

Technical Features

- **Generic Type**: The function block is defined as a generic placeholder by the attribute `GenericClassName = 'GEN_AUS_SPLIT'`. During instantiation, the actual adapter type (e.g., specific event signatures) can be replaced.
- **No States**: The component has no internal logic or state machine – routing is purely structural.
- **Unidirectional Communication**: All adapters are declared as `unidirectional::AUS`, meaning data flows only from the input to the outputs.

State Overview

The component has no internal state. It operates deterministically and entirely in a passive mode.

Application Scenarios

- **Signal Distribution**: A central event (e.g., “Start” or “Alarm”) is intended to control multiple components in parallel.
- **Bus Topologies**: Replacement for multiple manual wiring of a signal in the IEC 61499 environment.
- **Prototyping**: Rapid distribution of an event source across five target components during the development phase.

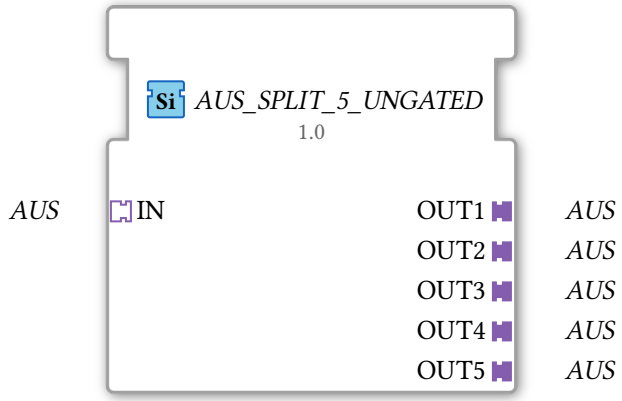
Comparison with Similar Function Blocks

- **OFF_SPLIT_2 / OFF_SPLIT_3** – Function blocks with the same functionality but a different number of outputs (2 or 3).
- **E_SPLIT** – A standard event split function block that uses event inputs and outputs instead of adapters. `AUS_SPLIT_5` is adapter-based and therefore more flexible in its reuse with different protocols.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output’s current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion



AUS_SPLIT_5` is a simple, generic distribution function block for unidirectional OFF signals. It simplifies modular control logic by implementing a 1:5 split without additional logic. Thanks to the adapter interface, it can be used in different contexts (e.g., event, data, or mixed streams).

OFF_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **OFF_SPLIT_6** is a generic block that distributes an incoming OFF signal (e.g., a uniform control signal or event) to six identical outputs. It serves as a splitter in IEC 61499 communication via adapters and enables simple multiple use of a signal without additional logic.

Interface Structure

Event Inputs

- No independent event inputs are available. All communication takes place via the integrated adapter socket.

Event Outputs

- No independent event outputs are available. Outputs are provided exclusively via the adapter plugs.

Data Inputs

- No direct data inputs. Data transfer is implemented indirectly via the adapter socket.

Data Outputs

- No direct data outputs. The output data is provided via the adapter plugs.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AUS`	**IN**	Socket	Incoming output signal distributed to all outputs.
`adapter::types::unidirectional::AUS`	**OUT1**	Plug	First output – identical to **IN**.
`adapter::types::unidirectional::AUS`	**OUT2**	Plug	Second output – identical to **IN**.
`adapter::types::unidirectional::AUS`	**OUT3**	Plug	Third output – identical to **IN**.

`adapter::types::unidirectional::AUS`	**OUT4**	Plug	Fourth output – identical to **IN**.
`adapter::types::unidirectional::AUS**	**OUT5**	Plug	Fifth output – identical to **IN**.
`adapter::types::unidirectional::AUS`	**OUT6**	Plug	Sixth output – identical to **IN**.

Note: The adapter type "AUS" is a unidirectional adapter that transmits a signal (event + data, if applicable) in one direction.

Functionality

The module functions as a passive distributor. The signal present at socket **IN** is copied unchanged and without delay to all six plugs **OUT1** to **OUT6**. No filtering, transformation, or buffering takes place. The function block behaves like a "fan-out" node for AUS adapter connections.

Technical Features

- **Generic Type**: The function block is implemented as a generic function block (GenericClassName = `'GEN_AUS_SPLIT'`). In the 4diac IDE, it can be instantiated depending on the specific AUS adapter type.
- **Dependencies**: Requires the adapter `adapter::types::unidirectional::AUS` from the package `adaper::events::unidirectional`. The implementation imports the Eclipse 4diac base types `GenericClassName` and `TypeHash`.
- **No State**: The function block does not have an internal state machine (no ECC). It operates purely combinatorially – any change at the input is immediately passed through to all outputs.
- **Unidirectional**: The adapters are designed for signal flow in only one direction. Feedback from the outputs to the input is not possible.

State Overview

The module has **no explicit states**. Its behavior is determined solely by the current configuration of the input adapter. State changes in the sense of an automaton do not occur.

Application Scenarios

- **Distributing an "OFF" Control Signal**: In a system, a single stop or shutdown signal is to be simultaneously forwarded to multiple actuators (motors, valves, etc.).
- **Redundant Signal Paths**: A signal is split across multiple parallel paths to trigger different actions in subsequent processing steps.
- **Test and Simulation Environments**: A generated test signal is sent unchanged to various monitoring or logic modules.

Comparison with Similar Function Blocks

- **Event Splitter (e.g., `E_SPLIT`)**: Processes discrete events at its own input/output events. In contrast, `AUS_SPLIT_6` operates at the adapter level and distributes both the event and its associated data in one step.
- **Data Splitter**: Pure data distributors (e.g., `F_MUX`, `F_DIST`) require separate data types. The present function block is specific to the adapter type `AUS` and encapsulates the signal structure.
- **Generic Capability**: Thanks to its generic declaration, the function block can be reused in various contexts with different output adapter implementations.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **OFF_SPLIT_6** is a simple yet useful generic function block for signal distribution in IEC 61499 applications. It reduces wiring complexity by converting a single OFF signal to six parallel outputs. Its generic nature makes it versatile, as long as the OFF adapter used adheres to the unidirectional contract.

OFF_SPLIT_6

i UNGATED variant: This block is the ungated version of AUS_SPLIT_6. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **OFF_SPLIT_6** is a generic block that distributes an incoming OFF signal (e.g., a uniform control signal or event) to six identical outputs. It serves as a splitter in IEC 61499 communication via adapters and enables simple multiple use of a signal without additional logic.

Interface Structure

Event Inputs

- No independent event inputs are available. All communication takes place via the integrated adapter socket.

Event Outputs

- No independent event outputs are available. Outputs are provided exclusively via the adapter plugs.

Data Inputs

- No direct data inputs. Data transfer is implemented indirectly via the adapter socket.

Data Outputs

- No direct data outputs. The output data is provided via the adapter plugs.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AUS`	**IN**	Socket	Incoming output signal distributed to all outputs.
`adapter::types::unidirectional::AUS`	**OUT1**	Plug	First output – identical to **IN**.
`adapter::types::unidirectional::AUS`	**OUT2**	Plug	Second output – identical to **IN**.
`adapter::types::unidirectional::AUS`	**OUT3**	Plug	Third output – identical to **IN**.

`adapter::types::unidirectional::AUS`	**OUT4**	Plug	Fourth output – identical to **IN**.
`adapter::types::unidirectional::AUS**	**OUT5**	Plug	Fifth output – identical to **IN**.
`adapter::types::unidirectional::AUS`	**OUT6**	Plug	Sixth output – identical to **IN**.

Note: The adapter type "AUS" is a unidirectional adapter that transmits a signal (event + data, if applicable) in one direction.

Functionality

The module functions as a passive distributor. The signal present at socket **IN** is copied unchanged and without delay to all six plugs **OUT1** to **OUT6**. No filtering, transformation, or buffering takes place. The function block behaves like a "fan-out" node for AUS adapter connections.

Technical Features

- **Generic Type**: The function block is implemented as a generic function block (GenericClassName = `'GEN_AUS_SPLIT'`). In the 4diac IDE, it can be instantiated depending on the specific AUS adapter type.
- **Dependencies**: Requires the adapter `adapter::types::unidirectional::AUS` from the package `adaper::events::unidirectional`. The implementation imports the Eclipse 4diac base types `GenericClassName` and `TypeHash`.
- **No State**: The function block does not have an internal state machine (no ECC). It operates purely combinatorially – any change at the input is immediately passed through to all outputs.
- **Unidirectional**: The adapters are designed for signal flow in only one direction. Feedback from the outputs to the input is not possible.

State Overview

The module has **no explicit states**. Its behavior is determined solely by the current configuration of the input adapter. State changes in the sense of an automaton do not occur.

Application Scenarios

- **Distributing an "OFF" Control Signal**: In a system, a single stop or shutdown signal is to be simultaneously forwarded to multiple actuators (motors, valves, etc.).
- **Redundant Signal Paths**: A signal is split across multiple parallel paths to trigger different actions in subsequent processing steps.
- **Test and Simulation Environments**: A generated test signal is sent unchanged to various monitoring or logic modules.

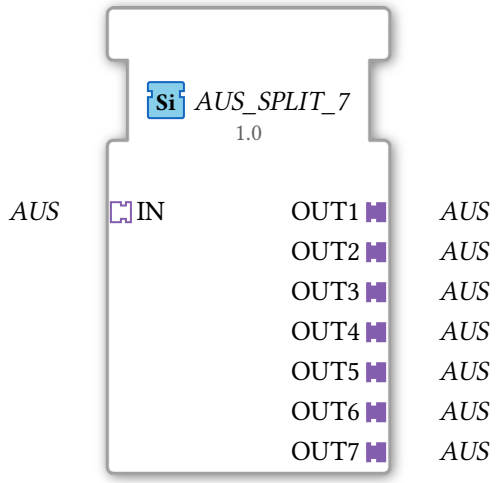
Comparison with Similar Function Blocks

- **Event Splitter (e.g., `E_SPLIT`)**: Processes discrete events at its own input/output events. In contrast, `AUS_SPLIT_6_UNGATED` operates at the adapter level and distributes both the event and its associated data in one step.
- **Data Splitter**: Pure data distributors (e.g., `F_MUX`, `F_DIST`) require separate data types. The present function block is specific to the adapter type `AUS` and encapsulates the signal structure.
- **Generic Capability**: Thanks to its generic declaration, the function block can be reused in various contexts with different output adapter implementations.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The **OFF_SPLIT_6** is a simple yet useful generic function block for signal distribution in IEC 61499 applications. It reduces wiring complexity by converting a single OFF signal to six parallel outputs. Its generic nature makes it versatile, as long as the OFF adapter used adheres to the unidirectional contract.

OFF_SPLIT_7

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **OFF_SPLIT_7** is a generic block for distributing a single OFF adapter signal to seven identical OFF outputs. It serves as a signal multiplier in control applications based on the IEC 61499 standard. The block has no event- or data-based interfaces, but communicates exclusively via adapters of type `adapter::types::unidirectional::AUS`. The actual signal type is only determined at runtime via the generic attribute `GenericClassName`.

Interface Structure

Event Inputs

None available.

Event Outputs

None available.

Data Inputs

None available.

Data Outputs

None available.

Adapter

Direction	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::AUS`	Uniform OFF input signal
Plug (Output)	`OUT1` – `OUT7`	`adapter::types::unidirectional::AUS`	Seven parallel OFF signals

Functionality

The module receives an OFF signal via the adapter socket `IN`. This signal is passed on unchanged and without delay to all seven adapter plugs `OUT1` to `OUT7`. Since the function block is declared as a generic function block (`GenericClassName = 'GEN_AUS_SPLIT'`), the specific type of the OFF adapter can be overridden at design time or during system configuration. The behavior always remains the same: a one-to-many distribution.

Technical Features

- **Generic Function Block**: The actual adapter type is defined via the attribute `eclipse4diac::core::GenericClassName`. By default, `'GEN_AUS_SPLIT'` is set.

- **No ECC / State Machine**: Due to the absence of event inputs, the function block does not have an internal state machine. The outputs follow the input signal directly (combinatory behavior).
- **Pure Adapter Communication**: No IEC 61499 data types (BOOL, INT, etc.) are used; all data transmission occurs via unidirectional OFF adapters.
- **Compatibility**: The function block is designed for use in 4diac IDE and runtime environments that support adapters of type `adapter::types::unidirectional::AUS`.

State Overview

The function block does not have a state machine. The output signal of each of the seven OUT adapters always corresponds to the current value of the IN adapter. There is no time delay or state storage.

Application Scenarios

- **Signal Distribution in Redundant Systems**: A central OFF control signal (e.g., "emergency stop") is to be forwarded to several decentralized actuators or subsystems.
- **Modular Automation Structures**: An OFF signal received from a higher-level controller is split into seven parallel paths that control independent machine modules.
- **Test and Simulation Environments**: For easily replicating a test signal without changing the logic.

Comparison with Similar Function Blocks

- **AUS_SPLIT_N** (e.g., for 2, 4, or 8 outputs) exist in variants with different numbers of outputs. AUS_SPLIT_7 is a specific variant for exactly seven outputs.
- Unlike data splitters (e.g., `SPLIT_INT`, `SPLIT_BOOL`), this function block works exclusively with adapters and not with elementary data types. This makes it particularly suitable for protocol-based or type-safe connections.
- Function blocks with event interfaces (e.g., `E_SPLIT`) distribute events, not signals. AUS_SPLIT_7, on the other hand, distributes a continuous signal value.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AUS_SPLIT_7** is a simple yet effective generic function block for the unidirectional distribution of an OFF adapter signal to seven parallel outputs. Its purely adapter-based interface and lack of event logic make it suitable for all applications where a signal needs to be duplicated without delay or state storage. It offers a clean, modular solution for signal distribution in IEC 61499-based automation systems.

OFF_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The **OFF_SPLIT_8** is a generic function block for distributing an incoming OFF signal to up to eight separate outputs. It serves as a simple "splitter" for signals of the type **adapter::types::unidirectional::OFF** and enables the parallel control of multiple devices or subsequent function blocks.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Interface	Type	Direction	Description
IN	`adapter::types::unidirectional::AUS`	Socket	Input – receives the OFF signal to be distributed
OUT1	`adapter::types::unidirectional::AUS`	Plug	Output 1 – forwards the incoming signal
OUT2	`adapter::types::unidirectional::AUS`	Plug	Output 2 – forwards the incoming signal
OUT3	`adapter::types::unidirectional::AUS`	Plug	Output 3 – forwards the incoming signal
OUT4	`adapter::types::unidirectional::AUS`	Plug	Output 4 – forwards the incoming signal
OUT5	`adapter::types::unidirectional::AUS`	Plug	Output 5 – forwards the incoming signal

OUT6	`adapter::types::unidirectional::AUS`	Plug	Output 6 – forwards the incoming signal
OUT7	`adapter::types::unidirectional::AUS`	Plug	Output 7 – forwards the incoming signal
OUT8	`adapter::types::unidirectional::AUS`	Plug	Output 8 – forwards the incoming signal

Functionality

This function block forwards the OFF signal present at socket **IN** unchanged to all eight plugs **OUT1** to **OUT8**. No delay, filtering, or logical processing takes place. The signal is available on all outputs simultaneously. The function corresponds to a 1:8 distribution.

Technical Features

- **Generic Function Block**: The function block is executed as a generic type (`GEN_AUS_SPLIT`). The specific type is determined at runtime via the attribute `eclipse4diac::core::GenericClassName`.
- **No State Machine**: Since the function block only performs direct signal forwarding without logic, it does not have its own execution control (ECC). Signal transmission occurs solely via the adapter interfaces.
- **Adapter Type**: All interfaces use the unidirectional `AUS` adapter type, which enables standardized signal transmission.

State Overview

The function block does not have a state machine. There are no internal states or transitions.

Application Scenarios

- **Distributing a Central Control Signal**: A single "off" signal (e.g., a switch-off command) is passed on to multiple actuators or sub-functions.
- **Parallel Control of Loads**: In agricultural or industrial control systems, when a signal needs to control multiple valves, motors, or lights simultaneously.
- **Splitting Bus Signals**: When an adapter-based signal path needs to be branched into multiple parallel paths.

Comparison with Similar Function Blocks

- **AUS_SPLIT_4**: Distributes a signal to four outputs. The AUS_SPLIT_8 offers higher fan-out capacity with eight outputs.
- **AUS_MERGE / AUS_JOIN**: Combine multiple signals – functionally the opposite.
- **AUS_ROUTER**: Can selectively route a signal to one of several outputs, while the splitter always activates all outputs.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AUS_SPLIT_8** is a simple yet useful function block for multiplying an OFF signal. Its lack of logic and states makes it efficient and easy to understand. It is particularly suitable for applications where a control signal needs to be distributed to multiple receivers without requiring selection or processing.

OFF_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The **OFF_SPLIT_9** function block is a generic component that distributes an incoming OFF signal to nine separate outputs. It serves as a fan-out for unidirectional adapter connections and is particularly suitable for applications where a signal needs to be forwarded to multiple receivers in parallel.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Direction	Name	Type	Description
SOCKET	IN	`adapter::types::unidirectional::AUS`	Incoming OFF signal
PLUG	OUT1 ... OUT9	`adapter::types::unidirectional::AUS`	Nine outgoing OFF signals

Functionality

This function block forwards the OFF signal arriving at the SOCKET *IN* unchanged to all nine PLUG outputs *OUT1* to *OUT9*. The forwarding occurs continuously without any additional logic or delay. Since

this is a generic function block, the specific data format of the OFF adapter type is not defined – it can be Boolean values, scalars, or complex structures, depending on the adapter definition used.

Technical Features

- **Generic Function Block**: The function block is declared as generic by the attribute `GenericClassName` (`GEN_AUS_SPLIT`) and can be parameterized for various OFF adapter instances.
- **Adapter-Based**: Communication occurs exclusively via adapters (sockets/plugs) – no event or data inputs are required.
- **Unidirectional**: The adapter type used, `adapter::types::unidirectional::AUS`, supports only one direction of data flow (from the socket to the plugs).

State Overview

The function block does not have its own states or event flow control (ECC). Signal transmission is purely data-driven via the adapter connections.

Application Scenarios

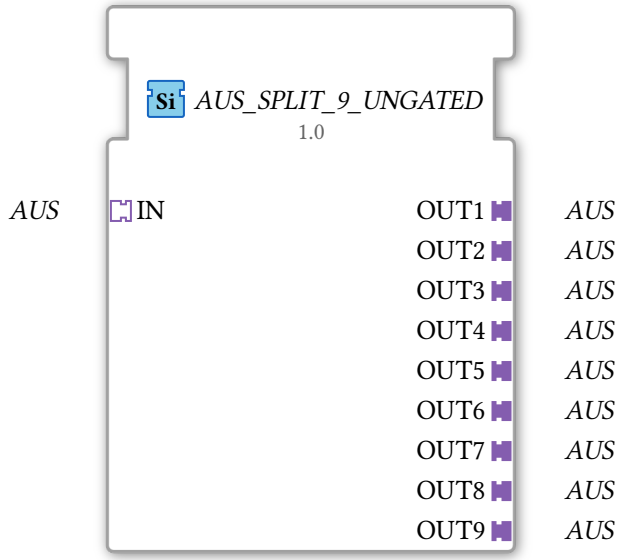
- **Signal Distribution**: A central control signal (e.g., "OFF" for a machine) is to be sent to multiple actuators or subsystems simultaneously.
- **Redundancy**: Parallel outputs for redundant control paths.
- **Test and Simulation Setups**: A simulation signal is distributed across multiple observers or logging blocks.

Comparison with Similar Function Blocks

Function Block	Type	Outputs	Special Feature
OFF_SPLIT_9	Adapter	9	Generic, for unidirectional OFF adapters
OFF_SPLIT_4	Adapter	4	Fewer outputs
SPLIT_1_2 (e.g., for data)	Data	any	Works with Data-Event Combinations

Unlike data-based split blocks, AUS_SPLIT_9 does not require event control, as the adapter connection handles data transmission implicitly.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AUS_SPLIT_9** is a simple yet effective function block for splitting a single OFF signal into nine parallel paths. Its generic nature and pure adapter interface make it flexible for use in IEC 61499-based control applications that require unidirectional signal duplication.

OFF_SPLIT_9

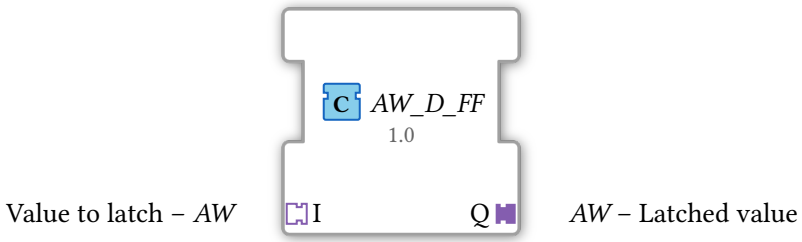
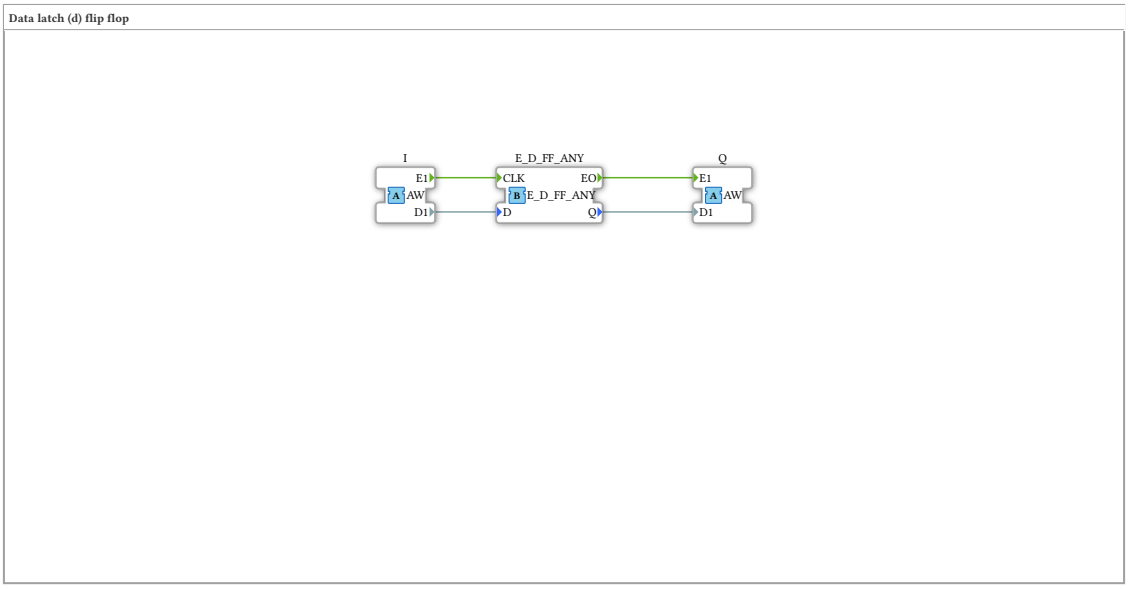
Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.



Conclusion



The **AUS_SPLIT_9_UNGATED** is a simple yet effective function block for splitting a single OFF signal into nine parallel paths. Its generic nature and pure adapter interface make it flexible for use in IEC 61499-based control applications that require unidirectional signal duplication.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AW_D_FF

• — ○ • — ○ • — ○ •

Introduction

The function block **AW_D_FF** implements a data-controlled flip-flop (D-latch) according to IEC 61499. It accepts a binary data value at its input and outputs it in a clock-controlled manner. The interface is exclusively via adapters, which enables modular and flexible integration into existing components.

Interface Structure

Event Inputs

No direct event inputs at the FB level. Event control is handled via the input adapter **I**.

Event Outputs

No direct event outputs at the FB level. Event output is handled via the output adapter **Q**.

Data Inputs

No direct data inputs at the FB level. Data is transferred via the input adapter **I**.

Data Outputs

No direct data outputs at the FB level. Data output is via the output adapter **Q**.

Adapters

Adapter	Type	Description
I (Socket)	`adapter::types::unidirectional::AW`	Input adapter – receives the data to be latched (D1) and the clock signal (E1).
Q (Plug)	`adapter::types::unidirectional::AW`	Output adapter – outputs the latched data (D1) and an acknowledgment event (E1).

Both adapters are of the same unidirectional type and each encapsulates one event and one data value.

Functionality

The component internally uses the IEC 61499 standard component `E_D_FF_ANY`.

On a rising edge of the clock signal (event `E1` at adapter **I**), the current data value (`D1`) is taken and made available at the output. The output value remains until a new rising clock edge takes over a new value.

The logic table (D flip-flop) is as follows:

Clock (E1)	Input D	Output Q (after clock)

↑	0	0
↑	1	1
otherwise	arbitrary	unchanged

Technical Features

- **Adapter-Based Interface**: The function block uses adapters exclusively for communication, enabling loose coupling and easy reuse in various contexts.
- **Standard Compliance**: Developed according to IEC 61499-1 Annex A and licensed under the Eclipse Public License 2.0 (EPL-2.0).
- **Internal Implementation**: Utilizes the predefined function block `E_D_FF_ANY`, which provides a general-purpose D flip-flop.
- **Unidirectional Data Flow**: The adapters are designed to be unidirectional, meaning that data and event flow is defined in only one direction.

State Overview

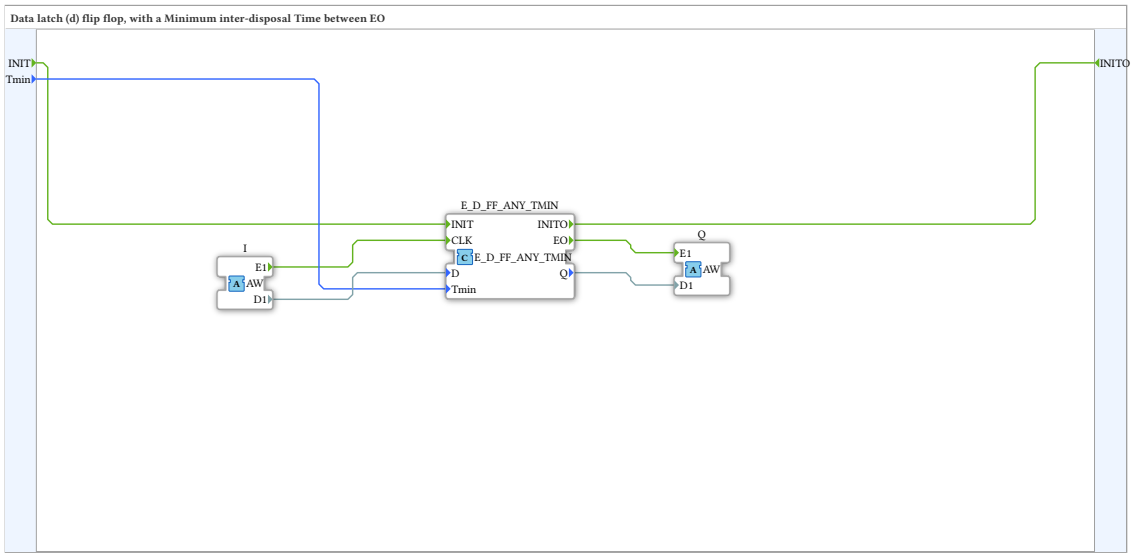
A D flip-flop has two stable states for the output Q (logic 0 or 1). The state change occurs exclusively on a rising edge of the clock signal:

- **State 0**: Output Q = 0 (as long as no clock signal with D=1 arrives)
- **State 1**: Output Q = 1 (after a clock signal with D=1, until a clock signal with D=0 arrives)

There is no other internal state machine; the functionality is purely storage-based.

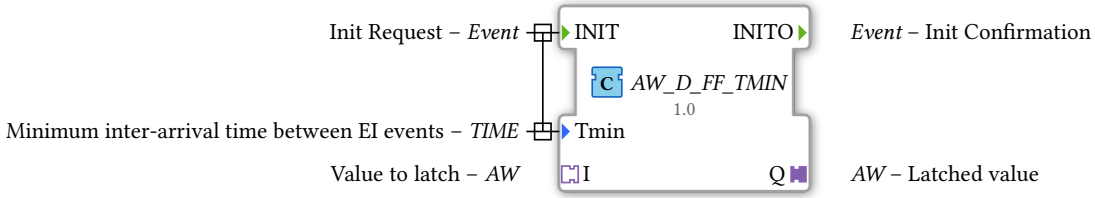
Application Scenarios

- **Synchronization of Asynchronous Signals**: A stable data value is acquired at a defined time (clock signal).
- **State Register**: As a 1-bit memory in simple control logic circuits.
- **Data Buffer**: Short-term storage of a binary value for subsequent processing steps.
- **Clock-Controlled Threshold Decisions**: An input value is considered valid only on a clock edge.



Comparison with Similar Components

Component	Property	Difference to AW_D_FF
RS Flip-Flop	Sets/resets asynchronously	AW_D_FF requires a clock signal, no separate set/reset inputs.
T Flip-Flop	Toggles on clock signal	AW_D_FF takes the value from D, no toggle function.
JK Flip-Flop	Universal (Set, Reset, Toggle)	AW_D_FF is simpler (only D input), no toggle mode.
E_D_FF_ANY	Directly usable with events/data	AW_D_FF encapsulates this function block and provides an adapter interface.



Conclusion

The **AW_D_FF** is a compact and standards-compliant D flip-flop device that, thanks to its adapter interface, is particularly flexible for use in modular IEC 61499 applications. It offers reliable clock-controlled data acquisition and is ideally suited for synchronized memory operations in industrial control systems.

AW_D_FF_TMIN

(Image of the function block – not included in the XML, therefore no image)

• – ○ • – ○ • – ○ •

Introduction

The **AW_D_FF_TMIN** is a composed IEC 61499 function block (a type of data latch flip-flop) that receives an incoming data value on an adapter, takes over upon an event, and passes it on to an output adapter with a minimal delay between two consecutive output events. It serves as a reliable buffer, extending the output events to a minimum time defined by the parameter `Tmin`.

Interface Structure

Event Inputs

Event	Type	Comment
`INIT`	EInit	Initialization request; sets the minimum inter-event time `Tmin`.

Event Outputs

Event	Type	Comment
`INITO`	EInit	Confirmation of successful initialization.

Data Inputs

Data	Type	Comment
`Tmin`	TIME	Minimum time (e.g., `T#100ms`) that must elapse between two consecutive output events (`Q.E1`).

Data Outputs

The function block (FB) has no direct data outputs; the latching value is provided via the adapter `Q`.

Adapters

Direction	Name	Type	Comment
Socket	I	adapter::types::unidirectional::AW	Value to be latched (input adapter). Contains the event and data interfaces I.E1 and I.D1.
Plug	Q	adapter::types::unidirectional::AW	Latched value (output adapter). Contains the event and data interfaces Q.E1 and Q.D1.

Functionality

The **AW_D_FF_TMIN** encapsulates the IEC 61499 standard function block E_D_FF_ANY_TMIN. The operation is as follows:

1. **Initialization**

The parameter Tmin is passed to the inner function block via the event input INIT. After successful initialization, INITO is output.

1. **Data Latching**

When an event arrives at the adapter input I.E1, the data value simultaneously present at I.D1 is adopted (edge-triggered D flip-flop).

1. **Output with Minimum Time**

The latched value is output at the adapter output Q.D1. Simultaneously, an event is generated on Q.E1 – but only if at least the time Tmin has elapsed since the last event on Q.E1. This ensures that the output events do not follow each other faster than allowed by Tmin.

1. **Further Cycles**

Each new event on I.E1 repeats the latching and the timed output.

Technical Features

- The function block is specified according to IEC 61499-1 Annex A and uses the adapter type definition adapter::types::unidirectional::AW.
- The implementation is based on the reproducible function block E_D_FF_ANY_TMIN, which provides the actual latch and timing logic.
- The minimum inter-event time Tmin is set at runtime via INIT and cannot be changed during operation.
- The function block is released under the Eclipse Public License 2.0 (EPL-2.0), version 1.0 (2026-05-15, HR Agrartechnik GmbH).

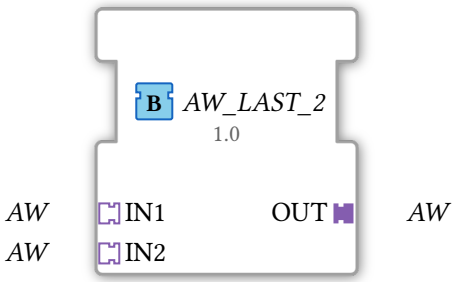
State Overview

The internal function block E_D_FF_ANY_TMIN has an implicit state machine:

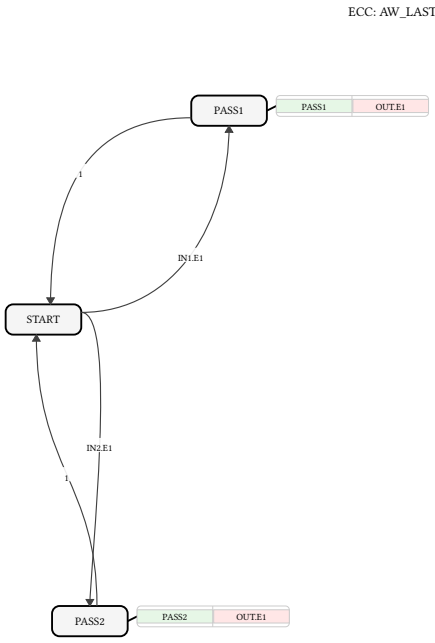
- **Initialization State**: The configuration is applied after INIT; Upon success, INITO is sent.
- **Operating State**: After initialization, the function block waits for events at I.E1. With each event, the data value is latched, timer monitoring is started, and output is only released if the minimum time Tmin has elapsed since the last output event.
- **Wait State**: If an output event cannot yet be released (because the time since the last event is less than Tmin), the latched value is held until the required delay has elapsed. Only then is Q.E1 triggered.

Application Scenarios

- **Signal Debouncing**: Prevents mechanical or communication-related bounces from affecting a downstream process in rapid succession.
- **Clock Control with Minimum Pulse Duration**: Ensures that subsequent components have a minimum time between processing steps.
- **Data Stream Synchronization**: Bufferes a data value and passes it on with a defined minimum delay to smooth jitter.



Comparison with Similar Components



Component	Feature	Difference
`E_D_FF`	Simple D flip-flop without a time limit	No control over the maximum output frequency.
`SR_FF`	Set-Reset flip-flop	No edge-triggered data transfer.
`E_D_FF_ANY_TMIN` (direct)	Like AW_D_FF_TMIN, but a pure event/data function block	Does not have an adapter interface; the variant with an adapter increases interchangeability and encapsulation in pluggable components.

Conclusion

The **AW_D_FF_TMIN** is a maintenance-friendly, adapter-based D-latch function block that combines the acquisition of a data value with a configurable minimum time between output events. By using a standardized adapter type, it can be easily integrated into hierarchical modules and offers a robust solution for time-critical signal chains in IEC 61499 systems.

AW_LAST_2

Introduction

The AW_LAST_2 function block merges two same-type WORD adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: WORD adapter (unidirectional) - first signal source
- **IN2**: WORD adapter (unidirectional) - second signal source

Output adapter (Plug):

- **OUT**: WORD adapter (unidirectional) - merged signal

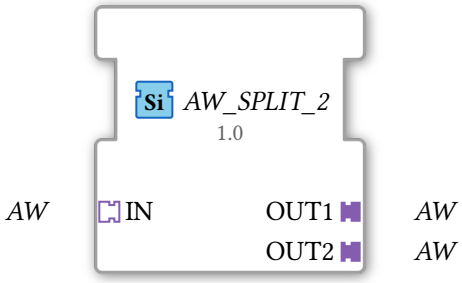
How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order

Application Scenarios



- Merging two equally-valid WORD signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same WORD value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AW_LAST_2 is the inverse of `AW_SPLIT_2`: AW_SPLIT_2 distributes 1 input to 2 outputs, AW_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

AW_SPLIT_2

!Image of the function block (not available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AW_SPLIT_2** splits an incoming unidirectional **adapter (AW)** into two identical outgoing adapters. It is implemented as a generic block and is suitable for applications where a signal path or adapter connection needs to be split between two subsequent components.

Interface Structure

Event Inputs
No event input available.

Event Outputs
No event output available.

Data Inputs
No data input available.

Data Outputs
No data output available.

Adapters

Name	Direction	Type	Description
`IN`	Socket	`adapter::types::unidirectional::AW`	Input Adapter – the unidirectional adapter to be shared.
`OUT1`	Plug	`adapter::types::unidirectional::AW`	First Output – receives an identical copy of the incoming adapter.
`OUT2`	Plug	`adapter::types::unidirectional::AW`	Second Output – also receives an identical copy of the incoming adapter.

Functionality
The function block forwards the unidirectional adapter (AW) connected to **IN** unchanged to both outputs **OUT1** and **OUT2**. No data manipulation, event control, or state logic takes place – the function block functions solely as a passive distribution unit at the adapter level.

Since the adapter type is declared as generic (`GEN_AW_SPLIT`), the function block can be used with various specific implementations of the AW adapter, as long as they follow the same `unidirectional::AW` protocol.

Technical Features
- **Generic Function Block**: The function block is defined as a generic component (GenericClassName `GEN_AW_SPLIT`). It can be used in projects with different AW adapter types without requiring any modification of the function block itself.
- **No Runtime Logic**: The partitioning is purely structural – the function block (FB) has neither a state machine (ECC) nor does it process events or data. This results in no additional computational overhead at runtime.
- **License**: The function block is licensed under the **Eclipse Public License 2.0 (EPL-2.0)**.

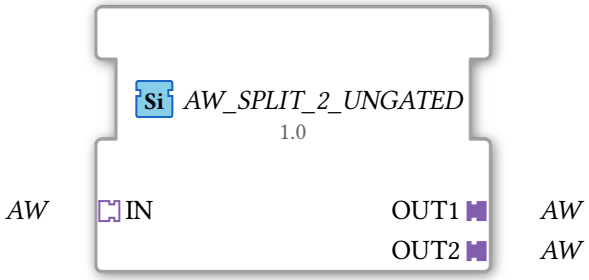
State Overview
The function block has no internal state machine. The routing is static and occurs without time- or event-dependent control.

Application Scenarios
- **Distributing a measurement or status adapter path** to two independent processing units (e.g., a main controller and a monitoring component).
- **Building redundant processing chains**, where the same adapter stream is fed in parallel into two separate logic branches.
- **Test and diagnostic architectures** that split a data stream into both production logic and an analysis path.

Comparison with Similar Function Blocks
- **AW_MERGE_2** – combines two AW inputs into one output (counterpart to the Split function).
- **Data Split Function Blocks** (e.g., `SPLIT_INT`, `SPLIT_BOOL`) operate on data signals, not on adapters. `AW_SPLIT_2` is specifically designed for splitting adapter interfaces.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.



Conclusion

AW_SPLIT_2` is a simple yet essential generic function block for adapter distribution. It enables clean, reusable splitting of a unidirectional AW path without additional logic or runtime costs. Especially in modular, adapter-based control systems, it simplifies signal distribution and promotes component reusability.

AW_SPLIT_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AW_SPLIT_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

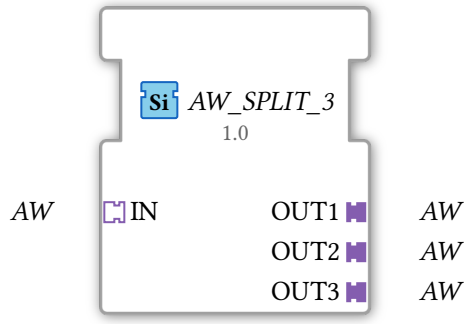
- **AW_MERGE_2** – combines two AW inputs into one output (counterpart to the Split function).
- **Data Split Function Blocks** (e.g., SPLIT_INT, SPLIT_BOOL) operate on data signals, not on adapters. AW_SPLIT_2_UNGATED is specifically designed for splitting adapter interfaces.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AW_SPLIT_2_UNGATED` is a simple yet essential generic function block for adapter distribution. It enables clean, reusable splitting of a unidirectional AW path without additional logic or runtime costs. Especially in modular, adapter-based control systems, it simplifies signal distribution and promotes component reusability.

AW_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AW_SPLIT_3** serves as a generic distributor for a unidirectional adapter of type `AW`. It accepts a single adapter connection (socket `IN`) and provides it identically to three outputs (plugs `OUT1`, `OUT2`, `OUT3`). The block is designed as a generic function block (Generic FB), so the specific data type of the adapter `AW` can be defined at runtime. Its application lies in signal coupling or command forwarding to multiple downstream components.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AW`	Input adapter – Source of the signal to be distributed.
Plug	`OUT1`	`adapter::types::unidirectional::AW`	First output – Identical signal to `IN`.
Plug	`OUT2`	`adapter::types::unidirectional::AW`	Second output – identical signal to `IN`.
Plug	`OUT3`	`adapter::types::unidirectional::AW`	Third output – identical signal to `IN`.

Functionality

The module operates without its own internal state machine or data processing. It represents a passive distribution structure: The adapter connection arriving at socket `IN` is routed to the three plugs `OUT1`, `OUT2`, and `OUT3`. All outgoing adapters are logically and temporally identical to the incoming signal. No delay, buffering, or transformation occurs.

Since this is a generic function block, the adapter type `AW` must be parameterized with a specific, compatible type (e.g., `Analogwert` or `Steuerbefehl`) before commissioning. This is done by specifying the attribute `eclipse4diac::core::GenericClassName`. Type resolution occurs either at design time (IDE) or at system runtime.

Technical Features

- **Generic Approach**: The function block is implemented as a *Generic FB* (`GenericClassName = 'GEN_AW_SPLIT'`). This allows the same function block to be used for different adapter types without having to create a separate FB for each type.
- **Unidirectional**: The adapters are declared as `unidirectional`. This means that data flow is only from the socket to the plugs. Feedback from the outputs to the input is not provided.
- **No Runtime Logic**: The function block is purely structural (passive) – no events, states, or calculations are executed. This reduces resource consumption in real-time systems.
- **Use of the Eclipse 4diac Environment**: The function block relies on the mechanisms provided by 4diac for generic types and adapters.

State Overview

The function block does not have its own state machine (ECC). It is a pure connection block without any time-based behavior or state changes. Its functionality is limited to the static forwarding of the adapter.

Application Scenarios

- **Signal Fan-out in Controllers**: A measured value (e.g., temperature, pressure) should be sent in parallel to several controllers or monitoring units.
- **Distributing Control Commands**: A central command is passed on to multiple actuators or subsystems simultaneously.
- **Redundant Signal Paths**: In safety-critical applications, the same signal can be split across multiple paths to enable independent evaluation.
- **Prototype Development**: The generic nature of the function block allows for early implementation and later specification of the specific adapter type.

Comparison with Similar Function Blocks

- **AW_MERGE_3** (hypothetical): A merger of three AW inputs into one output. AW_SPLIT_3 is the logical inverse.
- **SPLIT_ALL_2**: A non-generic splitter for two outputs that uses specific data types. AW_SPLIT_3 offers greater flexibility due to its generic nature.
- **REPEATER**: A simple amplifier or repeater for adapters with only one output. AW_SPLIT_3 extends this to three parallel outputs.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AW_SPLIT_3** is a fundamental yet flexible distribution block in Eclipse 4diac. Its generic design makes it universally applicable to all unidirectional adapter types. The clear, passive structure without additional logic allows for efficient and reliable signal distribution in automation solutions. Especially when combined with the type variability and 4diac adapter mechanics, it represents a valuable tool for modular and reusable control architectures.

AW_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AW_SPLIT_4` distributes an incoming AW adapter (unidirectional) to four identical AW output adapters. The block is designed generically and can be used with different AW types.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None (data transmission occurs exclusively via the adapter socket).

Data Outputs

None (output occurs exclusively via the adapter plugs).

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AW`	`IN`	Socket	Input for the AW data stream to be distributed
`adapter::types::unidirectional::AW`	`OUT1`	Plug	First output (copy of the input)
`adapter::types::unidirectional::AW`	`OUT2`	Plug	Second output
`adapter::types::unidirectional::AW`	`OUT3`	Plug	Third output
`adapter::types::unidirectional::AW`	`OUT4`	Plug	Fourth Output

Functionality

This function block acts as a passive distributor: Every value (or data packet) arriving via socket `IN` is forwarded unchanged to all four plugs `OUT1` to `OUT4`. No processing, buffering, or time synchronization takes place. The entire data flow is uneventful and purely adapter-based.

Technical Features

- **Generic Function Block**: The function block is declared with the generic name `GEN_AW_SPLIT`. This allows for late binding to specific AW adapter types (e.g., `AT_AW`, `CT_AW`, etc.) at compile or configuration time.
- **Unidirectional Communication**: The adapters used are of type `unidirectional::AW`, meaning data flows only in one direction. There are no return channels or acknowledgments.

- **No Dynamics**: The function block (FB) has no events, states, or time-dependent logic. It is purely combinatorial.

State Overview

Not applicable – the FB does not contain a state machine (ECC) and operates entirely in a data-driven manner.

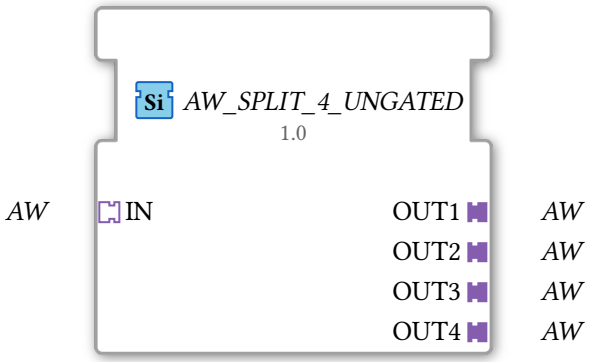
Application Scenarios

- Distribution of a single sensor or actuator signal path across multiple parallel evaluations.
- Preparation of a data source for different consumers in a control application.
- Generation of test or simulation points by multiplying an AW data stream.

Comparison with similar function blocks

Unlike data- or event-based split function blocks (e.g., `SPLIT`, `F_SPLIT`), `AW_SPLIT_4` operates exclusively at the adapter level. The advantage lies in its loose coupling and reusability across different AW types. The disadvantage: Only AW data can be distributed, not events or general values.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AW_SPLIT_4` function block is a simple, generic distributor for unidirectional AW adapters. It is ideally suited to split a single AW signal into up to four outputs and, thanks to its generic nature, integrates flexibly into various IEC 61499 applications.

AW_SPLIT_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AW_SPLIT_4`. Adapter

- **IN** (Socket) – Type: `adapter::types::unidirectional::AW`

Input interface for the original AW data stream.

- **OUT1** to **OUT5** (Plugs) – Type: `adapter::types::unidirectional::AW`

Five parallel output interfaces, each providing the same signal as the input.

Functionality

The function block passively forwards the incoming AW adapter to all five outputs. There is no active logic or state machine – the distribution is achieved structurally through the internal wiring of the function block. Changes to the input are immediately reflected at all outputs.

Technical Features

- **Generic Function Block** – The function block is declared as a generic type (`GEN_AW_SPLIT`) and can be reused in different contexts.
- **No Event Control** – Signal transmission occurs continuously without event-driven activation.
- **Unidirectional Adapters** – The adapter type used, `AW`, is unidirectional, meaning data flows only from the input to the outputs. Feedback from the outputs is not provided.

State Overview

The function block (FB) does not have an internal state machine (ECC). There are no defined states or state transitions – the functionality is purely data flow-oriented.

Application Scenarios

- **Distributing a sensor signal** to multiple downstream control units.
- **Parallel control** of multiple actuators that are to receive the same setpoint or command.
- **Test Setups** – Recording a signal or simultaneously forwarding it to various simulation and analysis components.

Comparison with Similar Function Blocks

- **AW_SPLIT_N** – Another generic split FB that can be extended to a variable number of outputs. `AW_SPLIT_5` is a specialized variant with five fixed outputs.
- **Pure Data Splitters** – These operate on data types like `INT` or `BOOL` and use different interface types. `AW_SPLIT_5` is specifically designed for the AW adapter.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AW_SPLIT_5` is a simple yet useful component for splitting an AW adapter signal into five parallel paths. Its generic design allows for flexible use in various control projects within the 4diac IDE. The absence of an event and data interface reduces complexity to the essentials – pure signal duplication.

AW_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The **AW_SPLIT_6** function block is used to split an incoming unidirectional **AW** adapter into six identical output adapters. It is designed as a generic function block used in the 4diac IDE for distributing AW signals. The function block is intended for applications where a signal value—e.g., an analog or digital value—is required multiple times in parallel without the need for manual duplication of the connections.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AW`	IN	Socket	Input adapter for the AW signal to be distributed
`adapter::types::unidirectional::AW`	OUT1 – OUT6	Plugs	Six output adapters, each providing an identical copy of the input signal

Functionality

The module receives a unidirectional **AW** signal via the **IN** socket. This signal is internally duplicated to all six output plugs (**OUT1** to **OUT6**). The signal is passed through without delay or data manipulation – the value of the incoming adapter is made directly available at each of the six outputs. The module has no state logic or event control of its own; it operates purely passively and simply passes the signal through.

Technical Features

- **Generic Type**: The function block is implemented as a generic function block (`GEN_AW_SPLIT`), allowing for flexible reuse in different projects.
- **Type Hash**: The type hash property is empty, meaning that no automatic type identity check is performed during instantiation.
- **No Event or Data Ports**: All signal transmission occurs exclusively via adapters. Events are not processed; therefore, the function block is only suitable for pure data transmission without timing.

State Overview

The function block has no internal states. It is a pure split function block without sequential logic. Its behavior is deterministic and always identical: The input signal is copied to all outputs.

Application Scenarios

- **Distribution of an analog measured value** to multiple consumers (e.g., displays, controllers, recording systems)
- **Splitting a digital control signal** to parallel actuator or sensor interfaces
- **Star-shaped signal distribution** in modular control architectures where one source supplies multiple sinks

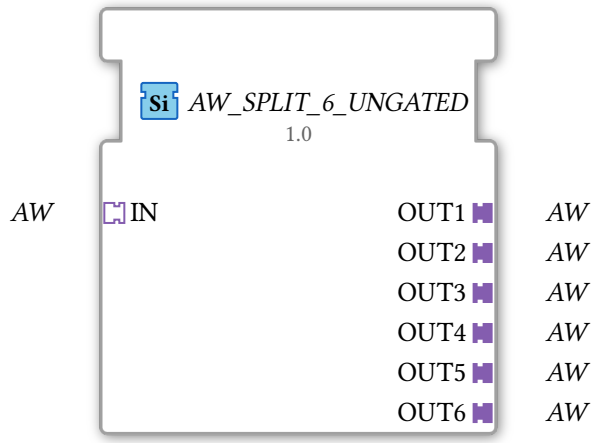
Comparison with Similar Function Blocks

Compared to an **AW_SPLIT_2** or **AW_SPLIT_4**, this function block offers a higher number of outputs (6). This makes it particularly suitable for systems with many parallel receivers. Alternatively, several smaller Split function blocks could be cascaded, but this can negatively impact clarity and performance. The **AW_SPLIT_6** is optimized as a complete solution for this requirement.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion



The **AW_SPLIT_6** is a simple yet useful function block for multiplying a unidirectional AW signal to six outputs. Due to its generic nature and adapter-based interface, it integrates seamlessly into a 4diac environment. It is recommended for all applications where a single signal is needed multiple times without any detours.

AW_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AW_SPLIT_7` is used to distribute a single incoming AW adapter (unidirectional) to seven identical AW adapter outputs. It is designed as a generic function block and enables the simple distribution of adapter connections without data processing.

Interface Structure

Event Inputs

- None

Event Outputs

- None

Data Inputs

- None

Data Outputs

- None

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::AW`	IN	Socket (Input)	Incoming AW adapter, which is distributed to the outputs.
`adapter::types::unidirectional::AW`	OUT1 ... OUT7	Plug (Output)	Seven outgoing adapters, each providing the same data as the input.

Functionality

This module does not have its own event or data ports. It functions purely as an adapter duplication: The incoming AW adapter (`IN`) is internally passed through to all seven output adapters (`OUT1` to `OUT7`) without any processing. Each module connected to one of the outputs thus receives exactly the same instance of the AW adapter.

The implementation is generic (Generic FB), so the actual adapter type can be dynamically determined by parameters. This makes the function block suitable for any unidirectional AW interface.

Technical Features

- **Generic Type**: The function block uses the generic function block mechanism to determine the specific adapter type at runtime or during compilation. The placeholder `GEN_AW_SPLIT` is replaced by the actual adapter.
- **Pure Adapter Distribution**: No data copying or serialization takes place – the references to the AW adapter are passed on.
- **No Event Control Required**: The function block operates asynchronously and without time dependencies, as adapters are inherently data-specific.

State Overview

The `AW_SPLIT_7` function block does not have an internal state machine. Its behavior is deterministic and consists solely of passing through the adapter. A state machine is therefore not required.

Application Scenarios

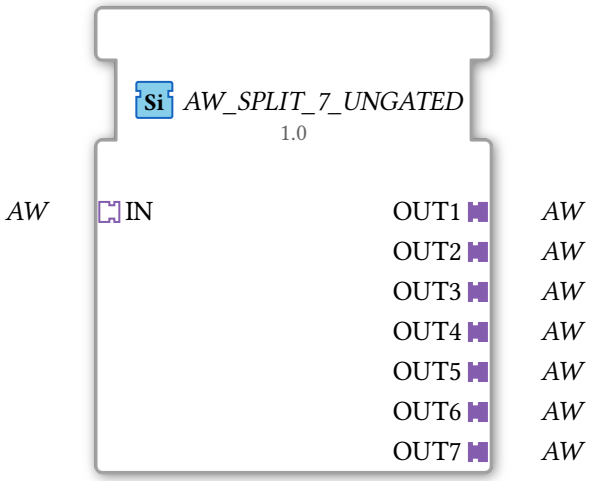
- **Distributing sensor adapters** to multiple evaluation or control units in an automation axis.
- **Splitting a bus signal** into multiple parallel connections (e.g., for redundant monitoring).
- **Cascading adapters** in an IEC 61499 system when multiple function blocks need to access the same data stream.

Comparison with Similar Function Blocks

- **SPLIT Function Blocks with a Limited Number of Outputs**: Other split function blocks (e.g., `SPLIT_2`, `SPLIT_4`) distribute adapters across fewer channels – here, exactly seven outputs are provided.

- **Adapter Multiplexers**: Unlike multiplexers that select between multiple inputs, the `AW_SPLIT_7` distributes a single input without selection.
- **Data Split Function Blocks**: If the function block had data and event ports, it would have to copy data. Adapter-based splits are more efficient because only references are passed on.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AW_SPLIT_7` is a simple yet useful generic function block for duplicating a unidirectional AW adapter to seven outputs. Its strengths lie in its flexible type adaptation and efficient, event-free routing. It is particularly suitable for modular automation systems where an adapter needs to be used multiple times.

AW_SPLIT_7_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AW_SPLIT_7`. - **Data Split Function Blocks**: If the function block had data and event ports, it would have to copy data. Adapter-based splits are more efficient because only references are passed on.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AW_SPLIT_7_UNGATED` is a simple yet useful generic function block for duplicating a unidirectional AW adapter to seven outputs. Its strengths lie in its flexible type adaptation and efficient, event-free routing. It is particularly suitable for modular automation systems where an adapter needs to be used multiple times.

AW_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AW_SPLIT_8** is a generic block that splits an incoming unidirectional AW adapter signal into eight identical output signals. The block is implemented as a generic FB and can be assigned a specific type name and type check code at runtime. It serves as a 1:8 distributor for AW data streams and is typically used in automation technology when a signal needs to be forwarded to multiple sinks simultaneously.

Interface Structure

Event Inputs

No event inputs are available. Communication occurs exclusively via the adapter interfaces.

Event Outputs

No event outputs are available. Data is passed via the adapter plugs.

Data Inputs

No data inputs are available. All input data is provided via the socket adapter `IN`.

Data Outputs

No data outputs are available. Output data is provided via the plug adapters `OUT1` to `OUT8`.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AW`	`IN`	Socket (Input)	Source adapter that provides the signal to be split
`adapter::types::unidirectional::AW`	`OUT1`	Plug (Output)	First output, identical to the IN signal
adapter::types::unidirectional::AW`	`OUT2`	Plug (Output)	Second output
adapter::types::unidirectional::AW`	`OUT3`	Plug (Output)	Third output
adapter::types::unidirectional::AW`	`OUT4`	Plug (Output)	Fourth output
adapter::types::unidirectional::AW`	`OUT5`	Plug (Output)	Fifth output
adapter::types::unidirectional::AW`	`OUT6`	Plug (Output)	Sixth Output

adapter::types::unidirectional::AW	OUT7	Plug (Output)	Seventh Output
adapter::types::unidirectional::AW	OUT8	Plug (Output)	Eighth Output

Functionality

The module behaves like a passive splitter. As soon as a valid AW adapter signal is present at socket `IN` (e.g., due to an event from the adapter protocol), this signal is simultaneously passed on to all eight plug adapters (`OUT1`–`OUT8`). No data modification, buffering, or delay occurs. The function block is event-driven in accordance with the underlying adapter protocol: Data transmission is triggered by the adapter mechanism of IEC 61499-2.

The outputs always provide the same data content as the input. If the input does not contain valid data, the outputs will also be silent.

Technical Features

- **Generic Function Block (FB):** The function block is declared as generic and carries the attributes `eclipse4diac::core::GenericClassName` (default: `'GEN_AW_SPLIT'`) and `eclipse4diac::core::TypeHash` (default: `''`). This allows for late binding to a specific function block type, for example, to create more type-safe instances.
- **No Own Events or Variables:** The function block has no explicit event inputs/outputs and no data inputs/outputs in the traditional sense. All communication is handled via the adapter interfaces, which reduces complexity and increases reusability.
- **Unidirectional Adapters:** Only unidirectional AW adapters are used. Feedback from the outputs to the input is not provided.

State Overview

The function block does not have its own state machine (e.g., ECC – Execution Control Chart). Its behavior is entirely determined by the behavior of the adapter type used, `adapter::types::unidirectional::AW`. In the simplest case, there are two implicit states:

- **Idle:** No valid signal at the input. All outputs are inactive.
- **Active:** A valid signal is present at the input and is replicated to all outputs.

A more detailed state description can be derived from the adapter definitions.

Application Scenarios

- **Parallel Supply of Multiple Consumers:** A sensor or control signal (e.g., speed setpoint) should be distributed simultaneously to multiple actuators or subsystems without requiring the programming of a separate distribution module.
- **Test and Simulation Environments:** A single test signal can be connected to multiple analysis or logging channels.
- **Data Multiplication in Hierarchical Control Systems:** In modular systems, a central control data stream can be distributed to multiple decentralized units (e.g., field devices).

Comparison with Similar Modules

- **AW_SPLIT_2, AW_SPLIT_4:** Analogous splitters with fewer outputs (2 or 4, respectively). The number of outputs is the only difference. For applications requiring exactly 8 outputs, `AW_SPLIT_8` is the appropriate choice.
- **General Splitters (e.g., for other adapter types):** Splitters exist for various adapter data types (e.g., `BOOL_SPLIT`, `INT_SPLIT`) that have an analog structure but different adapter interfaces.
- **Multicast Blocks:** More complex blocks can additionally offer filtering, prioritization, or buffering functions; `AW_SPLIT_8` is intentionally kept minimalist to avoid unwanted side effects.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AW_SPLIT_8` block is a simple yet useful generic 1:8 splitter for unidirectional AW adapters. It fulfills the basic requirement of distributing an incoming signal to eight outputs without delay or modification. Its

generic design allows it to be used in various contexts where type-safe replication of adapter data streams is required. Strict adherence to the IEC 61499-2 standard and the use of adapters facilitate integration into existing 4diac projects.

AW_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AW_SPLIT_9` serves as a generic distributor for one incoming adapter of type `AW` to nine identically configured output adapters. It enables the multiple use of a single adapter signal without duplicating the original data source. The designation “SPLIT 1 AW into 9 AW” describes the core function: One AW input is distributed to nine AW outputs.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Type	Name	Direction	Description
adapter::types::unidirectional::AW	IN	Socket (Input)	Incoming AW adapter that is distributed to all outputs.
adapter::types::unidirectional::AW	OUT1	Plug (Output)	First outgoing AW adapter.
adapter::types::unidirectional::AW	OUT2	Plug (Output)	Second outgoing AW adapter.
adapter::types::unidirectional::AW	OUT3	Plug (Output)	Third outgoing AW adapter.
adapter::types::unidirectional::AW`	OUT4	Plug (Output)	Fourth outgoing AW adapter.
adapter::types::unidirectional::AW`	OUT5	Plug (Output)	Fifth outgoing AW adapter.
adapter::types::unidirectional::AW`	OUT6	Plug (Output)	Sixth outgoing AW adapter.
adapter::types::unidirectional::AW`	OUT7	Plug (Output)	Seventh outgoing AW adapter.
adapter::types::unidirectional::AW	OUT8	Plug (Output)	Eighth outgoing AW adapter.
adapter::types::unidirectional::AW	OUT9	Plug (Output)	Ninth outgoing AW adapter.

Functionality

The component has no processing logic whatsoever (no ECC, no algorithms). It functions purely as a wiring aid: The AW signal present at socket `IN` is structurally forwarded to all nine plug adapters `OUT1` to `OUT9`. In the IEC 61499 model, this means that all connections to the outputs receive the same signal present at the input. No timing or data manipulation takes place.

Technical Features

- **Generic Function Block**: The function block is declared as a generic class (`GEN_AW_SPLIT`). This allows reuse with different AW adapter types, provided the basic structure (unidirectional AW adapter) is maintained.
- **No Events or Data**: All communication occurs exclusively via adapter interfaces. This simplifies handling in purely adapter-based architectures.
- **No State Logic**: The function block has no inherent behavior; it is a purely "passive" element for signal copying.

State Overview

The function block does not have its own state machine, as no events or algorithms are defined. Its behavior is purely structural: As long as the input adapter is connected, all outputs are always active – no state change occurs.

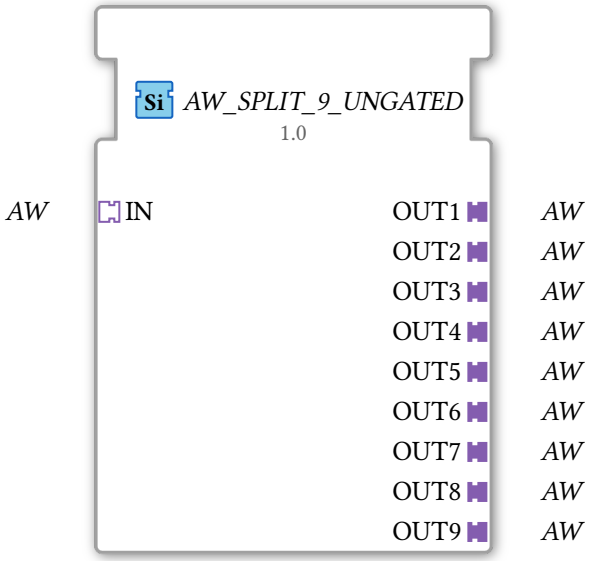
Application Scenarios

- **Signal Fan**: A central output signal (e.g., a control command or sensor value) must be distributed to several downstream components.
- **Redundant Connections**: In safety-critical systems, the same output signal can be sent to multiple parallel evaluation units.
- **Wiring Simplification**: The function block replaces manual star wiring in the application and improves the clarity of the function diagram.

Comparison with Similar Function Blocks

- **AW_SPLIT_N**: A generic split function block with a variable number of outputs (e.g., `AW_SPLIT_4`, `AW_SPLIT_16`). `AW_SPLIT_9` is a special implementation for exactly nine outputs.
- **Data Split Blocks**: Blocks that split data inputs (e.g., `INT`, `REAL`). `AW_SPLIT_9` operates exclusively at the adapter level and not at individual data points.
- **Multiplexers (MUX)**: A multiplexer selects one of several inputs, while this block distributes one input to many outputs (fan-out).

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AW_SPLIT_9` is a simple yet useful generic function block for splitting a unidirectional AW adapter signal into nine parallel outputs. Its structure is minimalist and purely passive, making it a reliable tool in adapter-oriented control architectures. It requires neither events nor data and can be integrated into existing applications without side effects.

AW_SPLIT_9_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AW_SPLIT_9`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AW_SPLIT_9_UNGATED` serves as a generic distributor for one incoming adapter of type `AW` to nine identically configured output adapters. It enables the multiple use of a single adapter signal without duplicating the original data source. The designation "SPLIT 1 AW into 9 AW" describes the core function: One AW input is distributed to nine AW outputs.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

Adapters

Type	Name	Direction	Description
adapter::types::unidirectional::AW	IN	Socket (Input)	Incoming AW adapter that is distributed to all outputs.
adapter::types::unidirectional::AW	OUT1	Plug (Output)	First outgoing AW adapter.
adapter::types::unidirectional::AW	OUT2	Plug (Output)	Second outgoing AW adapter.
adapter::types::unidirectional::AW	OUT3	Plug (Output)	Third outgoing AW adapter.
adapter::types::unidirectional::AW`	OUT4	Plug (Output)	Fourth outgoing AW adapter.
adapter::types::unidirectional::AW`	OUT5	Plug (Output)	Fifth outgoing AW adapter.
adapter::types::unidirectional::AW`	OUT6	Plug (Output)	Sixth outgoing AW adapter.
adapter::types::unidirectional::AW`	OUT7	Plug (Output)	Seventh outgoing AW adapter.
adapter::types::unidirectional::AW	OUT8	Plug (Output)	Eighth outgoing AW adapter.
adapter::types::unidirectional::AW	OUT9	Plug (Output)	Ninth outgoing AW adapter.

Functionality

The component has no processing logic whatsoever (no ECC, no algorithms). It functions purely as a wiring aid: The AW signal present at socket `IN` is structurally forwarded to all nine plug adapters `OUT1` to `OUT9`. In the IEC 61499 model, this means that all connections to the outputs receive the same signal present at the input. No timing or data manipulation takes place.

Technical Features

- **Generic Function Block**: The function block is declared as a generic class (`GEN_AW_SPLIT`). This allows reuse with different AW adapter types, provided the basic structure (unidirectional AW adapter) is maintained.
- **No Events or Data**: All communication occurs exclusively via adapter interfaces. This simplifies handling in purely adapter-based architectures.
- **No State Logic**: The function block has no inherent behavior; it is a purely "passive" element for signal copying.

State Overview

The function block does not have its own state machine, as no events or algorithms are defined. Its behavior is purely structural: As long as the input adapter is connected, all outputs are always active – no state change occurs.

Application Scenarios

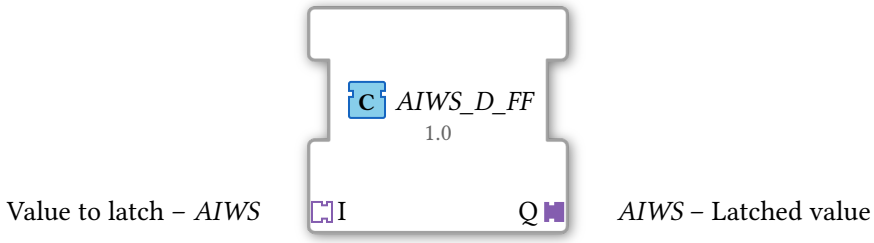
- **Signal Fan**: A central output signal (e.g., a control command or sensor value) must be distributed to several downstream components.
- **Redundant Connections**: In safety-critical systems, the same output signal can be sent to multiple parallel evaluation units.
- **Wiring Simplification**: The function block replaces manual star wiring in the application and improves the clarity of the function diagram.

Comparison with Similar Function Blocks

- **AW_SPLIT_N**: A generic split function block with a variable number of outputs (e.g., `AW_SPLIT_4`, `AW_SPLIT_16`). `AW_SPLIT_9_UNGATED` is a special implementation for exactly nine outputs.
- **Data Split Blocks**: Blocks that split data inputs (e.g., `INT`, `REAL`). `AW_SPLIT_9_UNGATED` operates exclusively at the adapter level and not at individual data points.
- **Multiplexers (MUX)**: A multiplexer selects one of several inputs, while this block distributes one input to many outputs (fan-out).

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.



Conclusion

The `AW_SPLIT_9_UNGATED` is a simple yet useful generic function block for splitting a unidirectional AW adapter signal into nine parallel outputs. Its structure is minimalist and purely passive, making it a reliable tool in adapter-oriented control architectures. It requires neither events nor data and can be integrated into existing applications without side effects.

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AIWS_D_FF

Value to latch – *AIWS* *AIWS* – Latched value

• – ○ • – ○ • – ○ •

Introduction

The AIWS_D_FF function block implements a data latch (D) flip-flop that stores an incoming data value and passes it to the output upon an event. Communication occurs exclusively via adapters, allowing the block to be seamlessly integrated into modular systems.

Interface Structure

Event Inputs

Name	Data Type	Description
I.E1	Event (via adapter)	Event that triggers the transfer of the data value

Event Outputs

Name	Data Type	Description
Q.E1	Event (via adapter)	Event that displays the stored data value

Data Inputs

Name	Data Type	Description
I.D1	ANY (via adapter)	Data value that is received upon arrival of I.E1

Data Outputs

Name	Data Type	Description
Q.D1	ANY (via adapter)	Stored data value that is output with Q.E1

Adapter

Name	Type	Direction	Description
I	`adapter::types::unidirectional::AIWS`	Socket (Input)	Provides the value to be latched and the triggering event
Q	`adapter::types::unidirectional::AIWS`	Plug (Output)	Outputs the stored value with an event

Functionality

The AIWS_D_FF encapsulates an internal `E_D_FF_ANY` module. The incoming adapter `I` provides an event via `I.E1`, which takes the value present at data port `I.D1`. The stored value is then output via `Q.D1`, accompanied by an event on `Q.E1`. Thus, the function block behaves like a classic clocked D flip-flop, but with a fully adapter-based interface.

Technical Features

- **Adapter-Based Interface:** All inputs and outputs are implemented via unidirectional adapters, enabling easy encapsulation and reuse in different contexts.
- **Internal Standard Function Block:** The implementation uses the IEC 61499 standard function block `E_D_FF_ANY`, which provides generic and proven latch functionality.
- **Unidirectional Data Flow:** The adapter type `AIWS` allows data flow in only one direction, improving clarity and preventing errors in networking.

State Overview

The AIWS_D_FF has no explicit internal states at the top level. The integrated `E_D_FF_ANY` goes through two phases:

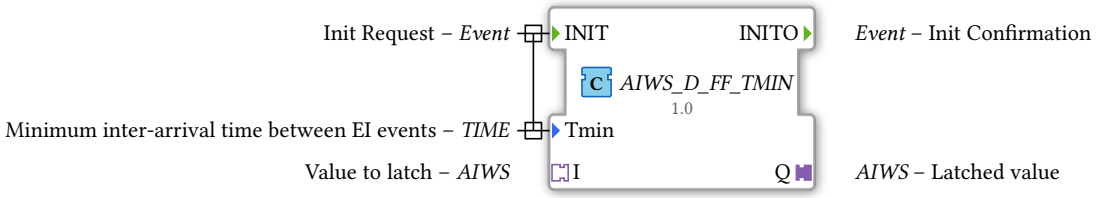
1. **Waiting:** It waits for an event at the clock input.
2. **Accept & Output:** Upon a clock event, the data value is accepted and an output event is generated.

This sequence repeats with each incoming event.

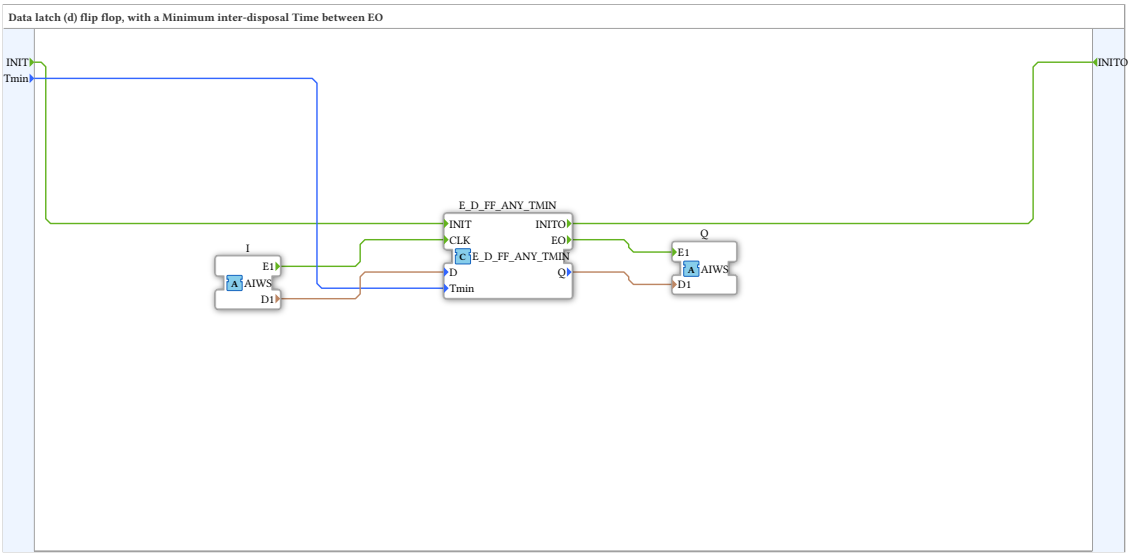
Application Scenarios

- **Data Synchronization:** Buffering a sensor signal that is only to be passed on upon a specific trigger event.

- **Control Logic:** Storing a control signal as a function of a clock signal, e.g., for time-synchronized actuator control.
- **Modular Systems:** Integration into adapter-based architectures where functional blocks are connected via standardized interfaces.



Comparison with Similar Components



- **Simple D flip-flop (e.g., `E_D_FF`):** Has separate event and data ports, while the AIWS_D_FF encapsulates the same logic via adapters.
- **SR flip-flop:** Stores two states (Set/Reset), whereas the AIWS_D_FF only stores a single data value and does not offer a reset function.
- **Register components:** Can store multiple bits in parallel, while the AIWS_D_FF is designed for a single data value (ANY).

Conclusion

The AIWS_D_FF is a compact and modular functional block for implementing a D flip-flop in IEC 61499 systems. The exclusive use of adapters ensures high flexibility and reusability. It is particularly suitable for applications that require decoupled, event-driven data transfer.

AIWS_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **AIWS_D_FF_TMIN** implements a data latch (D flip-flop) with a minimum inter-disposal time between two consecutive output events. It is accessed via adapter interfaces (type: AIWS, unidirectional) that receive a value and output it as a latched value. Control is achieved via the input adapter's event (CLK edge), with output occurring only after a configurable dead time (Tmin) has elapsed.

Interface Structure

Event Inputs

Event	Type	Comment

INIT	EInit	Initialization Request (with Tmin parameter)

Event Outputs

Event	Type	Comment
INITO	EInit	Initialization Acknowledgement

Data Inputs

Name	Type	Comment
Tmin	TIME	Minimum time between two output events (inter-disposal time)

Data Outputs

No dedicated data outputs – the latched value is provided exclusively via the **Q** adapter.

Adapters

Direction	Name	Type	Comment
Socket (Input)	I	adapter::types::unidirectional::AIWS	Value to be latched
Plug (Output)	Q	adapter::types::unidirectional::AIWS	Latched Value

Functionality

The function block internally uses the block `E_D_FF_ANY_TMIN` from the IEC 61499 library. The process is as follows:

1. At **INIT**, the minimum time `Tmin` is used, and the block is initialized (`INITO` confirms the successful start).
2. Each incoming event from adapter `I.E1` is interpreted as a clock edge (CLK).
3. The data value from adapter `I.D1` is transferred to the internal flip-flop on each CLK edge.
4. The latched value is provided on the output adapter `Q.D1`.
5. However, the corresponding event `Q.E1` is only sent after the time `Tmin` has elapsed since the last EO event (inter-disposal time). This limits the output rate.

The connection in the FB network ensures that events and data are correctly forwarded between the adapter `I`, the internal FB, and the adapter `Q`.

Technical Features

- **Adapter-Based Input/Output:** The function block uses only adapters of type `AIWS` (unidirectional) for signal processing. This allows for loose coupling and reuse of the interfaces.
- **Internal use of `E_D_FF_ANY_TMIN`:** The actual latch and timer logic is implemented by a specialized function block that already ensures a minimum time between two EO events.
- **Initialization required:** The function block must be initialized with `INIT` before its first use. This sets `Tmin`.

State overview

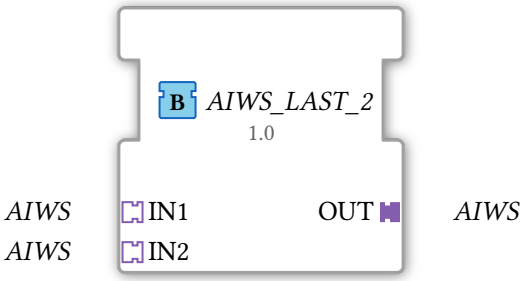
The function block essentially has two operating modes:

- **Initialization phase:** After receiving `INIT`, the internal timer and the flip-flop are reset. Upon completion, `INITO` is sent.
- **Normal operation:** After initialization, the function block waits for CLK events (`I.E1`). The data value is latched at each CLK (Current Control Point). An EO (Endpoint Output) event (`Q.E1`) is only triggered if the time elapsed since the last EO is ≥ **Tmin**. If this condition is not met, the EO is delayed.

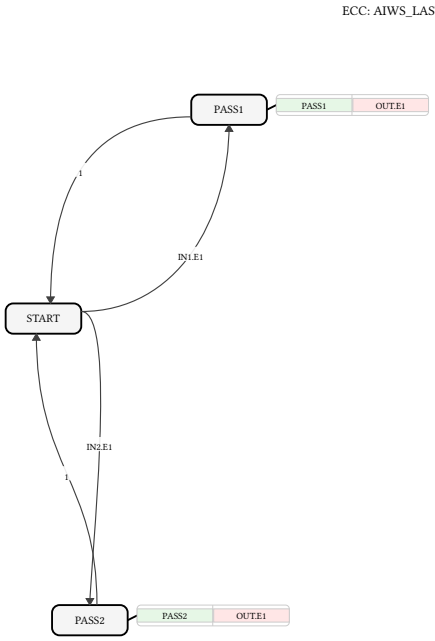
A complete state machine is implemented in the internal FB (Function Block); the block described here transparently represents this.

Application Scenarios

- **Sensor Value Acquisition with Minimum Repetition Rate:** In automation, an analog or digital measured value should be passed on to a downstream controller at defined minimum intervals to avoid overload or unwanted switching cycles.
- **Edge Debouncing:** The latch can be used to keep an input value stable while the output is debounced by `Tmin`.
- **Time-controlled data buffer:** In communication protocols where data packets must be sent with a minimal pause.



Comparison with similar function blocks



- **Standard D flip-flop (e.g., `E_D_FF`):** A standard D flip-flop accepts the input on every CLK edge and immediately outputs an event. It lacks a time limit on the output rate.
- **`AIWS_D_FF_TMIN`:** Extends the simple D flip-flop with a configurable minimum time between output events. This makes it particularly suitable for time-critical and rate-limited applications.
- **Timer-based latch function blocks (e.g., `E_D_FF_ANY_TMIN`):** The internal function block used here is the actual implementation; `AIWS_D_FF_TMIN` encapsulates this in an adapter-based interface, thus facilitating integration into an IEC 61499 architecture.

Conclusion

The `AIWS_D_FF_TMIN` function block combines the function of a data latch with a programmable minimum output delay. Thanks to its adapter-based interface definition, it can be flexibly deployed in distributed automation systems. It offers a simple and robust solution, particularly for applications where signal changes must occur only at specific time intervals.

AIWS_LAST_2

Introduction

The AIWS_LAST_2 function block merges two same-type WSTRING adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: WSTRING adapter (unidirectional) - first signal source
- **IN2**: WSTRING adapter (unidirectional) - second signal source

Output adapter (Plug):

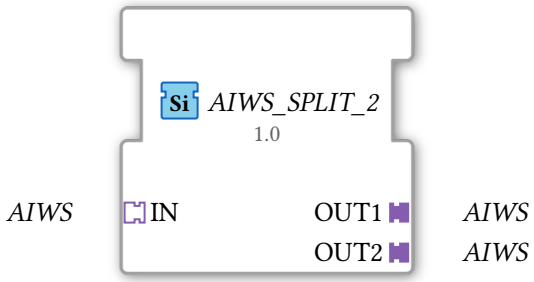
- **OUT**: WSTRING adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid WSTRING signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same WSTRING value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AIWS_LAST_2 is the inverse of AIWS_SPLIT_2: AIWS_SPLIT_2 distributes 1 input to 2 outputs, AIWS_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use AX_AE_MERGE instead, which merges only the event without altering the data value.

AIWS_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIWS_SPLIT_2** is used to split an incoming AIWS adapter signal into two identical outputs. It is designed as a generic function block and allows multiple uses of an AIWS signal within the same application without requiring separate signal distribution programming.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Direction	Name	Type	Description
Socket (Input)	**IN**	adapter::types::unidirectional::AIWS	Incoming AIWS signal, which is distributed to both outputs.
Plug (Output)	**OUT1**	adapter::types::unidirectional::AIWS	First output – identical signal to the input.
Plug (Output)	**OUT2**	adapter::types::unidirectional::AIWS	Second output – identical signal to the input.

Functionality

The module passes the AIWS signal present at socket **IN** unchanged to both plugs **OUT1** and **OUT2**. No logical or timing processing takes place – the distribution occurs purely passively through the wiring within the functional block. This allows two independent adapter instances to be supplied with the same data simultaneously.

Technical Features

- **Generic Block**: The function block is declared as a generic type (`GEN_AIWS_SPLIT`), so it can be reused for different AIWS implementations.
- **Pure Adapter Logic**: Neither events nor data I/O are used; all communication takes place exclusively via the adapter interfaces.
- **No State Dependency**: The function block has no internal state machine – the output signal follows the input signal without delay or buffering.

State Overview

The function block is stateless. There are no internal states or transitions. The outputs are a direct mapping of the input at any given time.

Application Scenarios

- **Distributing a Sensor Signal**: A single AIWS sensor (e.g., analog value) is to be read simultaneously by two independent control or monitoring modules.
- **Redundant Processing**: In safety applications, the same signal can be passed to multiple parallel evaluation functions.
- **Logical Branching**: Splitting a data stream for different evaluations or visualizations in a 4diac application.

Comparison with Similar Modules

- **AIWS_SPLIT_3, AIWS_SPLIT_4**: Extended versions with three or four outputs, respectively – essentially the same functionality.
- **SPLIT Modules for Other Adapter Types**: 4diac offers analog split modules for other adapters (e.g., `DINT_SPLIT`) that distribute a data signal to multiple outputs – but at the data level, not via adapters.
- **Event Split Blocks**: Blocks like `E_SPLIT` distribute events, not data streams – AIWS_SPLIT_2 specifically addresses AIWS adapter communication.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AIWS_SPLIT_2** is a simple yet useful generic function block for duplicating an AIWS adapter signal. It reduces wiring complexity in applications that require the same analog or mixed signal multiple times and, thanks to its passive, stateless architecture, integrates seamlessly into existing workflows.

AIWS_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIWS_SPLIT_3** is used to split a single incoming AIWS adapter (type `adapter::types::unidirectional::AIWS`) into three identical output adapters. All data received via the input adapter is forwarded unchanged to all three outputs. The block is designed to be generic and can be used with various AIWS types.

Interface Structure

Event Inputs
None.

Event Outputs
None.

Data Inputs
None.

Data Outputs
None.

Adapters

Direction	Name	Type	Description
Socket (Input)	IN	adapter::types::unidirectional::AIWS	Input adapter that receives the signal to be distributed.
Plug (Output)	OUT1	adapter::types::unidirectional::AIWS	First output adapter.
Plug (Output)	OUT2	adapter::types::unidirectional::AIWS	Second output adapter.
Plug (Output)	OUT3	adapter::types::unidirectional::AIWS	Third output adapter.

Functionality
The internal logic of the component is remarkably simple: As soon as the socket **IN** receives data from the connected adapter, this data is simultaneously passed on to the three plugs **OUT1**, **OUT2**, and **OUT3**. No transformation, filtering, or buffering takes place. Data is passed unidirectionally and without delay.

Technical Features
- **Generic Function Block:** The function block is implemented as a generic block (`eclipse4diac::core::GenericClassName = 'GEN_AIWS_SPLIT'`). This allows it to be used with various AIWS adapter specializations, as long as they adhere to the unidirectional communication protocol. The specific type is defined at design time in the 4diac IDE.
- **No State Automation:** The block has no events and no state machine (ECC). Data is passed purely flow-driven.
- **Scalability:** The block is specifically designed for a 1:3 split. Separate blocks (e.g., AIWS_SPLIT_2, AIWS_SPLIT_4) are available for other split ratios.

State Overview
This function block does not have a state machine (ECC), therefore there are no states or state transitions. Its function is purely combinatorial at the adapter level.

Application Scenarios
- **Signal Distribution:** An AIWS data stream from one source is to be forwarded in parallel to several subsequent processing blocks (e.g., monitoring, parallel filtering, or visualization).
- **Redundancy:** The same signal is used on different paths to achieve redundancy or comparability.
- **Testing and Simulation:** In test environments, the input signal can be made available to several test modules simultaneously without side effects.

Comparison with Similar Function Blocks
- **AIWS_SPLIT_2 / AIWS_SPLIT_N:** Function blocks with the same functionality but a different number of outputs (2 or n outputs).
- **ALL_SPLIT (for data):** A generic function block for splitting data inputs/outputs, not specific to adapters. AIWS_SPLIT_3, on the other hand, is specifically optimized for the AIWS adapter type and operates at the adapter level.
- **AIWS_JOIN_3:** The inverse function block that combines three AIWS inputs into one output.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AIWS_SPLIT_3** is a simple yet effective generic function block for duplicating an AIWS adapter signal to three parallel outputs. Thanks to its generic nature, it can be flexibly used in various automation and control applications where a data stream is required multiple times.

AIWS_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AIWS_SPLIT_4` is used to split an incoming unidirectional **AIWS** adapter connection into four parallel outputs. It acts as a passive splitter, forwarding the values received via the socket to all four plugs without processing events or data itself.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Type	Direction	Name	Description
`adapter::types::unidirectional::AIWS`	Socket	**IN**	Input adapter for the AIWS connection to be distributed
`adapter::types::unidirectional::AIWS`	Plug	**OUT1**	First output adapter
`adapter::types::unidirectional::AIWS`	Plug	**OUT2**	Second output adapter
`adapter::types::unidirectional::AIWS**	Plug	**OUT3**	Third output adapter
`adapter::types::unidirectional::AIWS`	Plug	**OUT4**	Fourth output adapter

Functionality

This component is a simple “splitter” for the unidirectional data type **AIWS**. It has no internal logic, no states, and no events of its own. All values arriving via the input adapter `IN` are copied identically to the four output adapters `OUT1` through `OUT4`. This allows multiple subsequent function blocks (FBs) to be supplied with the same data in parallel.

Since the FB is designed generically (`GenericClassName = 'GEN_AIWS_SPLIT'`), the specific data type **AIWS** must be defined when inserting it into a project.

Technical Features

- **Generic Implementation**: The FB is marked as a generic splitter via the attribute `eclipse4diac::core::GenericClassName`. The actual type is only determined during instantiation.
- **No Active Control**: The FB does not require any events to trigger – distribution occurs passively via the adapter connections.
- **Complete Transparency**: Changes to the adapter data are passed on to all outputs without delay.

State Overview

The function block (FB) has no states or sequences of its own. It uses purely combinatorial routing.

Application Scenarios

- **Distribution of Sensor Data** – A sensor value (e.g., temperature, pressure) is to be made available to multiple processing blocks simultaneously.
- **Redundant Data Backup** – A data stream is to be sent in parallel to two or more independent logic units.
- **Test and Simulation Setups** – A signal is split across multiple paths to test different response patterns.

Comparison with Similar Function Blocks

- **Manual Wiring**: Without a splitter, each subsequent FB would have its own connection to the source FB, which reduces clarity.
- **Event-Based Splitters**: Some splitters use event outputs (e.g., `SPLIT` for arbitrary events). `AIWS_SPLIT_4` is specifically designed for the unidirectional **AIWS** adapter and requires no events.
- **Multiple Outputs**: Variants with two (e.g., `AIWS_SPLIT_2`) or more outputs are available; `AIWS_SPLIT_4` provides four outputs by default.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AIWS_SPLIT_4` is a simple yet essential component for distributing unidirectional **AIWS** adapter connections. It reduces wiring complexity, ensures clear structures, and enables the parallel use of a data stream by multiple function blocks without additional logic.

AIWS_SPLIT_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIWS_SPLIT_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AIWS_SPLIT_4_UNGATED` is used to split an incoming unidirectional **AIWS** adapter connection into four parallel outputs. It acts as a passive splitter, forwarding the values received via the socket to all four plugs without processing events or data itself.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Type	Direction	Name	Description
`adapter::types::unidirectional::AIWS`	Socket	**IN**	Input adapter for the AIWS connection to be distributed
`adapter::types::unidirectional::AIWS`	Plug	**OUT1**	First output adapter
`adapter::types::unidirectional::AIWS`	Plug	**OUT2**	Second output adapter
`adapter::types::unidirectional::AIWS**	Plug	**OUT3**	Third output adapter
`adapter::types::unidirectional::AIWS`	Plug	**OUT4**	Fourth output adapter

Functionality

This component is a simple “splitter” for the unidirectional data type **AIWS**. It has no internal logic, no states, and no events of its own. All values arriving via the input adapter `IN` are copied identically to the four output adapters `OUT1` through `OUT4`. This allows multiple subsequent function blocks (FBs) to be supplied with the same data in parallel.

Since the FB is designed generically (`GenericClassName = 'GEN_AIWS_SPLIT'`), the specific data type **AIWS** must be defined when inserting it into a project.

Technical Features

- **Generic Implementation**: The FB is marked as a generic splitter via the attribute `eclipse4diac::core::GenericClassName`. The actual type is only determined during instantiation.

- **No Active Control**: The FB does not require any events to trigger – distribution occurs passively via the adapter connections.
- **Complete Transparency**: Changes to the adapter data are passed on to all outputs without delay.

State Overview

The function block (FB) has no states or sequences of its own. It uses purely combinatorial routing.

Application Scenarios

- **Distribution of Sensor Data** – A sensor value (e.g., temperature, pressure) is to be made available to multiple processing blocks simultaneously.
- **Redundant Data Backup** – A data stream is to be sent in parallel to two or more independent logic units.
- **Test and Simulation Setups** – A signal is split across multiple paths to test different response patterns.

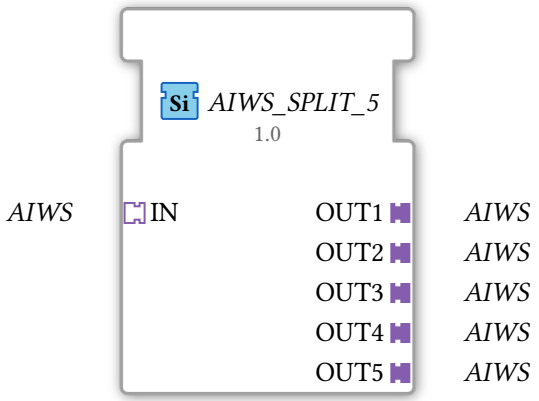
Comparison with Similar Function Blocks

- **Manual Wiring**: Without a splitter, each subsequent FB would have its own connection to the source FB, which reduces clarity.
- **Event-Based Splitters**: Some splitters use event outputs (e.g., `SPLIT` for arbitrary events). `AIWS_SPLIT_4_UNGATED` is specifically designed for the unidirectional **AIWS** adapter and requires no events.
- **Multiple Outputs**: Variants with two (e.g., `AIWS_SPLIT_2`) or more outputs are available; `AIWS_SPLIT_4_UNGATED` provides four outputs by default.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The `AIWS_SPLIT_4_UNGATED` is a simple yet essential component for distributing unidirectional **AIWS** adapter connections. It reduces wiring complexity, ensures clear structures, and enables the parallel use of a data stream by multiple function blocks without additional logic.

AIWS_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIWS_SPLIT_5** is a generic block for splitting a single **AIWS** adapter into five identical **AIWS** adapters. It allows an AIWS signal provided by a socket to be forwarded to multiple independent adapter plugs without requiring event or data processing logic. This function block is

particularly suitable for signal distribution in industrial automation architectures based on the **IEC 61499** standard.

Interface Structure

Event Inputs
No event inputs are available. The block operates purely on a data-based or adapter-based basis.

Event Outputs
No event outputs are available. Forwarding is implicit via the adapter interfaces.

Data Inputs
No data inputs are available. All information is transmitted via the socket adapter.

Data Outputs
No data outputs are available. Output is via the plug adapters.

Adapters

Type	Label	Direction	Adapter Type
Socket (Input)	IN	Input	`adapter::types::unidirectional::AIWS`
Plug (Output)	OUT1	Output	`adapter::types::unidirectional::AIWS`
Plug (Output)	OUT2	Output	`adapter::types::unidirectional::AIWS`
Plug (Output)	OUT3	Output	`adapter::types::unidirectional::AIWS`
Plug (Output)	OUT4	Output	`adapter::types::unidirectional::AIWS`
Plug (Output)	OUT5	Output	`adapter::types::unidirectional::AIWS`

The function block contains a single **socket** (`IN`) and five **plugs** (`OUT1` ... `OUT5`), all of the same unidirectional **AIWS adapter type**.

Functionality
The **AIWS_SPLIT_5** forwards the adapter signal present at its socket `IN` unchanged to all five plug adapters `OUT1` to `OUT5`. No data transformation or filtering occurs – the function block acts purely as a **signal distributor** (fan-out). As soon as a connection is established via the socket, the output adapters are immediately available for communication. Event control or state-dependent logic is not required.

Technical Features
- **Generic Design**: The function block (FB) has the attributes `eclipse4diac::core::GenericClassName` and `eclipse4diac::core::TypeHash`, which allow for subsequent configuration or type adjustment. By default, the class name is set to `'GEN_AIWS_SPLIT'`; the type hash is empty.
- **Uniform Adapter Type**: All interfaces use the same unidirectional AIWS adapter. This ensures compatibility between inputs and outputs.
- **No Data or Event Ports**: All communication takes place exclusively via the adapter interfaces, which simplifies configuration and reduces the number of connections.

State Overview
The **AIWS_SPLIT_5** does not have an explicit state machine. Its functionality is purely combinatorial – as soon as the socket is connected, the same adapter signals are present at all outputs. Therefore, there are no internal states that influence the behavior.

Application Scenarios
- **Signal Distribution in Modular Systems**: An AIWS signal provided by a sensor or controller must be forwarded in parallel to multiple consumers (e.g., actuators, HMI systems, higher-level controllers).
- **Test and Simulation Environments**: A single AIWS signal is distributed to various test and analysis components for monitoring or recording.
- **Redundant Processing**: In safety-critical systems, the identical signal can be routed to multiple independent logic units to enable parallel evaluation.

Comparison with Similar Components

Component	Number of Outputs	Type	Special Feature
AIWS_SPLIT_5	5	AIWS Adapter	Generic, no events/data
AIWS_SPLIT_2	2	AIWS Adapter	Same functionality, minimal distribution
AIWS_SPLIT_3	3	AIWS Adapter	Medium number of outputs
AIWS_SPLIT_4	4	AIWS Adapter	Alternative to **5**

All split variants are based on the same principle and differ only in the number of output adapters. The **AIWS_SPLIT_5** covers a medium distribution requirement and is particularly advantageous when exactly five parallel outputs are needed.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AIWS_SPLIT_5** is a simple yet essential function block for duplicating AIWS adapter signals. Its generic design and the absence of events or data porting allow it to be integrated into existing IEC 61499 applications without additional configuration. Ideal for applications requiring precise distribution of an adapter across up to five independent paths.

AIWS_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The AIWS_SPLIT_6 function block is used to distribute an incoming AIWS signal (adapter type) to six identical outputs. It is designed as a generic function block and enables simple signal multiplication in control applications based on the 4diac IDE framework.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Socket (Input):

- `IN` (Type: `adapter::types::unidirectional::AIWS`): Input adapter for the AIWS signal to be distributed.

Plugs (Outputs):

- `OUT1` (Type: `adapter::types::unidirectional::AIWS`): First output with the split signal.
- `OUT2` (Type: `adapter::types::unidirectional::AIWS`): Second output.
- `OUT3` (Type: `adapter::types::unidirectional::AIWS`): Third output.
- `OUT4` (Type: `adapter::types::unidirectional::AIWS`): Fourth output.
- `OUT5` (Type: `adapter::types::unidirectional::AIWS`): Fifth output.
- `OUT6` (Type: `adapter::types::unidirectional::AIWS`): Sixth output.

Functionality

The AIWS_SPLIT_6 module receives the AIWS signal present at its socket `IN` and forwards it unchanged to all six plug outputs `OUT1` to `OUT6`. No signal processing or modification takes place; the module functions as a passive splitter (1:6). Communication occurs via adapters according to the unidirectional AIWS interface definition.

Technical Features

- The function block is implemented as a generic function block, identifiable by the attributes `GenericClassName` and `TypeHash`. This allows it to be created in various forms (e.g., AIWS_SPLIT_2, AIWS_SPLIT_4) as an instance of a generic type.
- There are no event or data inputs/outputs; all data transmission occurs exclusively via the adapter interfaces.
- The function block does not contain its own state logic or processing algorithms.

State Overview

The function block has no defined states, as it does not require event-driven execution. Signal propagation is continuous and passive.

Application Scenarios

- Distribution of an analog input signal (e.g., from a sensor) to multiple downstream function blocks.
- Provision of a reference signal for multiple parallel control loops.
- Use in modular automation solutions that require signal multiplication without additional hardware.

Comparison with similar function blocks

- **AIWS_SPLIT_2, AIWS_SPLIT_4:** These function blocks distribute the signal to two and four outputs, respectively. AIWS_SPLIT_6 extends the number to six.
- **AIWS_MERGE:** A compound function block that combines multiple AIWS inputs into one output – the functional inverse of a splitter.
- **Direct connection:** Instead of a splitter function block, multiple parallel connections could be made in the application model, but this reduces clarity and is more complex to modify.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion
The AIWS_SPLIT_6 is a simple yet useful function block for multiplying AIWS signals in IEC 61499-based controllers. Its generic nature and clear adapter interface facilitate reuse and integration into larger projects.

AIWS_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIWS_SPLIT_7** is a generic component that splits a single incoming AIWS adapter (unidirectional) into seven identical outgoing AIWS adapters. It serves as a signal distributor for automation applications where a data stream or connection needs to be copied to multiple parallel paths.

Interface Structure

Event Inputs

None (the function block has no event inputs).

Event Outputs

None (the function block has no event outputs).

Data Inputs

None (the function block has no direct data inputs; data transmission occurs exclusively via the adapter interfaces).

Data Outputs

None (the function block has no direct data outputs; data transmission occurs exclusively via the adapter interfaces).

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AIWS`	**IN**	Socket (Input)	Receives the AIWS data stream to be distributed.
`adapter::types::unidirectional::AIWS`	**OUT1**	Plug (Output)	First identical output channel.
`adapter::types::unidirectional::AIWS`	**OUT2**	Plug (Output)	Second identical output channel.
`adapter::types::unidirectional::AIWS`	**OUT3**	Plug (Output)	Third identical output channel.
`adapter::types::unidirectional::AIWS`	**OUT4**	Plug (Output)	Fourth identical output channel.
`adapter::types::unidirectional::AIWS`	**OUT5**	Plug (Output)	Fifth identical output channel.
`adapter::types::unidirectional::AIWS`	**OUT6**	Plug (Output)	Sixth identical output channel.
`adapter::types::unidirectional::AIWS`	**OUT7**	Plug (Output)	Seventh identical output channel.

Functionality

The function block receives a unidirectional data stream of type `AIWS` via socket **IN**. This data stream is duplicated internally without modification and simultaneously passed to all seven plugs **OUT1** through **OUT7**. Each output channel receives exactly the same data as the input. There is neither delay nor data manipulation.

Technical Features

- **Generic Function Block** – The function block is defined as a generic component (attribute `GenericClassName = 'GEN_AIWS_SPLIT'`), which enables type-safe reuse in different contexts.
- **Unidirectional Adapters** – All adapters used are unidirectional, meaning data flows only from the socket to the plugs.
- **No Event Control** – The function block has no internal state machine and no event inputs/outputs; distribution is purely data-driven.
- **Scalable Architecture** – Thanks to the modular adapter interface, the function block can be used in complex hierarchies of function blocks.

State Overview

Since the function block does not have a state machine (Execution Control Chart), there are no explicit states. The output signals are always directly dependent on the input signals. The function block (FB) operates as a pure data distributor without delay or switching operations.

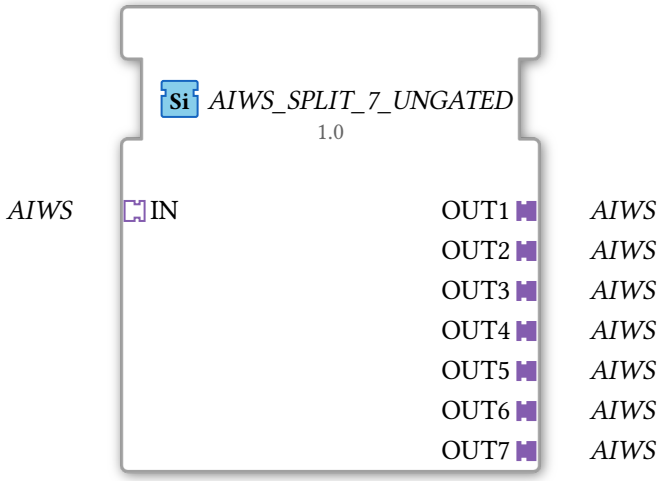
Application Scenarios

- **Parallel Processing** – Distribution of a measured value or control signal to multiple independent control or monitoring paths.
- **Signal Monitoring** – The same signal is routed to different diagnostic or logic blocks.
- **Redundancy** – Provision of identical data streams for different receivers (e.g., operation, visualization, and archiving).
- **Test Environments** – A test signal can be sent to multiple simulation blocks simultaneously.

Comparison with Similar splitters

- **AIWS_SPLIT_2, AIWS_SPLIT_4** – splitters with the same functionality but a different number of outputs (2 or 4). AIWS_SPLIT_7 offers the maximum number of outputs within this splitter family.
- **Generic 1:N Splitters** – Other IEC 61499 libraries often contain generic splitters for data types such as `ANY`. AIWS_SPLIT_7 is specifically designed for the adapter type `AIWS` and therefore requires no type conversion.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AIWS_SPLIT_7** is a simple yet powerful function block for multiplying a unidirectional AIWS data stream to seven parallel outputs. Its generic definition and purely adapter-based interface enable flexible integration into IEC 61499 applications, particularly for signal distribution and parallel processing tasks.

AIWS_SPLIT_7_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIWS_SPLIT_7`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Adapters

Direction	Name	Type	Description
Input (Socket)	IN	adaptor::types::unidirectional::AIWS	Incoming AIWS signal to be split.
Output (Plug)	OUT1	adaptor::types::unidirectional::AIWS	First parallel output of the signal.
Output (Plug)	OUT2	adaptor::types::unidirectional::AIWS	Second parallel output of the signal.
Output (Plug)	OUT3	adaptor::types::unidirectional::AIWS	Third parallel output of the signal.
Output (Plug)	OUT4	adaptor::types::unidirectional::AIWS	Fourth parallel output of the signal.

Output (Plug)	OUT5	adapater::types::unidirectional::AIWS	Fifth parallel output of the signal.
Output (Plug)	OUT6	adapater::types::unidirectional::AIWS	Sixth parallel output of the signal.
Output (Plug)	OUT7	adapater::types::unidirectional::AIWS	Seventh parallel output of the signal.
Output (Plug)	OUT8	adapater::types::unidirectional::AIWS	Eighth parallel output of the signal.

Functionality

The module receives an AIWS (adapter) signal via the **IN** socket. This signal is duplicated to all eight **OUT** plugs without processing or delay. Changes to the input signal are immediately reflected at all outputs.

Technical Features

- The module is generic and designed for a fixed number of eight outputs.
- There are no event-driven processes – signal transmission is purely adapter-based and continuous.
- The implementation is a pure splitter without internal logic or state management.

State Overview

The module does not have a state machine. There are no internal states or event sequences – the output directly follows the input.

Application Scenarios

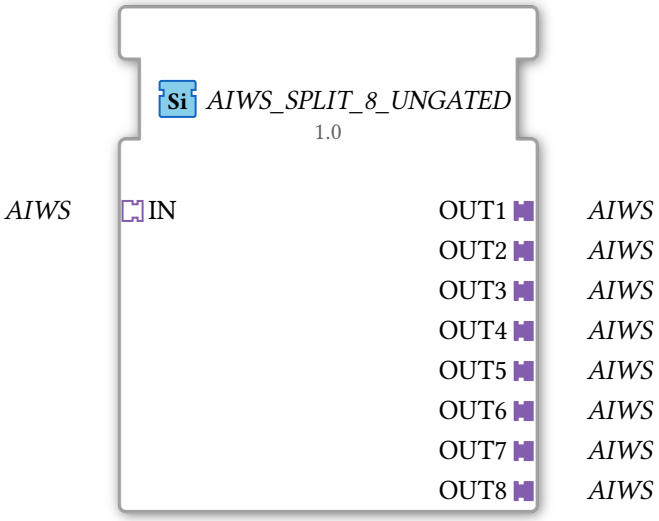
- **Signal Distribution** in Automation Applications: An AIWS sensor value is to be made available to several independent control or monitoring blocks simultaneously.
- **Parallelization** of Algorithms: Subsequent modules require the same adapter data stream but operate in parallel on different resources.
- **Test and Simulation Environments**: An incoming signal is distributed across multiple evaluation instances to compare different processing paths.

Comparison with Similar Components

- **AIWS_SPLIT_4** – Splitter with four outputs.
- **AIWS_SPLIT_16** – Splitter with 16 outputs.
- **AIWS_MERGE** – Combines multiple AIWS adapters into a single output (counterpart).

All split components share the feature of passing the signal through unchanged; they differ only in the number of outputs.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AIWS_SPLIT_8 is a simple yet essential component for multiplying an AIWS adapter signal across eight parallel paths. Its implementation without event-driven control or state logic makes it lightweight and reliable for use in distributed automation systems.

AIWS_SPLIT_8_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIWS_SPLIT_8`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Introduction

The function block **AIWS_SPLIT_8_UNGATED** splits an incoming AIWS adapter signal into eight identical outputs. It functions as a generic splitter for unidirectional adapter connections and enables the parallel forwarding of a signal to multiple subsequent function blocks.

Interface Structure

The function block has neither event nor data inputs or outputs. All communication takes place exclusively via adapters.

Event Inputs

None.

Event Outputs

None.

Data Inputs

Adapters

Direction	Name	Type	Description
Input (Socket)	IN	adaptor::types::unidirectional::AIWS	Incoming AIWS signal to be split.
Output (Plug)	OUT1	adaptor::types::unidirectional::AIWS	First parallel output of the signal.
Output (Plug)	OUT2	adaptor::types::unidirectional::AIWS	Second parallel output of the signal.
Output (Plug)	OUT3	adaptor::types::unidirectional::AIWS	Third parallel output of the signal.
Output (Plug)	OUT4	adaptor::types::unidirectional::AIWS	Fourth parallel output of the signal.

Output (Plug)	OUT5	adapater::types::unidirectional::AIWS	Fifth parallel output of the signal.
Output (Plug)	OUT6	adapater::types::unidirectional::AIWS	Sixth parallel output of the signal.
Output (Plug)	OUT7	adapater::types::unidirectional::AIWS	Seventh parallel output of the signal.
Output (Plug)	OUT8	adapater::types::unidirectional::AIWS	Eighth parallel output of the signal.

Functionality

The module receives an AIWS (adapter) signal via the **IN** socket. This signal is duplicated to all eight **OUT** plugs without processing or delay. Changes to the input signal are immediately reflected at all outputs.

Technical Features

- The module is generic and designed for a fixed number of eight outputs.
- There are no event-driven processes – signal transmission is purely adapter-based and continuous.
- The implementation is a pure splitter without internal logic or state management.

State Overview

The module does not have a state machine. There are no internal states or event sequences – the output directly follows the input.

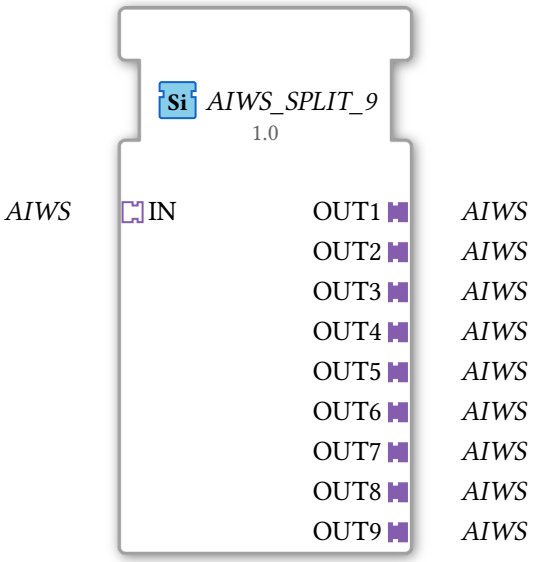
Application Scenarios

- **Signal Distribution** in Automation Applications: An AIWS sensor value is to be made available to several independent control or monitoring blocks simultaneously.
- **Parallelization** of Algorithms: Subsequent modules require the same adapter data stream but operate in parallel on different resources.
- **Test and Simulation Environments**: An incoming signal is distributed across multiple evaluation instances to compare different processing paths.

Comparison with Similar Components

- **AIWS_SPLIT_4** – Splitter with four outputs.
- **AIWS_SPLIT_16** – Splitter with 16 outputs.
- **AIWS_MERGE** – Combines multiple AIWS adapters into a single output (counterpart).

All split components share the feature of passing the signal through unchanged; they differ only in the number of outputs.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AIWS_SPLIT_8_UNGATED is a simple yet essential component for multiplying an AIWS adapter signal across eight parallel paths. Its implementation without event-driven control or state logic makes it lightweight and reliable for use in distributed automation systems.

AIWS_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AIWS_SPLIT_9` splits an incoming `AIWS` adapter signal into nine separate, identically typed outputs. It is provided as a generic function block (FB) and enables the distribution of a single adapter data stream to multiple subsequent function units. The block is unidirectional and requires no event or data inputs, as data transmission occurs exclusively via the adapter interfaces.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AIWS`	Incoming AIWS signal, distributed to the nine outputs.
Plug	`OUT1`	`adapter::types::unidirectional::AIWS`	First AIWS outgoing output.
Plug	`OUT2`	`adapter::types::unidirectional::AIWS`	Second AIWS outgoing output.
Plug	`OUT3`	`adapter::types::unidirectional::AIWS`	Third AIWS outgoing output.
Plug	`OUT4`	`adapter::types::unidirectional::AIWS`	Fourth AIWS outgoing output.
Plug	`OUT5`	`adapter::types::unidirectional::AIWS`	Fifth AIWS outgoing output.
Plug	`OUT6`	`adapter::types::unidirectional::AIWS`	Sixth AIWS outgoing output.

Plug	`OUT7`	`adapter::types::unidirectional::AIWS`	Seventh AIWS outgoing output.
Plug	`OUT8`	`adapter::types::unidirectional::AIWS`	Eighth AIWS output.
Plug	`OUT9`	`adapter::types::unidirectional::AIWS`	Ninth AIWS output.

Functionality

The module receives an AIWS adapter signal at socket `IN` and forwards it unchanged to all nine plugs `OUT1` to `OUT9`. No data processing, conversion, or delay takes place – it is a pure signal multiplication (fan-out). The internal logic is implemented as a generic function block, which can be parameterized at runtime by specifying a generic class name (`eclipse4diac::core::GenericClassName`).

Technical Features

- **Generic Function Block**: The block is marked as generic `GEN_AIWS_SPLIT`. This allows it to be reused in different contexts by defining the specific adapter type at design time.
- **Unidirectionality**: Both the input and all outputs are unidirectional (`adapter::types::unidirectional::AIWS`), meaning data flows only from the socket to the plugs.
- **No Event Control**: The split block operates without events – data is passed implicitly via the adapter connections.
- **No State Machine**: There is no Execution Control Chart (ECC), therefore the block is stateless and requires no initialization.
- **Type Hash**: An optional attribute `eclipse4diac::core::TypeHash` can be set for identification and versioning purposes, but is empty in this case.

State Overview

The function block has no internal states. It is purely combinatorial and does not execute any sequential processes.

Application Scenarios

- **Signal Distribution in Automation Systems**: When a sensor or control signal (e.g., an AIWS-compliant temperature or pressure value) needs to be distributed to multiple independent modules.
- **Redundant Processing**: A signal is distributed to identical, parallel-operating algorithms or safety logic.
- **Test and Simulation Environments**: A single AIWS signal is to be split across multiple test or monitoring blocks.
- **Architecture Simplification**: Eliminates the need for manual wiring of multiple split blocks and reduces the complexity of the application diagram.

Comparison with Similar Function Blocks

- **AIWS_SPLIT_n (e.g., AIWS_SPLIT_4)**: Other variants exist with a different number of outputs (e.g., 2, 4, 8). This block specializes in splitting the signal into exactly nine strands.
- **Manual Split with Multiple Function Block Instances**: Without this function block, the AIWS signal would have to be implemented by cascading several 2- or 3-way split blocks, which reduces clarity.
- **Event-Based Data Distributor**: Function blocks controlled by events require additional event wiring and are less efficient for simple data forwarding.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AIWS_SPLIT_9` is a simple yet useful generic function block for multiplying a unidirectional AIWS adapter signal to nine outputs. It avoids unnecessary complexity, requires no event control, and can be used directly in IEC 61499 applications without additional configuration. Thanks to its generic nature, it is flexibly adaptable to various adapter types and is particularly suitable for signal distribution in modular automation architectures.

ADI_ADD_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ADI_ADD_2` is a generic function block for performing arithmetic addition operations. Unlike conventional mathematical function blocks, this block uses an adapter-based interface concept (unidirectional `ADI` adapters) to transmit data and associated control signals in a bundled manner. It enables the addition of two input values to produce one output value.

Interface Structure

Event Inputs

This function block does not have direct, dedicated event inputs. Event control is handled entirely via the adapters.

Event Outputs

This function block does not have direct, dedicated event outputs. Event forwarding is handled entirely via the output adapter.

Data Inputs

This function block does not have any standard, direct data inputs.

Data Outputs

This function block does not have any standard, direct data outputs.

Adapters

Sockets (Inputs)

- **IN1**: Type `adapter::types::unidirectional::ADI`
- *Description:* First input value for mathematical addition.
- **IN2**: Type `adapter::types::unidirectional::ADI`
- *Description:* Second input value for mathematical addition.

Plugs (Connectors - Outputs)

- **OUT**: Type `adapter::types::unidirectional::ADI`
- *Description:* Output that provides the result of the addition (`IN1 + IN2`).

Functionality

The function block `ADI_ADD_2` performs the arithmetic operation:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} \tag{2.4}$$

As soon as data changes at the input adapters `IN1` or `IN2`, or a corresponding transmission event is signaled via the adapter structure, the function block processes the values. The sum is calculated and forwarded to subsequent function blocks via the corresponding event/data bundle of the output adapter `OUT`.

Since this is a generic function block (`GEN_ADI_ADD`), the specific data type used depends on the specifications and instantiation of the `ADI` adapters used.

Technical Features

- **Generic Type:** The function block is declared as `GEN_ADI_ADD`. This allows for flexible handling of different numeric data types, provided they are supported by the adapters used.
- **Adapter-Based Design:** By using unidirectional adapters of type `ADI`, the number of explicit connection lines (wiring overhead in the 4diac IDE's Application Editor) is drastically reduced, as data and synchronization events are encapsulated in a single connection.

•

State Overview

The function block behaves like a stateless (or purely event-driven combinational) function block:

1. **Waiting for Data Update:** The function block remains in idle state until new values are signaled via `IN1` or `IN2`.
2. **Calculation:** When an event arrives at the inputs, the mathematical sum is calculated.
3. **Output:** The result is directly passed to the output adapter `OUT`, and the corresponding trigger event is triggered.

–

Application Scenarios

- **Modular Signal Processing:** Addition of measured values (e.g., Sensor 1 + Sensor 2 to determine a total value) in systems that are consistently based on an adapter architecture.
- **Cascaded Computations:** Easy integration into complex arithmetic computation networks through clean, structured adapter connections.

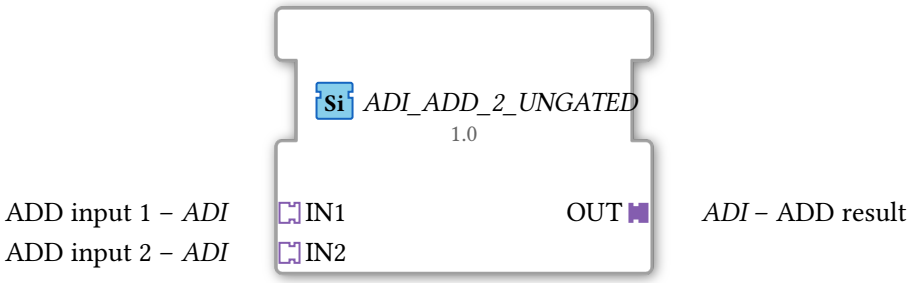
Comparison with Similar Components

Compared to a classic `ADD` component according to IEC 61499 (which typically has dedicated `REQ` and `CNF` event ports, as well as direct data inputs such as `IN1` and `IN2` as `ANY_NUM`), the `ADI_ADD_2` encapsulates these interfaces in adapters.

- **Standard ADD:** Requires manual wiring of a minimum of 2 events and 3 data lines (5 connections in total).

- **ADI_ADD_2:** Only requires connecting the three adapter lines (`IN1`, `IN2`, `OUT`), which significantly improves the readability of complex control diagrams.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ADI_ADD_2` is a highly efficient, clear, and modern component for arithmetic addition in the 4diac IDE. It is ideally suited for demanding architectures where clarity through the use of standardized adapters is paramount.

ADI_ADD_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_ADD_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Event Outputs

This function block does not have direct, dedicated event outputs. Event forwarding is handled entirely via the output adapter.

Data Inputs

This function block does not have any standard, direct data inputs.

Data Outputs

This function block does not have any standard, direct data outputs.

Adapters

Sockets (Inputs)

- **IN1**: Type `adapter::types::unidirectional::ADI`
- *Description:* First input value for mathematical addition.
- **IN2**: Type `adapter::types::unidirectional::ADI`
- *Description:* Second input value for mathematical addition.

Plugs (Connectors - Outputs)

- **OUT**: Type `adapter::types::unidirectional::ADI`
- *Description:* Output that provides the result of the addition (`IN1 + IN2`).

Functionality

The function block `ADI_ADD_2_UNGATED` performs the arithmetic operation:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} \tag{2.5}$$

As soon as data changes at the input adapters `IN1` or `IN2`, or a corresponding transmission event is signaled via the adapter structure, the function block processes the values. The sum is calculated and forwarded to subsequent function blocks via the corresponding event/data bundle of the output adapter `OUT`.

Since this is a generic function block (`GEN_ADI_ADD`), the specific data type used depends on the specifications and instantiation of the `ADI` adapters used.

Technical Features

- **Generic Type:** The function block is declared as `GEN_ADI_ADD`. This allows for flexible handling of different numeric data types, provided they are supported by the adapters used.
- **Adapter-Based Design:** By using unidirectional adapters of type `ADI`, the number of explicit connection lines (wiring overhead in the 4diac IDE's Application Editor) is drastically reduced, as data and synchronization events are encapsulated in a single connection.

•

State Overview

The function block behaves like a stateless (or purely event-driven combinational) function block:

1. **Waiting for Data Update:** The function block remains in idle state until new values are signaled via `IN1` or `IN2`.
2. **Calculation:** When an event arrives at the inputs, the mathematical sum is calculated.
3. **Output:** The result is directly passed to the output adapter `OUT`, and the corresponding trigger event is triggered.

–

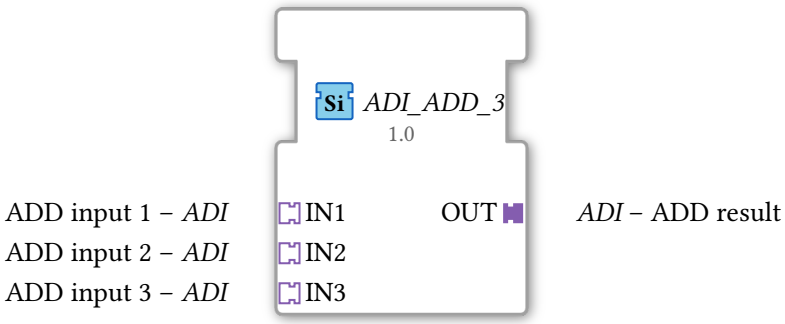
Application Scenarios

- **Modular Signal Processing:** Addition of measured values (e.g., Sensor 1 + Sensor 2 to determine a total value) in systems that are consistently based on an adapter architecture.
- **Cascaded Computations:** Easy integration into complex arithmetic computation networks through clean, structured adapter connections.

Comparison with Similar Components

Compared to a classic `ADD` component according to IEC 61499 (which typically has dedicated `REQ` and `CNF` event ports, as well as direct data inputs such as `IN1` and `IN2` as `ANY_NUM`), the `ADI_ADD_2_UNGATED` encapsulates these interfaces in adapters.

- **Standard ADD:** Requires manual wiring of a minimum of 2 events and 3 data lines (5 connections in total).
- **ADI_ADD_2_UNGATED:** Only requires connecting the three adapter lines (`IN1`, `IN2`, `OUT`), which significantly improves the readability of complex control diagrams.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `ADI_ADD_2_UNGATED` is a highly efficient, clear, and modern component for arithmetic addition in the 4diac IDE. It is ideally suited for demanding architectures where clarity through the use of standardized adapters is paramount.

ADI_ADD_3

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ADI_ADD_3` is a generic arithmetic block used to add three input values. It is based on the IEC 61499-2 standard and uses an adapter-based communication model. By using unidirectional adapters of type `ADI` (adapters for data integration/interaction), the block enables structured and clean signal and data routing within 4diac-ide.

Interface Structure

Event Inputs

There are no direct, standalone event inputs. Event control is implemented via the assigned adapter inputs (sockets).

Event Outputs

There are no direct, standalone event outputs. Event forwarding is implemented via the adapter output (plug).

Data Inputs

There are no direct data inputs. Data transmission occurs via the adapters.

Data Outputs

There are no direct data outputs. Data transmission occurs via the output adapter.

Adapters

Sockets (Input Interfaces)

- **IN1** (Type: `adapter::types::unidirectional::ADI`): First input summation for addition.
- **IN2** (Type: `adapter::types::unidirectional::ADI`): Second input summation.
- **IN3** (Type: `adapter::types::unidirectional::ADI`): Third input summand for addition.

Plugs (Output Interfaces)

- **OUT** (Type: `adapter::types::unidirectional::ADI`): Output for the calculated addition result ($OUT = IN1 + IN2 + IN3$).

Functionality

As soon as a new event or new data arrives at one of the input sockets (`IN1`, `IN2`, or `IN3`), the function block reads the values from the three adapters. It performs an arithmetic addition of the three values:

$$\text{Result} = \text{IN1} + \text{IN2} + \text{IN3} \tag{2.6}$$

The calculated result and the associated update event are then transmitted to the subsequent function blocks in the system via the output plug `OUT`.

Technical Features

- **Generic Function Block (FB):** Due to the attribute `eclipse4diac::core::GenericClassName` with the value `GEN_ADI_ADD`, this function block behaves polymorphically. It is not fixed to a specific data type (such as `INT` or `REAL`), but adapts flexibly to the data type defined in the adapter.
- **Adapter-Based Architecture:** Encapsulating data and events in the `ADI` adapters significantly reduces cable clutter in the 4diac IDE, as separate event and data lines are not required for each summand.

State Overview

The function block operates in a purely stateless (reactive) state:

1. **Idle State:** The block waits for trigger signals from the input sockets.
2. **Calculation & Forwarding:** Upon triggering at `IN1`, `IN2`, or `IN3`, the sum is calculated instantly and output via the `OUT` plug.

Application Scenarios

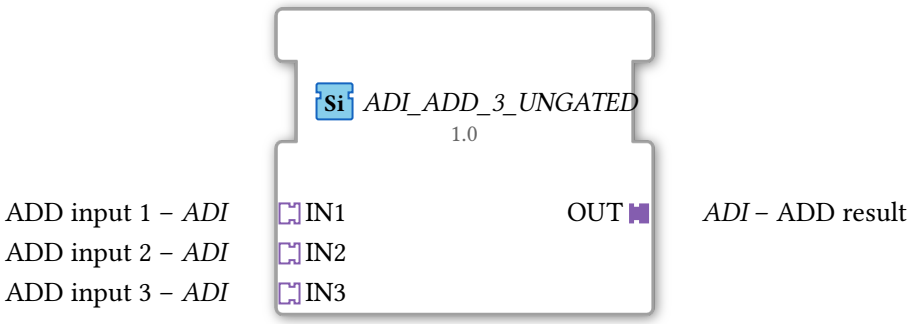
- **Sensor Consolidation:** Summing of three different physical quantities (e.g., three partial flows in a system to determine the total flow).
- **Setpoint Offset Calculation:** Combination of a main setpoint, a correction value, and an additional tolerance or offset value.
- **Process Value Calculation:** Balancing of inflows at three different measuring points in process engineering.
-

Comparison with Similar Components

- **Standard `ADD` (IEC 61131-3):** The classic ADD component uses direct pins for data and events. `ADI_ADD_3`, due to its use of unidirectional adapters, is better suited for modular and hierarchical architectures in IEC 61499.
- **Two-way adder (e.g., `ADI_ADD_2`):** While adding three values with standard function blocks would require cascading two blocks, `ADI_ADD_3` performs this task in a single step, saving resources and improving clarity.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.



Conclusion

The `ADI_ADD_3` is a practical, generic auxiliary function block for arithmetic operations in modern IEC 61499 control applications. Its consistent use of adapters allows it to integrate seamlessly into clean software architectures and minimizes wiring effort in the development environment.

ADI_ADD_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_ADD_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/

frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ADI_ADD_3_UNGATED` is a generic arithmetic block used to add three input values. It is based on the IEC 61499-2 standard and uses an adapter-based communication model. By using unidirectional adapters of type `ADI` (adapters for data integration/interaction), the block enables structured and clean signal and data routing within 4diac-ide.

Interface Structure

Event Inputs

There are no direct, standalone event inputs. Event control is implemented via the assigned adapter inputs (sockets).

Event Outputs

There are no direct, standalone event outputs. Event forwarding is implemented via the adapter output (plug).

Data Inputs

There are no direct data inputs. Data transmission occurs via the adapters.

Data Outputs

There are no direct data outputs. Data transmission occurs via the output adapter.

Adapters

Sockets (Input Interfaces)

- **IN1** (Type: `adapter::types::unidirectional::ADI`): First input summation for addition.
- **IN2** (Type: `adapter::types::unidirectional::ADI`): Second input summation.
- **IN3** (Type: `adapter::types::unidirectional::ADI`): Third input summand for addition.

Plugs (Output Interfaces)

- **OUT** (Type: `adapter::types::unidirectional::ADI`): Output for the calculated addition result ($OUT = IN1 + IN2 + IN3$).

Functionality

As soon as a new event or new data arrives at one of the input sockets (`IN1`, `IN2`, or `IN3`), the function block reads the values from the three adapters. It performs an arithmetic addition of the three values:

$$\text{Result} = \text{IN1} + \text{IN2} + \text{IN3} \tag{2.7}$$

The calculated result and the associated update event are then transmitted to the subsequent function blocks in the system via the output plug `OUT`.

Technical Features

- **Generic Function Block (FB):** Due to the attribute `eclipse4diac::core::GenericClassName` with the value `GEN_ADI_ADD`, this function block behaves polymorphically. It is not fixed to a specific data type (such as `INT` or `REAL`), but adapts flexibly to the data type defined in the adapter.
- **Adapter-Based Architecture:** Encapsulating data and events in the `ADI` adapters significantly reduces cable clutter in the 4diac IDE, as separate event and data lines are not required for each summand.

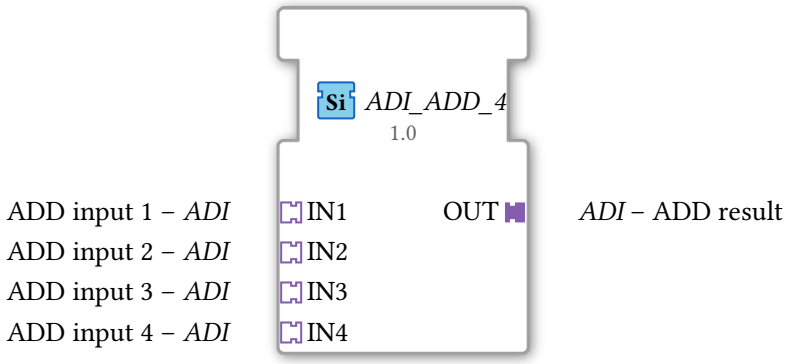
- **Sensor Consolidation:** Summing of three different physical quantities (e.g., three partial flows in a system to determine the total flow).
- **Setpoint Offset Calculation:** Combination of a main setpoint, a correction value, and an additional tolerance or offset value.
- **Process Value Calculation:** Balancing of inflows at three different measuring points in process engineering.
-

Comparison with Similar Components

- **Standard `ADD` (IEC 61131-3):** The classic ADD component uses direct pins for data and events. `ADI_ADD_3_UNGATED`, due to its use of unidirectional adapters, is better suited for modular and hierarchical architectures in IEC 61499.
- **Two-way adder (e.g., `ADI_ADD_2`):** While adding three values with standard function blocks would require cascading two blocks, `ADI_ADD_3_UNGATED` performs this task in a single step, saving resources and improving clarity.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `ADI_ADD_3_UNGATED` is a practical, generic auxiliary function block for arithmetic operations in modern IEC 61499 control applications. Its consistent use of adapters allows it to integrate seamlessly into clean software architectures and minimizes wiring effort in the development environment.

ADI_ADD_4

(Image of function block not available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ADI_ADD_4` performs arithmetic addition of up to four values. It is a generic function block (FB) based on the unidirectional adapter type `ADI`. It enables clear and modularized addition within IEC 61499 applications in the 4diac IDE.

Interface Structure

Since the block is entirely adapter-based, it does not have any traditional, separate event or data channels at the type's main level.

Event Inputs

No direct event inputs are available. Event control is implemented via the connected adapters.

Event Outputs

No direct event outputs are available. Event forwarding is implemented via the output adapter.

Data Inputs

No direct data inputs are available.

Data Outputs

No direct data outputs are available.

Adapters

- **Sockets (Input Adapters / Jacks):**
- `IN1` (Type: `adapter::types::unidirectional::ADI`): Input for the first summand.
- `IN2` (Type: `adapter::types::unidirectional::ADI`): Input for the second summand.
- `IN3` (Type: `adapter::types::unidirectional::ADI`): Input for the third addend.
- `IN4` (Type: `adapter::types::unidirectional::ADI`): Input for the fourth addend.
- **Plugs (Output Adapters):**
- `OUT` (Type: `adapter::types::unidirectional::ADI`): Output for the calculated total result of the addition.

Functionality

As soon as new data values or corresponding trigger events are present at the input adapters (`IN1` to `IN4`), the function block performs the addition of the values. The result is calculated using the formula:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} + \mathrm{IN4} \tag{2.8}$$

The calculated result and the corresponding trigger event are provided directly via the output adapter `OUT`.

Technical Features

- **Generic Module:** By assigning the attribute `GenericClassName` with the value `'GEN_ADI_ADD'`, the module is flexibly structured. Depending on the implementation of the underlying `ADI` adapter, it can be used for various numeric data types.
- **Adapter-Based Design:** Encapsulating data and events in adapters (here of type `ADI`) drastically minimizes the wiring effort in the 4diac IDE function block diagram and ensures a clean, structured application design.
- **Unidirectional Coupling:** The use of unidirectional adapters ensures that data flow is strictly sequential from inputs to output.

State Overview

Since this is an adapter-based component for purely arithmetic data processing, the `ADI_ADD_4` does not have a complex internal state machine (ECC). Its operation is purely reactive:

- **Trigger on one of the inputs (`IN1` - `IN4`):** Calculates the sum of all four inputs and immediately forwards the result to `OUT`.

Application Scenarios

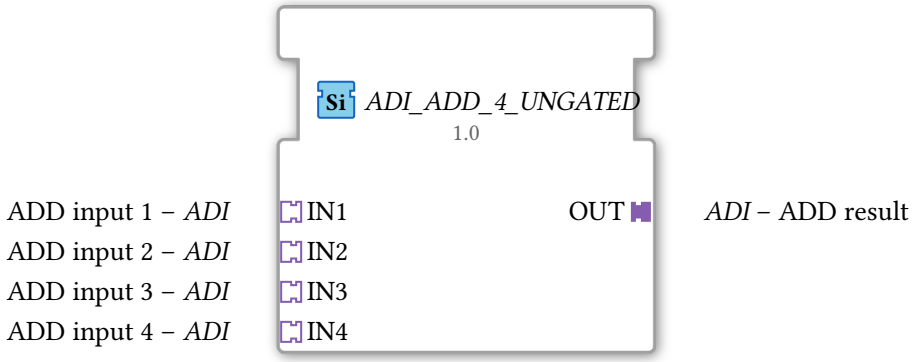
- **Sensor Data Aggregation:** Combines up to four analog measured values (e.g., four individual flow meters or temperature sensors) into a single total value.

- **Setpoint Calculation with Offsets:** Adds a primary setpoint with up to three different correction factors or offsets in control processes.
- **Structured Signal Processing:** Use in systems where the signal processing chain is consistently based on the `ADI` adapter standard to avoid unnecessary signal unpacking and repacking.

Comparison with Similar Function Blocks

- **Standard Adder (e.g., `F_ADD`):** A classic IEC 61131-3 adder block requires separate data lines and event connections. `ADI_ADD_4` bundles these in adapters, reducing visual complexity in the editor.
- **Dual Adder (`ADI_ADD_2`):** To add four values, three dual adders would have to be cascaded. `ADI_ADD_4` significantly saves space and execution time by combining the calculation into a single step.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ADI_ADD_4` is a high-performance and efficient function block for adding four numeric signals. By consistently using adapters, he reduces the number of physical connections in the control program and makes a significant contribution to a clear and maintenance-friendly software architecture.

ADI_ADD_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_ADD_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Conclusion

The `ADI_ADD_4_UNGATED` is a high-performance and efficient function block for adding four numeric signals. By consistently using adapters, he reduces the number of physical connections in the control program and makes a significant contribution to a clear and maintenance-friendly software architecture.

ADI_DIV_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ADI_DIV_2` performs an arithmetic division (DIV) of two input values via adapter connections. It is a generic function block (Generic FB) based on type `GEN_ADI_DIV`. The consistent use of unidirectional adapters of type `ADI` ensures clean encapsulation of data and events. This simplifies application design in the 4diac IDE, as the number of visible connection lines is significantly reduced.

Since this function block operates entirely on an adapter basis, it does not have traditional, discrete event or data connections at the top level. All interaction takes place via the adapter interfaces.

Interface Structure

Event Inputs

No direct event inputs are available. Event control is handled via the input adapters (`IN1`, `IN2`).

Event Outputs

No direct event outputs are available. Event output is handled via the output adapter (`OUT`).

Data Inputs

No direct data inputs are available.

Data Outputs

No direct data outputs are available.

Adapters

- **Sockets (Input Adapters):**
- **`IN1`** (Type: `adapter::types::unidirectional::ADI`): First input value (dividend/counter) for division.
- **`IN2`** (Type: `adapter::types::unidirectional::ADI`): Second input value (divisor/denominator) for the division.
- **Plugs (Output Adapters):**
- **`OUT`** (Type: `adapter::types::unidirectional::ADI`): The calculated result (quotient) of the division.

Functionality

The function block divides the value received via adapter `IN1` by the value received via adapter `IN2`:

$$\text{Result (OUT)} = \frac{\text{Value of IN1}}{\text{Value of IN2}} \tag{2.10}$$

The calculation is triggered as soon as corresponding update events are received at the input adapters. After successful calculation, the new quotient, along with an output event, is passed via the adapter `OUT`. Due to the generic nature of the function block (`GEN_ADI_DIV`), its behavior adapts to the underlying data types of the `ADI` adapters used.

- **Generic Instantiation:** The function block uses the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_ADI_DIV'`. This allows for flexible typing at runtime, depending on the adapter subtype used.
- **Adapter Encapsulation:** Data and the associated trigger events are bundled in the adapter type `ADI`, which facilitates loose coupling of the software components.
- **Division by Zero:** During implementation and use, it is essential to ensure that the value at adapter `IN2` (divisor) is not zero. Division by zero must be handled in an application-oriented manner before the function block to prevent runtime errors.

The function block behaves in a stateless (i.e., purely reactive) manner:

Technical Features

1. **Wait State:** The function block waits for events at sockets `IN1` or `IN2`.
2. **Calculation:** After receiving valid data/events at the inputs, the division is performed.
3. **Update:** The result is passed to output plug `OUT`, and the corresponding send event is triggered.

State Overview

- **Measurement Scaling:** Normalization of analog sensor values (e.g., dividing a raw value by a scaling factor).
- **Calculation of Ratios:** Determination of mixing ratios or percentages in process engineering plants.
- **Average Calculations:** Division of a sum by the number of recorded values in simple mathematical computational networks.

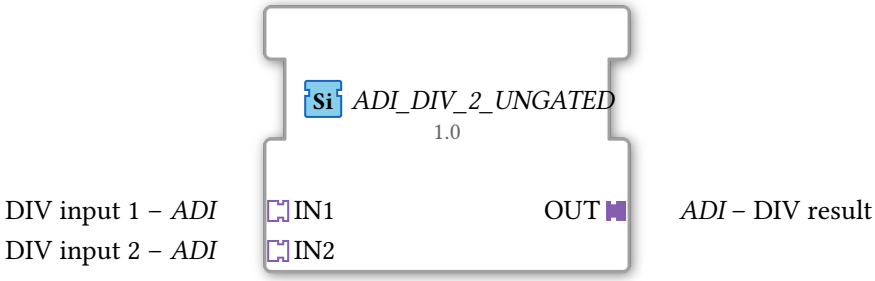
Application Scenarios

Compared to a classic, standard `DIV` function block (according to IEC 61131-3), which uses discrete data pins (`IN1`, `IN2`, `OUT`) and explicit event pins (`REQ`, `CNF`):

Comparison with Similar Function Blocks

- **Advantages of `ADI_DIV_2`:** Significantly cleaner appearance in the 4diac function block diagram (FBD). Data consistency is directly enforced through the coupling in the adapter.
- **Disadvantages:** Direct use with standard data streams without adapter encapsulation is not possible. Dedicated converter modules must be used if the signal source does not support adapters.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

`ADI_DIV_2` is a specialized and efficient module for modern IEC 61499 architectures within 4diac. It is ideally suited for developers who rely on a clean, adapter-based, and modular software architecture and want to implement mathematical division in a clear and concise manner.

ADI_DIV_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_DIV_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Conclusion

`ADI_DIV_2_UNGATED` is a specialized and efficient module for modern IEC 61499 architectures within 4diac. It is ideally suited for developers who rely on a clean, adapter-based, and modular software architecture and want to implement mathematical division in a clear and concise manner.

ADI_MUL_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ADI_MUL_2` is a generic arithmetic multiplication block for the 4diac IDE, based on the IEC 61499 standard. It is used to multiply two input values. The unique feature of this block is the use of unidirectional adapters (`ADI`) for data transmission instead of traditional data and event connections. This enables modular and loosely coupled signal processing.

Interface Structure

Event Inputs

There are no direct event inputs. Control and synchronization are implicit via the adapters used.

Event Outputs

There are no direct event outputs. Event forwarding is coupled via the output adapter.

Data Inputs

The function block does not have traditional data inputs. Data acquisition is handled entirely via the adapter interfaces.

Data Outputs

The function block does not have traditional data outputs. Data output is handled via the output adapter.

Adapters

The function block uses adapters to encapsulate data and events:

- **Sockets (Input Adapters):**
- **IN1** (Type: `adapter::types::unidirectional::ADI`): First factor for multiplication (multiplicand).
- **IN2** (Type: `adapter::types::unidirectional::ADI`): Second factor for the multiplication (multiplier).
- **Plugs (Output Adapters):**
- **OUT** (Type: `adapter::types::unidirectional::ADI`): The result of the multiplication ($OUT = IN1 \times IN2$).

Functionality

As soon as valid values and the corresponding trigger events are received via the adapters `IN1` and `IN2`, the function block performs the arithmetic multiplication:

$$\$OUT = IN1 \times IN2$$

The result is immediately passed to the output adapter `OUT` and is available for subsequent function blocks. Since the function block is declared as a generic type (`GEN_ADI_MUL`), the exact data type width (e.g., INT, REAL, LREAL) is flexible and is determined during instantiation in the 4diac IDE based on the connected adapters.

Technical Features

- **Generic Implementation:** The `GenericClassName = 'GEN_ADI_MUL'` attribute makes the function block data type independent.
- **Adapter Encapsulation:** Using the unidirectional adapter `ADI` reduces the number of visible lines in the function block diagram because data and events are bundled and transferred in a single connection.
- **Compiler Context:** The function block is organized in the package `adapter::iec61131::arithmetic` and imports the class `eclipse4diac::core::GenericClassName`.

State Overview

The function block behaves in a purely stateless (or combinatorial) manner. There is no internal state machine (ECC). Each activation of the input adapters directly leads to the calculation of the output value and the updating of the output adapter `OUT`.

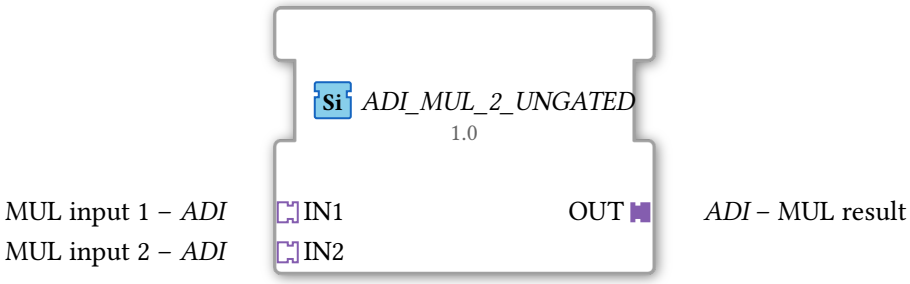
Application Scenarios

- **Modular Signal Processing:** Perfectly suited for control architectures that consistently rely on adapter connections to maintain the clarity of complex function plans.
- **Scalable Calculations:** Use in mathematical computing networks within IEC 61499 applications where different numerical data types need to be multiplied.

Comparison with Similar Function Blocks

Compared to a standard multiplication block (such as the classic `MUL` block from the IEC 61131-3 library), which uses explicit data pins (`IN1`, `IN2`, `OUT`) and events (`REQ`, `CNF`), the `ADI_MUL_2` eliminates the need for manual wiring of trigger events. This increases reusability and results in cleaner software design.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ADI_MUL_2` is a modern, flexible, and easy-to-wire multiplication block. Through the consistent use of unidirectional adapters, it is ideally suited for service-oriented architectures in industrial automation and facilitates the creation of cleanly structured IEC 61499 applications.

ADI_MUL_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_MUL_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. The `ADI_MUL_2_UNGATED` is a modern, flexible, and easy-to-wire multiplication block. Through the consistent use of unidirectional adapters, it is ideally suited for service-oriented architectures in industrial automation and facilitates the creation of cleanly structured IEC 61499 applications.

ADI_MUL_3

No image available

• – ◦ • – ◦ • – ◦ •

Introduction

The `ADI_MUL_3` function block is a generic arithmetic function block for the 4diac IDE. It is used to multiply three numeric input values, which are transmitted via standardized, unidirectional adapters. By encapsulating the mathematical operation in an adapter interface, this function block is particularly suitable for modular and clean application architectures within the IEC 61499 standard.

Interface Structure

Because it is an adapter-based function block, the `ADI_MUL_3` does not have any direct, classic event or data pins at the top level. All communication is handled via the adapter interfaces.

Event Inputs

No direct event inputs available (control is handled via the adapters).

Event Outputs

No direct event outputs available (control is handled via the adapters).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::ADI`)
- First multiplicand for the calculation operation.
- **IN2** (Type: `adapter::types::unidirectional::ADI`)
- Second multiplicand for the calculation operation.
- **IN3** (Type: `adapter::types::unidirectional::ADI`)
- Third multiplicand for the calculation operation.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::ADI`)
- Output adapter that provides the mathematical product of the three input values.

Functionality

As soon as new values are signaled at the input adapters (`IN1`, `IN2`, `IN3`), the function block performs the multiplication. The result is calculated using the following formula:

$$\mathrm{OUT} = \mathrm{IN1} \times \mathrm{IN2} \times \mathrm{IN3} \tag{2.12}$$

The calculated result is immediately passed to the output adapter `OUT`, and a corresponding update event is forwarded via the adapter.

Technical Features

- **Generic Type:** The function block is based on the generic class `'GEN_ADI_MUL'`. This allows for flexible handling of different numeric data types (e.g., `INT`, `UINT`, `REAL`, `LREAL`), depending on how the underlying ADI adapters are implemented.
- **Generic Type:** The function block is based on the generic class `'GEN_ADI_MUL'`. This enables flexible handling of different numeric data types (e.g., `INT`, `UINT`, `REAL`, `LREAL`). * **Unidirectional Adapters:** Using the type `unidirectional::ADI` ensures a clear, one-way data flow, minimizing coupling between program components and increasing system stability.

State Overview

The function block is designed as a purely mathematical, stateless block. It does not store any internal history values. Every update to the inputs results in a direct recalculation of the output.

Application Scenarios

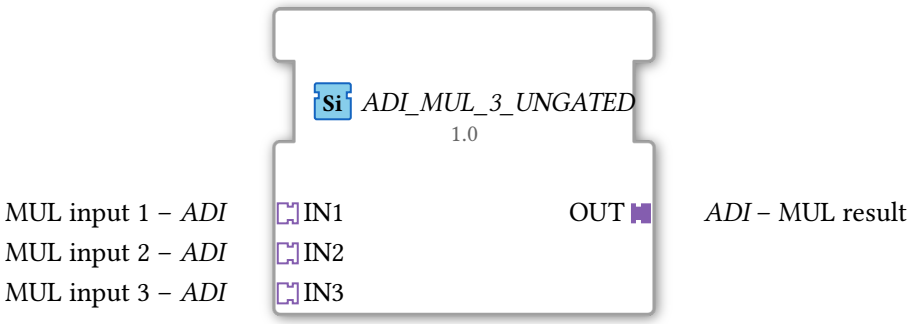
- **Volume Calculations:** Calculating the volume from three dimensions (length × width × height).
- **Three-Phase Measurements:** Power or energy calculations where several factors (e.g., current, voltage, and a scaling/correction factor) need to be multiplied together.
- **Multi-Level Scaling:** Reading a sensor value that needs to be multiplied by a calibration value and an additional gain factor.

Comparison with Similar Blocks

Compared to classic IEC 61131-3 `MUL` blocks, the `ADI_MUL_3` offers the advantage of encapsulating events and data logically in a single connection through the use of adapters. This significantly reduces wiring effort in the 4diac IDE. Compared to a dual multiplier (`ADI_MUL_2`), this block also eliminates the need to cascade blocks, which reduces execution time and makes the application diagram clearer.

- `ADI_MUL_3_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ADI_MUL_3` is a practical auxiliary block for arithmetic calculations in IEC 61499 applications. Its consistent use of unidirectional adapters contributes to a clean, readable, and maintainable control design.

ADI_MUL_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_MUL_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Introduction

The `ADI_MUL_3_UNGATED` function block is a generic arithmetic function block for the 4diac IDE. It is used to multiply three numeric input values, which are transmitted via standardized, unidirectional adapters. By encapsulating the mathematical operation in an adapter interface, this function block is particularly suitable for modular and clean application architectures within the IEC 61499 standard.

Interface Structure

Because it is an adapter-based function block, the `ADI_MUL_3_UNGATED` does not have any direct, classic event or data pins at the top level. All communication is handled via the adapter interfaces.

Event Inputs

No direct event inputs available (control is handled via the adapters).

Event Outputs

No direct event outputs available (control is handled via the adapters).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::ADI`)
- First multiplicand for the calculation operation.
- **IN2** (Type: `adapter::types::unidirectional::ADI`)
- Second multiplicand for the calculation operation.
- **IN3** (Type: `adapter::types::unidirectional::ADI`)
- Third multiplicand for the calculation operation.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::ADI`)
- Output adapter that provides the mathematical product of the three input values.

Functionality

As soon as new values are signaled at the input adapters (`IN1`, `IN2`, `IN3`), the function block performs the multiplication. The result is calculated using the following formula:

$$\mathrm{OUT} = \mathrm{IN1} \times \mathrm{IN2} \times \mathrm{IN3} \tag{2.13}$$

The calculated result is immediately passed to the output adapter `OUT`, and a corresponding update event is forwarded via the adapter.

Technical Features

- **Generic Type:** The function block is based on the generic class `'GEN_ADI_MUL'`. This allows for flexible handling of different numeric data types (e.g., `INT`, `UINT`, `REAL`, `LREAL`), depending on how the underlying ADI adapters are implemented.
- **Generic Type:** The function block is based on the generic class `'GEN_ADI_MUL'`. This enables flexible handling of different numeric data types (e.g., `INT`, `UINT`, `REAL`, `LREAL`). * **Unidirectional Adapters:** Using the type `unidirectional::ADI` ensures a clear, one-way data flow, minimizing coupling between program components and increasing system stability.

State Overview

The function block is designed as a purely mathematical, stateless block. It does not store any internal history values. Every update to the inputs results in a direct recalculation of the output.

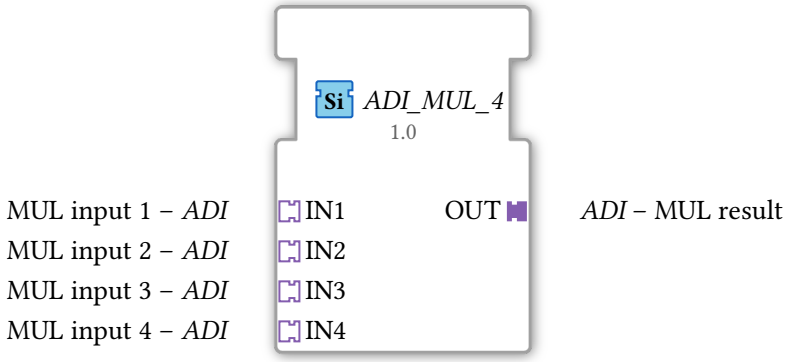
Application Scenarios

- **Volume Calculations:** Calculating the volume from three dimensions (length × width × height).
- **Three-Phase Measurements:** Power or energy calculations where several factors (e.g., current, voltage, and a scaling/correction factor) need to be multiplied together.
- **Multi-Level Scaling:** Reading a sensor value that needs to be multiplied by a calibration value and an additional gain factor.

Comparison with Similar Blocks

Compared to classic IEC 61131-3 `MUL` blocks, the `ADI_MUL_3_UNGATED` offers the advantage of encapsulating events and data logically in a single connection through the use of adapters. This significantly reduces wiring effort in the 4diac IDE. Compared to a dual multiplier (`ADI_MUL_2`), this block also eliminates the need to cascade blocks, which reduces execution time and makes the application diagram clearer.

- **`ADI_MUL_3`**: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `ADI_MUL_3_UNGATED` is a practical auxiliary block for arithmetic calculations in IEC 61499 applications. Its consistent use of unidirectional adapters contributes to a clean, readable, and maintainable control design.

ADI_MUL_4

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ADI_MUL_4` is a generic, adapter-based block for IEC 61499, used to perform arithmetic multiplications. It calculates the product of four input values provided via unidirectional ADI adapters (`adapter::types::unidirectional::ADI`) and outputs the result via a corresponding output adapter. By encapsulating signals in adapters, this block ensures a clearer application diagram in the 4diac IDE.

Interface Structure

Event Inputs

This block does not have direct event inputs. Event control is encapsulated within the adapters used.

Event Outputs

This block does not have direct event outputs. Event forwarding is encapsulated within the adapters used.

Data Inputs

This block does not have direct data inputs. Data is transferred via the sockets.

Data Outputs

This block does not have direct data outputs. Data is output via the plug.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::ADI`): First factor for multiplication.
- **IN2** (Type: `adapter::types::unidirectional::ADI`): Second factor for multiplication.
- **IN3** (Type: `adapter::types::unidirectional::ADI`): Third factor for multiplication.

- **IN4** (Type: `adapter::types::unidirectional::ADI`): Fourth factor for multiplication.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::ADI`): Result of the multiplication ($OUT = IN1 \times IN2 \times IN3 \times IN4$).

Functionality

As soon as new values and their corresponding events arrive at the input adapters (`IN1` to `IN4`), the function block performs the multiplication of the four values:

$$OUT = \text{IN1} \cdot \text{IN2} \cdot \text{IN3} \cdot \text{IN4} \tag{2.14}$$

The calculated result, along with the corresponding trigger event, is forwarded via the output adapter `OUT` to the subsequent function blocks. Since this is a generic function block (`GEN_ADI_MUL`), the calculation behavior adapts to the data type defined in the adapter.

Technical Features

- **Generic Type (`GEN_ADI_MUL`):** The function block is internally declared as a generic function block. This allows for flexible handling of various data types (e.g., `INT`, `REAL`, `LREAL`), depending on the specifications of the connected ADI adapters.
- **Encapsulation by Adapters:** Since both data and events are routed via unidirectional adapters (`ADI`), the number of visible connection lines in the 4diac IDE is drastically reduced. This improves the clarity of complex control applications.

State Overview

The function block `ADI_MUL_4` is a **stateless** function block. It does not have an internal State Machine (ECC). Each activation by an event at the input adapters directly leads to a recalculation of the output based on the currently applied input values.

Application Scenarios

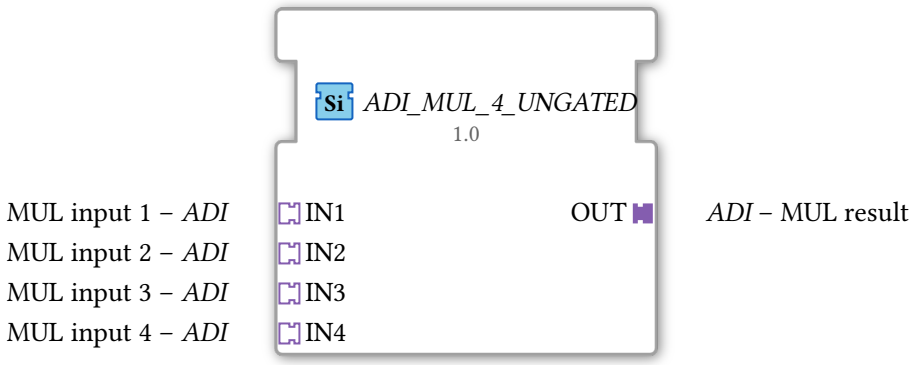
- **Physical Calculations:** Calculation of volumes (V = l × b × h) with an additional scaling or correction factor.
- **Measurement Scaling:** Multi-level weighting or scaling of analog sensor values across multiple factors.
- **Power Calculations:** Multiplication of various electrical or mechanical parameters to determine total power or efficiency in process automation.

Comparison with Similar Function Blocks

- **Standard `MUL` function block (IEC 61131-3):** Classic multipliers use direct data and event pins. `ADI_MUL_4`, on the other hand, uses adapters, which simplifies routing but requires a corresponding adapter infrastructure in the project. * **ADI_MUL_2 / ADI_MUL_3:** Similar function blocks with fewer inputs. The `ADI_MUL_4` is particularly suitable when exactly four factors need to be multiplied together without cascading multiple 2x multipliers.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.



Conclusion

The `ADI_MUL_4` is a highly efficient auxiliary function block for mathematical signal processing in IEC 61499 systems. Through the consistent use of unidirectional adapters, it promotes clean, modular software design and reduces the complexity of graphical wiring within the 4diac IDE.

ADI_MUL_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_MUL_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/

frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

- **IN2** (Type: `adapter::types::unidirectional::ADI`): Second factor for multiplication.
- **IN3** (Type: `adapter::types::unidirectional::ADI`): Third factor for multiplication.
- **IN4** (Type: `adapter::types::unidirectional::ADI`): Fourth factor for multiplication.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::ADI`): Result of the multiplication ($OUT = IN1 \times IN2 \times IN3 \times IN4$).

Functionality

As soon as new values and their corresponding events arrive at the input adapters (`IN1` to `IN4`), the function block performs the multiplication of the four values:

$$OUT = \mathrm{IN1} \cdot \mathrm{IN2} \cdot \mathrm{IN3} \cdot \mathrm{IN4} \tag{2.15}$$

The calculated result, along with the corresponding trigger event, is forwarded via the output adapter `OUT` to the subsequent function blocks. Since this is a generic function block (`GEN_ADI_MUL`), the calculation behavior adapts to the data type defined in the adapter.

Technical Features

- **Generic Type (`GEN_ADI_MUL`):** The function block is internally declared as a generic function block. This allows for flexible handling of various data types (e.g., `INT`, `REAL`, `LREAL`), depending on the specifications of the connected ADI adapters.
- **Encapsulation by Adapters:** Since both data and events are routed via unidirectional adapters (`ADI`), the number of visible connection lines in the 4diac IDE is drastically reduced. This improves the clarity of complex control applications.

State Overview

The function block `ADI_MUL_4_UNGATED` is a **stateless** function block. It does not have an internal State Machine (ECC). Each activation by an event at the input adapters directly leads to a recalculation of the output based on the currently applied input values.

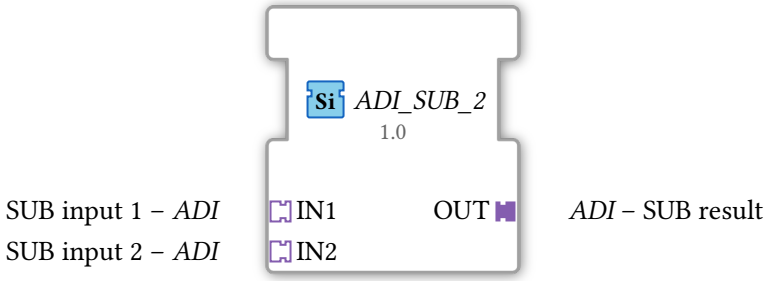
Application Scenarios

- **Physical Calculations:** Calculation of volumes (V = l × b × h) with an additional scaling or correction factor.
- **Measurement Scaling:** Multi-level weighting or scaling of analog sensor values across multiple factors.
- **Power Calculations:** Multiplication of various electrical or mechanical parameters to determine total power or efficiency in process automation.

Comparison with Similar Function Blocks

- **Standard `MUL` function block (IEC 61131-3):** Classic multipliers use direct data and event pins. `ADI_MUL_4_UNGATED`, on the other hand, uses adapters, which simplifies routing but requires a corresponding adapter infrastructure in the project. * **ADI_MUL_2 / ADI_MUL_3:** Similar function blocks with fewer inputs. The `ADI_MUL_4_UNGATED` is particularly suitable when exactly four factors need to be multiplied together without cascading multiple 2x multipliers.

Change Detection



This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `ADI_MUL_4_UNGATED` is a highly efficient auxiliary function block for mathematical signal processing in IEC 61499 systems. Through the consistent use of unidirectional adapters, it promotes clean, modular software design and reduces the complexity of graphical wiring within the 4diac IDE.

ADI_SUB_2

```
    +-----------------------------------+
| ADI_SUB_2 | | | IN1 ==# [ADI] [ADI] #== OUT IN2 ==# [ADI] | +—————————————+
```

```
• – ◦ • – ◦ • – ◦ •
```

Introduction

The function block `ADI_SUB_2` is a generic function block (Generic FB) for performing arithmetic subtractions in IEC 61499 applications. The block uses unidirectional adapters of type `ADI` to receive input data and output the calculated result. Using adapters simplifies the wiring within the 4diac IDE and increases modularity.

Interface Structure

Event Inputs

The function block does not have direct event inputs. Event control is handled entirely via the connected adapters.

Event Outputs

The function block does not have direct event outputs. Event forwarding is handled via the output adapter.

Data Inputs

No direct data inputs are defined. Data is passed via the input adapters.

Data Outputs

No direct data outputs are defined. The result is provided via the output adapter.

Adapters

Type	Name	Adapter Type	Description
Socket (Input)	`IN1`	`adapter::types::unidirectional::ADI`	First input value (minuend) for subtraction.
Socket (Input)	`IN2`	`adapter::types::unidirectional::ADI`	Second input value (subtrahend) for subtraction.
Plug (Output)	`OUT`	`adapter::types::unidirectional::ADI`	Result (difference) of the subtraction ($OUT = IN1 - IN2$).

Functionality

As soon as a corresponding calculation event is signaled at the input adapters `IN1` or `IN2`, the function block performs the subtraction:

$$\$OUT = IN1 - IN2$$

The result is passed to the output adapter `OUT`, and the corresponding output event of the adapter is triggered to inform subsequent function blocks of the new value.

- **Generic Type:** The function block is defined as a generic type (`eclipse4diac::core::GenericClassName` with the value `'GEN_ADI_SUB'`). This allows for flexible adaptation to different data types within the `ADI` adapter.
- **Unidirectional Adapters:** By using the unidirectional adapter structure (`adapter::types::unidirectional::ADI`), the data flow remains directed and cyclic dependencies are avoided.

Since this is a mathematical calculation function block, its behavior is essentially stateless and event-driven:

Technical Features

1. **Waiting:** The function block waits for a trigger event at one of the input adapters (`IN1` or `IN2`).
2. **Calculation:** Upon event input, the data values are read and subtracted.
3. **Output:** The calculated value is written to the adapter `OUT`, triggering the corresponding send event.

State Overview

- **Control Engineering:** Calculation of a control deviation ($e = w - x$), where the setpoint (w) and actual value (x) are transmitted via standardized ADI interfaces.
- **Measurement Processing:** Differential pressure measurement or offset correction of sensor values integrated into the application via adapters.

- **Signal Preprocessing:** Reduction of signal values by fixed or variable limits before forwarding them to actuators.

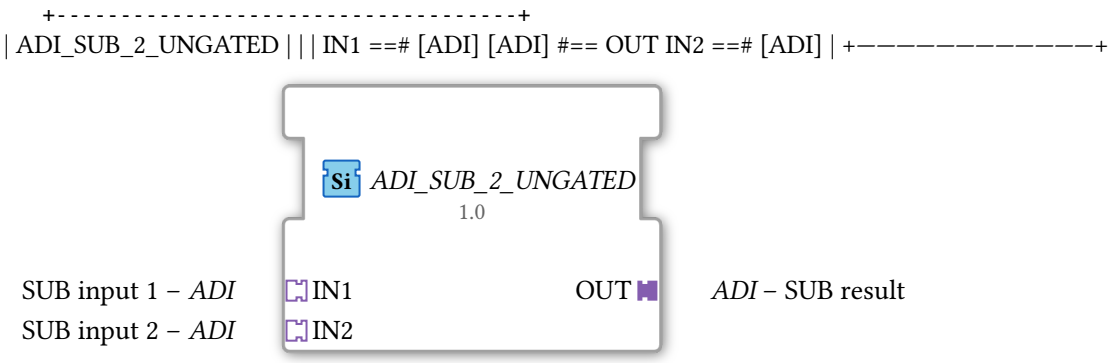
Application Scenarios

Compared to a standard subtraction block (such as the classic `SUB` block according to IEC 61131-3), which uses direct data and event pins, `ADI_SUB_2` offers the following advantages:

Comparison with Similar Function Blocks

- **Fewer connection lines:** Data and events are bundled in the `ADI` adapter, making the application diagram in 4diac clearer.
- **Standardized interfaces:** Facilitates the exchange of calculation and processing blocks, as only the adapters need to be connected.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ADI_SUB_2` is an efficient auxiliary block for structured IEC 61499 control applications. It is ideally suited for demanding architectures where clarity and standardized adapter interfaces are paramount.

ADI_SUB_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_SUB_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

The `ADI_SUB_2_UNGATED` is an efficient auxiliary block for structured IEC 61499 control applications. It is ideally suited for demanding architectures where clarity and standardized adapter interfaces are paramount.

AI_ADD_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block (FB) **AI_ADD_2** is a generic block for performing the arithmetic addition of two analog input values. It is based on the concept of generic function blocks (`GEN_AI_ADD`) and uses adapter interfaces instead of classic, loosely coupled data and event connections. This enables structured, clear, and modular signal processing within 4diac-ide-based control applications.

Interface Structure

Event Inputs

There are no direct event inputs. Event control is encapsulated via the adapters used.

Event Outputs

There are no direct event outputs. Event control is encapsulated via the adapters used.

Data Inputs

There are no direct data inputs.

Data Outputs

There are no direct data outputs.

Adapters

Sockets (Input Interfaces)

- **IN1** (Type: `adapter::types::unidirectional::AI`): The first addend of the addition operation. Both the value and the corresponding update event are received via this adapter.
- **IN2** (Type: `adapter::types::unidirectional::AI`): The second addend of the addition operation.

Plugs (Output Interfaces)

- **OUT** (Type: `adapter::types::unidirectional::AI`): The result of the addition ($OUT = IN1 + IN2$). This adapter passes the result and the corresponding update event to subsequent function blocks.

Functionality

The function block **AI_ADD_2** functions as a mathematical adder. As soon as a new event is signaled at one of the input adapters (`IN1` or `IN2`) indicating that the input data has been updated, the function block performs the addition:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} \tag{2.16}$$

The calculated result is immediately passed to the output adapter `OUT`, and the corresponding update event is triggered to inform subsequent program parts of the new value.

Since this is a generic function block (`GEN_AI_ADD`), the underlying data type (e.g., `REAL`, `INT`, `LREAL`) is flexible and determined by the configuration of the connected adapters.

Technical Features

- **Generic Type (`GEN_AI_ADD`):** The function block is not tied to a specific data type, which increases its reusability for different analog signal ranges.
- **Unidirectional Adapters:** Using the `adapter::types::unidirectional::AI` type drastically reduces wiring complexity in the 4diac-ide, as values and events are bundled in a single connection.
- – **Clean Encapsulation:** No loose event and data lines on the surface of the function block.

State Overview

The function block operates in an event-driven and stateless manner. No internal state is maintained (as with a memory element). Each incoming event at the inputs immediately triggers recalculation and output at output `OUT`.

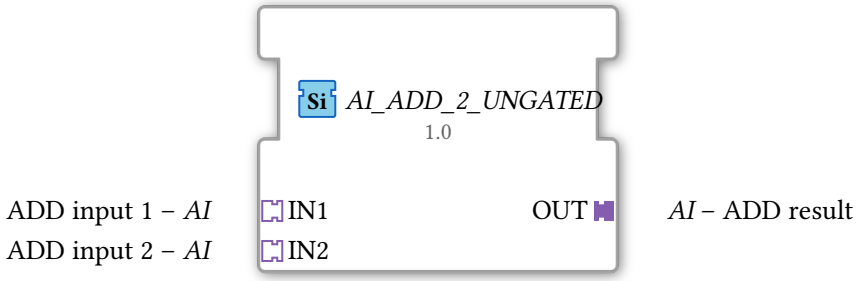
Application Scenarios

- **Sensor Data Aggregation:** Adding two flow rates (e.g., main flow and bypass flow) to obtain a total flow rate.
- **Setpoint Offsetting:** Adding a fixed or dynamic offset (e.g., calibration value) to an analog input signal.
- **Signal Mixing:** Simple mathematical combination of two analog control signals in process automation.

Comparison with Similar Function Blocks

Compared to the standard IEC 61131-3 add block (`ADD`), which uses classic data pins (e.g., `IN1`, `IN2` of type `ANY_NUM`) and explicit control events (`REQ` / `CNF`), **AI_ADD_2** offers a significantly cleaner visual representation. Encapsulation within adapters eliminates the need to manually draw separate event lines, minimizing the risk of errors during application development.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The **AI_ADD_2** is a modern, highly efficient function block for the 4diac-ide. It combines the fundamental mathematical function of addition with the structural advantages of IEC 61499 adapters. This makes it the ideal choice for modular control architectures.

AI_ADD_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_ADD_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

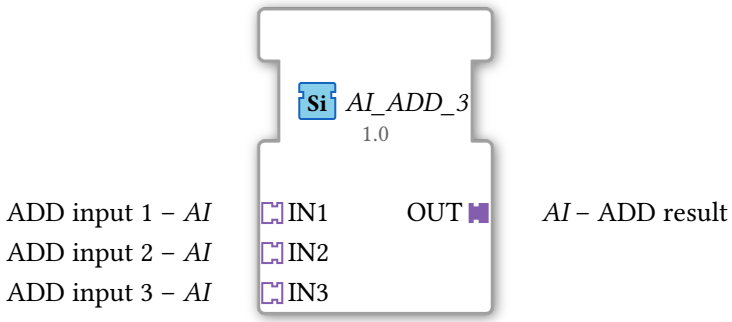
Compared to the standard IEC 61131-3 add block (`ADD`), which uses classic data pins (e.g., `IN1`, `IN2` of type `ANY_NUM`) and explicit control events (`REQ` / `CNF`), **AI_ADD_2_UNGATED** offers a significantly cleaner visual representation. Encapsulation within adapters eliminates the need to manually draw separate event lines, minimizing the risk of errors during application development.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The **AI_ADD_2_UNGATED** is a modern, highly efficient function block for the 4diac-ide. It combines the fundamental mathematical function of addition with the structural advantages of IEC 61499 adapters. This makes it the ideal choice for modular control architectures.

AI_ADD_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AI_ADD_3` is a generic, arithmetic addition block for the 4diac-ide development environment. It is used to add the values of three analog inputs (AI) and output the result to an analog output. The use of unidirectional adapters ensures clean encapsulation of data and associated events.

Interface Structure

The block uses an adapter-based interface design. It does not have direct, traditional event or data channels at the main level, but delegates these entirely to the adapters.

Event Inputs

No direct event inputs are available. (Event control is handled via the adapter interfaces).

Event Outputs

No direct event outputs available. (Event control is handled via the adapter interfaces).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AI`): First analog input value for the addition operation.
- **IN2** (Type: `adapter::types::unidirectional::AI`): Second analog input value for the addition operation.
- **IN3** (Type: `adapter::types::unidirectional::AI`): Third analog input value for the addition operation.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AI`): Output adapter that provides the calculated result of the addition.

Functionality

As soon as an update event arrives at one of the input adapters (`IN1`, `IN2`, or `IN3`), the function block reads the analog values of the three sockets.

The following mathematical operation is performed:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} \tag{2.18}$$

After successful calculation, the result value is passed to the output plug `OUT`, and a corresponding update event is triggered at the output.

Technical Features

- **Generic Function Block (FB):** The function block is internally typed as `GEN_AI_ADD`. This allows for flexible adaptation to different numeric data types (e.g., `INT`, `REAL`, `LREAL`), depending on the specific type defined by the connected adapters.
- **Adapter Coupling:** By using unidirectional adapters (`unidirectional::AI`), signal routing in the application diagram is greatly simplified. Data and trigger events are bundled in a single connection line.
- **Adapter Coupling:** The use of unidirectional adapters (`unidirectional::AI`) greatly simplifies signal routing in the application diagram. —

State Overview

The function block operates purely event-driven:

1. **Standby State (Idle):** The function block waits for incoming events at sockets `IN1`, `IN2`, or `IN3`.
2. **Calculation Phase:** An event triggers the addition of the incoming values.
3. **Update Phase:** The result is applied to `OUT`, and the output event is triggered. The function block immediately returns to standby state.

–

Application Scenarios

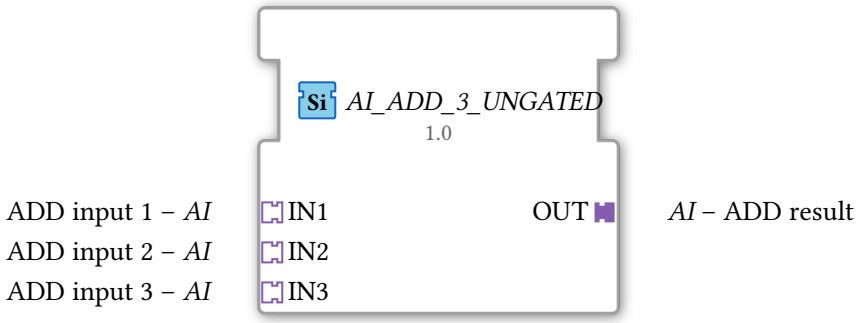
- **Sensor Data Fusion:** Combining and summing three analog measured values (e.g., determining a total volume flow from three individual partial flows).
- **Setpoint Calculation:** Calculation of an overall setpoint consisting of a base setpoint and two correction or offset values.
- **Mixing Processes:** Weighting and combining analog control signals in process automation.

Comparison with Similar Function Blocks

Compared to classic IEC 61131-3 adders (such as `F_ADD`) or standard IEC 61499 function blocks, `AI_ADD_3` eliminates the manual and error-prone wiring of separate `REQ` and `CNF` event lines.

While standard adders typically only support two inputs, the `AI_ADD_3` eliminates the need to cascade two separate modules when adding three values, thus optimizing execution time and improving system clarity.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AI_ADD_3` is a modular and user-friendly auxiliary module for efficient analog signal processing. Its consistent use of adapters significantly reduces the visual "spaghetti wiring" in 4diac applications and contributes to a high-performance, event-driven control architecture.

AI_ADD_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_ADD_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

- **IN2** (Type: `adapter::types::unidirectional::AI`): Second analog input value for the addition operation.
- **IN3** (Type: `adapter::types::unidirectional::AI`): Third analog input value for the addition operation.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AI`): Output adapter that provides the calculated result of the addition.

Functionality

As soon as an update event arrives at one of the input adapters (`IN1`, `IN2`, or `IN3`), the function block reads the analog values of the three sockets.

The following mathematical operation is performed:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} \tag{2.19}$$

After successful calculation, the result value is passed to the output plug `OUT`, and a corresponding update event is triggered at the output.

Technical Features

- **Generic Function Block (FB):** The function block is internally typed as `GEN_AI_ADD`. This allows for flexible adaptation to different numeric data types (e.g., `INT`, `REAL`, `LREAL`), depending on the specific type defined by the connected adapters.
- **Adapter Coupling:** By using unidirectional adapters (`unidirectional::AI`), signal routing in the application diagram is greatly simplified. Data and trigger events are bundled in a single connection line.
- **Adapter Coupling:** The use of unidirectional adapters (`unidirectional::AI`) greatly simplifies signal routing in the application diagram. —

State Overview

The function block operates purely event-driven:

1. **Standby State (Idle):** The function block waits for incoming events at sockets `IN1`, `IN2`, or `IN3`.
2. **Calculation Phase:** An event triggers the addition of the incoming values.
3. **Update Phase:** The result is applied to `OUT`, and the output event is triggered. The function block immediately returns to standby state.

–

Application Scenarios

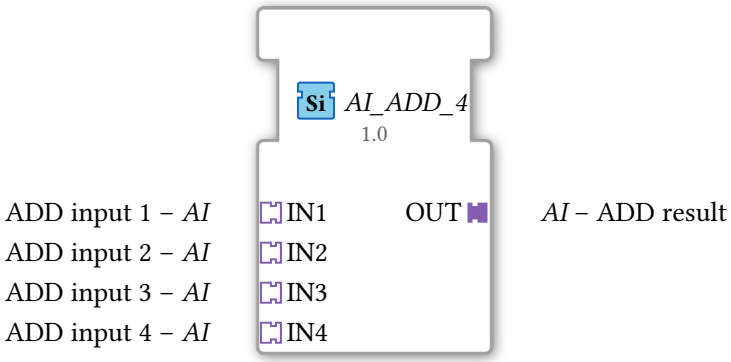
- **Sensor Data Fusion:** Combining and summing three analog measured values (e.g., determining a total volume flow from three individual partial flows).
- **Setpoint Calculation:** Calculation of an overall setpoint consisting of a base setpoint and two correction or offset values.
- **Mixing Processes:** Weighting and combining analog control signals in process automation.

Comparison with Similar Function Blocks

Compared to classic IEC 61131-3 adders (such as `F_ADD`) or standard IEC 61499 function blocks, `AI_ADD_3_UNGATED` eliminates the manual and error-prone wiring of separate `REQ` and `CNF` event lines.

While standard adders typically only support two inputs, the `AI_ADD_3_UNGATED` eliminates the need to cascade two separate modules when adding three values, thus optimizing execution time and improving system clarity.

Change Detection



This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AI_ADD_3_UNGATED` is a modular and user-friendly auxiliary module for efficient analog signal processing. Its consistent use of adapters significantly reduces the visual "spaghetti wiring" in 4diac applications and contributes to a high-performance, event-driven control architecture.

AI_ADD_4

```
     +------------------------+
IN1 =| [Socket] | IN2 =| [Socket] [Plug] |= OUT IN3 =| [Socket] | IN4 =| [Socket] | +——————————+
```

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AI_ADD_4` is a generic arithmetic block for the 4diac IDE, used to add four analog or numeric values. The unique feature of this block is the use of unidirectional adapters of type `AI` (Analog Input/Arithmetic Input) instead of traditional discrete data and event inputs. This enables a clean, modular, and clear structuring of signal flows in IEC 61499 applications.

Interface Structure

The block does not have any traditional event- or data-based inputs and outputs at the top level. All communication is handled via adapters.

Event Inputs

No direct event inputs are available. Event control is encapsulated within the adapters.

Event Outputs

No direct event outputs are available. Event control is encapsulated within the adapters.

Data Inputs

No direct data inputs are available.

Data Outputs

No direct data outputs are available.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AI`): First addend for the addition operation.
- **IN2** (Type: `adapter::types::unidirectional::AI`): Second addend for the addition operation.
- **IN3** (Type: `adapter::types::unidirectional::AI`): Third addend for the addition operation.
- **IN4** (Type: `adapter::types::unidirectional::AI`): Fourth addend for the addition operation.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AI`): Output adapter that provides the result of the addition (`IN1 + IN2 + IN3 + IN4`).

Functionality

As soon as a new event is signaled at one of the input adapters (`IN1` to `IN4`) indicating that a value has changed, the function block performs the following internal addition:

$$\text{OUT} = \text{IN1} + \text{IN2} + \text{IN3} + \text{IN4} \tag{2.20}$$

The result is immediately passed to the output adapter `OUT`, and the corresponding update event of the output adapter is triggered. Since this is a generic function block (`GEN_AI_ADD`), the actual data type (e.g., `REAL`, `INT`, `LREAL`) depends on the specific implementation and instantiation of the adapter type used.

Technical Features

- **Generic Design:** The function block uses the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AI_ADD'`. This makes it highly flexible and allows it to be applied to different numeric data types, provided the adapters used support this.
- **Generic Design:** The function block uses the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AI_ADD'`. * **Unidirectional Adapters:** Using `unidirectional::AI` adapters drastically reduces wiring complexity in the function block diagram, as data and trigger events are bundled in a single connection.

State Overview

The function block behaves purely reactively (event-driven):

1. **Wait State (Idle):** The function block waits for an update event at one of the sockets (`IN1` to `IN4`).
2. **Calculation:** Upon receiving an event, the current values of all four inputs are read and added together.
3. **Output:** The calculated value is written to the plug `OUT`, triggering the corresponding output event. The function block immediately returns to the wait state.

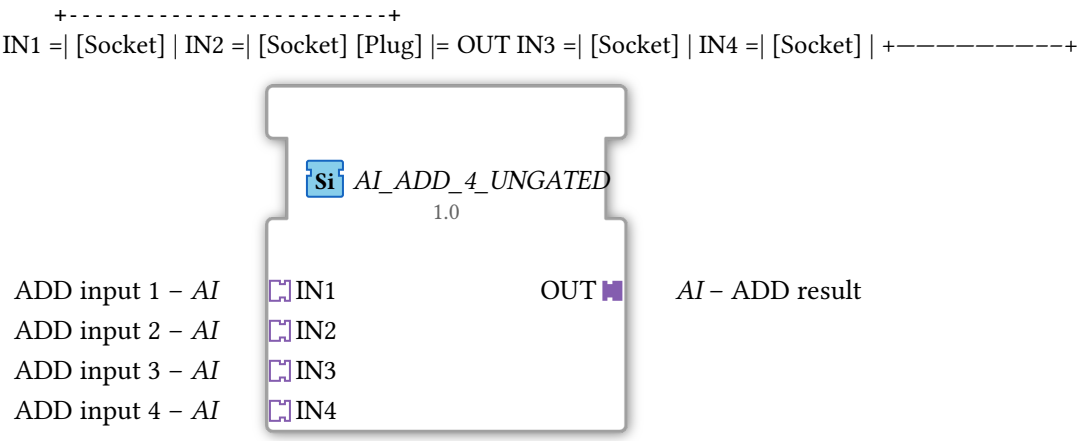
Application Scenarios

- **Measurement Aggregation:** Summing of currents, powers, or flow rates from four different sources or sensors.
- **Average Preparation:** Combining four analog measurement values for subsequent division (e.g., for moving average calculation or redundancy checks).
- **Setpoint Offset Calculation:** Adding base setpoints, correction values, and user offsets in process engineering plants.

Comparison with Similar Function Blocks

Feature / Function Block	`AI_ADD_4`	Standard `ADD` (IEC 61131-3)
Interface Type	Adapter-based (`AI`)	Standard Data and Event Pins
Number of Inputs	Fixed (4)	Variable / Fixed (usually 2)
Wiring Effort	Very low (only 5 connections)	High (separate event and data lines)
Typing	Generic via adapter	Explicit via FB typing (e.g., `ADD_REAL`)

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AI_ADD_4` is a highly efficient and modern function block that fully utilizes the advantages of adapter-based coupling in IEC 61499. It is ideally suited for complex control architectures where clarity in the application diagram and a clear signal structure are paramount.

AI_ADD_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_ADD_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

AI_DIV_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AI_DIV_2` is a generic arithmetic block for the 4diac platform. It is used to perform mathematical division (DIV) of two analog values. Unlike classic arithmetic blocks, this block uses standardized, unidirectional adapters of type `AI` (Analog Input) for its inputs and outputs. This enables structured, modular, and clear signal wiring within IEC 61499 applications.

Interface Structure

Event Inputs

The block does not have direct event inputs. Synchronization and event control are handled implicitly via the connected adapters.

Event Outputs

This function block has no direct event outputs.

Data Inputs

There are no direct data inputs. Data transmission is handled entirely via the adapter interfaces.

Data Outputs

There are no direct data outputs.

Adapter

Name	Type	Interface Type	Description
IN1	`adapter::types::unidirectional::AI`	Socket	First Input Value (Dividend)
IN2	`adapter::types::unidirectional::AI`	Socket	Second Input Value (Divisor)
OUT	`adapter::types::unidirectional::AI`	Plug	Result of Division (Quotient)

Functionality

The function block calculates the quotient of the values of the two input adapters:

$$OUT = \frac{IN1}{IN2} \tag{2.22}$$

As soon as the values at sockets `IN1` or `IN2` change and a corresponding update event is received via the adapter, the division is performed. The result and the associated update event are immediately forwarded to the output adapter `OUT` (plug).

Due to its generic type (`GEN_AI_DIV`), the function block is not limited to a specific data type (such as `REAL` or `INT`). The specific data type is determined flexibly during instantiation in the 4diac IDE.

Technical Features

- **Generic Typing:** The function block can be used polymorphically via the attribute `GenericClassName` with the value `GEN_AI_DIV` and can work with various compatible analog data types.
- **Adapter Encapsulation:** By using unidirectional adapters (`unidirectional::AI`), data and event lines are bundled into a single connection. This reduces the risk of wiring errors and improves clarity in the function block diagram (FBD).
- **Division by Zero:** Since this is a mathematical division, the system or upstream logic must ensure that the value at `IN2` is not zero to avoid calculation errors or division-by-zero exceptions at runtime.

State Overview

The function block `AI_DIV_2` is a stateless combination block. It does not have an internal Execution Control Chart (ECC). Every event at the input adapters directly triggers the calculation and update of the output adapter.

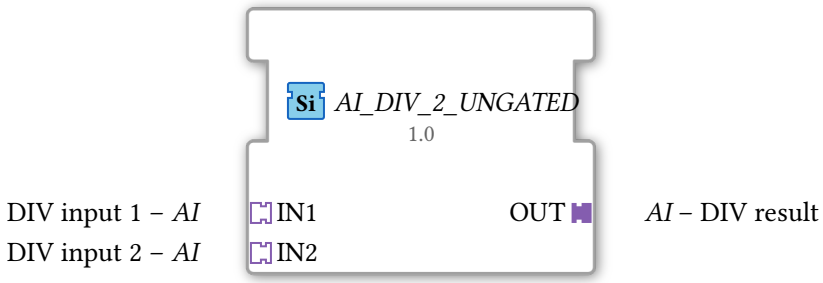
Application Scenarios

- **Ratio Calculations:** Determining ratios in process engineering plants (e.g., air-fuel ratio or mixing ratios of liquids).
- **Scaling and Normalization:** Dividing an analog raw value (e.g., sensor reading) by a scaling factor to convert it into physical units.
- **Measurement Averaging:** Used in computing networks where sum values need to be divided by a fixed or variable number.

Comparison with Similar Components

- **Standard Arithmetic Component (DIV):** A classic `DIV` component of IEC 61131-3 / IEC 61499 operates with direct PIN inputs (e.g., `IN1`, `IN2` as `REAL`) and separate event pins (`REQ`, `CNF`). `AI_DIV_2`, on the other hand, bundles these signals into adapters, enabling cleaner interface separation in complex signal paths.
- **AI_SUB_2 / AI_ADD_2:** These modules share the same adapter philosophy but perform subtractions and additions, respectively, instead of division.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AI_DIV_2` is a highly efficient and modern auxiliary module for analog signal processing in 4diac. Through the consistent use of adapters, it integrates seamlessly into service-oriented control architectures and minimizes the implementation and testing effort for basic mathematical operations.

AI_DIV_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_DIV_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. - **AI_SUB_2 / AI_ADD_2:** These modules share the same adapter philosophy but perform subtractions and additions, respectively, instead of division.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AI_DIV_2_UNGATED` is a highly efficient and modern auxiliary module for analog signal processing in 4diac. Through the consistent use of adapters, it integrates seamlessly into service-oriented control architectures and minimizes the implementation and testing effort for basic mathematical operations.

AI_MUL_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AI_MUL_2` is a generic arithmetic function block for the 4diac IDE, compliant with the IEC 61131-3 standard. Its primary function is the multiplication of two input values provided via unidirectional adapters. The result of this multiplication is also output via a unidirectional adapter.

By using adapters instead of traditional discrete inputs and outputs, the complexity of the wiring in the control design is significantly reduced, as related data and events are bundled in a single connection.

The interface of this function block is entirely adapter-based. There are no direct, traditional event or data inputs and outputs on the block's interface.

Interface Structure

Event Inputs

No direct event inputs available (control is handled via the adapters).

Event Outputs

No direct event outputs available (control is handled via the adapters).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Name	Type	Direction (Mode)	Description
IN1	`adapter::types::unidirectional::AI`	Socket (Input)	First input value (multiplicand) for the arithmetic operation.
IN2	`adapter::types::unidirectional::AI`	Socket (Input)	Second input value (multiplier) for the arithmetic operation.
OUT	`adapter::types::unidirectional::AI`	Plug (Output)	Output for the calculated product of the two input values.

Functionality

The function block performs mathematical multiplication:

$$OUT = IN1 \times IN2 \tag{2.24}$$

Since the block is defined as a generic function block (`GEN_AI_MUL`), it can process different numeric data types (e.g., `REAL`, `LREAL`, `INT`, etc.) depending on the instantiation and typing of the adapters used.

As soon as an update event is received via the input adapters (`IN1` and/or `IN2`), the function block performs the multiplication internally and signals the update of the result via the output adapter `OUT`.

Technical Features

- **Generic Implementation:** The function block uses the class `GEN_AI_MUL`. This allows for high flexibility, as the specific data type is only determined when used in the system.
- **Unidirectional Adapters:** The interfaces use the type `adapter::types::unidirectional::AI`. This means that the information flow is strictly unidirectional, which increases system stability and performance.
- **Encapsulation:** The absence of individual signal pins keeps the application diagram clear and uncluttered, even with many mathematical operations.

State Overview

The module essentially behaves in a stateless manner (exhibiting analog characteristics):

Application Scenarios

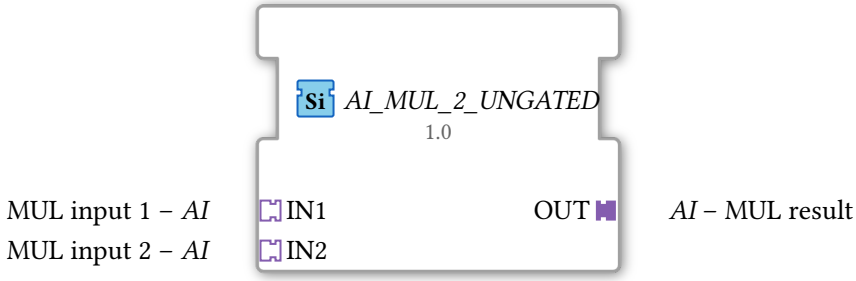
- **Initialization / Idle State:** The module waits for incoming values via the adapters `IN1` and `IN2`.
- **Calculation:** Upon arrival of a new value or trigger signal at the sockets, the product is recalculated.
- **Output:** The result is immediately passed to the plug `OUT`, triggering a corresponding output event in the adapter.
- **Scaling of Sensor Values:** Multiplication of a raw analog value (e.g., from a 4–20 mA current input) by a scaling factor to convert it into a physical quantity.

- **Scaling of Sensor Values:** * **Calculation of physical quantities:** Calculation of power ($P = U \times I$) from measured voltage and current, provided these are supplied via appropriate adapter structures.
- **Amplifiers in control loops:** Use as a proportional gain factor (P-element) in software-based control.

Comparison with Similar Function Blocks

Compared to the standard IEC 61131-3 component `MUL`, the `AI_MUL_2` eliminates the need for manual wiring of trigger events (as with `REQ` and `CNF`) and individual data pins. While a classic `MUL` block requires separate lines for data and events for each connection, the `AI_MUL_2` bundles these using the `AI` adapters. This is particularly suitable for advanced, object-oriented, or modularized software architectures in 4diac.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AI_MUL_2` is a specialized, yet flexible, block for multiplying two values via adapter connections. It is ideally suited for clean, well-organized control architectures where analog signals need to be transmitted and processed in a standardized way using unidirectional adapters.

AI_MUL_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_MUL_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

AI_MUL_3

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AI_MUL_3` is a generic arithmetic function block designed for multiplying three input values. It conforms to the classification for standard arithmetic functions according to IEC 61131-3 and utilizes the 4diac adapter concept. Encapsulating the signals in adapters significantly reduces the visual complexity of the function block diagram.

Interface Structure

Event Inputs

This function block does not have direct event inputs. Event control is handled internally via the adapters.

Event Outputs

This function block does not have direct event outputs. Event control is handled internally via the adapters.

Data Inputs

This function block has no direct data inputs. Data is transferred via the input adapters.

Data Outputs

This function block has no direct data outputs. Data is output via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AI`): The first multiplicand (input value 1).
- **IN2** (Type: `adapter::types::unidirectional::AI`): The second multiplicand (input value 2).
- **IN3** (Type: `adapter::types::unidirectional::AI`): The third multiplicand (input value 3).

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AI`): The result of the multiplication.

Functionality

The function block performs a continuous or event-driven arithmetic multiplication of the three values connected via the sockets.

The mathematical formula is:

$$\mathrm{OUT} = \mathrm{IN1} \times \mathrm{IN2} \times \mathrm{IN3} \tag{2.26}$$

As soon as the values at the input adapters change or a corresponding update event is triggered via the adapters, the function block calculates the product and makes it available at the output adapter `OUT`.

Technical Features

- **Generic Nature:** The function block is declared as a generic type (`GenericClassName = 'GEN_AI_MUL'`). This means it can flexibly work with various numeric data types (such as REAL, LREAL, INT), provided these are supported by the adapter type `AI`.
- **Adapter Coupling:** By using unidirectional adapters (`unidirectional::AI`), data and its validation events are combined. This drastically simplifies the wiring in the 4diac IDE, as separate event and data lines are no longer required.

–

State Overview

The function block does not have a complex internal state diagram (stateless). It reacts purely to changes in values or trigger events at inputs `IN1`, `IN2`, and `IN3` and immediately forwards the result to `OUT`.

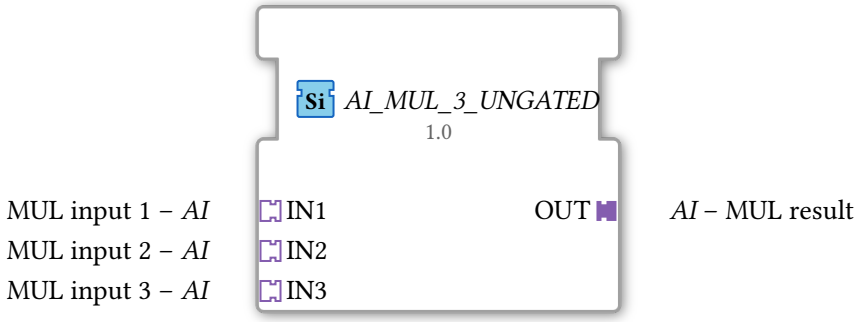
Application Scenarios

- **Measurement Scaling:** Multiplication of an analog raw value (`IN1`) by a calibration factor (`IN2`) and a further correction factor (`IN3`).
- **Physical Calculations:** Calculation of volumes (V = l × b × h) or power, where three factors must be multiplied directly together.
- – **Cascaded Amplifications:** Signal processing chains in which a signal passes through two amplification stages sequentially.

Comparison with Similar Components

- **Standard MUL Component (IEC 61131-3):** Classic multiplication components have direct data pins (e.g., `ANY_NUM`) and require explicit event connections (`REQ` / `CNF`). `AI_MUL_3` bundles this logic into adapters.
- **AI_MUL_2 (Dual Multiplier):** While multiplying three values with a standard dual multiplier requires two components cascaded, `AI_MUL_3` accomplishes this in a single step, saving resources and space in the control diagram.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AI_MUL_3` function block offers an efficient, clean, and high-performance way to implement triple multiplications within a 4diac application. Through the consistent use of the adapter concept, it significantly contributes to the clarity and maintainability of control software.

AI_MUL_3_UNGATED

i UNGATED variant: This block is the ungated version of `AI_MUL_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AI_MUL_3_UNGATED` is a generic arithmetic function block designed for multiplying three input values. It conforms to the classification for standard arithmetic functions according to IEC 61131-3 and utilizes the 4diac adapter concept. Encapsulating the signals in adapters significantly reduces the visual complexity of the function block diagram.

Interface Structure

Event Inputs

This function block does not have direct event inputs. Event control is handled internally via the adapters.

Event Outputs

This function block does not have direct event outputs. Event control is handled internally via the adapters.

Data Inputs

This function block has no direct data inputs. Data is transferred via the input adapters.

Data Outputs

This function block has no direct data outputs. Data is output via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AI`): The first multiplicand (input value 1).
- **IN2** (Type: `adapter::types::unidirectional::AI`): The second multiplicand (input value 2).
- **IN3** (Type: `adapter::types::unidirectional::AI`): The third multiplicand (input value 3).

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AI`): The result of the multiplication.

Functionality

The function block performs a continuous or event-driven arithmetic multiplication of the three values connected via the sockets.

The mathematical formula is:

$$\text{OUT} = \text{IN1} \times \text{IN2} \times \text{IN3} \tag{2.27}$$

As soon as the values at the input adapters change or a corresponding update event is triggered via the adapters, the function block calculates the product and makes it available at the output adapter `OUT`.

Technical Features

- **Generic Nature:** The function block is declared as a generic type (`GenericClassName = 'GEN_AI_MUL'`). This means it can flexibly work with various numeric data types (such as REAL, LREAL, INT), provided these are supported by the adapter type `AI`.

- **Adapter Coupling:** By using unidirectional adapters (`unidirectional::AI`), data and its validation events are combined. This drastically simplifies the wiring in the 4diac IDE, as separate event and data lines are no longer required.

–

State Overview

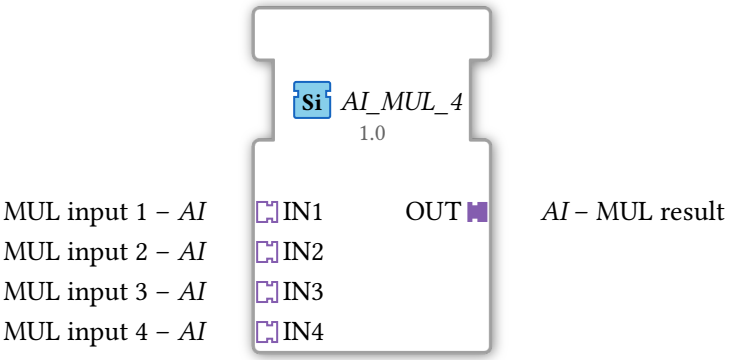
The function block does not have a complex internal state diagram (stateless). It reacts purely to changes in values or trigger events at inputs `IN1`, `IN2`, and `IN3` and immediately forwards the result to `OUT`.

Application Scenarios

- **Measurement Scaling:** Multiplication of an analog raw value (`IN1`) by a calibration factor (`IN2`) and a further correction factor (`IN3`).
- **Physical Calculations:** Calculation of volumes (V = l × b × h) or power, where three factors must be multiplied directly together.
- – **Cascaded Amplifications:** Signal processing chains in which a signal passes through two amplification stages sequentially.

Comparison with Similar Components

- **Standard MUL Component (IEC 61131-3):** Classic multiplication components have direct data pins (e.g., `ANY_NUM`) and require explicit event connections (`REQ` / `CNF`). `AI_MUL_3_UNGATED` bundles this logic into adapters.
- **AI_MUL_2 (Dual Multiplier):** While multiplying three values with a standard dual multiplier requires two components cascaded, `AI_MUL_3_UNGATED` accomplishes this in a single step, saving resources and space in the control diagram.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AI_MUL_3_UNGATED` function block offers an efficient, clean, and high-performance way to implement triple multiplications within a 4diac application. Through the consistent use of the adapter concept, it significantly contributes to the clarity and maintainability of control software.

AI_MUL_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AI_MUL_4` is a generic arithmetic function block for 4diac-IDE, compliant with the IEC 61131-3 standard. Its primary function is to calculate the mathematical product of four analog input values. The block utilizes unidirectional adapters of type `AI` (Analog Input) to transmit both data and the

associated events in encapsulated form. This significantly reduces the wiring effort in the function block diagram and ensures a cleaner structure for the control logic.

Interface Structure

Event Inputs

The function block does not have direct, independent event inputs. Event control is handled entirely via the connected adapters.

Event Outputs

This function block does not have direct, independent event outputs. Subsequent blocks are triggered via the output adapter.

Data Inputs

There are no direct data inputs. Values are provided via the adapter inputs.

Data Outputs

There are no direct data outputs. The calculated value is output via the adapter output.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AI`): First multiplicand.
- **IN2** (Type: `adapter::types::unidirectional::AI`): Second multiplicand.
- **IN3** (Type: `adapter::types::unidirectional::AI`): Third multiplicand.
- **IN4** (Type: `adapter::types::unidirectional::AI`): Fourth multiplicand.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AI`): Product of the multiplication of all four inputs ($OUT = IN1 \cdot IN2 \cdot IN3 \cdot IN4$).

Functionality

As soon as a new event is signaled at one of the input adapters (`IN1` to `IN4`) indicating that the data has been updated, the function block reads the analog values of the four adapters.

The calculation is performed according to the formula:

$$\text{Result} = \text{Value}\ (IN1) \cdot \text{Value}\ (IN2) \cdot \text{Value}\ (IN3) \cdot \text{Value}\ (IN4) \tag{2.28}$$

The result of this calculation is passed to the output adapter `OUT`, and the corresponding update event of the adapter is triggered to inform subsequent blocks in the control flow about the new value.

- **Generic Class:** The block is internally based on the generic class `GEN_AI_MUL`. This enables flexible processing of data streams independent of specific hardware implementations.
- **Unidirectional Adapters:** By using the type `adapter::types::unidirectional::AI`, data and trigger signals flow in only one direction (from sender to receiver). This simplifies signal design and avoids feedback loops.
- **Compact Structure:** Processing four inputs in a single function block eliminates the need to cascade multiple multiplication blocks.

Technical Features

Since `AI_MUL_4` is a purely mathematical, data- and event-driven function block, it does not have an internal state machine (ECC). Its execution is purely stateless:

State Overview

1. **Wait:** The function block waits for an update event at one of the sockets (`IN1` to `IN4`).
2. **Calculate:** Upon triggering, the current values of all four inputs are multiplied.
3. **Output:** The result is applied to the plug `OUT`, and the output event is triggered. The module immediately returns to standby mode.

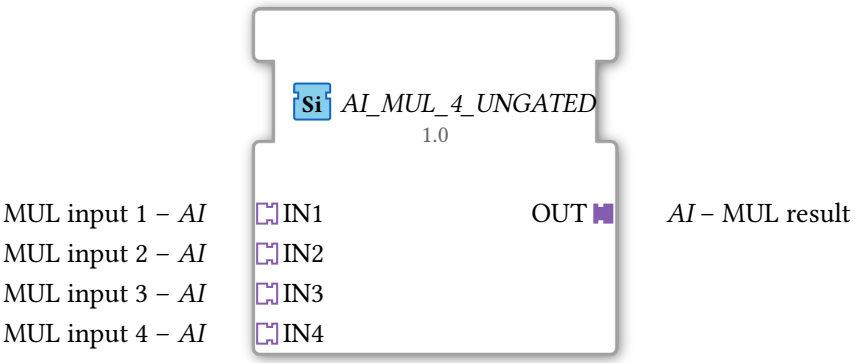
Application Scenarios

- **Scaling and Calibration:** Calculation of compound correction factors for analog sensor values (e.g., sensor value \cdot $ calibration factor \cdot $ temperature compensation \cdot $ unit conversion).
- **Physical Calculations:** Calculation of values that depend on multiple analog factors, such as volumetric flow rates or electrical power, taking into account different efficiencies.
- **Cascaded Gains:** Use in control loops where multiple gains must be applied sequentially to an analog signal.

Comparison with Similar Function Blocks

- **Standard MUL (IEC 61131-3):** Classic multiplication function blocks typically only work with elementary data types (e.g., `REAL`, `INT`) and require separate event lines (`REQ` / `CNF`). Furthermore, they often only support two inputs by default. `AI_MUL_4`, on the other hand, directly processes four inputs and uses adapters for encapsulation, resulting in a clearer network layout.
- **AI_MUL_2:** A similar adapter-based function block, but only for two inputs. `AI_MUL_4` saves additional wiring effort and function block instances for more complex calculations with up to four factors.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AI_MUL_4` function block offers an efficient and clean way to implement complex multiplication tasks with up to four analog signals in 4diac-IDE. The consistent use of unidirectional adapters minimizes cabling effort and significantly improves the readability of the application design.

AI_MUL_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_MUL_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

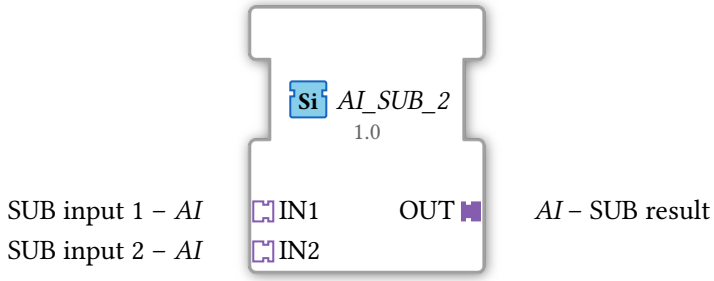
Furthermore, they often only support two inputs by default. `AI_MUL_4_UNGATED`, on the other hand, directly processes four inputs and uses adapters for encapsulation, resulting in a clearer network layout.
- **AI_MUL_2:** A similar adapter-based function block, but only for two inputs. `AI_MUL_4_UNGATED` saves additional wiring effort and function block instances for more complex calculations with up to four factors.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AI_MUL_4_UNGATED` function block offers an efficient and clean way to implement complex multiplication tasks with up to four analog signals in 4diac-IDE. The consistent use of unidirectional adapters minimizes cabling effort and significantly improves the readability of the application design.

AI_SUB_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AI_SUB_2` is a generic arithmetic function block for performing subtraction. It is specifically designed for use with analog interface adapters. The block calculates the difference between two analog input values and outputs the result to an analog output adapter. Using adapters keeps the interface design in the 4diac-ide clear and concise.

Interface Structure

Since this function block is based entirely on an adapter architecture, it does not have any direct, traditional event or data channels on the block interface. All communication is handled via the adapters.

Event Inputs

No direct event inputs available (event control is encapsulated in the adapters).

Event Outputs

No direct event outputs available (event control is encapsulated in the adapters).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AI`): The first analog input value (minuend) for the subtraction operation.
- **IN2** (Type: `adapter::types::unidirectional::AI`): The second analog input value (subtrahend), which is subtracted from `IN1`.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AI`): The result of the subtraction (difference: `IN1 - IN2`).

Functionality

This function block performs basic arithmetic subtraction:

$$OUT = IN1 - IN2 \tag{2.30}$$

As soon as the input values at sockets `IN1` or `IN2` change, or a corresponding update event is received via the adapters, the function block calculates the difference internally. The result and the associated update event are immediately forwarded to output plug `OUT`.

Technical Features

- **Generic Block Type (`GEN_AI_SUB`)**: The block is internally defined as a generic type. This allows for flexible adaptation to the analog data types used by the adapters in the system.
- **Adapter Encapsulation**: The use of unidirectional analog adapters (`unidirectional::AI`) consolidates data and event lines. This minimizes the wiring effort in the FBD (Function Block Diagram) and significantly improves clarity.

State Overview

The block behaves like a purely functional block without internal memory (analogous to a classic combinational gate). It does not have a complex Execution Control Chart (ECC). Any activity on the input adapters directly triggers the calculation and updates the output adapter.

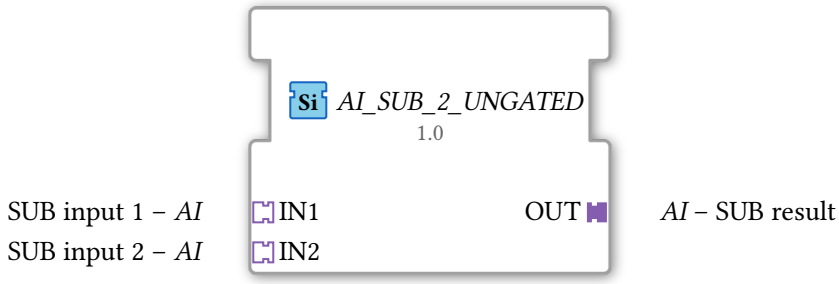
Application Scenarios

- **Differential Pressure and Differential Temperature Measurement**: Calculation of physical differential values in process engineering (e.g., determining the pressure drop across a filter or the temperature difference between the flow and return lines).
- **Control Deviation**: Calculation of the control deviation ($e = w - x$) in control loops where the setpoint and actual value are available as adapter structures.
- **Zero Point Correction / Offset Subtraction**: Subtraction of a calibration or offset value from a continuous measurement signal.

Comparison with Similar Components

Compared to standard subtraction components of IEC 61131-3 (such as a classic `SUB` component with discrete pins), the `AI_SUB_2` eliminates the need for manually wiring separate `REQ` and `CNF` event lines as well as individual analog data lines. All relevant information is cleanly transmitted in the `AI` adapters.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AI_SUB_2` is a specialized and highly efficient component for modern, adapter-based programming in 4diac. It is ideally suited for clean software architectures in the field of analog signal preprocessing, where clarity and encapsulation are paramount.

AI_SUB_2_UNGATED

i UNGATED variant: This block is the ungated version of `AI_SUB_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Conclusion

The `AI_SUB_2_UNGATED` is a specialized and highly efficient component for modern, adapter-based programming in 4diac. It is ideally suited for clean software architectures in the field of analog signal preprocessing, where clarity and encapsulation are paramount.

ALI_ADD_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALI_ADD_2` is a generic arithmetic block for performing addition (ADD) based on the IEC 61131-3 standard. It is classified as a standard arithmetic function and serves to add two input values via an adapter interface and output the result.

By using adapters, this block enables highly modular and clear wiring within the 4diac IDE.

Interface Structure

Event Inputs
No direct event inputs are available. Control and synchronization are handled via the adapters.

Event Outputs
No direct event outputs are available. Control and synchronization are handled via the adapters.

Data Inputs
No direct data inputs available.

Data Outputs
No direct data outputs available.

Adapters
- **IN1 (Socket)**: Input adapter type `adapter::types::unidirectional::ALI`. Represents the first addend of the addition.
- **IN2 (Socket)**: Input adapter type `adapter::types::unidirectional::ALI`. Represents the second addend of the addition.
- **OUT (Plug)**: Output adapter type `adapter::types::unidirectional::ALI`. Provides the mathematical result of the addition (`IN1 + IN2`).

Functionality
The function block `ALI_ADD_2` performs a classic mathematical addition. As soon as the values at the input adapters `IN1` and/or `IN2` change, or a corresponding transfer event is triggered via the adapters, the block calculates the sum:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} \tag{2.32}$$

The result is immediately available via the output adapter `OUT`. Since the block is defined as a generic type (implemented via the generic class `GEN_ALI_ADD`), it is not tied to a specific data type but can adapt to various compatible numeric data types.

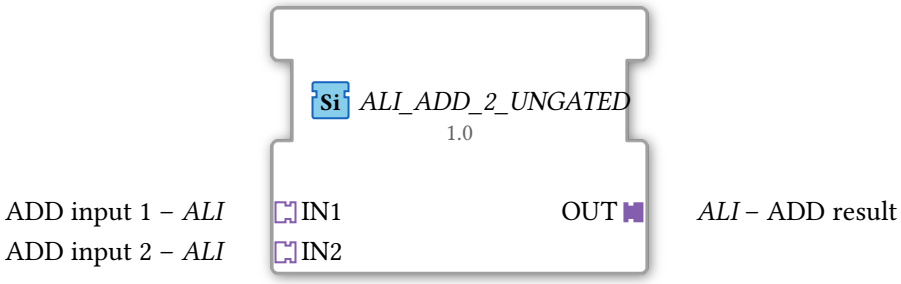
Technical Features
- **Generic Implementation**: The attribute `GenericClassName` with the value `'GEN_ALI_ADD'` allows the function block to be flexibly instantiated for different data types (e.g., INT, REAL, LREAL).
- **Adapter Coupling**: Unlike traditional function blocks that use discrete pins for data and events, this function block bundles the signals in unidirectional `ALI` adapters. This significantly reduces the number of wires in the function block diagram.

State Overview
The function block is stateless (combinatorial behavior). It does not have an internal state machine (ECC). Any change to the inputs directly updates the output.

Application Scenarios
- **Signal Processing**: Summing two sensor values or physical quantities that are already distributed within the application via an adapter system.
- **Setpoint Generation**: Adding a base setpoint and a correction offset.
- **Modular Plant Engineering**: Use in systems where interfaces are consistently mapped via adapters to maximize code reusability and readability.

Comparison with Similar Components
Classic `ADD` components according to IEC 61131-3 typically have direct data inputs (`IN1`, `IN2`...) and event pins (`REQ`, `CNF`). The `ALI_ADD_2` differs in that it encapsulates these channels in adapters (`ALI`). This results in better encapsulation and cleaner structuring in complex 4diac applications, but requires that the connected components also support the `ALI` adapter protocol.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ALI_ADD_2` is a specialized, highly efficient addition component for adapter-based architectures in the 4diac IDE. It combines the standard mathematical functionality of addition with the structural advantages of modern, adapter-based communication paradigms.

ALI_ADD_2_UNGATED

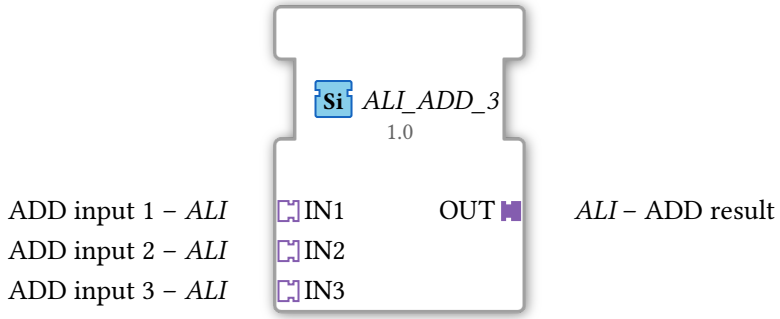
Classic `ADD` components according to IEC 61131-3 typically have direct data inputs (`IN1`, `IN2`...) and event pins (`REQ`, `CNF`). The `ALI_ADD_2_UNGATED` differs in that it encapsulates these channels in adapters (`ALI`). This results in better encapsulation and cleaner structuring in complex 4diac applications, but requires that the connected components also support the `ALI` adapter protocol.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `ALI_ADD_2_UNGATED` is a specialized, highly efficient addition component for adapter-based architectures in the 4diac IDE. It combines the standard mathematical functionality of addition with the structural advantages of modern, adapter-based communication paradigms.

ALI_ADD_3

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALI_ADD_3` is a generic arithmetic block for adding three values. It is based on the IEC 61131-3 standard for arithmetic functions. Instead of classic, separate data and event connections, this block uses unidirectional adapters of type `ALI` to enable structured and clear signal transmission in 4diac-ide.

Interface Structure

Event Inputs

No direct event inputs are available. Control and triggering are implicit via the connected adapters.

Event Outputs

No direct event outputs are available. Events are forwarded via the output adapter.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

The module communicates exclusively via adapter interfaces:

- **Sockets (Input Interfaces):**
- `IN1` (Type: `adapter::types::unidirectional::ALI`): Interface for the first summand (input value 1).
- `IN2` (Type: `adapter::types::unidirectional::ALI`): Interface for the second summand (input value 2).
- `IN3` (Type: `adapter::types::unidirectional::ALI`): Interface for the third addend (input value 3).
- **Plugs (Output Interfaces):**
- `OUT` (Type: `adapter::types::unidirectional::ALI`): Interface for outputting the calculated result.

Functionality

The function block `ALI_ADD_3` performs a standard arithmetic addition. As soon as new values are signaled at the input adapters (`IN1`, `IN2`, `IN3`), the function block calculates the sum using the following formula:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} \tag{2.34}$$

The result and the corresponding update event are then passed on to the subsequent function blocks via the output adapter `OUT`.

Technical Features

- **Generic Implementation:** The function block is declared as a generic type (`GEN_ALI_ADD`). This allows for flexible adaptation to various data types supported by the `ALI` adapter.
- **Use of Adapters:** By encapsulating data and events in unidirectional adapters (`ALI`), the number of necessary connection lines in the 4diac-ide application editor is drastically reduced, resulting in improved clarity.

State Overview

The function block operates purely stateless. There is no internal state machine (ECC). The calculation is purely data- or event-driven: An incoming event at one of the input adapters directly triggers the addition and updating of the output adapter.

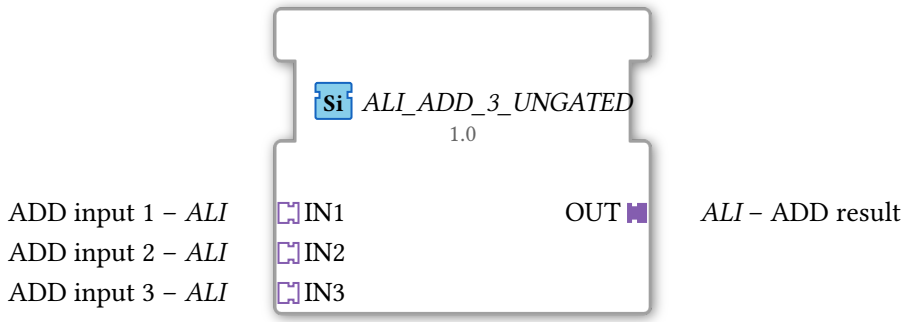
Application Scenarios

- **Measurement Summing:** Summarizing three individual analog measurements (e.g., power consumption of three phases, flow rates from three pipes) into a total value.
- **Average Preparation:** Summing three values for subsequent division by 3 in a subsequent function block.
- **Structured Signal Processing:** Used in complex projects where analog signals need to be standardized and routed clearly via adapter channels.

Comparison with Similar Components

- **Standard ADD (IEC 61131-3):** A standard ADD component uses classic data and event connections. `ALI_ADD_3`, on the other hand, encapsulates these interfaces in adapters, reducing visual complexity in system design.
- **Cascaded Dual Adders:** To add three values with conventional dual adders, two components would have to be connected in series. `ALI_ADD_3` eliminates the need for one component as well as the intermediate instantiation and wiring.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

`ALI_ADD_3` is a compact and efficient auxiliary component for 4diac-ide. Through the consistent use of unidirectional adapters, he makes a significant contribution to the creation of clean, modularized and easily readable control code for processing analog signals.

ALI_ADD_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_ADD_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALI_ADD_3_UNGATED` is a generic arithmetic block for adding three values. It is based on the IEC 61131-3 standard for arithmetic functions. Instead of classic, separate data and event connections, this block uses unidirectional adapters of type `ALI` to enable structured and clear signal transmission in 4diac-ide.

Interface Structure

Event Inputs

No direct event inputs are available. Control and triggering are implicit via the connected adapters.

Event Outputs

No direct event outputs are available. Events are forwarded via the output adapter.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

The module communicates exclusively via adapter interfaces:

- **Sockets (Input Interfaces):**
- `IN1` (Type: `adapter::types::unidirectional::ALI`): Interface for the first summand (input value 1).
- `IN2` (Type: `adapter::types::unidirectional::ALI`): Interface for the second summand (input value 2).
- `IN3` (Type: `adapter::types::unidirectional::ALI`): Interface for the third addend (input value 3).
- **Plugs (Output Interfaces):**
- `OUT` (Type: `adapter::types::unidirectional::ALI`): Interface for outputting the calculated result.

Functionality

The function block `ALI_ADD_3_UNGATED` performs a standard arithmetic addition. As soon as new values are signaled at the input adapters (`IN1`, `IN2`, `IN3`), the function block calculates the sum using the following formula:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} \tag{2.35}$$

The result and the corresponding update event are then passed on to the subsequent function blocks via the output adapter `OUT`.

Technical Features

- **Generic Implementation:** The function block is declared as a generic type (`GEN_ALI_ADD`). This allows for flexible adaptation to various data types supported by the `ALI` adapter.
- **Use of Adapters:** By encapsulating data and events in unidirectional adapters (`ALI`), the number of necessary connection lines in the 4diac-ide application editor is drastically reduced, resulting in improved clarity.

State Overview

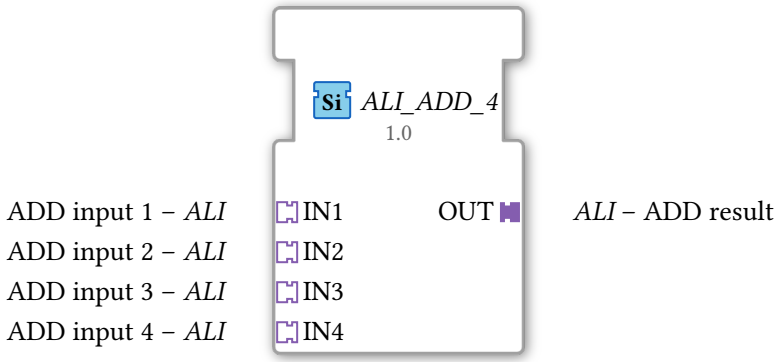
The function block operates purely stateless. There is no internal state machine (ECC). The calculation is purely data- or event-driven: An incoming event at one of the input adapters directly triggers the addition and updating of the output adapter.

Application Scenarios

- **Measurement Summing:** Summarizing three individual analog measurements (e.g., power consumption of three phases, flow rates from three pipes) into a total value.
- **Average Preparation:** Summing three values for subsequent division by 3 in a subsequent function block.
- **Structured Signal Processing:** Used in complex projects where analog signals need to be standardized and routed clearly via adapter channels.

Comparison with Similar Components

- **Standard ADD (IEC 61131-3):** A standard ADD component uses classic data and event connections. `ALI_ADD_3_UNGATED`, on the other hand, encapsulates these interfaces in adapters, reducing visual complexity in system design.
- **Cascaded Dual Adders:** To add three values with conventional dual adders, two components would have to be connected in series. `ALI_ADD_3_UNGATED` eliminates the need for one component as well as the intermediate instantiation and wiring.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

`ALI_ADD_3_UNGATED` is a compact and efficient auxiliary component for 4diac-ide. Through the consistent use of unidirectional adapters, he makes a significant contribution to the creation of clean, modularized and easily readable control code for processing analog signals.

ALI_ADD_4

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALI_ADD_4` is a generic arithmetic function block according to the IEC 61131-3 standard. Its main task is to calculate the sum of four input values. Unlike classic arithmetic blocks that work with elementary data types and standard event inputs/outputs, this block uses unidirectional adapter connections of type `ALI` (Analog Line Interface). This enables encapsulated and clear signal transmission of data and the associated trigger events within the 4diac-ide.

Interface Structure

Event Inputs

The block does not have direct event inputs. Event control is handled entirely via the connected adapters.

Event Outputs

This function block does not have direct event outputs. Events are forwarded via the output adapter.

Data Inputs

This function block does not have direct data inputs. Data is transferred via the input adapters (sockets).

Data Outputs

This function block does not have direct data outputs. Data is output via the output adapter (plug).

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::ALI`): First addend for addition.
- **IN2** (Type: `adapter::types::unidirectional::ALI`): Second addend for addition.
- **IN3** (Type: `adapter::types::unidirectional::ALI`): Third addend for the addition.
- **IN4** (Type: `adapter::types::unidirectional::ALI`): Fourth addend for the addition.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::ALI`): Output of the calculated addition result.

Functionality

As soon as a new event with an updated data value is received at one of the input adapters (`IN1` to `IN4`), the function block performs the mathematical addition of the four values:

$$\text{OUT} = \text{IN1} + \text{IN2} + \text{IN3} + \text{IN4} \tag{2.36}$$

The result of the calculation is immediately passed to the output adapter `OUT`, and a corresponding output event is triggered to inform subsequent function blocks in the control flow.

–

Technical Features

- **Generic Class:** The function block is based on the generic base class `GEN_ALI_ADD` (attribute: `eclipse4diac::core::GenericClassName`).
- **Adapter Coupling:** By using unidirectional adapters (`ALI`), data and events are bundled into a single connection. This drastically reduces the visual complexity (the "cable clutter") in the 4diac-ide Function Block Diagram (FBD) editor.
- **IEC 61131-3 Compliance:** Complies with the guidelines for standard arithmetic functions.

State Overview

The `ALI_ADD_4` function block is a stateless (combinatorial) function block. It does not store any internal states or historical values between calculation cycles. Each calculation is based solely on the values currently present at the input adapters at the time of the trigger event.

Application Scenarios

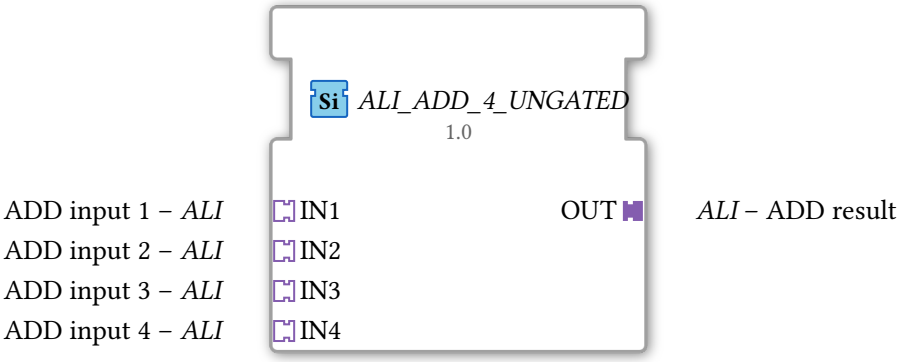
- **Measurement Consolidation:** Summing four analog measurements (e.g., partial load currents, flow rates, or individual power outputs) into a single total value.
- **Mixing Processes:** Calculating total weights or volumes in recipe systems where four components are combined.
- **Signal Processing:** Structured preprocessing of sensor signals in modular control architectures that consistently rely on adapter connections.

–

Comparison with Similar Components

- **Standard ADD Component (IEC 61131-3):** A standard ADD component uses elementary data types (e.g., `REAL`, `INT`) and separate event ports (`REQ` / `CNF`). `ALI_ADD_4`, on the other hand, encapsulates these interfaces in adapters, which increases reusability and clarity.
- **ALI_ADD_2 / ALI_ADD_3:** These function blocks operate on the same principle but are designed for adding only two or three input signals, respectively.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ALI_ADD_4` function block offers an elegant and clean way to add four analog values within an adapter-based 4diac application. By encapsulating data and event channels in `ALI` adapters, it supports the creation of modular, clear, and easily maintainable control software.

ALI_ADD_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_ADD_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `ALI_ADD_4_UNGATED` function block offers an elegant and clean way to add four analog values within an adapter-based 4diac application. By encapsulating data and event channels in `ALI` adapters, it supports the creation of modular, clear, and easily maintainable control software.

ALI_DIV_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALI_DIV_2` is a generic arithmetic function block for IEC 61499, designed for performing division operations. The unique feature of this block is the use of unidirectional adapters (`ALI`) instead of traditional data and event interfaces. This enables a modular and clear structuring of data flows within the 4diac IDE.

Interface Structure

Event Inputs
This function block does not have direct event inputs. Execution is controlled via the connected adapters.

Event Outputs
This function block does not have direct event outputs. Events are forwarded via the output adapter.

Data Inputs
This function block has no direct data inputs.

Data Outputs
This function block has no direct data outputs.

Adapters

Sockets (Input Adapters)
- **IN1** (Type: `adapter::types::unidirectional::ALI`): The dividend (numerator) of the division.
- **IN2** (Type: `adapter::types::unidirectional::ALI`): The divisor (denominator) of the division.

Plugs (Output Adapters)
- **OUT** (Type: `adapter::types::unidirectional::ALI`): The result of the mathematical division ($OUT = IN1/IN2$).

Functionality
The function block `ALI_DIV_2` calculates the quotient of the values provided via the input adapters `IN1` and `IN2`. The result is passed to the output adapter `OUT`.

Since it is a generic function block (`GEN_ALI_DIV`), the block can flexibly work with various data types, provided the `ALI` adapters support them (e.g., integers or floating-point numbers). The actual calculation is triggered by the events defined in the adapter. As soon as new data is present at the inputs and a corresponding trigger signal is received via the adapter interface, the division is performed and the result is provided at the output.

Because it is a generic function block (`GEN_ALI_DIV`), the block can flexibly work with different data types, provided the `ALI` adapters support them (e.g., integers or floating-point numbers). The actual calculation is triggered by the events defined in the adapter. As soon as new data is present at the inputs and a corresponding trigger signal is received via the adapter interface, the division is performed and the result is provided at the output.

... ## Technical Features

- **Generic Implementation:** By assigning it to the generic class `GEN_ALI_DIV`, the function block is not limited to a fixed data type (such as `REAL` or `INT`). It dynamically adapts to the type definitions of the connected adapters.
- **Adapter Encapsulation:** The use of unidirectional `ALI` adapters drastically reduces cabling in the 4diac IDE, as data and associated trigger events are bundled and transmitted in a single connection.
- – **Division by Zero:** During implementation and in the runtime environment, care must be taken to handle the value of `0` at input `IN2` to prevent system crashes (e.g., by default returning `NaN`, infinity, or by intercepting the error via adapter error handling).

State Overview
Since `ALI_DIV_2` is a data- and event-driven block, it does not have a complex internal state machine (no classic ECC). It behaves like a functional block:

1. **Waiting for Trigger:** The block waits for an update event at input adapters `IN1` or `IN2`.
2. **Calculation:** Upon signal reception, the data is read and divided
3. **Output:** The result is assigned to `OUT`, and the corresponding event is signaled via the output adapter.

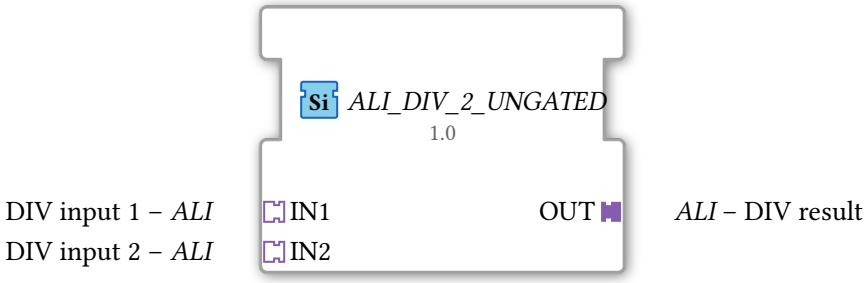
Application Scenarios
- **Signal Normalization and Scaling:** Division of sensor values by constant factors for unit conversion within an adapter-based control architecture.

- **Ratio Calculation:** Determination of ratios (e.g., fuel-air mixture, flow ratios) in process engineering plants.
- **Distributed Control Systems:** Use in complex IEC 61499 applications where a clean, modular signal flow is enforced via adapters.

Comparison with Similar Function Blocks

Compared to a standard `DIV` function block according to IEC 61131-3 or IEC 61499, which uses classic data pins (`IN1`, `IN2`, `OUT`) and separate event pins (`REQ`, `CNF`), the `ALI_DIV_2` offers a significantly cleaner interface in the function block diagram through the use of adapters. It is particularly suitable for advanced software architectures that consistently leverage the advantages of adapters for structuring.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ALI_DIV_2` is a highly efficient and flexible division block for modern IEC 61499 applications. Through the consistent use of generic types and the `ALI` adapter concept, it significantly contributes to the clarity, reusability, and maintainability of control software in the 4diac IDE.

ALI_DIV_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_DIV_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

ALI_MUL_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALI_MUL_2` is used to perform an arithmetic multiplication of two values. It is a generic function block designed for a clean and modular architecture in IEC 61499 systems. Instead of classic discrete data and event ports, this block uses unidirectional adapters to transmit control events and data values in a bundled manner.

Interface Structure

Event Inputs

There are no direct event inputs. Event control is integrated into the input adapters.

Event Outputs

There are no direct event outputs. Event control is integrated into the output adapter.

Data Inputs

There are no direct data inputs. Data transmission occurs via the adapters.

Data Outputs

There are no direct data outputs. Data transmission occurs via the output adapter.

Adapters

- **Sockets (Input Adapters):**
- `IN1` (Type: `adapter::types::unidirectional::ALI`): First input for multiplication (multiplicand).
- `IN2` (Type: `adapter::types::unidirectional::ALI`): Second input for multiplication (multiplier).
- **Plugs (Output Adapters):**
- `OUT` (Type: `adapter::types::unidirectional::ALI`): Output for the result of the multiplication (product).

Functionality

The function block `ALI_MUL_2` multiplies the values provided via the adapter sockets `IN1` and `IN2`. As soon as a corresponding trigger event is signaled via the input adapters, the block performs the calculation:

$$\mathrm{OUT} = \mathrm{IN1} \times \mathrm{IN2} \tag{2.38}$$

The calculated result and the associated output event are then forwarded to subsequent blocks via the output plug `OUT`.

- **Generic Nature:** The function block is declared as `GEN_ALI_MUL` via the attribute `GenericClassName`. This allows for flexible handling of various data types specified by the higher-level system or the adapter type used.
- **Adapter Coupling:** By using the unidirectional adapter type `ALI`, data and trigger events are bundled in a single connection, significantly minimizing wiring effort in the development environment.

Technical Features

Since this is a purely data-flow and adapter-based function block, it does not have a complex internal state machine (Execution Control Chart - ECC). Execution is event-driven and directly coupled to the triggers received via the adapters.

State Overview

Adapter Coupling: ## Application Scenarios

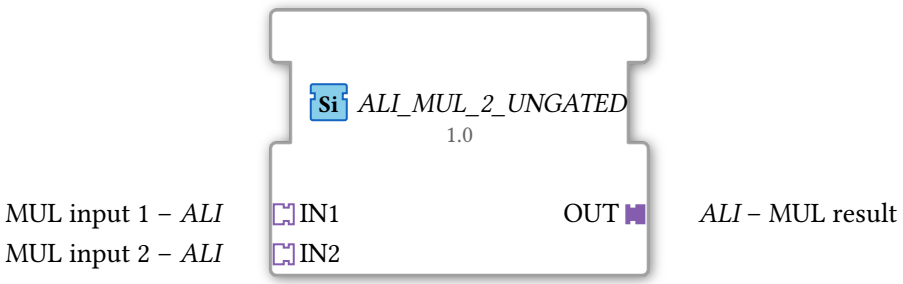
Application Scenarios

- **Measurement Scaling:** Multiplication of sensor values by calibration or scaling factors.
- **Power Calculation:** Determination of physical quantities such as electrical power ($P = U \times I$) in adapter-based control networks.
- **Compact Computing Networks:** Use in complex mathematical calculations where the visual clarity of the control diagram must be maintained through the use of adapters.

Comparison with Similar Function Blocks

Compared to classic mathematical components of IEC 61131-3 (such as a standard `MUL` component with discrete `REQ` / `CNF` events and separate data lines), the `ALI_MUL_2` eliminates the need for manual linking of event and data paths. This prevents errors in event data mapping and results in a significantly cleaner and more readable application diagram in 4diac-ide.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ALI_MUL_2` is a modern and efficient function block for multiplication. Thanks to the consistent use of unidirectional adapters, it is ideally suited for service-oriented and modular control systems where clarity and ease of maintenance are paramount.

ALI_MUL_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_MUL_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. ALI_MUL_3

No image available. The function block is graphically represented with three input sockets (IN1, IN2, IN3) and one output plug (OUT).

• – ◦ • – ◦ • – ◦ •

Introduction

The `ALI_MUL_3` function block is a generic arithmetic block for the 4diac IDE, used for multiplying three input values. It is characterized by the fact that the inputs and outputs are not implemented via classic data and event pins, but entirely via unidirectional adapters of type `ALI`. This enables structured, modular, and clear encapsulation of signal and data flows in IEC 61499 applications.

Since this functional block is entirely based on adapter technology, it has no direct, traditional event or data channels at the main level.

Interface Structure

Event Inputs

No direct event inputs are available (signal processing is handled by the adapters).

Event Outputs

No direct event outputs are available (signal forwarding is handled by the output adapter).

Data Inputs

No direct data inputs are available.

Data Outputs

No direct data outputs are available.

Adapters

Sockets (Inputs)

- **IN1** (Type: `adapter::types::unidirectional::ALI`): The first factor (multiplicand 1) for arithmetic multiplication.

- **IN3** (Type: `adapter::types::unidirectional::ALI`): The third factor (multiplicand 3) for arithmetic multiplication.

Plugs (Outputs)

- **OUT** (Type: `adapter::types::unidirectional::ALI`): The result of the multiplication (product).

Functionality

The primary task of `ALI_MUL_3` is to calculate the product of three values:

$$\text{OUT} = \text{IN1} \times \text{IN2} \times \text{IN3} \tag{2.40}$$

The calculation timing and the transfer of values are controlled by the `ALI` adapters. As soon as a corresponding trigger event is signaled via the input adapters, the function block reads the values from sockets `IN1`, `IN2`, and `IN3`, calculates the mathematical product, and provides the result at plug `OUT`, whereupon a corresponding output event is initiated.

- **Generic Building Block:** The attribute `GenericClassName` with the value `'GEN_ALI_MUL'` makes the function block data-type independent. It can be used for various numeric data types (e.g., `INT`, `REAL`, `LREAL`) depending on the specific `ALI` adapter used.
- **Clean Design:** The use of adapters significantly reduces wiring complexity in the function block diagram (FBD) because control and data flow are combined in a single connection.
- – **Unidirectional Adapters:** Since this is the `adapter::types::unidirectional` package, data and triggers flow directly from the sockets (`IN1`-`IN3`) to the plug (`OUT`).

The function block behaves like a classic, stateless mathematical operator (combinatorial behavior):

- **Readiness:** The block waits for incoming update events at the adapters `IN1`, `IN2`, or `IN3`.
- **Calculation:** When triggered, the multiplication is performed.
- – **Output:** The result is directly passed to output `OUT`, triggering the subsequent function block.

- **Calculation of Physical Quantities:** Determining volumes (length × width × height) or three-dimensional scales in factory automation.
- **Cascaded Gain Factors:** Multiplication of three different gain factors or correction values in control loops (e.g., sensor value × calibration factor × scaling factor).
- **Signal Processing:** Combining multiple weighting factors in process monitoring.
-

Compared to a standard IEC 61131-3 `MUL` component:

- **Classic `MUL` block:** Requires explicit `REQ` and `CNF` events, as well as individual data pins for each operand. This quickly leads to complex schematics with multiple inputs.
- **`ALI_MUL_3`:** Consolidates the interfaces into four clearly arranged adapter connections. Furthermore, it is designed for exactly three inputs, eliminating the need for an intermediate stage (cascading two 2x multipliers).

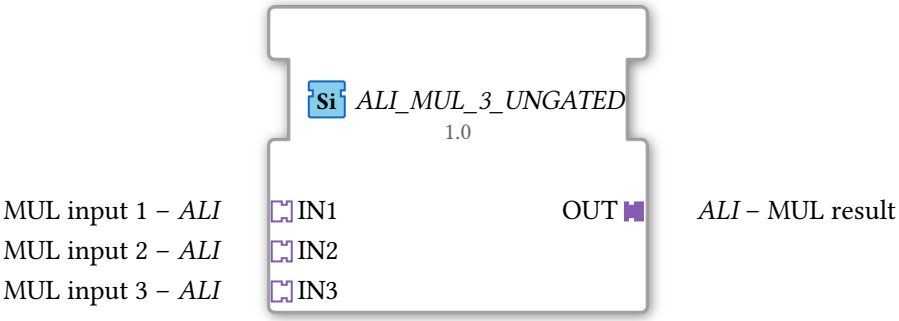
The `ALI_MUL_3` is a modern and highly efficient function block for mathematical operations in the 4diac environment. Through the consistent use of unidirectional adapters, it promotes clean, modularized software design and is ideally suited for complex calculations with three input variables.

Technical Features

State Overview

Application Scenarios

Comparison with Similar Function Blocks



Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

ALI_MUL_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_MUL_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

No image available. The function block is graphically represented with three input sockets (IN1, IN2, IN3) and one output plug (OUT).

• – ◦ • – ◦ • – ◦ •

Introduction

The `ALI_MUL_3_UNGATED` function block is a generic arithmetic block for the 4diac IDE, used for multiplying three input values. It is characterized by the fact that the inputs and outputs are not implemented via classic data and event pins, but entirely via unidirectional adapters of type `ALI`. This enables structured, modular, and clear encapsulation of signal and data flows in IEC 61499 applications.

Since this functional block is entirely based on adapter technology, it has no direct, traditional event or data channels at the main level.

Interface Structure

Event Inputs

No direct event inputs are available (signal processing is handled by the adapters).

Event Outputs

No direct event outputs are available (signal forwarding is handled by the output adapter).

Data Inputs

No direct data inputs are available.

Data Outputs

No direct data outputs are available.

Adapters

Sockets (Inputs)

- **IN1** (Type: `adapter::types::unidirectional::ALI`): The first factor (multiplicand 1) for arithmetic multiplication.
- **IN3** (Type: `adapter::types::unidirectional::ALI`): The third factor (multiplicand 3) for arithmetic multiplication.

Plugs (Outputs)

- **OUT** (Type: `adapter::types::unidirectional::ALI`): The result of the multiplication (product).

Functionality

The primary task of `ALI_MUL_3_UNGATED` is to calculate the product of three values:

$$\text{OUT} = \text{IN1} \times \text{IN2} \times \text{IN3} \tag{2.41}$$

The calculation timing and the transfer of values are controlled by the `ALI` adapters. As soon as a corresponding trigger event is signaled via the input adapters, the function block reads the values from sockets `IN1`, `IN2`, and `IN3`, calculates the mathematical product, and provides the result at plug `OUT`, whereupon a corresponding output event is initiated.

- **Generic Building Block:** The attribute `GenericClassName` with the value `'GEN_ALI_MUL'` makes the function block data-type independent. It can be used for various numeric data types (e.g., `INT`, `REAL`, `LREAL`) depending on the specific `ALI` adapter used.
- **Clean Design:** The use of adapters significantly reduces wiring complexity in the function block diagram (FBD) because control and data flow are combined in a single connection.
- – **Unidirectional Adapters:** Since this is the `adapter::types::unidirectional` package, data and triggers flow directly from the sockets (`IN1`-`IN3`) to the plug (`OUT`).

The function block behaves like a classic, stateless mathematical operator (combinatorial behavior):

- **Readiness:** The block waits for incoming update events at the adapters `IN1`, `IN2`, or `IN3`.
- **Calculation:** When triggered, the multiplication is performed.
- – **Output:** The result is directly passed to output `OUT`, triggering the subsequent function block.

- **Calculation of Physical Quantities:** Determining volumes (length × width × height) or three-dimensional scales in factory automation.
- **Cascaded Gain Factors:** Multiplication of three different gain factors or correction values in control loops (e.g., sensor value × calibration factor × scaling factor).
- **Signal Processing:** Combining multiple weighting factors in process monitoring.
-

Compared to a standard IEC 61131-3 `MUL` component:

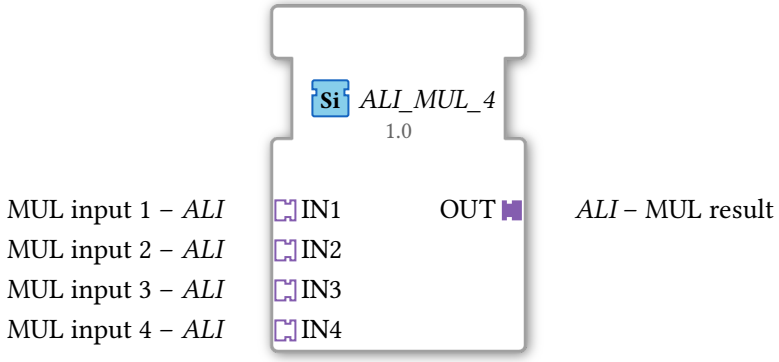
- **Classic `MUL` block:** Requires explicit `REQ` and `CNF` events, as well as individual data pins for each operand. This quickly leads to complex schematics with multiple inputs.
- **`ALI_MUL_3_UNGATED`:** Consolidates the interfaces into four clearly arranged adapter connections. Furthermore, it is designed for exactly three inputs, eliminating the need for an intermediate stage (cascading two 2x multipliers).

The `ALI_MUL_3_UNGATED` is a modern and highly efficient function block for mathematical operations in the 4diac environment. Through the consistent use of unidirectional adapters, it promotes clean, modularized software design and is ideally suited for complex calculations with three input variables.

Technical Features

State Overview

Application Scenarios



Comparison with Similar Function Blocks

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

ALI_MUL_4

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALI_MUL_4` is used to perform an arithmetic multiplication of four input values. It is a generic function block (Generic FB) based on the use of unidirectional adapters (`ALI`). By using adapters instead of classic data and event pins, the wiring in 4diac-ide is made clearer and more modular.

Interface Structure

Event Inputs

This function block has no direct event inputs. Control and triggering are handled via the connected adapters.

Event Outputs

This function block has no direct event outputs. Events are forwarded via the output adapter.

Data Inputs

There are no direct data inputs. Data is transferred via the input adapters.

Data Outputs

There are no direct data outputs. The result is provided via the output adapter.

Adapters

Sockets (Input Adapters)

The sockets serve as inputs for the values to be multiplied.

- **IN1** (Type: `adapter::types::unidirectional::ALI`): First factor for multiplication.
- **IN2** (Type: `adapter::types::unidirectional::ALI`): Second factor for multiplication.
- **IN3** (Type: `adapter::types::unidirectional::ALI`): Third factor for multiplication.
- **IN4** (Type: `adapter::types::unidirectional::ALI`): Fourth factor for multiplication.

Plugs (Output Adapters)

The plug outputs the calculated result.

- **OUT** (Type: `adapter::types::unidirectional::ALI`): The calculated product of the four input adapters.

Functionality

As soon as the input values at adapters `IN1` to `IN4` change, or a corresponding update event is triggered via the adapters, the function block internally multiplies the four values according to the following mathematical principle:

$$OUT = \text{IN1} \times \text{IN2} \times \text{IN3} \times \text{IN4} \tag{2.42}$$

The result and the associated update event are then output via the output adapter `OUT`.

–

Technical Features

- **Generic Function Block:** The attribute `GenericClassName` with the value `GEN_ALI_MUL` makes the function block data type-independent. Depending on the implementation of the `ALI` adapters, it can process various numeric data types (e.g., `INT`, `REAL`, `LREAL`).
- **Adapter Coupling:** By using unidirectional `ALI` adapters, clean encapsulation of data and trigger events is achieved, reducing complexity in system design.

State Overview

The function block is stateless (stateless, purely combinatorial processing). There are no internal state machines (Execution Control Chart / ECC). The output values depend directly on the values applied to the input adapters.

Application Scenarios

- **Scaling and Weighting:** Calculation of composite scaling factors in process automation.
- **Volume and Mass Calculation:** Continuous calculation of physical quantities (e.g., length × width × height × density).
- **Multi-Stage Gain Control:** Cascaded signal amplification in measurement and control technology.

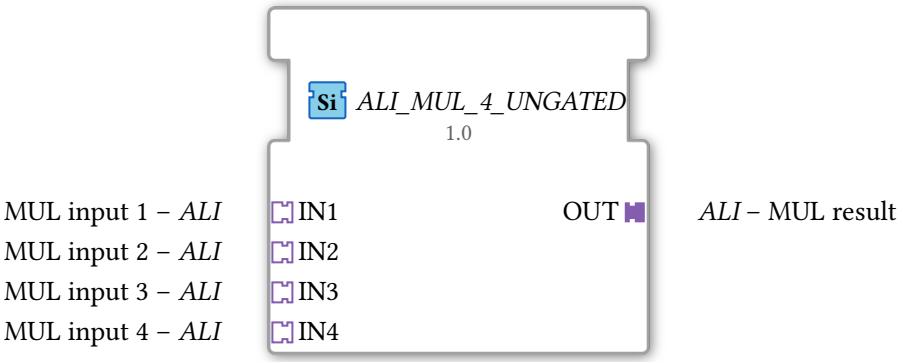
–

Comparison with Similar Function Blocks

Compared to a standard multiplication function block (`MUL`) according to IEC 61131-3, which typically has only two direct data inputs, `ALI_MUL_4` offers:

1. Direct multiplication of **four** factors in a single step (fewer function blocks required on the control canvas).
2. The use of adapters instead of individual wiring significantly improves the overall clarity of the program.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ALI_MUL_4` is an efficient auxiliary module for arithmetic calculations in complex 4diac systems. It is particularly suitable for applications where multiple values need to be multiplied compactly and systematically without cluttering the user interface with countless connection lines.

ALI_MUL_4_UNGATED

i UNGATED variant: This block is the ungated version of `ALI_MUL_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). ALI_SUB_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block (FB) `ALI_SUB_2` is a generic arithmetic function block for performing a subtraction. It conforms to the IEC 61131-3 standard for standard arithmetic functions. The block uses adapter connections (`ALI` - Arithmetic Logical Interface) to receive input data and output the result of the subtraction.

Interface Structure

Event Inputs

This function block does not have direct event inputs. Control and event processing are implemented via the connected adapters.

Event Outputs

This function block does not have direct event outputs. Event forwarding occurs via the output adapters.

Data Inputs

There are no direct data inputs. Data transmission is encapsulated via the input adapters.

Data Outputs

There are no direct data outputs. The result is provided via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::ALI`): The first input (minuend) for subtraction calculation.
- **IN2** (Type: `adapter::types::unidirectional::ALI`): The second input (subtrahend) for subtraction calculation.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::ALI`): The output (difference) of the calculation ($OUT = IN1 - IN2$).

Functionality

The function block `ALI_SUB_2` performs a mathematical subtraction. As soon as values are received or updated via the input adapters, the function block calculates the difference:

$$\text{OUT} = \text{IN1} - \text{IN2} \tag{2.44}$$

The result is immediately passed to the output adapter `OUT`. Since this is a generic function block based on the internal class `GEN_ALI_SUB`, the function block can flexibly adapt to the data types defined in the adapter.

Technical Features

- **Generic Implementation:** The function block uses the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_ALI_SUB'`. This allows for flexible handling of various data types defined by the adapter interfaces.
- **Encapsulation by Adapters:** By using unidirectional `ALI` adapters, data and the associated control events (such as update events) are bundled in a single connection. This reduces the number of visible connection lines in the 4diac application editor and improves clarity.

–

State Overview

The function block behaves in a purely stateless and reactive manner. There is no internal state machine (Execution Control Chart - ECC). Processing is triggered directly by incoming data changes or events on the input adapters `IN1` and `IN2`.

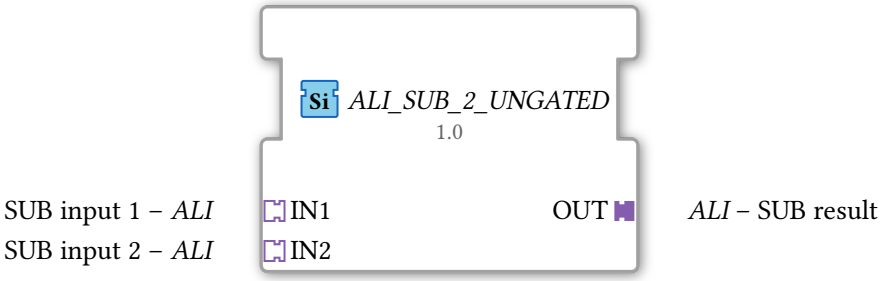
Application Scenarios

- **Signal Processing and Scaling:** Calculation of deviations, such as the difference between a setpoint and an actual value (control deviation) in control applications.
- **Offset Compensation:** Subtraction of zero-point errors or offsets from sensor data fed into the system via adapter structures.
- **Modular System Architectures:** Use in complex, distributed control systems where a structured and transparent data flow is required through the use of adapters.
-

Comparison with Similar Function Blocks

Compared to the standard subtraction function block `SUB` from the IEC 61131-3 library, `ALI_SUB_2` does not require explicit wiring of data types (like `INT`, `REAL`) and control events (like `REQ` / `CNF`). While the standard `SUB` function block has discrete inputs and outputs, `ALI_SUB_2` combines these in `ALI` adapters, which significantly improves reusability and clarity in system design.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ALI_SUB_2` is a versatile and easy-to-maintain function block for arithmetic subtraction in 4diac. Thanks to the consistent use of adapters, it integrates perfectly into service-oriented and modular control architectures and minimizes wiring effort in the development tool.

ALI_SUB_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_SUB_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `ALI_SUB_2_UNGATED` is a versatile and easy-to-maintain function block for arithmetic subtraction in 4diac. Thanks to the consistent use of adapters, it integrates perfectly into service-oriented and modular control architectures and minimizes wiring effort in the development tool.

ALR_ADD_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALR_ADD_2` is a generic, arithmetic addition block for the 4diac IDE, compliant with the IEC 61131-3 standard. It is used to mathematically add two input values. The special feature of this block lies in the use of unidirectional adapters (`ALR`), which encapsulate both the data and the associated control logic to enable clean and modular signal processing.

Interface Structure

Event Inputs
This function block does not have direct, dedicated event inputs. Event control is handled via the adapters.

Event Outputs
This function block does not have direct, dedicated event outputs. Event control is handled via the adapters.

Data Inputs
No direct data inputs are defined, as data transfer is handled entirely via the adapters.

Data Outputs
No direct data outputs are defined, as the result is provided via the output adapter.

Adapters

Sockets (Input Adapters)
- **IN1** (Type: `adapter::types::unidirectional::ALR`): The first addend of the addition operation.
- **IN2** (Type: `adapter::types::unidirectional::ALR`): The second addend of the addition operation.

Plugs (Output Adapters)
- **OUT** (Type: `adapter::types::unidirectional::ALR`): The result of the addition ($OUT = IN1 + IN2$).

Functionality
The `ALR_ADD_2` reads the values via the two input adapters `IN1` and `IN2`. As soon as a corresponding event signals via the adapters that new data is available, the function block performs the addition:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} \tag{2.46}$$

The calculated result is then forwarded via the output adapter `OUT`, along with the corresponding output event, to subsequent function blocks. Since it is a generic function block (`GEN_ALR_ADD`), it can flexibly work with various numeric data types supported by the ALR adapter interface.

Technical Features
- **Generic Type (`GEN_ALR_ADD`):** The function block is implemented in a data-type-independent manner and adapts to the data types defined in the ALR adapter.
- **Adapter Encapsulation:** By using unidirectional adapters, the number of visible connections in the 4diac IDE's control flow diagram is drastically reduced, thus improving the clarity and maintainability of the overall system.
- **Compliance:** Complies with the mathematical standards according to IEC 61131-3 for standard arithmetic functions.
-

State Overview
Since the logic of this function block operates purely data- and event-driven via the adapters, the block does not have a complex internal state machine (ECC). It reacts immediately to incoming data changes/ events at sockets `IN1` and `IN2` and forwards the result to plug `OUT`.

–

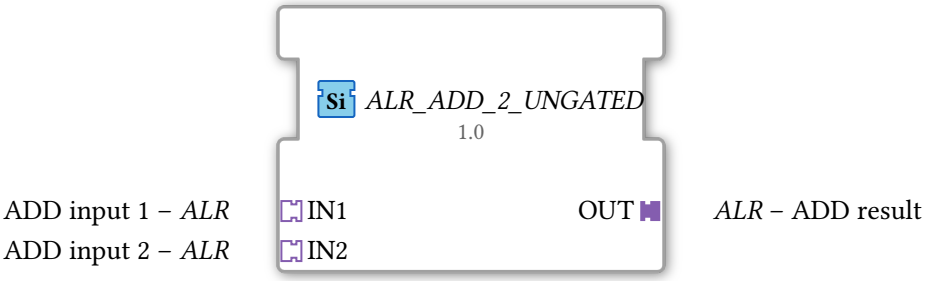
Application Scenarios
- **Signal Combining:** Addition of two analog sensor values (e.g., determining a total volume flow rate from two individual flow meters).
- **Setpoint Offset Calculation:** Applying a correction offset to a base setpoint in process engineering plants.
- **Compact Programming:** Use in complex control loops where clear routing via adapters is preferred.

Comparison with Similar Function Blocks

Compared to a standard `ADD` function block (which has separate event inputs like `REQ`, event outputs like `CNF`, and classic data pins), the `ALR_ADD_2` completely omits these classic pins. It replaces them with standardized `ALR` adapters. This significantly simplifies wiring in the 4diac IDE, as event and data are bundled in a single connection.

–

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ALR_ADD_2` is a modern and highly efficient variant of the classic addition function block. It is ideally suited for service-oriented architectures and distributed control systems within the 4diac environment, where clarity and standardized adapter interfaces are paramount.

ALR_ADD_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALR_ADD_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALR_ADD_2_UNGATED` is a generic, arithmetic addition block for the 4diac IDE, compliant with the IEC 61131-3 standard. It is used to mathematically add two input values. The special feature of this block lies in the use of unidirectional adapters (`ALR`), which encapsulate both the data and the associated control logic to enable clean and modular signal processing.

Interface Structure

Event Inputs

This function block does not have direct, dedicated event inputs. Event control is handled via the adapters.

Event Outputs

This function block does not have direct, dedicated event outputs. Event control is handled via the adapters.

Data Inputs

No direct data inputs are defined, as data transfer is handled entirely via the adapters.

Data Outputs

No direct data outputs are defined, as the result is provided via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::ALR`): The first addend of the addition operation.
- **IN2** (Type: `adapter::types::unidirectional::ALR`): The second addend of the addition operation.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::ALR`): The result of the addition ($OUT = IN1 + IN2$).

Functionality

The `ALR_ADD_2_UNGATED` reads the values via the two input adapters `IN1` and `IN2`. As soon as a corresponding event signals via the adapters that new data is available, the function block performs the addition:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} \tag{2.47}$$

The calculated result is then forwarded via the output adapter `OUT`, along with the corresponding output event, to subsequent function blocks. Since it is a generic function block (`GEN_ALR_ADD`), it can flexibly work with various numeric data types supported by the ALR adapter interface.

Technical Features

- **Generic Type (`GEN_ALR_ADD`):** The function block is implemented in a data-type-independent manner and adapts to the data types defined in the ALR adapter.
- **Adapter Encapsulation:** By using unidirectional adapters, the number of visible connections in the 4diac IDE's control flow diagram is drastically reduced, thus improving the clarity and maintainability of the overall system.
- **Compliance:** Complies with the mathematical standards according to IEC 61131-3 for standard arithmetic functions.
-

State Overview

Since the logic of this function block operates purely data- and event-driven via the adapters, the block does not have a complex internal state machine (ECC). It reacts immediately to incoming data changes/events at sockets `IN1` and `IN2` and forwards the result to plug `OUT`.

–

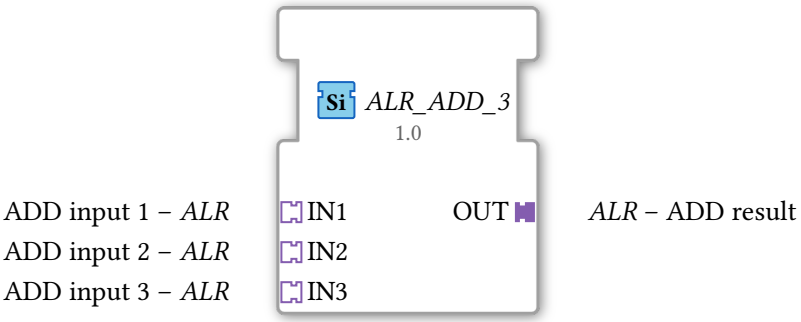
Application Scenarios

- **Signal Combining:** Addition of two analog sensor values (e.g., determining a total volume flow rate from two individual flow meters).
- **Setpoint Offset Calculation:** Applying a correction offset to a base setpoint in process engineering plants.
- **Compact Programming:** Use in complex control loops where clear routing via adapters is preferred.

Comparison with Similar Function Blocks

Compared to a standard `ADD` function block (which has separate event inputs like `REQ`, event outputs like `CNF`, and classic data pins), the `ALR_ADD_2_UNGATED` completely omits these classic pins. It replaces them with standardized `ALR` adapters. This significantly simplifies wiring in the 4diac IDE, as event and data are bundled in a single connection.

–



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `ALR_ADD_2_UNGATED` is a modern and highly efficient variant of the classic addition function block. It is ideally suited for service-oriented architectures and distributed control systems within the 4diac environment, where clarity and standardized adapter interfaces are paramount.

ALR_ADD_3

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALR_ADD_3` is a generic arithmetic block for the 4diac IDE, used to add three input values. It conforms to the standard arithmetic functions according to IEC 61131-3, but uses an adapter-based interface design. Instead of individual data and event pins, this block uses unidirectional adapters to enable clean encapsulation and clearer wiring within the application.

Interface Structure

Event Inputs

No direct event inputs are available. Event-based control is handled internally via the adapters.

Event Outputs

No direct event outputs are available. Event forwarding is handled via the output adapter.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Interfaces)

- **IN1** (Type: `adapter::types::unidirectional::ALR`): First addend of the addition operation.
- **IN2** (Type: `adapter::types::unidirectional::ALR`): Second addend of the addition operation.
- **IN3** (Type: `adapter::types::unidirectional::ALR`): Third addend of the addition operation.

Plugs (Output Interfaces)

- **OUT** (Type: `adapter::types::unidirectional::ALR`): Output adapter that provides the result of the addition (`IN1 + IN2 + IN3`) and the associated trigger event.

Functionality

This function block adds the values provided via the three input adapters (`IN1`, `IN2`, and `IN3`).

As soon as a new event or value is registered at one of the input adapters, the function block performs the calculation according to the following scheme:

$$OUT = IN1 + IN2 + IN3 \tag{2.48}$$

The result is immediately passed to the output adapter `OUT`, and a corresponding update event is triggered to initiate subsequent function blocks in the data flow.

Technical Features

- **Generic Function Block:** The attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_ALR_ADD'` makes the function block data type-independent (generic). It can therefore work flexibly with various numeric data types (e.g., INT, REAL, LREAL), provided the adapter type used, `ALR`, supports them.
- **Adapter Coupling:** Using adapters instead of traditional data and event pins drastically reduces the number of visible connection lines in the 4diac Application Editor. This significantly improves the readability of complex control diagrams.

State Overview

Since `ALR_ADD_3` is a mathematical, data-flow-oriented function block, it does not have a complex internal state machine (ECC). Execution is purely reactive (event-driven via the input adapters).

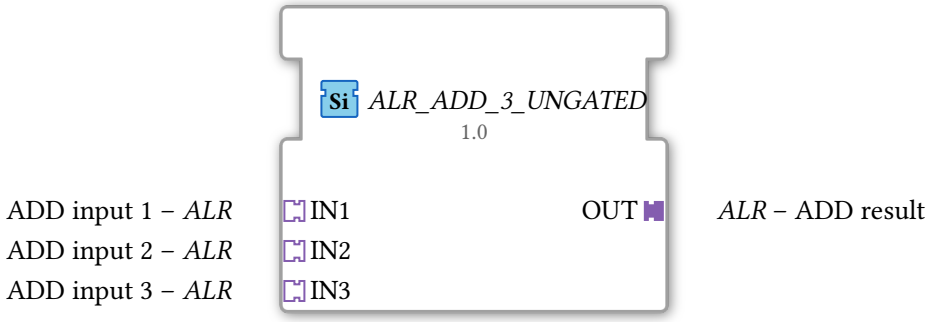
Application Scenarios

- **Measurement Summing:** Adding three analog partial flows to determine the total flow in an energy distribution system.
- **Mixing Calculations:** Combining three flow rates in a process plant to calculate the total inflow.
- **Setpoint Generation:** Calculating an overall setpoint from a base value, a correction value, and an offset.

Comparison with Similar Components

- **Standard `ADD` (IEC 61131-3):** The classic `ADD` component uses separate pins for data and events (REQ/CNF). In contrast, `ALR_ADD_3` combines these signals in adapters, increasing modularity and reusability in cross-project designs.
- **`ALR_ADD_2`:** A similar adapter-based component, but it only supports two inputs. `ALR_ADD_3` eliminates cascading when adding exactly three values, thus saving additional memory and computational effort.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ALR_ADD_3` is a flexible and high-performance component for adding three values in 4diac environments. Through its generic design and the consistent use of unidirectional adapters, it makes a significant contribution to the clarity, structuring and maintainability of modern, distributed control programs.

ALR_ADD_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALR_ADD_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALR_ADD_3_UNGATED` is a generic arithmetic block for the 4diac IDE, used to add three input values. It conforms to the standard arithmetic functions according to IEC 61131-3, but uses an adapter-based interface design. Instead of individual data and event pins, this block uses unidirectional adapters to enable clean encapsulation and clearer wiring within the application.

Interface Structure

Event Inputs

No direct event inputs are available. Event-based control is handled internally via the adapters.

Event Outputs

No direct event outputs are available. Event forwarding is handled via the output adapter.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Interfaces)

- **IN1** (Type: `adapter::types::unidirectional::ALR`): First addend of the addition operation.
- **IN2** (Type: `adapter::types::unidirectional::ALR`): Second addend of the addition operation.
- **IN3** (Type: `adapter::types::unidirectional::ALR`): Third addend of the addition operation.

Plugs (Output Interfaces)

- **OUT** (Type: `adapter::types::unidirectional::ALR`): Output adapter that provides the result of the addition (`IN1 + IN2 + IN3`) and the associated trigger event.

Functionality

This function block adds the values provided via the three input adapters (`IN1`, `IN2`, and `IN3`).

As soon as a new event or value is registered at one of the input adapters, the function block performs the calculation according to the following scheme:

$$OUT = IN1 + IN2 + IN3 \tag{2.49}$$

The result is immediately passed to the output adapter `OUT`, and a corresponding update event is triggered to initiate subsequent function blocks in the data flow.

Technical Features

- **Generic Function Block:** The attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_ALR_ADD'` makes the function block data type-independent (generic). It can therefore work flexibly

with various numeric data types (e.g., INT, REAL, LREAL), provided the adapter type used, ALR, supports them.
- **Adapter Coupling:** Using adapters instead of traditional data and event pins drastically reduces the number of visible connection lines in the 4diac Application Editor. This significantly improves the readability of complex control diagrams.

State Overview

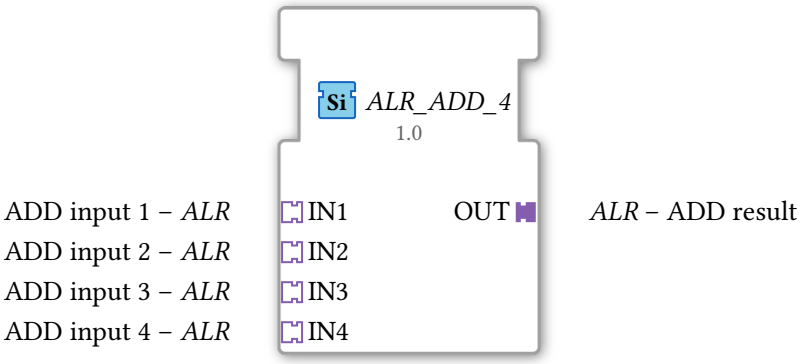
Since ALR_ADD_3_UNGATED is a mathematical, data-flow-oriented function block, it does not have a complex internal state machine (ECC). Execution is purely reactive (event-driven via the input adapters).

Application Scenarios

- **Measurement Summing:** Adding three analog partial flows to determine the total flow in an energy distribution system.
- **Mixing Calculations:** Combining three flow rates in a process plant to calculate the total inflow.
- **Setpoint Generation:** Calculating an overall setpoint from a base value, a correction value, and an offset.

Comparison with Similar Components

- **Standard ADD (IEC 61131-3):** The classic ADD component uses separate pins for data and events (REQ/CNF). In contrast, ALR_ADD_3_UNGATED combines these signals in adapters, increasing modularity and reusability in cross-project designs.
- **ALR_ADD_2:** A similar adapter-based component, but it only supports two inputs. ALR_ADD_3_UNGATED eliminates cascading when adding exactly three values, thus saving additional memory and computational effort.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The ALR_ADD_3_UNGATED is a flexible and high-performance component for adding three values in 4diac environments. Through its generic design and the consistent use of unidirectional adapters, it makes a significant contribution to the clarity, structuring and maintainability of modern, distributed control programs.

ALR_ADD_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block (FB) **ALR_ADD_4** is a generic arithmetic block for performing an addition operation. It is classified as a standard arithmetic function according to the IEC 61131-3 standard. The block allows up to four input values, provided via unidirectional adapters of type ALR, to be added and the result passed to a corresponding output adapter.

Interface Structure

Event Inputs

No direct event inputs are available. Synchronization and event control are handled implicitly via the adapters used.

Event Outputs

No direct event outputs are available. Event forwarding is implicit via the output adapter.

Data Inputs

No direct data inputs are available. Data is transferred entirely via the adapter interfaces.

Data Outputs

No direct data outputs are available. Data is transferred entirely via the adapter interface.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::ALR`): First input value (addend 1) for addition.
- **IN2** (Type: `adapter::types::unidirectional::ALR`): Second input value (addend 2) for addition.
- **IN3** (Type: `adapter::types::unidirectional::ALR`): Third input value (addend 3) for addition.
- **IN4** (Type: `adapter::types::unidirectional::ALR`): Fourth input value (addend 4) for addition.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::ALR`): The calculated result of the addition (sum).

Functionality

The function block `ALR_ADD_4` functions internally as a generic adder (`GEN_ALR_ADD`). As soon as the values at the input adapters `IN1` to `IN4` change, the function block calculates the sum of the incoming values:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} + \mathrm{IN4} \tag{2.50}$$

The result is immediately passed to the output plug `OUT`. Since this is a generic implementation, the specific data type depends on the specification of the `ALR` adapter type used.

Technical Features

- **Generic Class:** The function block is linked to the value `'GEN_ALR_ADD'` via the attribute `GenericClassName`, giving it high flexibility in processing various compatible data types within the adapter structures.
- **Adapter-Based Coupling:** By exclusively using adapters, the number of connection lines in the 4diac IDE is drastically reduced, resulting in clearer application diagrams.

State Overview

Since this function block performs a purely combinatorial, mathematical operation, it does not have an internal state machine (Execution Control Chart, ECC). The output directly follows changes in the inputs.

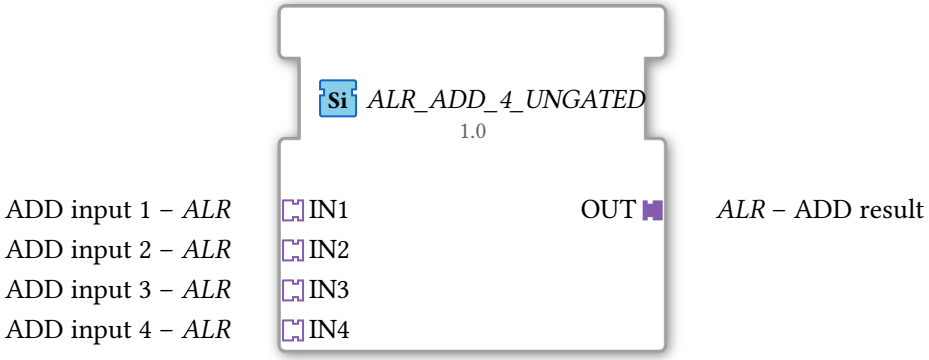
Application Scenarios

- **Measurement Aggregation:** Summing up to four energy, flow, or power values transmitted via standardized unidirectional adapters.
- **Signal Merging:** Structured bundling of sensor signals in complex control architectures prior to further data processing.

Comparison with Similar Components

- **Standard Add-in Component:** A classic IEC 61131-3 `ADD` component uses direct data inputs (e.g., `REAL`, `INT`) and often requires explicit event connections (`REQ` / `CNF`). `ALR_ADD_4` encapsulates this data and these events in adapters, simplifying project design.
- **Two-Way Adder (e.g., ALR_ADD_2):** Offers only two inputs. The `ALR_ADD_4` block eliminates the need to cascade multiple smaller adder blocks when summing three or four values.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ALR_ADD_4` block is an efficient and clean solution for arithmetic addition in component- and adapter-based system architectures within 4diac. It promotes reusability and ensures a streamlined system design.

ALR_ADD_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALR_ADD_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::ALR`): First input value (addend 1) for addition.
- **IN2** (Type: `adapter::types::unidirectional::ALR`): Second input value (addend 2) for addition.

- **IN3** (Type: `adapter::types::unidirectional::ALR`): Third input value (addend 3) for addition.
- **IN4** (Type: `adapter::types::unidirectional::ALR`): Fourth input value (addend 4) for addition.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::ALR`): The calculated result of the addition (sum).

Functionality

The function block `ALR_ADD_4_UNGATED` functions internally as a generic adder (`GEN_ALR_ADD`). As soon as the values at the input adapters `IN1` to `IN4` change, the function block calculates the sum of the incoming values:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} + \mathrm{IN4} \tag{2.51}$$

The result is immediately passed to the output plug `OUT`. Since this is a generic implementation, the specific data type depends on the specification of the `ALR` adapter type used.

Technical Features

- **Generic Class:** The function block is linked to the value `'GEN_ALR_ADD'` via the attribute `GenericClassName`, giving it high flexibility in processing various compatible data types within the adapter structures.
- **Adapter-Based Coupling:** By exclusively using adapters, the number of connection lines in the 4diac IDE is drastically reduced, resulting in clearer application diagrams.

State Overview

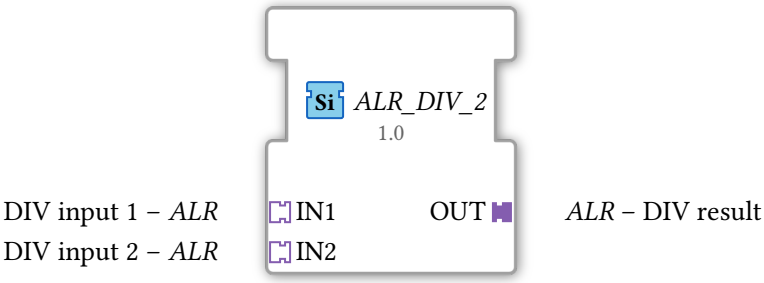
Since this function block performs a purely combinatorial, mathematical operation, it does not have an internal state machine (Execution Control Chart, ECC). The output directly follows changes in the inputs.

Application Scenarios

- **Measurement Aggregation:** Summing up to four energy, flow, or power values transmitted via standardized unidirectional adapters.
- **Signal Merging:** Structured bundling of sensor signals in complex control architectures prior to further data processing.

Comparison with Similar Components

- **Standard Add-in Component:** A classic IEC 61131-3 `ADD` component uses direct data inputs (e.g., `REAL`, `INT`) and often requires explicit event connections (`REQ` / `CNF`). `ALR_ADD_4_UNGATED` encapsulates this data and these events in adapters, simplifying project design.
- **Two-Way Adder (e.g., ALR_ADD_2):** Offers only two inputs. The `ALR_ADD_4_UNGATED` block eliminates the need to cascade multiple smaller adder blocks when summing three or four values.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `ALR_ADD_4_UNGATED` block is an efficient and clean solution for arithmetic addition in component- and adapter-based system architectures within 4diac. It promotes reusability and ensures a streamlined system design.

ALR_DIV_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALR_DIV_2` is a generic function block (Generic FB) for performing arithmetic divisions. It is defined in the package `adapter::iec61131::arithmetic` and is based on the generic class `GEN_ALR_DIV`.

Unlike classic arithmetic function blocks that work with direct data and event inputs, this block uses adapters of type `ALR` (unidirectional). This enables significantly simplified and structured wiring within 4diac applications, as signals and their associated control flows are bundled in adapters.

Interface Structure

Event Inputs

This block has no direct event inputs. Control and triggering are implicit via the connected adapters.

Event Outputs

This block has no direct event outputs.

Data Inputs

This block has no direct data inputs.

Data Outputs

This block has no direct data outputs.

Adapters

Type	Name	Adapter Type	Description
Socket (Input)	`IN1`	`adapter::types::unidirectional::ALR`	First Operand of Division (Dividend)
Socket (Input)	`IN2`	`adapter::types::unidirectional::ALR`	Second operand of the division (divisor)
Plug (output)	`OUT`	`adapter::types::unidirectional::ALR`	Result of the division (quotient)

Functionality

The function block `ALR_DIV_2` performs a mathematical division of the values provided via the adapters. The calculation follows the formula:

$$\mathrm{OUT} = \frac{\mathrm{IN1}}{\mathrm{IN2}} \tag{2.52}$$

Since this is a generic function block, the exact data type of the mathematical operation is determined at runtime or during instantiation by the specific data type used by the underlying `ALR` adapter. Data transmission is unidirectional, from the sockets (`IN1` and `IN2`) to the plug (`OUT`).

Technical Features

- **Generic Block:** The property `GenericClassName = "GEN_ALR_DIV"` allows the block to be used flexibly for various data types, provided they are supported by the adapter type.
- **Adapter Coupling:** Using adapters instead of individual pins minimizes the graphical wiring effort in the 4diac IDE and improves clarity in the application editor.
- **Division by Zero:** During implementation and use, ensure that the value on the adapter `IN2` is not zero to avoid runtime errors or undefined system behavior.

State Overview

This module does not have a complex internal state diagram (ECC). It operates as a purely functional processing module that calculates the result when values change at the input adapters (`IN1` or `IN2`) and forwards it via the output adapter (`OUT`).

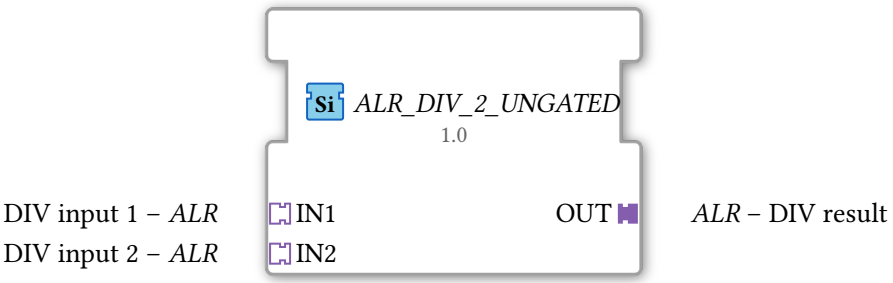
Application Scenarios

- **Signal Scaling:** Division of analog measured values by constant factors for unit conversion within an adapter-based signal processing chain.
- **Averaging and Ratio Control:** Calculation of ratios (e.g., air-fuel ratio) in control systems where signal paths are implemented modularly via adapters.
- **Standardization:** Use in complex control architectures to reduce the number of interconnects.

Comparison with Similar Function Blocks

Compared to the standard IEC 61131-3 compact component `DIV`, the `ALR_DIV_2` has no direct data pins (unlike `IN1`, `IN2`, and `ANY_NUM`). While the standard `DIV` component is optimized for simple, point-to-point calculations, the `ALR_DIV_2` is primarily suited for service-oriented architectures and applications that consistently rely on loose coupling via adapter structures.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ALR_DIV_2` is a specialized yet flexible division component for the 4diac IDE. It is ideally suited for demanding projects that value clean encapsulation of data flows using the unidirectional `ALR` adapter.

ALR_DIV_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALR_DIV_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALR_DIV_2_UNGATED` is a generic function block (Generic FB) for performing arithmetic divisions. It is defined in the package `adapter::iec61131::arithmetic` and is based on the generic class `GEN_ALR_DIV`.

Unlike classic arithmetic function blocks that work with direct data and event inputs, this block uses adapters of type `ALR` (unidirectional). - **Standardization:** Use in complex control architectures to reduce the number of interconnects.

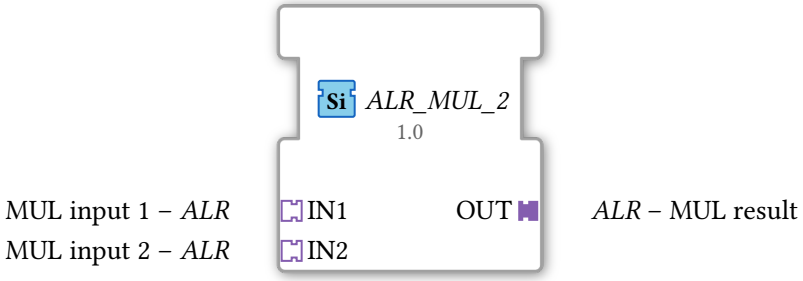
Comparison with Similar Function Blocks

Compared to the standard IEC 61131-3 compact component `DIV`, the `ALR_DIV_2_UNGATED` has no direct data pins (unlike `IN1`, `IN2`, and `ANY_NUM`). While the standard `DIV` component is optimized for simple, point-to-point calculations, the `ALR_DIV_2_UNGATED` is primarily suited for service-oriented architectures and applications that consistently rely on loose coupling via adapter structures.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `ALR_DIV_2_UNGATED` is a specialized yet flexible division component for the 4diac IDE. It is ideally suited for demanding projects that value clean encapsulation of data flows using the unidirectional `ALR` adapter.

ALR_MUL_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALR_MUL_2` is a generic arithmetic function block designed for multiplying two values. It is based on the IEC 61499 architecture and uses adapter interfaces to encapsulate and transmit data and events. This enables clean structuring and reduces wiring effort in 4diac IDE applications, as data and associated control flows are bundled in common connections (adapters).

Interface Structure

Event Inputs

This function block does not have direct event inputs. Control flow is managed implicitly via the adapters used.

Event Outputs

This function block does not have direct event outputs. Events are forwarded implicitly via the output adapter.

Data Inputs

This function block has no direct data inputs. The input data is provided via the adapter interfaces.

Data Outputs

This function block has no direct data outputs. The calculation result is provided via the output adapter.

Adapters

The function block communicates exclusively via adapter connections of type `ALR` (unidirectional):

- **IN1 (Socket)**:
- **Type**: `adapter::types::unidirectional::ALR`
- **Description**: First input (multiplicand 1) for multiplication.
- **IN2 (Socket)**:

Type: `adapter::types::unidirectional::ALR`
Description: Second input (multiplicand 2) for multiplication.
OUT (Plug):
Type: `adapter::types::unidirectional::ALR`
Description: Output for the calculated multiplication result.

Functionality

The function block `ALR_MUL_2` performs a mathematical multiplication according to the following principle:

$$OUT = IN1 \times IN2 \tag{2.54}$$

As soon as a new event is signaled at the input adapters `IN1` and/or `IN2`, indicating a data update, the function block receives the corresponding values, multiplies them, and outputs the result along with a corresponding update event via the output adapter `OUT`.

Since this is a generic function block (`GEN_ALR_MUL`), the underlying calculation adapts to the data type defined in the adapter.

Technical Features

- **Generic Implementation**: The function block is classified as `GEN_ALR_MUL`. This allows for flexible use with various numeric data types defined by the adapter profile `ALR`.
- **Adapter Encapsulation**: By using unidirectional adapters, the control flow (events) is directly linked to the data flow (values). This prevents synchronization errors between data and events.
- **Compiler Package**: The function block is declared in the package `adapter::iec61131::arithmetic` and uses the core library `eclipse4diac::core::GenericClassName`.

–

State Overview

The function block behaves like a classic, stateless (or purely functional) function block. There are no internal states that are stored beyond a single calculation cycle:

1. **Wait State**: The function block waits for an event at `IN1` or `IN2`.
2. **Calculation**: Upon arrival of an event, the values from the adapters are read and multiplied.
3. **Output**: The result is applied to `OUT`, and the output event is triggered. The function block immediately returns to the wait state.

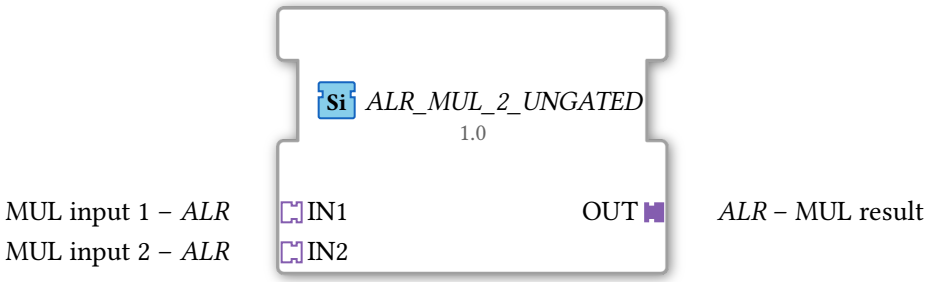
Application Scenarios

- **Signal Processing in Distributed Systems**: When sensor values are already available as adapter structures and need to be scaled or calculated together (e.g., calculating power from current and voltage).
- **Modular Control Design**: Reduction of line crossings in the function block diagram of 4diac applications by using adapters instead of separate event and data lines. * **Cascaded Calculations**: Simple chaining of multiple mathematical operations without additional overhead for event wiring.

Comparison with Similar Function Blocks

- **Standard `MUL` Function Block (IEC 61131-3)**: The classic `MUL` function block uses separate event inputs (e.g., `REQ`) and data inputs (e.g., `IN1`, `IN2` as REAL/INT). `ALR_MUL_2` simplifies this by combining these channels in adapters.
- **ALR_ADD_2 / ALR_SUB_2**: These function blocks operate on the same adapter principle, but perform additions or subtractions instead of multiplications.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

ALR_MUL_2 is a specialized, highly efficient function block for modern IEC 61499 architectures. Through its consistent use of adapters, it promotes clean, object-oriented software design in industrial automation and is ideally suited for complex, distributed control tasks.

ALR_MUL_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of ALR_MUL_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block ALR_MUL_2_UNGATED is a generic arithmetic function block designed for multiplying two values. It is based on the IEC 61499 architecture and uses adapter interfaces to encapsulate and transmit data and events. This enables clean structuring and reduces wiring effort in 4diac IDE applications, as data and associated control flows are bundled in common connections (adapters).

`ALR_MUL_2_UNGATED` is a specialized, highly efficient function block for modern IEC 61499 architectures. Through its consistent use of adapters, it promotes clean, object-oriented software design in industrial automation and is ideally suited for complex, distributed control tasks.

ALR_MUL_3

(Symbolic representation of the function block)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALR_MUL_3` is a generic block from the `adapter::iec61131::arithmetic` library, designed for the arithmetic multiplication of three input values. Instead of classic, discrete data inputs, this block uses unidirectional adapters of type `ALR` to encapsulate and transmit data and control events. This enables structured, modular, and clear wiring within the 4diac IDE.

Interface Structure

Event Inputs

No direct event inputs are available. Event-based control is handled entirely via the integrated adapters.

Event Outputs

No direct event outputs are available. Event-based control is handled entirely via the integrated adapters.

Data Inputs

No direct data inputs are available. The data values are encapsulated in the input adapters.

Data Outputs

No direct data outputs are available. The result is encapsulated in the output adapter.

Adapters

Sockets (Input Interfaces)

- **IN1** (Type: `adapter::types::unidirectional::ALR`): The first factor for multiplication.
- **IN2** (Type: `adapter::types::unidirectional::ALR`): The second factor for multiplication.
- **IN3** (Type: `adapter::types::unidirectional::ALR`): The third factor for the multiplication.

Plugs (Output Interfaces)

- **OUT** (Type: `adapter::types::unidirectional::ALR`): The calculated product of the three input values.

Functionality

The function block `ALR_MUL_3` performs the mathematical multiplication of three input variables. As soon as new values or trigger events are present at the sockets, the function block executes the calculation according to the following formula:

$$\mathrm{OUT} = \mathrm{IN1} \times \mathrm{IN2} \times \mathrm{IN3} \tag{2.56}$$

The result of the calculation and the corresponding update event are output via the plug `OUT`.

Since this is a generic function block (Generic class: `GEN_ALR_MUL`), the actual data type (e.g., `REAL`, `LREAL`, `INT`) depends on the definition of the `ALR` adapter used.

Technical Features

- **Generic Design:** By assigning the attribute `GenericClassName = 'GEN_ALR_MUL'`, the function block can be used flexibly for various data types, provided the adapters used support them.
- **Adapter-Based Coupling:** Using adapters instead of loose event/data connections drastically reduces the wiring effort (routing) within the 4diac application and improves clarity.
- – **Unidirectionality:** The `ALR` adapters used are defined as unidirectional, ensuring a clear and feedback-free data flow from the sources (sockets) to the sink (plug).

State Overview

The component does not have a complex internal state machine (ECC). It operates as a purely combinatorial/mathematical component that reacts directly to events at the input adapters and immediately forwards the result to the output.

Application Scenarios

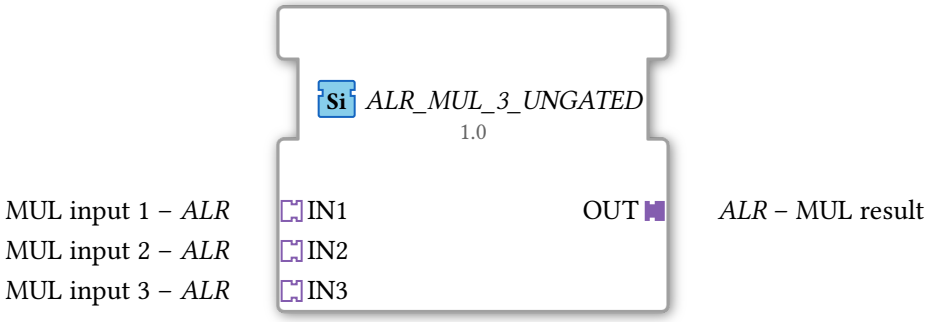
- **Sensor Scaling and Correction:** Multiplication of a raw value (IN1) by a calibration factor (IN2) and an application-specific weighting factor (IN3).
- **Three-Dimensional Calculations:** Calculation of volumes or throughputs where three physical variables need to be multiplied together.
- **Cascaded Gainers:** Calculation of combined gains in control loops.

Comparison with Similar Function Blocks

- **Standard MUL Function Block (IEC 61131-3):** Classic multipliers work with direct elementary data types (e.g., `REAL`). `ALR_MUL_3`, on the other hand, bundles data and events in adapters, which improves modularity and reusability in distributed systems according to IEC 61499.
- **ALR_MUL_2 (Dual Multiplier):** For multiplying only two values, a corresponding dual function block is preferred. `ALR_MUL_3` eliminates the need to cascade two separate function blocks when multiplying three factors.

–

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ALR_MUL_3` function block is an efficient and clean solution for triple multiplication tasks in IEC 61499 applications. By consistently using unidirectional adapters, he promotes clean software design and ensures well-structured data flows in the 4diac IDE.

ALR_MUL_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALR_MUL_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

(Symbolic representation of the function block)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALR_MUL_3_UNGATED` is a generic block from the `adapter::iec61131::arithmetic` library, designed for the arithmetic multiplication of three input values. Instead of classic, discrete data inputs, this block uses unidirectional adapters of type `ALR` to encapsulate and transmit data and control events. This enables structured, modular, and clear wiring within the 4diac IDE.

Interface Structure

Event Inputs

No direct event inputs are available. Event-based control is handled entirely via the integrated adapters.

Event Outputs

No direct event outputs are available. Event-based control is handled entirely via the integrated adapters.

Data Inputs

No direct data inputs are available. The data values are encapsulated in the input adapters.

Data Outputs

No direct data outputs are available. The result is encapsulated in the output adapter.

Adapters

Sockets (Input Interfaces)

- **IN1** (Type: `adapter::types::unidirectional::ALR`): The first factor for multiplication.
- **IN2** (Type: `adapter::types::unidirectional::ALR`): The second factor for multiplication.
- **IN3** (Type: `adapter::types::unidirectional::ALR`): The third factor for the multiplication.

Plugs (Output Interfaces)

- **OUT** (Type: `adapter::types::unidirectional::ALR`): The calculated product of the three input values.

Functionality

The function block `ALR_MUL_3_UNGATED` performs the mathematical multiplication of three input variables. As soon as new values or trigger events are present at the sockets, the function block executes the calculation according to the following formula:

$$\mathrm{OUT} = \mathrm{IN1} \times \mathrm{IN2} \times \mathrm{IN3} \tag{2.57}$$

The result of the calculation and the corresponding update event are output via the plug `OUT`.

Since this is a generic function block (Generic class: `GEN_ALR_MUL`), the actual data type (e.g., `REAL`, `LREAL`, `INT`) depends on the definition of the `ALR` adapter used.

Technical Features

- **Generic Design:** By assigning the attribute `GenericClassName = 'GEN_ALR_MUL'`, the function block can be used flexibly for various data types, provided the adapters used support them.
- **Adapter-Based Coupling:** Using adapters instead of loose event/data connections drastically reduces the wiring effort (routing) within the 4diac application and improves clarity.
- – **Unidirectionality:** The `ALR` adapters used are defined as unidirectional, ensuring a clear and feedback-free data flow from the sources (sockets) to the sink (plug).

State Overview

The component does not have a complex internal state machine (ECC). It operates as a purely combinatorial/mathematical component that reacts directly to events at the input adapters and immediately forwards the result to the output.

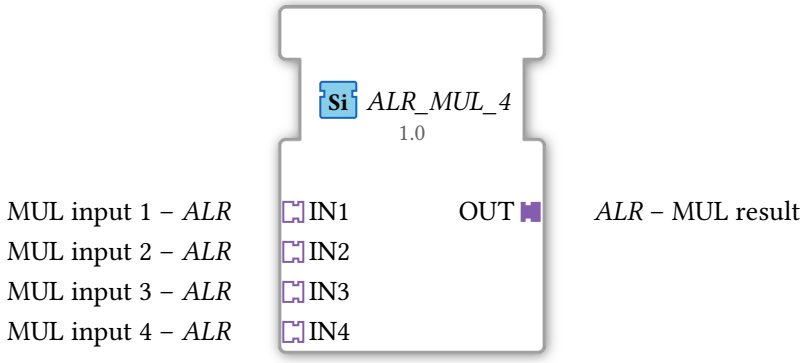
Application Scenarios

- **Sensor Scaling and Correction:** Multiplication of a raw value (IN1) by a calibration factor (IN2) and an application-specific weighting factor (IN3).
- **Three-Dimensional Calculations:** Calculation of volumes or throughputs where three physical variables need to be multiplied together.
- **Cascaded Gainers:** Calculation of combined gains in control loops.

Comparison with Similar Function Blocks

- **Standard MUL Function Block (IEC 61131-3):** Classic multipliers work with direct elementary data types (e.g., `REAL`). `ALR_MUL_3_UNGATED`, on the other hand, bundles data and events in adapters, which improves modularity and reusability in distributed systems according to IEC 61499.
- **ALR_MUL_2 (Dual Multiplier):** For multiplying only two values, a corresponding dual function block is preferred. `ALR_MUL_3_UNGATED` eliminates the need to cascade two separate function blocks when multiplying three factors.

–



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `ALR_MUL_3_UNGATED` function block is an efficient and clean solution for triple multiplication tasks in IEC 61499 applications. By consistently using unidirectional adapters, he promotes clean software design and ensures well-structured data flows in the 4diac IDE.

ALR_MUL_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALR_MUL_4` performs an arithmetic multiplication of four input values. It is a generic function block (FB) for the 4diac IDE, based on the IEC 61499 standard. Signal transmission and processing are handled via special unidirectional analog adapters, enabling clean encapsulation of the data streams.

Interface Structure

Event Inputs

No direct event inputs are defined for this function block, as control and updates are handled via adapters.

Event Outputs

No direct event outputs are defined for this function block.

Data Inputs

No direct data inputs are defined for this function block.

Data Outputs

No direct data outputs are defined for this function block.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::ALR`): First input value (multiplicand 1) for multiplication.
- **IN2** (Type: `adapter::types::unidirectional::ALR`): Second input value (multiplicand 2) for multiplication.
- **IN3** (Type: `adapter::types::unidirectional::ALR`): Third input value (multiplicand 3) for multiplication.
- **IN4** (Type: `adapter::types::unidirectional::ALR`): Fourth input value (multiplicand 4) for multiplication.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::ALR`): Output for the calculated product of the four input values.

Functionality

The `ALR_MUL_4` module multiplies the analog values provided by the four input adapters (`IN1` to `IN4`). The mathematical result is output via the `OUT` output adapter.

The underlying calculation formula is:

$$OUT = IN1 \times IN2 \times IN3 \times IN4 \tag{2.58}$$

Since this is a generic function block that uses the class `GEN_ALR_MUL`, the implementation is flexible with respect to the data types used in the adapter (e.g., `REAL` or `LREAL`).

Technical Features

- **Generic Function Block**: The attribute `GenericClassName` with the value `GEN_ALR_MUL` allows the function block to adapt flexibly to the specific data type implementation of the adapter used at runtime or during compilation.
- **Encapsulation via Adapter**: The use of the unidirectional adapter `ALR` (`adapter::types::unidirectional::ALR`) ensures that data values and any associated status or trigger events are bundled compactly in a single connection. This significantly reduces the wiring effort in the function block diagram.

State Overview

The function block has no internal state behavior (no state machine/ECC) and operates purely in a data flow-oriented manner. As soon as the values at the input adapters change or a corresponding update event is triggered via the adapters, the multiplication is performed and the result is provided at the output `OUT`.

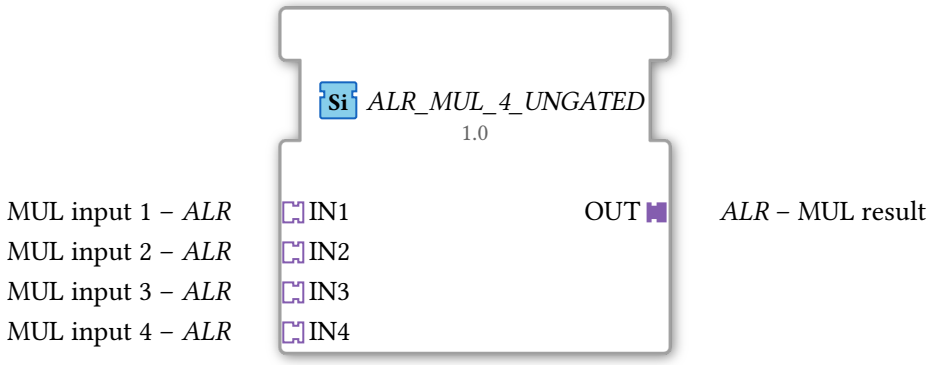
Application Scenarios

- **Physical Calculations**: Calculation of more complex quantities that represent the product of several variables (e.g., power, energy calculations, or volumetric flow rates taking correction factors into account).
- **Cascaded Scaling**: Applying multiple scaling or correction factors to an analog input signal in a single step.
- **Signal Processing**: Preprocessing sensor values in control systems before the data is passed on to visualizations or actuators.

Comparison with Similar Function Blocks

- **Standard MUL Function Blocks (IEC 61131-3)**: Classic multiplication function blocks typically work directly with standard data types (e.g., `REAL`) and require separate event connections (`REQ`/`CNF`). `ALR_MUL_4` simplifies this through the use of adapters.
- **ALR_MUL_2 / ALR_MUL_3**: These function blocks are designed for multiplying only two or three values. The `ALR_MUL_4` function block eliminates the need for additional intermediate steps and block cascades when four multiplicands are required, thus improving the performance and clarity of the control program.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ALR_MUL_4` function block is a practical auxiliary block for mathematical signal processing in 4diac. By consistently utilizing the adapter concept, it significantly reduces the number of connecting lines in the application diagram while simultaneously offering the flexibility of a generic function block.

ALR_MUL_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALR_MUL_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALR_MUL_4_UNGATED` performs an arithmetic multiplication of four input values. It is a generic function block (FB) for the 4diac IDE, based on the IEC 61499 standard. Signal transmission and processing are handled via special unidirectional analog adapters, enabling clean encapsulation of the data streams.

Interface Structure

Event Inputs
No direct event inputs are defined for this function block, as control and updates are handled via adapters.

Event Outputs
No direct event outputs are defined for this function block.

Data Inputs
No direct data inputs are defined for this function block.

Data Outputs
No direct data outputs are defined for this function block.

Adapters

Sockets (Input Adapters)
- **IN1** (Type: `adapter::types::unidirectional::ALR`): First input value (multiplicand 1) for multiplication.
- **IN2** (Type: `adapter::types::unidirectional::ALR`): Second input value (multiplicand 2) for multiplication.
- **IN3** (Type: `adapter::types::unidirectional::ALR`): Third input value (multiplicand 3) for multiplication.
- **IN4** (Type: `adapter::types::unidirectional::ALR`): Fourth input value (multiplicand 4) for multiplication.

Plugs (Output Adapters)
- **OUT** (Type: `adapter::types::unidirectional::ALR`): Output for the calculated product of the four input values.

Functionality
The `ALR_MUL_4_UNGATED` module multiplies the analog values provided by the four input adapters (`IN1` to `IN4`). The mathematical result is output via the `OUT` output adapter.

The underlying calculation formula is:

$$OUT = IN1 \times IN2 \times IN3 \times IN4 \tag{2.59}$$

Since this is a generic function block that uses the class `GEN_ALR_MUL`, the implementation is flexible with respect to the data types used in the adapter (e.g., `REAL` or `LREAL`).

Technical Features
- **Generic Function Block**: The attribute `GenericClassName` with the value `GEN_ALR_MUL` allows the function block to adapt flexibly to the specific data type implementation of the adapter used at runtime or during compilation.
- **Encapsulation via Adapter**: The use of the unidirectional adapter `ALR` (`adapter::types::unidirectional::ALR`) ensures that data values and any associated status or trigger events are bundled compactly in a single connection. This significantly reduces the wiring effort in the function block diagram.

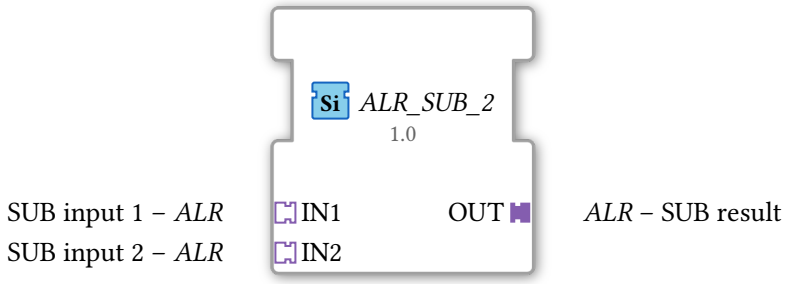
State Overview
The function block has no internal state behavior (no state machine/ECC) and operates purely in a data flow-oriented manner. As soon as the values at the input adapters change or a corresponding update event is triggered via the adapters, the multiplication is performed and the result is provided at the output `OUT`.

Application Scenarios
- **Physical Calculations**: Calculation of more complex quantities that represent the product of several variables (e.g., power, energy calculations, or volumetric flow rates taking correction factors into account).
- **Cascaded Scaling**: Applying multiple scaling or correction factors to an analog input signal in a single step.

- **Signal Processing**: Preprocessing sensor values in control systems before the data is passed on to visualizations or actuators.

Comparison with Similar Function Blocks

- **Standard MUL Function Blocks (IEC 61131-3)**: Classic multiplication function blocks typically work directly with standard data types (e.g., `REAL`) and require separate event connections (`REQ`/`CNF`). `ALR_MUL_4_UNGATED` simplifies this through the use of adapters.
- **ALR_MUL_2 / ALR_MUL_3**: These function blocks are designed for multiplying only two or three values. The `ALR_MUL_4_UNGATED` function block eliminates the need for additional intermediate steps and block cascades when four multiplicands are required, thus improving the performance and clarity of the control program.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `ALR_MUL_4_UNGATED` function block is a practical auxiliary block for mathematical signal processing in 4diac. By consistently utilizing the adapter concept, it significantly reduces the number of connecting lines in the application diagram while simultaneously offering the flexibility of a generic function block.

ALR_SUB_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALR_SUB_2` is a generic block for performing mathematical subtractions within an IEC 61499 development environment (such as 4diac IDE). Instead of using direct data and event pins, this block is based on an adapter-driven architecture. This enables structured and clean signal encapsulation and simplifies wiring in complex control applications.

Interface Structure

Event Inputs

This block does not have direct event inputs. Control and triggering are handled via the connected adapters.

Event Outputs

This block does not have direct event outputs. Event forwarding is handled via the output adapter.

Data Inputs

There are no direct data inputs.

Data Outputs

There are no direct data outputs.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::ALR`):

The first input value (minuend) of the subtraction. This adapter receives both the value and the triggering event.

- **IN2** (Type: `adapter::types::unidirectional::ALR`):

The second input value (subtrahend) to be subtracted from the first value.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::ALR`):

The result of the subtraction (difference). This adapter outputs the calculated result along with the corresponding output event.

Functionality

The module's internal logic calculates the difference between the two values provided via the sockets. The mathematical formula is:

$$\mathrm{OUT} = \mathrm{IN1} - \mathrm{IN2} \tag{2.60}$$

As soon as the values at the input adapters change or a corresponding trigger event is received at `IN1` or `IN2`, the module performs the calculation and updates the value at the output plug `OUT`, followed by an output event.

Technical Features

- **Generic Behavior**: The module is defined as a generic type (`GEN_ALR_SUB`). It is therefore not rigidly bound to a single data type (such as only `REAL` or only `INT`), but adapts flexibly to the data types defined in the adapter `ALR`.
- **Unidirectional Adapters**: By using unidirectional adapters (`unidirectional::ALR`), the data flow is clearly directed in one direction, which increases system stability and minimizes unnecessary communication overhead.

State Overview

Since `ALR_SUB_2` is a purely mathematical, data-flow-oriented function block, it does not have an internal state machine (ECC - Execution Control Chart). Execution is purely event- and data-driven.

Application Scenarios

- **Control Engineering (Calculation of Control Deviation)**:

Determining the difference between a setpoint (reference input at `IN1`) and an actual value (controlled variable at `IN2`) to provide the control deviation at output `OUT` for a downstream PID controller.

- **Difference Measurements**:

Calculation of physical difference values, for example, to determine the pressure drop across a filter (pressure before the filter at `IN1` minus pressure after the filter at `IN2`).

- **Offset Correction**:

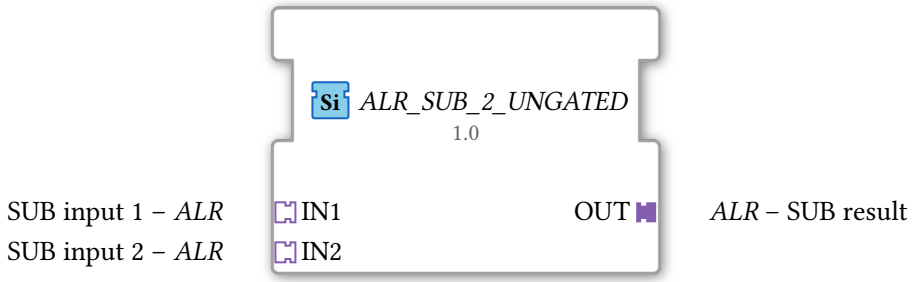
Subtracting a constant or variable correction value from a raw analog signal.

Comparison with Similar Components

Compared to classic IEC 61131-3 subtraction blocks (such as `SUB`), which use standard data types and direct pins, the `ALR_SUB_2` offers significant advantages in program code clarity thanks to its encapsulation in adapters. Complex signal paths (data + event) are bundled in a single adapter connection.

Compared to bidirectional calculation blocks, the `ALR_SUB_2` features deterministic, non-reactive signal processing.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `ALR_SUB_2` is an efficient and flexible standard component for arithmetic calculations in modern, service-oriented control systems. By utilizing adapter technology, it supports a modular and maintainable software design according to the IEC 61499 standard.

ALR_SUB_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALR_SUB_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

The `ALR_SUB_2_UNGATED` is an efficient and flexible standard component for arithmetic calculations in modern, service-oriented control systems. By utilizing adapter technology, it supports a modular and maintainable software design according to the IEC 61499 standard.

AR_ADD_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AR_ADD_2** is used to calculate the arithmetic addition of two values. It is designed as a generic function block and implements the basic arithmetic operation via adapter interfaces. The block is platform-independent and complies with the IEC 61499 standard.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapters

Name	Direction	Type	Comment
`IN1`	Socket	`adapter::types::unidirectional::AR`	ADD input 1
`IN2`	Socket	`adapter::types::unidirectional::AR`	ADD input 2
`OUT`	Plug	`adapter::types::unidirectional::AR`	ADD result

The adapters are of type `unidirectional::AR` and enable type-safe connections with other function blocks that support the same adapter type.

Functionality

The function block adds the two values received via adapters `IN1` and `IN2`. The result is provided at adapter `OUT`. The precise data interpretation (data type, value range) is determined by the adapter type used; the function block itself operates generically and delegates the type information to the underlying framework.

The actual calculation takes place in the background via the configured runtime environments – the function block merely defines the interfaces and the semantics of the addition.

Technical Features

- **Generic Structure** – The function block uses a generic class name (`GEN_AR_ADD`) at runtime, which is defined by the attribute `eclipse4diac::core::GenericClassName`. This allows for later specialization for specific data types (e.g., integers or floating-point numbers).
- **Adapter-Based** – Instead of individual data inputs and outputs, all signals are routed via unidirectional adapters. This simplifies encapsulation and reuse in complex systems.
- **Package Information** – The function block is organized in the package `adapter::iec61131::arithmetic`, indicating its origin from an IEC 61131 adapter library.

- **No State Logic** – The addition is stateless; there is no internal state machine.

State Overview

The function block does not have a state machine. The calculation is purely data-driven – if the input adapters change, the result is recalculated.

Application-Specific Scenarios

- **Signal Processing** – Combining two analog or digital measured values into a sum.
- **Control Engineering** – Summing counter readings or time values.
- **Generic Library Function Blocks** – Use as a basis for application-specific, typed addition function blocks (e.g., `AR_ADD_INT`, `AR_ADD_REAL`).

Comparison with Similar Function Blocks

Compared to classic, data-input-based addition blocks (e.g., `ADD`), `AR_ADD_2` is distinguished by its adapter interfaces. While standard adders often operate with single inputs (`IN1`, `IN2`) and one output (`OUT`), adapters enable direct connection to more complex data structures and greater reusability through type safety. The block is intentionally generic, allowing for dynamic type adjustment at runtime.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AR_ADD_2` is a compact, generic function block for adding two values using adapter interfaces. It is particularly suitable for cross-system applications where type flexibility and loose coupling via adapters are required. Its simple, stateless architecture makes it robust and easy to integrate into existing automation projects.

None.

Data Inputs

No direct data inputs. Input values are provided via adapter interfaces.

Data Outputs

No direct data outputs. The result is provided via an adapter output.

Adapter

Direction	Name	Type	Comment

Sockets	IN1	`adapter::types::unidirectional::AR`	ADD input 1
Sockets	IN2	`adapter::types::unidirectional::AR`	ADD input 2
Sockets	IN3	`adapter::types::unidirectional::AR`	ADD input 3
Plugs	OUT	`adapter::types::unidirectional::AR`	ADD result

Functionality

The function block adds the three values received via the adapter sockets `IN1`, `IN2`, and `IN3` and provides the result via the adapter plug `OUT`. The exact semantics of the addition (e.g., supported data types, overflow behavior) are determined by the implementation of the adapter type used, `AR`. The function block is generic, meaning it can be parameterized for different data types (e.g., by type hash or generic class name).

Technical Features

- **Generic Block:** The actual data type handling is controlled via the attributes `eclipse4diac::core::GenericClassName` (value: `'GEN_AR_ADD'`) and `eclipse4diac::core::TypeHash`.
- **Adapter-Based Communication:** The block uses adapters (`adapter::types::unidirectional::AR`) exclusively for input and output. This enables loose coupling and reusability in different contexts.
- **License:** Released under the Eclipse Public License 2.0 (EPL-2.0).
- **Compatibility:** Developed for the 4diac IDE and the Eclipse 4diac runtime environment.

State Overview

The block does not have an explicit state diagram (ECC). It is a purely combinatorial function: The output is always the sum of the three inputs. There are no internal states or time dependencies.

Application Scenarios

- **Multiple Addition in Control Systems:** When three analog or digital values (e.g., sensor data, setpoints) need to be summed.
- **Generic Library Blocks:** Used in reusable function block libraries where the data types are defined at configuration time.
- **Adapter-Based Architectures:** In systems that rely on standardized adapter interfaces to enable flexible chaining of functions.

Comparison with Similar Blocks

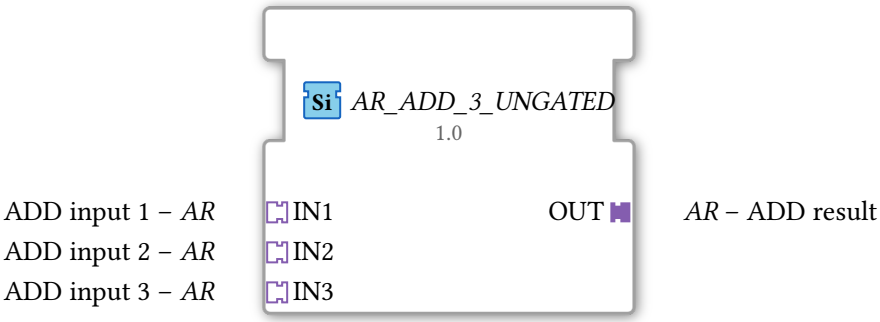
AR_ADD_2 / AR_ADD_4 etc.: These blocks differ only in the number of inputs (two or four). `AR_ADD_3` is specifically optimized for adding exactly three values. The generic approach allows all these variants to be implemented, if needed, by parameterizing a common base type.

- **`AR_ADD_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion



AR_ADD_3` is a clear, generic function block for adding three values using adapters. Its abstraction via generic attributes and adapters makes it well-suited for IEC 61499 applications that require flexible and reusable signal processing.

AR_ADD_3_UNGATED

i UNGATED variant: This block is the ungated version of `AR_ADD_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AR_ADD_3_UNGATED` is used to calculate the arithmetic addition of three values. It is a generic function block (FB) according to IEC 61499-2, which operates via adapter interfaces. The block is designed to be used in conjunction with the adapter `adapter::types::unidirectional::AR` from the library `adapter::iec61131::arithmetic`.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

No direct data inputs. Input values are provided via adapter interfaces.

Data Outputs

No direct data outputs. The result is provided via an adapter output.

Adapter

Direction	Name	Type	Comment
Sockets	IN1	`adapter::types::unidirectional::AR`	ADD input 1
Sockets	IN2	`adapter::types::unidirectional::AR`	ADD input 2
Sockets	IN3	`adapter::types::unidirectional::AR`	ADD input 3
Plugs	OUT	`adapter::types::unidirectional::AR`	ADD result

Functionality

The function block adds the three values received via the adapter sockets `IN1`, `IN2`, and `IN3` and provides the result via the adapter plug `OUT`. The exact semantics of the addition (e.g., supported data types, overflow behavior) are determined by the implementation of the adapter type used, `AR`. The function block is generic, meaning it can be parameterized for different data types (e.g., by type hash or generic class name).

Technical Features

- **Generic Block:** The actual data type handling is controlled via the attributes `eclipse4diac::core::GenericClassName` (value: `'GEN_AR_ADD'`) and `eclipse4diac::core::TypeHash`.
- **Adapter-Based Communication:** The block uses adapters (`adapter::types::unidirectional::AR`) exclusively for input and output. This enables loose coupling and reusability in different contexts.
- **License:** Released under the Eclipse Public License 2.0 (EPL-2.0).
- **Compatibility:** Developed for the 4diac IDE and the Eclipse 4diac runtime environment.

State Overview

The block does not have an explicit state diagram (ECC). It is a purely combinatorial function: The output is always the sum of the three inputs. There are no internal states or time dependencies.

Application Scenarios

- **Multiple Addition in Control Systems:** When three analog or digital values (e.g., sensor data, setpoints) need to be summed.
- **Generic Library Blocks:** Used in reusable function block libraries where the data types are defined at configuration time.
- **Adapter-Based Architectures:** In systems that rely on standardized adapter interfaces to enable flexible chaining of functions.

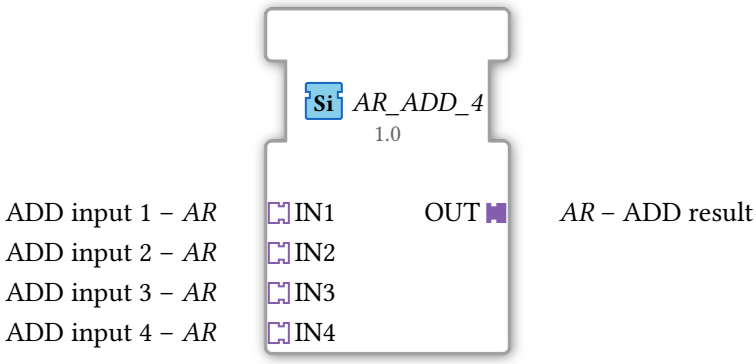
Comparison with Similar Blocks

AR_ADD_2 / AR_ADD_4 etc.: These blocks differ only in the number of inputs (two or four). `AR_ADD_3_UNGATED` is specifically optimized for adding exactly three values. The generic approach allows all these variants to be implemented, if needed, by parameterizing a common base type.

- `AR_ADD_3`: The gated variant – updates the output only on an actual value change.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.



Conclusion

AR_ADD_3_UNGATED` is a clear, generic function block for adding three values using adapters. Its abstraction via generic attributes and adapters makes it well-suited for IEC 61499 applications that require flexible and reusable signal processing.

AR_ADD_4

Note: A graphical symbol for the function block is not available.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AR_ADD_4** is a generic function block for the arithmetic addition of multiple values. It is designed according to the IEC 61499-2 standard and allows the flexible processing of up to four additive operands via adapter interfaces. The function block is typically used in automation systems where numerical summation of multiple signals is required.

Interface Structure

Event Inputs

- None (The function block operates without explicit event control.)

Event Outputs

- None

Data Inputs

- None (All input operands are provided via adapters.)

Data Outputs

- None (The result is output via an adapter.)

Adapter

Name	Type	Direction	Description
IN1	`adapter::types::unidirectional::AR`	Socket (Input)	First Addend of the Addition
IN2	`adapter::types::unidirectional::AR`	Socket (Input)	Second Addend
IN3	`adapter::types::unidirectional::AR`	Socket (Input)	Third Addend
IN4	`adapter::types::unidirectional::AR`	Socket (Input)	Fourth Addend
OUT	`adapter::types::unidirectional::AR`	Plug (Output)	Result of the Addition (Sum of Inputs)

The adapters are of type `unidirectional::AR`, indicating that they provide or process an arithmetic value (e.g., a numerical value) as a directed connection.

Functionality

The function block **AR_ADD_4** performs the summation of the four values applied to the input adapters and outputs the result to the output adapter **OUT**. The calculation is performed according to the general formula:

[\text{OUT} = \text{IN1} + \text{IN2} + \text{IN3} + \text{IN4}
]

Since the function block is declared as a generic type (`eclipse4diac::core::GenericClassName = 'GEN_AR_ADD'`), the underlying data type (e.g., Integer, Real, or user-defined arithmetic types) is only determined at runtime through the specific configuration. Processing is data-driven – as soon as valid values are present at all four inputs, the sum is calculated and updated at the output.

Technical Features

- **Generic Function Block**: The function block is marked as generic (`eclipse4diac::core::GenericClassName`). This allows the specific arithmetic data type to be defined only when used in the project, enabling high reusability.
- **Adapter-Based Communication**: Instead of classic data inputs/outputs, all values are exchanged via adapters. This allows for loose coupling with other components and promotes modular structures.
- **No Event Control**: The component has no event inputs or outputs. Calculation and data transmission occur automatically as soon as all input values are available (similar to a continuous function).
- **Typical Package Structure**: The component is organized in the package `adapter::iec61131::arithmetic`, indicating an adapter implementation close to IEC 61131.

State Overview

Due to its purely data-driven and eventless operation, the component has **no internal states**. There are no sequential processes or state machines. The output is always the current sum of the four inputs.

Application Scenarios

1. **Calculating the sum of multiple process values** (e.g., adding flow signals from multiple sensors).
2. **Scaling and Summation** – In combination with scalable adapters, the function block can be used for weighted summation.
3. **Calculation of total consumption or total energy** from multiple partial measurements.
4. **Generic summation in modular automation solutions** where the number of summands is fixed, but the data type is variable.

Comparison with similar function blocks

Function block	Number of inputs	Special feature
AR_ADD_4	4	Adapter-based, generic, no events
AR_ADD_2 (hypothetical)	2	Reduced inputs, same concept
F_ADD (from IEC 61131)	2	Standard data types, event-driven (via ENABLE/ ENO)
AR_SUM (hypothetical)	variable	More flexible number, but more complex

The **AR_ADD_4** function block stands out from classic IEC 61499 arithmetic function blocks due to its pure adapter communication and generic design. It is particularly suitable for systems that already rely on adapter technology and do not require explicit event control.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The **AR_ADD_4** is a compact, generic function block for adding four values via adapter interfaces. Its simple and robust data-driven operation makes it a useful basic building block for modular automation applications. The absence of events and the generic typing enable flexible integration into heterogeneous systems. For applications with more or fewer than four addends, adapted variants or extended function blocks must be used.

AR_DIVTIME

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AR_DIVTIME** is used to divide a time value (type TIME) by a numeric value. The divisor is supplied via an adapter, allowing the block to be used flexibly in different contexts. The result is likewise output via an adapter. The block is classified as a standard arithmetic function according to IEC 61131-3.

Interface Structure

Event Inputs

- **REQ** (Event): Normal execution request. An event at REQ triggers the division. Input IN1 must be connected to the REQ event (WITH).

Event Outputs

The block has no explicit event outputs in its interface list. However, the result is provided via the output adapter **OUT**, which sends an event (E1) once the calculation is complete (as shown by the internal wiring).

Data Inputs

- **IN1** (TIME): Time value to be divided (dividend).

Data Outputs

The block has no direct data outputs. The division result is output via the output adapter **OUT** as a data value (D1).

Adapters

- **IN2** (Adapter, type `adapter::types::unidirectional::AR`): Divisor. This adapter provides both a triggering event (E1) and the data value (D1).

- **OUT** (Adapter, type `adapter::types::unidirectional::ATM`): Output for the division result (TIME). Provides both an event (E1) and data (D1).

Functionality

The function block AR_DIVTIME encapsulates the functionality of the internal function block **F_DIVTIME** (type `iec61131::arithmetic::F_DIVTIME`). An event at input **REQ**, or alternatively at adapter input **IN2.E1**, triggers the division. The internal function block divides **IN1** (TIME) by **IN2.D1** (numeric value) and outputs the result to **OUT.D1**. Once the calculation is complete, an event is sent to **OUT.E1**, signaling to the downstream receiver that the result is valid.

Technical Features

- **Adapter-based interface:** Instead of classic data inputs/outputs, adapters are used, allowing for flexible interconnection in complex networks. The adapters are defined as unidirectional and require compatible counterparts.
- **Standard compliance:** The function block meets the requirements of IEC 61131-3 (classification: standard arithmetic function).
- **Internal encapsulation:** The actual calculation is performed by the reusable function block F_DIVTIME, so AR_DIVTIME acts as a wrapper with adapter-based communication.
- **Mixed interface:** Unlike fully adapter-based blocks, AR_DIVTIME receives the dividend (IN1) as a classic data input, not via an adapter – see `ATM_AR_DIVTIME` for the fully adapter-based variant.

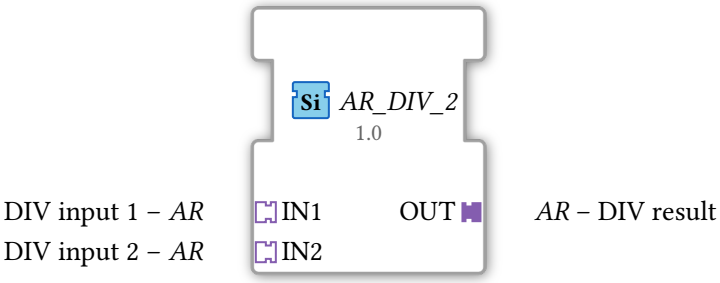
State Overview

The function block itself does not have an explicit state machine. Event-driven processing is deterministic:

- Waiting for an event at **REQ** or **IN2.E1**
- Executing the division
- Sending the result to **OUT.E1** and **OUT.D1**
- Returning to the wait state

Application Scenarios

- Splitting a time value into equal segments, e.g., converting a total runtime into individual cycles.
- In control applications where a time parameter must be dynamically divided by a variable factor.
- As part of libraries for IEC 61131-3 compliant automatic control, especially when adapters are used to decouple the signal paths.



Comparison with Similar Function Blocks

- **F_DIVTIME:** The direct, adapter-free function block for dividing TIME by numeric values. It offers classic event and data interfaces. AR_DIVTIME encapsulates this function block and provides the divisor via an adapter.
- **AR_MULTIME:** Multiplies instead of dividing, otherwise structurally identical (mixed interface: IN1 as a data input, IN2 as an adapter).
- **ATM_AR_DIVTIME:** The fully adapter-based variant – here IN1 is also an adapter socket (type `ATM`) instead of a fixed data input.

Conclusion

The **AR_DIVTIME** function block enables the division of a time value by a numeric factor via an adapter-based interface for the divisor. It combines proven IEC 61131-3 arithmetic with flexible connectivity and is particularly suitable for modular automation systems. The internal use of the F_DIVTIME function block guarantees reliable and efficient calculations.

AR_DIV_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AR_DIV_2` is a generic arithmetic block designed for performing division operations (`DIV`) in IEC 61499-based systems. Unlike traditional function blocks, this block uses adapters (`unidirectional::AR`) to bundle data and events. This results in clearer and more modular visual programming within the 4diac IDE.

Since it is a purely adapter-based function block, `AR_DIV_2` has no direct, traditional data or event inputs and outputs at the main level. All communication is handled via adapters.

Interface Structure

Event Inputs

No direct event inputs available. (Event control is implicit via the input adapters).

Event Outputs

No direct event outputs available. (Event control is implicit via the output adapter).

Data Inputs

No direct data inputs available. (Data is transferred via the input adapters).

Data Outputs

No direct data outputs available. (Data is transferred via the output adapter).

Adapters

Type	Name	Adapter Type	Description
Socket (Input)	`IN1`	`adapter::types::unidirectional::AR`	First input value (dividend) for the division.
Socket (Input)	`IN2`	`adapter::types::unidirectional::AR`	Second input value (divisor) for the division.
Plug (Output)	`OUT`	`adapter::types::unidirectional::AR`	The result of the division (quotient).

Functionality

This function block performs a mathematical division of the values provided via the adapters. As soon as an update event at the input adapters (`IN1` or `IN2`) signals that new data is available, the calculation is triggered:

$$\mathrm{OUT} = \frac{\mathrm{IN1}}{\mathrm{IN2}} \tag{2.62}$$

The calculated result is then passed to the output adapter `OUT`, and the corresponding send event of the adapter is triggered to inform subsequent function blocks about the new value.

Technical Features

- **Generic Type (`GEN_AR_DIV`):** The function block is internally declared as a generic type. This allows for flexible adaptation to various data types (e.g., `REAL`, `LREAL`, `INT`), depending on how the underlying `AR` adapter type is defined.
- **Adapter Coupling:** Using unidirectional adapters (`unidirectional::AR`) drastically reduces the number of connection lines in the function block diagram, improving the readability of complex mathematical calculations.
- **Protection Against Division by Zero:** System-integrated protection measures depend on the specific runtime environment. When using the function block, ensure that the divisor (`IN2`) is not zero to avoid calculation errors or runtime crashes.

State Overview

The function block is essentially stateless and reacts in an event-driven manner:

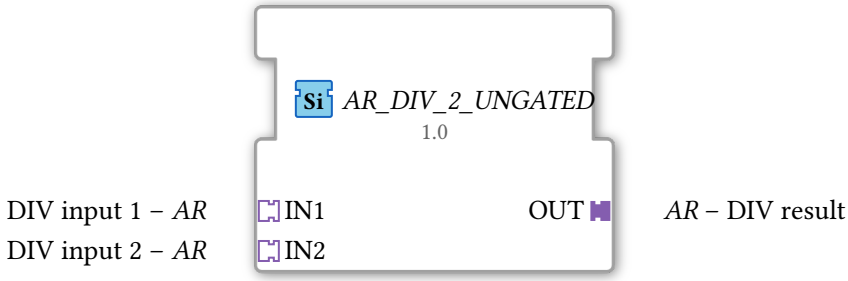
Application Scenarios

1. **Wait State (Idle):** The function block waits for an update event at the adapters `IN1` or `IN2`.
2. **Calculation:** After an event arrives, the division is performed.
3. **Update:** The result is applied to `OUT`, and the output event is triggered. The function block immediately returns to the wait state.

Comparison with Similar Function Blocks

- **Measurement Scaling:** Division of raw sensor data by a fixed scaling factor for conversion into physical units.
- **Average Calculation:** Division of a sum by the number of measured values in more complex computational networks.
- **Ratio Calculations:** Determining percentages or ratios in process engineering plants.
- **Classic `DIV` Module:** The classic IEC 61131-3 `DIV` module has dedicated pins for `IN1`, `IN2`, and `OUT`, as well as the corresponding `REQ` and `CNF` events. `AR_DIV_2` bundles these signals in adapters, simplifying wiring in large projects.
- **`AR_MUL_2` / `AR_ADD_2`:** These function blocks share the same adapter philosophy but perform multiplications and additions, respectively. They can be seamlessly chained with `AR_DIV_2` to form mathematical calculation trees.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AR_DIV_2` is a highly efficient, modular function block for arithmetic division. Through the consistent use of adapters, it is ideally suited for clean, well-organized software architectures in distributed automation according to the IEC 61499 standard.

AR_DIV_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AR_DIV_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AR_DIV_2_UNGATED` is a generic arithmetic block designed for performing division operations (`DIV`) in IEC 61499-based systems. Unlike traditional function blocks, this block uses adapters (`unidirectional::AR`) to bundle data and events. This results in clearer and more modular visual programming within the 4diac IDE.

Since it is a purely adapter-based function block, `AR_DIV_2_UNGATED` has no direct, traditional data or event inputs and outputs at the main level. All communication is handled via adapters.

Interface Structure

Event Inputs

No direct event inputs available. (Event control is implicit via the input adapters).

Event Outputs

No direct event outputs available. (Event control is implicit via the output adapter).

Data Inputs

No direct data inputs available. (Data is transferred via the input adapters).

Data Outputs

No direct data outputs available. (Data is transferred via the output adapter).

Adapters

Type	Name	Adapter Type	Description
Socket (Input)	`IN1`	`adapter::types::unidirectional::AR`	First input value (dividend) for the division.
Socket (Input)	`IN2`	`adapter::types::unidirectional::AR`	Second input value (divisor) for the division.
Plug (Output)	`OUT`	`adapter::types::unidirectional::AR`	The result of the division (quotient).

Functionality

This function block performs a mathematical division of the values provided via the adapters. As soon as an update event at the input adapters (`IN1` or `IN2`) signals that new data is available, the calculation is triggered:

$$\mathrm{OUT} = \frac{\mathrm{IN1}}{\mathrm{IN2}} \tag{2.63}$$

The calculated result is then passed to the output adapter `OUT`, and the corresponding send event of the adapter is triggered to inform subsequent function blocks about the new value.

Technical Features

- **Generic Type (`GEN_AR_DIV`):** The function block is internally declared as a generic type. This allows for flexible adaptation to various data types (e.g., `REAL`, `LREAL`, `INT`), depending on how the underlying `AR` adapter type is defined.
- **Adapter Coupling:** Using unidirectional adapters (`unidirectional::AR`) drastically reduces the number of connection lines in the function block diagram, improving the readability of complex mathematical calculations.
- **Protection Against Division by Zero:** System-integrated protection measures depend on the specific runtime environment. When using the function block, ensure that the divisor (`IN2`) is not zero to avoid calculation errors or runtime crashes.

State Overview

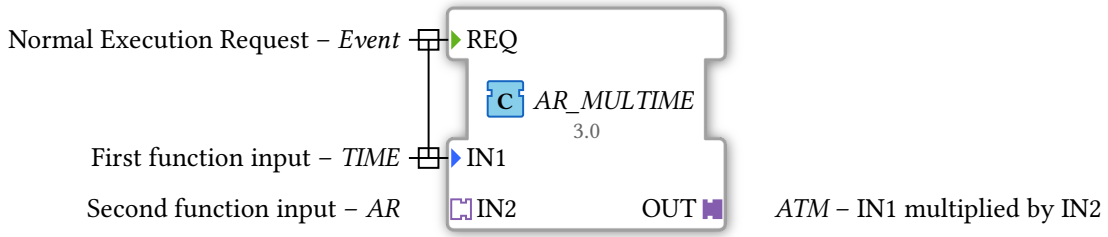
The function block is essentially stateless and reacts in an event-driven manner:

Application Scenarios

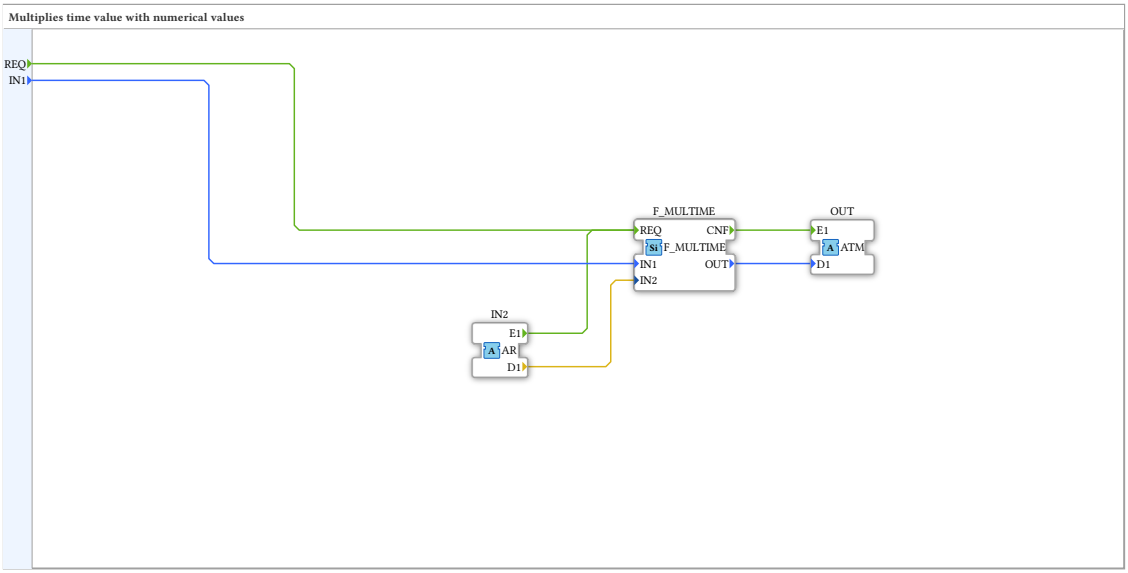
1. **Wait State (Idle):** The function block waits for an update event at the adapters `IN1` or `IN2`.
2. **Calculation:** After an event arrives, the division is performed.
3. **Update:** The result is applied to `OUT`, and the output event is triggered. The function block immediately returns to the wait state.

Comparison with Similar Function Blocks

- **Measurement Scaling:** Division of raw sensor data by a fixed scaling factor for conversion into physical units.
- **Average Calculation:** Division of a sum by the number of measured values in more complex computational networks.
- **Ratio Calculations:** Determining percentages or ratios in process engineering plants.
- **Classic `DIV` Module:** The classic IEC 61131-3 `DIV` module has dedicated pins for `IN1`, `IN2`, and `OUT`, as well as the corresponding `REQ` and `CNF` events. `AR_DIV_2_UNGATED` bundles these signals in adapters, simplifying wiring in large projects.
- **`AR_MUL_2` / `AR_ADD_2`:** These function blocks share the same adapter philosophy but perform multiplications and additions, respectively. They can be seamlessly chained with `AR_DIV_2_UNGATED` to form mathematical calculation trees.



Change Detection



This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AR_DIV_2_UNGATED` is a highly efficient, modular function block for arithmetic division. Through the consistent use of adapters, it is ideally suited for clean, well-organized software architectures in distributed automation according to the IEC 61499 standard.

AR_MULTIME

• – ○ • – ○ • – ○ •

Introduction

The function block **AR_MULTIME** is used to multiply a time value (type TIME) by a numeric value. The numeric factor is input via an adapter, allowing the function block to be used flexibly in various contexts. The result is also output via an adapter. The function block is classified as a standard arithmetic function according to IEC 61131-3.

Interface Structure

Event Inputs

- **REQ** (Event): Normal execution trigger. The multiplication is performed when an event occurs at REQ. The IN1 input must be connected to the REQ event (WITH).

Event Outputs

The function block does not have any explicit event outputs in the interface list. The result is provided via the adapter output **OUT**, which sends an event (E1) once the calculation is complete (as can be seen from the internal wiring).

Data Inputs

- **IN1** (TIME): First function input – the time value to be multiplied.

Data Outputs

The function block has no direct data outputs. The multiplication result is output as a data value (D1) via the adapter output **OUT**.

Adapters

- **IN2** (Adapter, type `adapter::types::unidirectional::AR`): Second function input – the numerical multiplier. This adapter provides an event (E1) for triggering the calculation as well as the data value (D1).
- **OUT** (Adapter, type `adapter::types::unidirectional::ATM`): Output for the multiplied result (TIME). Provides the event (E1) and data (D1).

Functionality

The function block AR_MULTIME encapsulates the functionality of the internal function block **F_MULTIME** (type `iec61131::arithmetic::F_MULTIME`).

When an event occurs at the **REQ** input or, alternatively, at the adapter input **IN2.E1**, the multiplication is initiated. The internal function block multiplies **IN1** (TIME) by **IN2.D1** (numeric value) and outputs the result to **OUT.D1**.

Once the calculation is complete, an event is sent to **OUT.E1**, signaling to the subsequent receiver that the result is valid.

Technical Features

- **Adapter-based interface:** Instead of classic data inputs/outputs, adapters are used, allowing for flexible interconnection in complex networks. The adapters are defined as unidirectional and require compatible counterparts.
- **Standard compliance:** The function block meets the requirements of IEC 61131-3 (classification: standard arithmetic function).
- **Internal Encapsulation:** The actual calculation is performed by the reusable function block F_MULTIME, so AR_MULTIME acts as a wrapper with adapter-based communication.

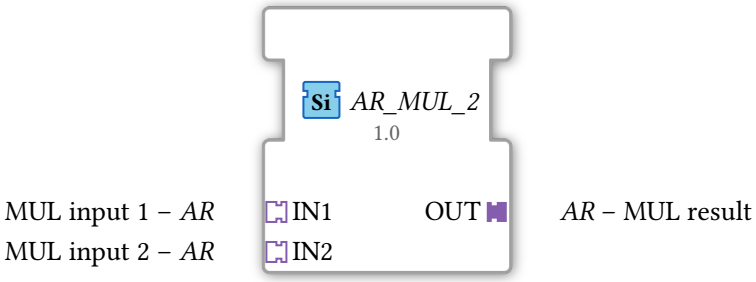
State Overview

The function block itself does not have an explicit state machine. Event-driven processing is deterministic:

- Waiting for an event at **REQ** or **IN2.E1**
- Executing the multiplication
- Sending the result to **OUT.E1** and **OUT.D1**
- Returning to the wait state

Application Scenarios

- Scaling time values by a constant or variable factor, e.g., converting seconds to milliseconds or extending delay times.
- In control applications where time parameters need to be dynamically adjusted, for example, in conjunction with PID controllers or scheduling.
- As part of libraries for IEC 61131-3 compliant automatic control, especially when adapters are used to decouple the signal paths.



Comparison with similar function blocks

- **F_MULTIME:** The direct, adapter-free function block for multiplying TIME by numeric values. It offers classic event and data interfaces. AR_MULTIME, on the other hand, encapsulates this function block and provides the interfaces via adapters, which increases reusability in adapter-based architectures.
- **AR_MUL:** A general multiplication function block with adapters that could be designed for any numeric type. AR_MULTIME is specifically specialized for TIME values.

Conclusion

The **AR_MULTIME** function block enables the multiplication of a time value by a numeric factor via a modern, adapter-based interface. It combines proven IEC 61131-3 arithmetic with flexible connectivity and is particularly suitable for modular automation systems that rely on standardized adapters. The internal use of the F_MULTIME function block guarantees reliable and efficient calculations.

AR_MUL_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block (FB) **AR_MUL_2** is a generic arithmetic block for the 4diac IDE. It is used to multiply two values that are transmitted via unidirectional adapters. By encapsulating the mathematical operation

in an adapter interface, this block enables clean, modular, and clear modeling of calculations within IEC 61499 applications.

Interface Structure

The block does not have any classic event- or data-based inputs and outputs. All communication is handled via adapters.

Event Inputs

No direct event inputs available. (Event control is implemented via the adapters.)

Event Outputs

No direct event outputs available.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AR`): First input value (multiplicand 1) for multiplication.
- **IN2** (Type: `adapter::types::unidirectional::AR`): Second input value (multiplicand 2) for multiplication.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AR`): Output for the calculated product of the multiplication ($OUT = IN1 \times IN2$).

Functionality

As soon as new values or corresponding trigger events arrive via the input adapters `IN1` and `IN2`, the function block multiplies the values of the two inputs. The result of the mathematical operation ($IN1 \cdot IN2$) is immediately passed to the output adapter `OUT` and made available for subsequent function blocks.

Since this is a generic function block (`GEN_AR_MUL`), its implementation is flexible with respect to the specific data types used within the `AR` adapter structure.

Technical Features

- **Generic Function Block:** The attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AR_MUL'` allows the function block to be used for various numeric data types, provided the adapters support them.
- **Unidirectional Adapters:** Using the type `unidirectional::AR` ensures a clean data flow without feedback loops, which increases application stability and minimizes latency.
- **Compiler Affiliation:** The function block is assigned to the package `adapter::iec61131::arithmetic` and conforms to the IEC 61499-2 standard.

State Overview

Since this function block primarily operates via adapters using data flow control, it does not have a complex internal state diagram (ECC). It acts as a stateless transfer element:

1. **Waiting:** The block waits for data updates at the adapters `IN1` and/or `IN2`.
2. **Calculation:** When a value changes, the product is calculated.
3. **Output:** The result is directly forwarded to the output `OUT`.

–

Application Scenarios

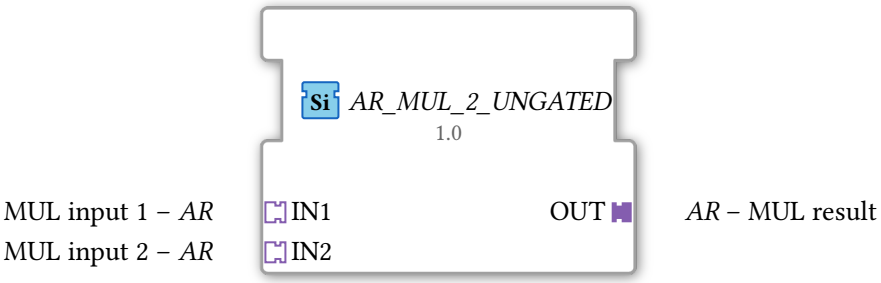
- **Measurement Scaling:** Multiplication of an analog sensor value (e.g., a voltage) by a scaling factor to convert it into a physical unit.
- **Signal Amplification:** Proportional amplification of control signals in process automation.
- **Mathematical Calculations:** Use as a modular component in more complex computational networks within 4diac applications.

Comparison with Similar Components

Compared to standard multiplication components (such as the classic `MUL` component according to IEC 61131-3), which work with elementary data types (e.g., `INT`, `REAL`), `AR_MUL_2` uses structured **adapters**. This offers the following advantages:

- **Reduced Wiring Effort:** Signals and associated control events are bundled in a single adapter connection.
- **Improved Readability:** Complex control diagrams remain clear because fewer individual connections need to be drawn on the workspace.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AR_MUL_2` function block is an efficient tool for arithmetic operations in modern, adapter-based control programs. Its encapsulation in unidirectional interfaces offers a high degree of reusability and ensures a clean and structured design within the 4diac environment.

AR_MUL_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AR_MUL_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

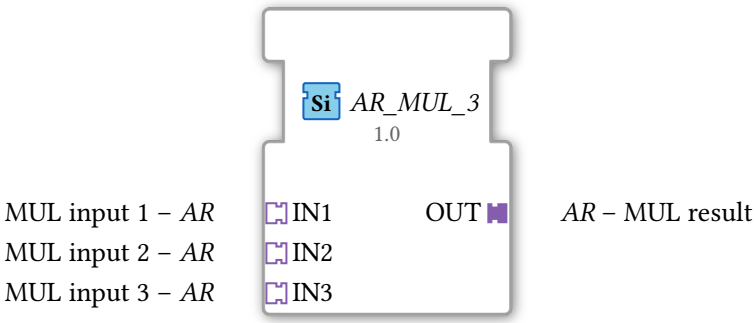
- **Mathematical Calculations:** Use as a modular component in more complex computational networks within 4diac applications.

Comparison with Similar Components

Compared to standard multiplication components (such as the classic `MUL` component according to IEC 61131-3), which work with elementary data types (e.g., `INT`, `REAL`), `AR_MUL_2_UNGATED` uses structured **adapters**. This offers the following advantages:

- **Reduced Wiring Effort:** Signals and associated control events are bundled in a single adapter connection.
- **Improved Readability:** Complex control diagrams remain clear because fewer individual connections need to be drawn on the workspace.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AR_MUL_2_UNGATED` function block is an efficient tool for arithmetic operations in modern, adapter-based control programs. Its encapsulation in unidirectional interfaces offers a high degree of reusability and ensures a clean and structured design within the 4diac environment.

AR_MUL_3

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AR_MUL_3` is a generic arithmetic block used to multiply three input values. It is based on the use of unidirectional adapters of type `AR` (Arithmetic), which enables structured and clear signal transmission within the 4diac IDE. As it is a generic block, it can be used flexibly with various numeric data types.

Interface Structure

The interfaces of this function block are implemented entirely via adapters. There are no directly accessible standard event or data channels.

Event Inputs

There are no direct event inputs. Event control is handled via the input adapters.

Event Outputs

There are no direct event outputs. Event control is handled via the output adapter.

Data Inputs

There are no direct data inputs. Data transmission occurs via the adapters.

Data Outputs

There are no direct data outputs. Data transmission occurs via the adapters.

Adapters

- **Sockets (Input Adapters):**
- `IN1` (Type: `adapter::types::unidirectional::AR`): First multiplicand (Input 1).
- `IN2` (Type: `adapter::types::unidirectional::AR`): Second multiplicand (Input 2).
- `IN3` (Type: `adapter::types::unidirectional::AR`): Third multiplicand (Input 3).
- **Plugs (Output Adapters):**
- `OUT` (Type: `adapter::types::unidirectional::AR`): Result of the multiplication ($OUT = IN1 \cdot IN2 \cdot IN3$).

Functionality

The function block performs a mathematical multiplication of the values present at the adapters `IN1`, `IN2`, and `IN3`:

$$OUT = IN1 \times IN2 \times IN3 \tag{2.64}$$

As soon as a calculation event (e.g., a value update) is signaled at the input adapters, the function block reads the current values, calculates the product, and outputs the result along with a corresponding update event via the output adapter `OUT`.

Technical Features

- **Generic Behavior (`GEN_AR_MUL`):** The function block is declared as a generic type. This allows it to be applied to various numeric data types (e.g., `INT`, `REAL`, `LREAL`) during development or runtime, provided the adapters used support these data types.
- **Adapter Structure:** Using `unidirectional::AR` adapters drastically reduces the number of visible connection lines in the function block diagram (FBD) because data and control events are bundled in a single connection.

State Overview

The function block behaves purely functionally and essentially has the following logical states:

- **Waiting (Idle):** The function block waits for a trigger event via the input adapters.
- **Evaluating:** After an event arrives, the input data is read and multiplied.
- **Update:** The calculated product is applied to output `OUT`, and the output event is triggered.

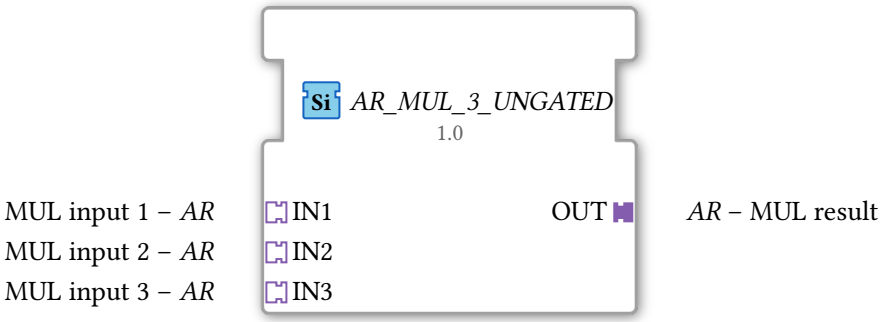
Application Scenarios

- **Volume Calculations:** Multiplying three dimensions (length × width × height) to determine a volume.
- **Scaling and Weighting:** Applying two consecutive scaling factors to a raw value (e.g., sensor value × calibration factor × unit conversion).
- **Physical Formulas:** Calculating quantities that depend directly on three variables (e.g., power $P = U \times I \times cos(\varphi)$ in a simplified view).

Comparison with Similar Function Blocks

- **Standard `MUL` (IEC 61131-3):** Classic multiplication blocks operate with discrete data and event pins. `AR_MUL_3` uses adapters instead, which makes the design clearer.
- **`AR_MUL_2`:** Multiplies only two values. `AR_MUL_3` eliminates the need for an additional cascading block when three variables need to be multiplied, thus optimizing performance and clarity.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AR_MUL_3` is a practical and reusable function block for modern IEC 61499 development in 4diac. By encapsulating the mathematical logic in an adapter-based structure, it significantly contributes to the clarity of complex control applications.

AR_MUL_3_UNGATED

i UNGATED variant: This block is the ungated version of AR_MUL_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

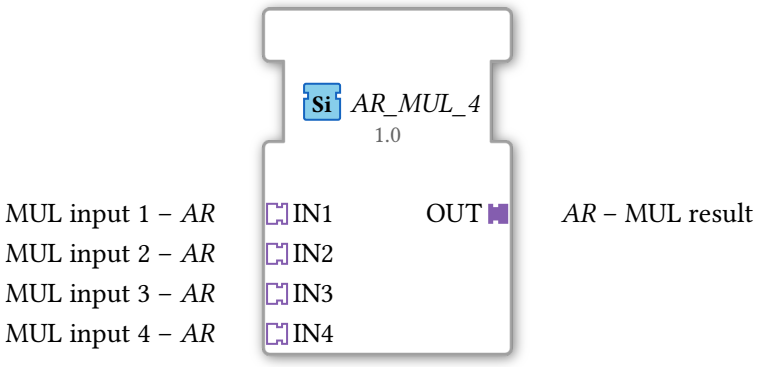
- **Evaluating:** After an event arrives, the input data is read and multiplied.
- **Update:** The calculated product is applied to output `OUT`, and the output event is triggered.

Application Scenarios

- **Volume Calculations:** Multiplying three dimensions (length × width × height) to determine a volume.
- **Scaling and Weighting:** Applying two consecutive scaling factors to a raw value (e.g., sensor value × calibration factor × unit conversion).
- **Physical Formulas:** Calculating quantities that depend directly on three variables (e.g., power $P = U \times I \times cos(\varphi)$ in a simplified view).

Comparison with Similar Function Blocks

- **Standard `MUL` (IEC 61131-3):** Classic multiplication blocks operate with discrete data and event pins. `AR_MUL_3_UNGATED` uses adapters instead, which makes the design clearer.
- **`AR_MUL_2`:** Multiplies only two values. `AR_MUL_3_UNGATED` eliminates the need for an additional cascading block when three variables need to be multiplied, thus optimizing performance and clarity.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AR_MUL_3_UNGATED` is a practical and reusable function block for modern IEC 61499 development in 4diac. By encapsulating the mathematical logic in an adapter-based structure, it significantly contributes to the clarity of complex control applications.

AR_MUL_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block AR_MUL_4 is a generic arithmetic block used to multiply four input values. It is based on an adapter interface that enables clean encapsulation and structuring of data and associated events. Due to its generic nature (GEN_AR_MUL), the block can flexibly adapt to various numeric data types.

Interface Structure

Event Inputs

The block does not have direct, dedicated event inputs. Synchronization and triggering of the calculation are implicit via the connected input adapters.

Event Outputs

The block does not have direct, dedicated event outputs. Calculation and update events are forwarded via the output adapter.

Data Inputs

There are no direct data inputs. The values for multiplication are read via the adapter interfaces.

Data Outputs

There are no direct data outputs. The result of the multiplication is provided via the output adapter.

Adapters

Communication with other function blocks is exclusively via adapters of type adapter::types::unidirectional::AR:

- **Sockets (Input Adapters):**
- IN1: First multiplicand (Input 1).
- IN2: Second multiplicand (Input 2).
- IN3: Third multiplicand (Input 3).
- IN4: Fourth multiplicand (Input 4).
- **Plugs (Output Adapters):**
- OUT: The calculated product of the four inputs.

Functionality

As soon as new values and the corresponding trigger events arrive via the input adapters (IN1 to IN4), the function block multiplies the values together. The mathematical behavior corresponds to the formula:

$$\mathrm{OUT} = \mathrm{IN1} \times \mathrm{IN2} \times \mathrm{IN3} \times \mathrm{IN4} \tag{2.66}$$

The result is output via the output adapter OUT, along with a corresponding update event.

Technical Features

- **Generic Behavior:** The attribute eclipse4diac::core::GenericClassName with the value GEN_AR_MUL makes the function block data type-independent. Depending on the application, it can work with various numeric data types (e.g., INT, REAL, LREAL) supported by the adapter type AR.
- **Adapter Coupling:** The use of unidirectional adapters (AR) significantly reduces wiring effort in the 4diac IDE, as data and control events are bundled in a single connection.

State Overview

Since this is a purely mathematical calculation function block, it is stateless. Each activation directly calculates the current product based on the input adapter values.

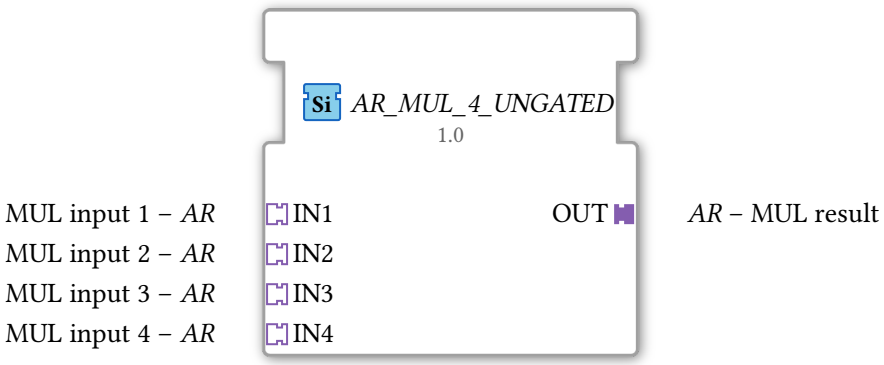
Application Scenarios

- **Signal Scaling:** Calibration or adjustment of sensor values where multiple factors (e.g., base value, gain, correction factor, unit conversion) need to be multiplied.
- **Physical Calculations:** Calculation of more complex quantities such as volumetric flow rates, electrical power, or energy flows, involving multiple measured variables and constant factors.
- **Cascade Avoidance:** Consolidating multiple multiplication steps into a single block to improve clarity in the application diagram.

Comparison with Similar Function Blocks

Compared to conventional IEC 61131-3 `MUL` function blocks, which often only have two inputs and use direct data and event pins, the `AR_MUL_4` offers a significantly cleaner visual representation in the control program by combining four inputs and using adapters. It eliminates the need to cascade multiple multipliers.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AR_MUL_4` is a practical auxiliary function block for arithmetic operations in the IEC 61499 environment. Through the consistent use of adapters, it significantly contributes to the clarity and modularity of control programs, especially when processing more complex mathematical formulas.

AR_MUL_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AR_MUL_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AR_MUL_4_UNGATED` is a generic arithmetic block used to multiply four input values. It is based on an adapter interface that enables clean encapsulation and structuring of data and associated events. Due to its generic nature (`GEN_AR_MUL`), the block can flexibly adapt to various numeric data types.

Interface Structure

Event Inputs

The block does not have direct, dedicated event inputs. Synchronization and triggering of the calculation are implicit via the connected input adapters.

Event Outputs

The block does not have direct, dedicated event outputs. Calculation and update events are forwarded via the output adapter.

Data Inputs

There are no direct data inputs. The values for multiplication are read via the adapter interfaces.

Data Outputs

There are no direct data outputs. The result of the multiplication is provided via the output adapter.

Adapters

Communication with other function blocks is exclusively via adapters of type `adapter::types::unidirectional::AR`:

- **Sockets (Input Adapters):**
- `IN1`: First multiplicand (Input 1).
- `IN2`: Second multiplicand (Input 2).
- `IN3`: Third multiplicand (Input 3).
- `IN4`: Fourth multiplicand (Input 4).
- **Plugs (Output Adapters):**
- `OUT`: The calculated product of the four inputs.

Functionality

As soon as new values and the corresponding trigger events arrive via the input adapters (`IN1` to `IN4`), the function block multiplies the values together. The mathematical behavior corresponds to the formula:

$$\mathrm{OUT} = \mathrm{IN1} \times \mathrm{IN2} \times \mathrm{IN3} \times \mathrm{IN4} \tag{2.67}$$

The result is output via the output adapter `OUT`, along with a corresponding update event.

Technical Features

- **Generic Behavior:** The attribute `eclipse4diac::core::GenericClassName` with the value `GEN_AR_MUL` makes the function block data type-independent. Depending on the application, it can work with various numeric data types (e.g., `INT`, `REAL`, `LREAL`) supported by the adapter type `AR`.
- **Adapter Coupling:** The use of unidirectional adapters (`AR`) significantly reduces wiring effort in the 4diac IDE, as data and control events are bundled in a single connection.

State Overview

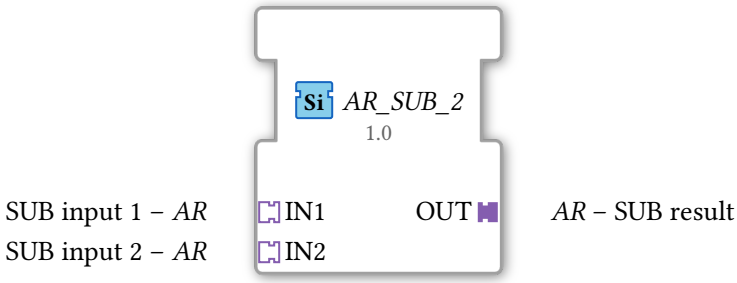
Since this is a purely mathematical calculation function block, it is stateless. Each activation directly calculates the current product based on the input adapter values.

Application Scenarios

- **Signal Scaling:** Calibration or adjustment of sensor values where multiple factors (e.g., base value, gain, correction factor, unit conversion) need to be multiplied.
- **Physical Calculations:** Calculation of more complex quantities such as volumetric flow rates, electrical power, or energy flows, involving multiple measured variables and constant factors.
- **Cascade Avoidance:** Consolidating multiple multiplication steps into a single block to improve clarity in the application diagram.

Comparison with Similar Function Blocks

Compared to conventional IEC 61131-3 `MUL` function blocks, which often only have two inputs and use direct data and event pins, the `AR_MUL_4_UNGATED` offers a significantly cleaner visual representation in the control program by combining four inputs and using adapters. It eliminates the need to cascade multiple multipliers.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AR_MUL_4_UNGATED` is a practical auxiliary function block for arithmetic operations in the IEC 61499 environment. Through the consistent use of adapters, it significantly contributes to the clarity and modularity of control programs, especially when processing more complex mathematical formulas.

AR_SUB_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AR_SUB_2` is used to perform an arithmetic subtraction (subtrahend of minuend). It is a generic function block (`GEN_AR_SUB`) that does not use classic discrete inputs and outputs for the calculation, but is based entirely on an adapter-based interface structure. The values and the associated control logic are transferred via unidirectional adapters of type `AR`.

Interface Structure

Event Inputs

This function block does not have direct, discrete event inputs. Event control is implemented via the connected adapters.

Event Outputs

This function block does not have direct, discrete event outputs. Event forwarding is encapsulated via the output adapter.

Data Inputs

There are no direct data inputs. Input data is received via the adapter inputs.

Data Outputs

There are no direct data outputs. The calculation result is provided via the adapter output.

Adapters

- **Sockets (Input Adapters):**
- **IN1** (Type: `adapter::types::unidirectional::AR`): First input for subtraction (minuend).
- **IN2** (Type: `adapter::types::unidirectional::AR`): Second input for subtraction (subtrahend).
- **Plugs (Output Adapters):**
- **OUT** (Type: `adapter::types::unidirectional::AR`): Output for the result of the subtraction ($OUT = IN1 - IN2$).

Functionality

The function block subtracts the value at adapter `IN2` from the value at adapter `IN1`. The result of this arithmetic operation is passed to the output plug `OUT`.

Since these are unidirectional adapters, incoming events on sockets `IN1` or `IN2` trigger the internal calculation. After the subtraction is complete, the corresponding update event is signaled to the subsequent function blocks via plug `OUT`.

Technical Features

- **Generic Type (`GEN_AR_SUB`)**: The function block is implemented generically. This allows for flexible handling of various numeric data types, provided they are permitted within the definition of the `AR` adapter structure.
- **Encapsulation**: By using adapters, data and event lines are bundled. This significantly reduces the number of visible connection lines in the 4diac IDE function block diagram.

State Overview

The function block does not have a complex internal state machine (no Execution Control Chart - ECC) because it is a purely data-flow-oriented computation block. The processing behavior is as follows:

1. **Waiting for Event**: The function block waits for an update event at `IN1` or `IN2`.
2. **Calculation**: Upon receiving an event, the current values from `IN1` and `IN2` are read and subtracted from each other.
3. **Output**: The result is written to `OUT`, and an output event is triggered at plug `OUT`.

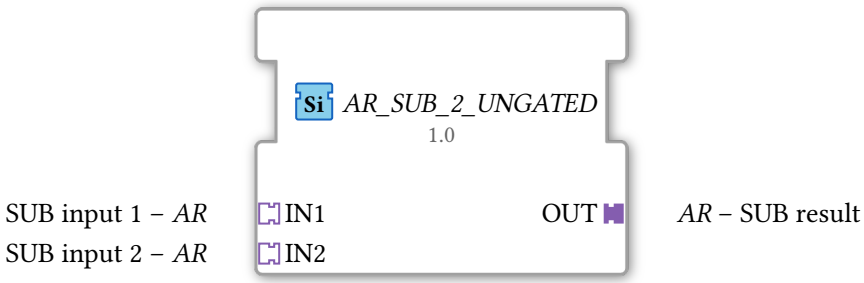
Application Scenarios

- **Target-Actual Value Comparison**: Calculation of the control deviation ($e = w - x$) in control loops where the signals are already available as adapter structures.
- **Offset Compensation**: Subtraction of a zero-point error or offset from an analog sensor value.
- **Structured Signal Processing**: Mathematical calculations in complex, distributed control systems to maintain a clear software architecture.

Comparison with Similar Components

Compared to the standard subtraction block `SUB` (based on classic IEC 61131-3 elements), which uses discrete inputs like `IN1` and `IN2` as well as explicit events (`REQ` / `CNF`), `AR_SUB_2` offers a significantly higher level of abstraction through the use of adapters. This saves development time when coupling complex signal elements, but requires consistent use of adapters throughout the entire project.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AR_SUB_2` is a specialized and modern computing component for the 4diac IDE. It is ideally suited for service-oriented architectures within IEC 61499, where clarity and standardized adapter interfaces are paramount.

AR_SUB_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AR_SUB_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AR_SUB_2_UNGATED` is used to perform an arithmetic subtraction (subtrahend of minuend). It is a generic function block (`GEN_AR_SUB`) that does not use classic discrete inputs and outputs for the calculation, but is based entirely on an adapter-based interface structure. The values and the associated control logic are transferred via unidirectional adapters of type `AR`.

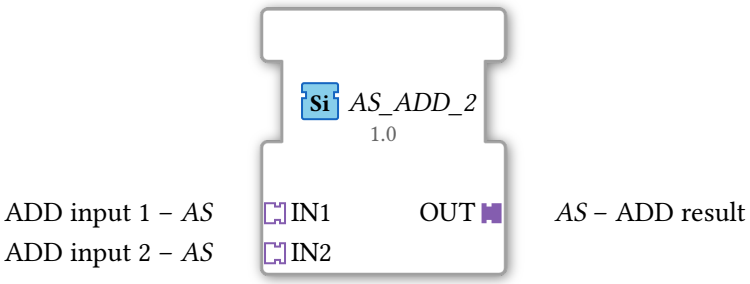
Comparison with Similar Components

Compared to the standard subtraction block `SUB` (based on classic IEC 61131-3 elements), which uses discrete inputs like `IN1` and `IN2` as well as explicit events (`REQ` / `CNF`), `AR_SUB_2_UNGATED` offers a significantly higher level of abstraction through the use of adapters. This saves development time when coupling complex signal elements, but requires consistent use of adapters throughout the entire project.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AR_SUB_2_UNGATED` is a specialized and modern computing component for the 4diac IDE. It is ideally suited for service-oriented architectures within IEC 61499, where clarity and standardized adapter interfaces are paramount.

AS_ADD_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AS_ADD_2` is a generic arithmetic block designed for adding two values. Unlike classic mathematical function blocks, this block uses an adapter-based interface concept. The use of unidirectional adapters allows data and the associated control events to be transmitted in encapsulated form, contributing to a clean and modular application design in the IEC 61499 development environment (such as 4diac IDE).

Interface Structure

Event Inputs

No direct event inputs are available. Event control is integrated into the input adapters.

Event Outputs

No direct event outputs are available. Event control is integrated into the output adapter.

Data Inputs

No direct data inputs are available. Data transmission is encapsulated via the input adapters.

Data Outputs

No direct data outputs are available. Data transmission is encapsulated via the output adapter.

Adapters

- **IN1 (Socket):** Type `adapter::types::unidirectional::AS`
- Interface for the first addend of the addition.
- **IN2 (Socket):** Type `adapter::types::unidirectional::AS`
- Interface for the second addend of the addition.
- **OUT (Plug):** Type `adapter::types::unidirectional::AS`
- Interface for outputting the calculated addition result.

Functionality

The function block `AS_ADD_2` performs the mathematical operation:

$$OUT = IN1 + IN2 \tag{2.68}$$

As soon as new data is signaled at the input adapters (`IN1` or `IN2`), the function block internally triggers the addition of the transmitted values. The result is then immediately calculated and passed on to the subsequent logic elements via the output adapter `OUT`, along with a corresponding update event.

Due to its generic nature (GEN_AS_ADD), the function block can flexibly work with various numeric data types, provided the underlying adapter type AS supports them.

- **Generic Implementation:** The function block is based on the generic class GEN_AS_ADD, making it reusable for different data types.
- **Adapter Coupling:** Encapsulating signals in adapters drastically reduces the number of visible connection lines in the function block diagram (FBD) and improves the readability of complex applications.
- **Unidirectional Data Flow:** Using the type unidirectional::AS ensures that the information flow is clearly defined, running from the signal sources (sockets) to the signal sink (plug).

Technical Features

As a purely mathematical combination block, AS_ADD_2 does not have a complex internal state diagram (ECC). Its behavior can be divided into three cyclical steps:

State Overview

1. **Waiting (Idle):** The module waits for an event at one of the input adapters (IN1 or IN2).
2. **Calculate:** Upon receiving an event, the current values from both adapters are read and added together.
3. **Send:** The result of the addition is written to the output adapter OUT, triggering an output event.

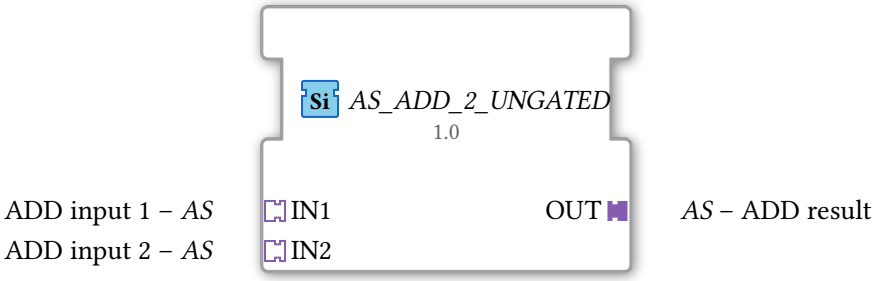
Application Scenarios

- **Measurement Offset Calculation:** Adding a calibration or correction value (offset) to an analog sensor value within an adapter-based signal processing chain.
- **Signal Combining:** Summing two independently measured physical quantities (e.g., two partial currents to determine the total current).
- **Cascaded Calculations:** Easy expansion for more than two summands by cascading multiple AS_ADD_2 blocks.
- **Standard ADD (e.g., F_ADD):** The classic IEC 61131-3 or IEC 61499 ADD block works with discrete variables (e.g., ANY_NUM) and separate event ports (REQ / CNF). AS_ADD_2, on the other hand, bundles these signals in adapters, which simplifies wiring but requires the use of the specific adapter type AS.
- **Multi-Adder (e.g., ADD_3):** Enables the addition of three or more values in a single function block, but is often more cumbersome when data structures need to be consistently transported via adapters.

Comparison with Similar Function Blocks

The AS_ADD_2 is a specialized auxiliary function block for modern, modular IEC 61499 control programs. Through the consistent use of adapters, it integrates seamlessly into service-oriented architectures and minimizes design and wiring effort in the 4diac IDE.

Change Detection



The result is only written to the output plug (OUT) and its adapter event only sent if the newly computed value differs from the value currently held on OUT. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AS_ADD_2 is a clean, adapter-based addition block that keeps a two-input arithmetic operation consistent with the rest of the adapter-based AS family, making it easy to wire and reuse across IEC 61499 applications.

AS_ADD_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AS_ADD_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

AS_ADD_3

Introduction

The function block `AS_ADD_3` is a generic function block (FB) for IEC 61499, designed to perform arithmetic addition of three input values. A key feature of this block is that it has no direct data or event inputs/outputs, but relies entirely on the use of unidirectional adapters. This significantly simplifies modeling and wiring in more complex systems.

Interface Structure

Event Inputs
This function block has no direct event inputs. Event control is handled via the connected adapters.

Event Outputs
This function block has no direct event outputs. Events are forwarded via the output adapter.

Data Inputs
There are no direct data inputs.

Data Outputs
There are no direct data outputs.

Adapters
The module communicates exclusively via adapter interfaces.

Sockets (Inputs):
- **IN1** (Type: `adapter::types::unidirectional::AS`): First input for addition.
- **IN2** (Type: `adapter::types::unidirectional::AS`): Second input for addition.
- **IN3** (Type: `adapter::types::unidirectional::AS`): Third input for addition.

Plugs (Outputs):
- **OUT** (Type: `adapter::types::unidirectional::AS`): Output providing the result of the addition (`IN1 + IN2 + IN3`).

Functionality
The function block `AS_ADD_3` performs a classic addition:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} \tag{2.70}$$

Since the block is defined as a generic function block (`GEN_AS_ADD`), it can process various numeric data types (e.g., `INT`, `REAL`, `DINT`) depending on the specific instantiation and the data type used in the adapter.

As soon as new values and their corresponding events are signaled at the input adapters (`IN1`, `IN2`, `IN3`), the function block calculates the sum and triggers the corresponding output event at the `OUT` adapter to pass the new value on to subsequent function blocks.

Technical Features
- **Generic Type (Generic FB):** The function block uses the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AS_ADD'`. This allows for flexible adaptation to different data types without having to create a separate function block for each type.
- **Encapsulation via Adapters:** By using unidirectional adapters (`AS`), data and the associated trigger events are encapsulated in a single connection. This ensures a clean and uncluttered user interface design in the 4diac IDE.

State Overview
The function block operates in an event-driven manner and does not have a complex internal state diagram (ECC). Its execution is triggered by the adapter events received at the sockets:

1. **Waiting:** The function block waits for an update event at the adapters `IN1`, `IN2`, or `IN3`.
2. **Calculation:** Upon receiving an event, the current values of the three inputs are added together.
3. **Output:** The result is created in the plug `OUT`, and an update event is sent via the adapter.

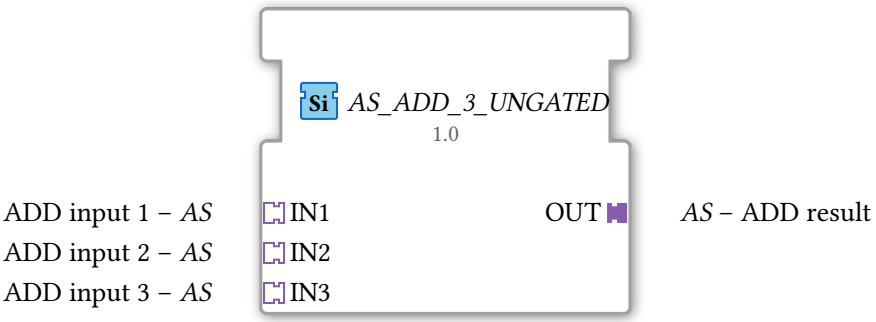
Application Scenarios
- **Measurement Summing:** Addition of three analog sensor values (e.g., three flow meters to calculate a total flow rate).

- **Setpoint Offset Calculation:** Calculation of an overall setpoint based on a base setpoint, a user offset, and a correction value from a higher-level controller.
- **Signal Source Combination:** Combining three partial signals in process automation using standardized adapter structures.
-

Comparison with Similar Components

- **Standard ADD Components (IEC 61131-3):** Classic ADD components use dedicated data pins (e.g., `IN1`, `IN2`) and separate event pins (`REQ`, `CNF`). `AS_ADD_3` minimizes the wiring effort in the FBD (Function Block Diagram) by using adapters.
- **AS_ADD_2 (Two-Way Adder):** Compared to a variant with only two inputs, the `AS_ADD_3` saves an entire component and the associated intermediate wiring when adding three values.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AS_ADD_3` is a highly efficient, modular component for adding three values. Thanks to the consistent use of unidirectional adapters, it integrates perfectly into modern, service-oriented, and well-structured IEC 61499 control applications.

AS_ADD_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AS_ADD_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

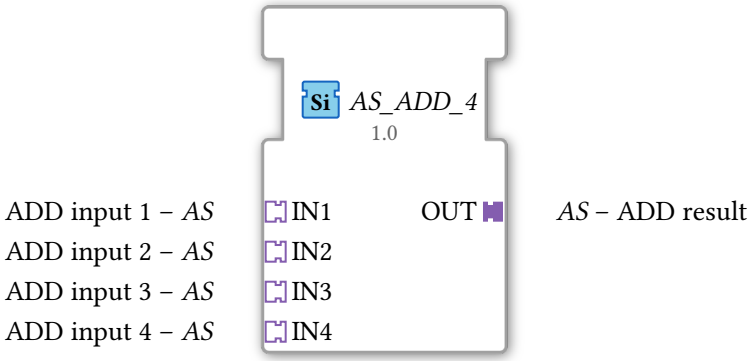
- **AS_ADD_2 (Two-Way Adder):** Compared to a variant with only two inputs, the `AS_ADD_3_UNGATED` saves an entire component and the associated intermediate wiring when adding three values.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AS_ADD_3_UNGATED` is a highly efficient, modular component for adding three values. Thanks to the consistent use of unidirectional adapters, it integrates perfectly into modern, service-oriented, and well-structured IEC 61499 control applications.

AS_ADD_4

(Image of function block not available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AS_ADD_4` is a generic function block (FB) designed to perform an arithmetic addition of four input values. The unique feature of this block lies in the use of unidirectional adapters (`AS`) for the inputs and outputs, enabling structured and clean encapsulation of data and associated events in IEC 61499 applications.

Interface Structure

Event Inputs

There are no direct event inputs. Event control is implicit via the adapter interfaces.

Event Outputs

There are no direct event outputs. Event forwarding is implicit via the output adapter.

Data Inputs

There are no direct data inputs. Data is transferred via the input adapters.

Data Outputs

There are no direct data outputs. The result is provided via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AS`): First input value (addend 1) for addition.
- **IN2** (Type: `adapter::types::unidirectional::AS`): Second input value (addend 2) for addition.

- **IN3** (Type: `adapter::types::unidirectional::AS`): Third input value (addend 3) for addition.
- **IN4** (Type: `adapter::types::unidirectional::AS`): Fourth input value (addend 4) for the addition.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AS`): Output adapter for displaying the calculated addition result.

Functionality

This function block performs a mathematical addition of the values received via the four input adapters (`IN1` to `IN4`). The mathematical formula is:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} + \mathrm{IN4} \tag{2.72}$$

The calculation is typically triggered as soon as a corresponding update event arrives at one or more of the input adapters. After successful calculation, the result, along with a trigger event, is forwarded via the output adapter `OUT`.

Technical Features

- **Generic Nature:** The function block is declared as a generic function block (`GEN_AS_ADD`). This allows for flexible handling of different data types (e.g., `INT`, `REAL`, `DINT`), depending on how the underlying adapter types are defined.
- **Adapter Coupling:** By using unidirectional adapters, the risk of incorrect pin wiring in the 4diac IDE is reduced, as data and events are transmitted together in a single connection.
-

State Overview

Since this is an algorithmic function block for calculations, the FB operates statelessly or event-driven:

1. **Waiting:** The function block waits for an update event at input adapters `IN1` to `IN4`.
2. **Calculation:** Upon arrival of an event, the current values of the inputs are added together.
3. **Output:** The new total value is written to adapter `OUT`, and the corresponding output event is triggered.

–

Application Scenarios

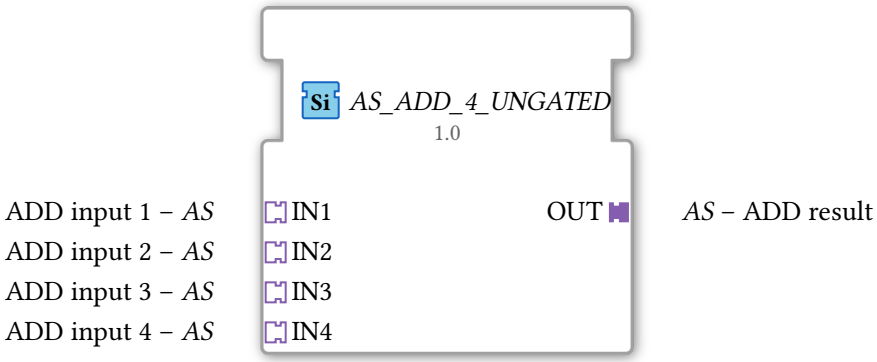
- **Measurement Value Summation:** Summarizing four analog sensor values (e.g., flow rates or power) into a single total value.
- **Setpoint Generation:** Adding base setpoints with various correction or offset values in a cascade control system.
- **Structured Signal Processing:** Used in complex control architectures where a strict separation of logic and data flow is required through adapter structures.

Comparison with Similar Components

Compared to a classic, standard `ADD` component (according to IEC 61131-3):

- **Advantage:** Reduced wiring effort in the graphical user interface, as separate event and data lines do not need to be drawn.
- **Disadvantage:** Requires the definition and use of the specific adapter type `adapter::types::unidirectional::AS`. Direct connection of standard data types (such as simple `REAL` or `INT` variables) without an adapter is not possible.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AS_ADD_4 is a specialized, highly efficient function block for modern, adapter-based programming in the 4diac IDE. It is ideally suited for applications that require a high degree of modularity and clarity in the signal flow and need to add four summands cleanly and efficiently.

AS_ADD_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AS_ADD_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

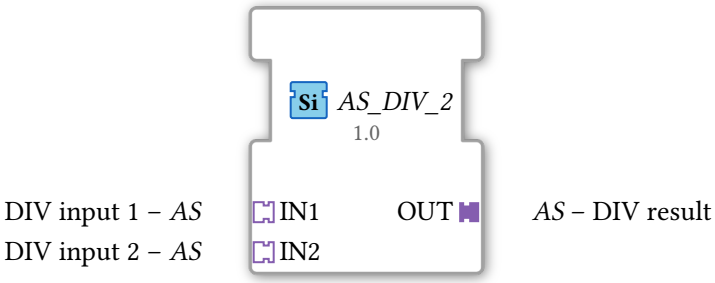
Compared to a classic, standard `ADD` component (according to IEC 61131-3):

- **Advantage:** Reduced wiring effort in the graphical user interface, as separate event and data lines do not need to be drawn.
- **Disadvantage:** Requires the definition and use of the specific adapter type `adapter::types::unidirectional::AS`. Direct connection of standard data types (such as simple `REAL` or `INT` variables) without an adapter is not possible.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AS_ADD_4_UNGATED` is a specialized, highly efficient function block for modern, adapter-based programming in the 4diac IDE. It is ideally suited for applications that require a high degree of modularity and clarity in the signal flow and need to add four summands cleanly and efficiently.

AS_DIV_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block (FB) `AS_DIV_2` is a generic block for performing arithmetic division within the context of the IEC 61499 architecture. It utilizes an adapter-based data transmission concept and enables clean and structured signal processing by receiving input data via standardized adapters, calculating the division, and passing the result to an output adapter.

Interface Structure

Event Inputs

This function block does not have direct event inputs. Control and triggering are implicit via the connected adapters.

Event Outputs

This function block does not have direct event outputs.

Data Inputs

This function block does not have direct data inputs.

Data Outputs

This function block does not have direct data outputs.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AS`):
- Represents the first input value of the division (dividend).
- **IN2** (Type: `adapter::types::unidirectional::AS`):
- Represents the second input value of the division (divisor).

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AS`):
- Outputs the result of the division (quotient).

Functionality

The function block `AS_DIV_2` performs a mathematical division of the passed input values. The basic formula is:

$$\mathrm{OUT} = \frac{\mathrm{IN1}}{\mathrm{IN2}} \tag{2.74}$$

As soon as the values at the input adapters `IN1` or `IN2` change, or a corresponding event is transmitted via the adapters, the division is performed and the result is provided via the output adapter `OUT`.

Technical Features

- **Generic Block:** The attribute `GenericClassName = 'GEN_AS_DIV'` defines the block as a generic type. This allows for high flexibility when processing different numeric data types.
- **Adapter Encapsulation:** Instead of using loose data and event lines, this block exclusively uses unidirectional adapters of type `AS`. This ensures a clean and clear application diagram in the 4diac IDE.
- **Division by Zero:** During implementation and use, it is important to ensure that the divisor (`IN2`) is not equal to zero to avoid a runtime error (division by zero).

State Overview

Since it is a purely mathematical/arithmetic function block, the `AS_DIV_2` does not have a complex internal state machine (ECC). The output values are calculated directly based on the input signals applied to the adapters.

–

Application Scenarios

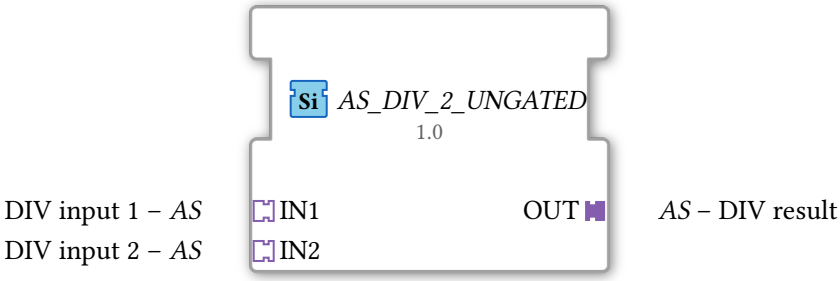
- **Measurement Scaling:** Conversion and normalization of analog sensor values (e.g., dividing a raw value to convert it into a physical unit).
- **Percentage Calculations:** Determination of ratios or percentages in industrial processes.
- **Signal Preprocessing:** Mathematical reduction of process data directly at the field level before forwarding to higher-level systems.

Comparison with Similar Components

Compared to classic IEC 61131-3 `DIV` components, which use direct data pins, the `AS_DIV_2` offers significantly improved encapsulation through the use of adapters. The number of connection lines in the CFC (Continuous Function Chart) is significantly reduced, which improves maintainability, especially for large and complex control programs.

–

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AS_DIV_2` is a robust and versatile component for arithmetic division in distributed control systems. Its consistent use of the adapter concept supports modern, modular software design according to the IEC 61499 standard.

AS_DIV_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AS_DIV_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

The function block `AS_DIV_2_UNGATED` performs a mathematical division of the passed input values. The basic formula is:

$$\mathrm{OUT} = \frac{\mathrm{IN1}}{\mathrm{IN2}} \tag{2.75}$$

As soon as the values at the input adapters `IN1` or `IN2` change, or a corresponding event is transmitted via the adapters, the division is performed and the result is provided via the output adapter `OUT`.

Technical Features

- **Generic Block:** The attribute `GenericClassName = 'GEN_AS_DIV'` defines the block as a generic type. This allows for high flexibility when processing different numeric data types.
- **Adapter Encapsulation:** Instead of using loose data and event lines, this block exclusively uses unidirectional adapters of type `AS`. This ensures a clean and clear application diagram in the 4diac IDE.
- **Division by Zero:** During implementation and use, it is important to ensure that the divisor (`IN2`) is not equal to zero to avoid a runtime error (division by zero).

State Overview

Since it is a purely mathematical/arithmetic function block, the `AS_DIV_2_UNGATED` does not have a complex internal state machine (ECC). The output values are calculated directly based on the input signals applied to the adapters.

–

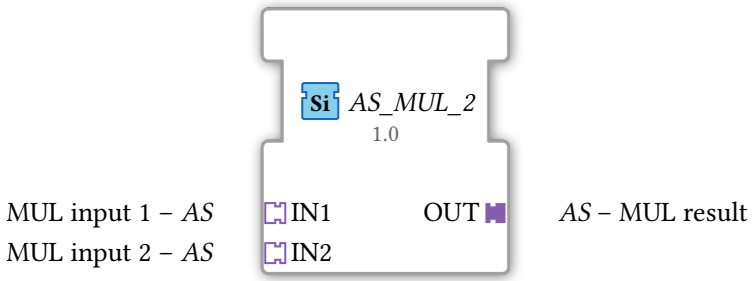
Application Scenarios

- **Measurement Scaling:** Conversion and normalization of analog sensor values (e.g., dividing a raw value to convert it into a physical unit).
- **Percentage Calculations:** Determination of ratios or percentages in industrial processes.
- **Signal Preprocessing:** Mathematical reduction of process data directly at the field level before forwarding to higher-level systems.

Comparison with Similar Components

Compared to classic IEC 61131-3 `DIV` components, which use direct data pins, the `AS_DIV_2_UNGATED` offers significantly improved encapsulation through the use of adapters. The number of connection lines in the CFC (Continuous Function Chart) is significantly reduced, which improves maintainability, especially for large and complex control programs.

–



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AS_DIV_2_UNGATED` is a robust and versatile component for arithmetic division in distributed control systems. Its consistent use of the adapter concept supports modern, modular software design according to the IEC 61499 standard.

AS_MUL_2

– ◦ – ◦ – ◦

Introduction

The function block `AS_MUL_2` is a generic, arithmetic multiplication block for IEC 61499 applications in the 4diac IDE. It is used to multiply two input values. The special feature of this block lies in the use of

adapter interfaces instead of classic, discrete event and data channels. This enables structured and clear signal transmission.

Interface Structure

The block does not have any directly accessible standard event or data pins, but rather encapsulates these completely in adapters.

Event Inputs

No direct event inputs available (events are received via the adapters).

Event Outputs

No direct event outputs available (events are sent via the adapters).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

- **Sockets (Input Interfaces):**
- `IN1` (Type: `adapter::types::unidirectional::AS`): The first input (multiplicand) for calculation.
- `IN2` (Type: `adapter::types::unidirectional::AS`): The second input (multiplier) for calculation.
- **Plugs (Output Interfaces):**
- `OUT` (Type: `adapter::types::unidirectional::AS`): The result of the multiplication ($OUT = IN1 \times IN2$).

Functionality

As soon as data and a triggering event are received via the input adapters `IN1` and `IN2`, the function block performs the multiplication. The mathematical product of the two input values is calculated and, together with the corresponding trigger event, is made available for further use in the system via the output adapter `OUT`.

Since the function block is designed generically (`GenericClassName = 'GEN_AS_MUL'`), it adapts flexibly to the underlying data types of the connected adapters (e.g., `INT`, `REAL`, `DINT`).

Technical Features

- **Generic Function Block:** By defining it as `GEN_AS_MUL`, the function block is not tied to a specific data type.
- **Unidirectional Adapter Coupling:** Using the adapter type `adapter::types::unidirectional::AS` ensures a clear, directed flow of data and signals, thus preventing feedback loops.
- **Reduced Editor Complexity:** Encapsulating data and events in adapters minimizes the visual "spaghetti code" problem (too many connecting lines) in the 4diac IDE.

State Overview

The function block behaves purely event-driven:

1. **Waiting State:** The function block waits for an event at sockets `IN1` or `IN2`.
2. **Calculation:** Upon receipt of an event, the current values from `IN1` and `IN2` are read and multiplied.
3. **Output:** The result is applied to `OUT`, and an output event is emitted via plug `OUT`.

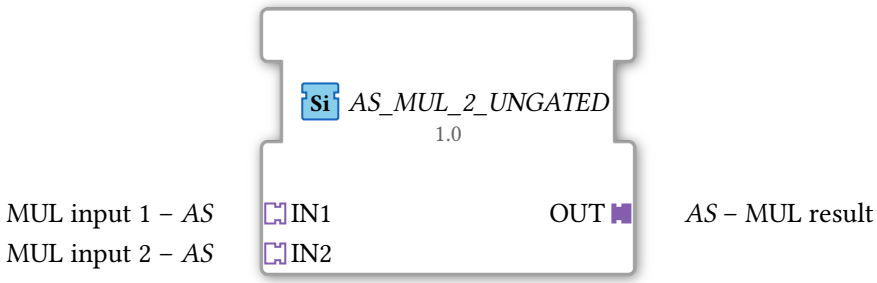
Application Scenarios

- **Signal Scaling:** Multiplication of analog sensor values by a scaling factor supplied via an adapter.
- **Modular Calculations:** Used in more complex mathematical computing networks where structured data streams need to be transported via adapter buses.
- **Power Calculation:** Multiplication of current and voltage values to determine electrical power in real-time systems.

Comparison with Similar Components

Compared to a standard IEC 61131-3 / IEC 61499 `MUL` component, which uses individual pins for `REQ`, `CNF`, `IN1`, `IN2`, and `OUT`, `AS_MUL_2` combines these signals into a single logical channel per pin. This increases reusability and ensures a cleaner application design, but requires the definition and use of appropriate adapter types in the project.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AS_MUL_2` is a modern and flexible function block for arithmetic operations in IEC 61499 control programs. Thanks to its generic structure and consistent use of adapters, it is ideally suited for clean, modular, and easily maintainable software architectures in industrial automation.

AS_MUL_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AS_MUL_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

The `AS_MUL_2_UNGATED` is a modern and flexible function block for arithmetic operations in IEC 61499 control programs. Thanks to its generic structure and consistent use of adapters, it is ideally suited for clean, modular, and easily maintainable software architectures in industrial automation.

AS_MUL_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AS_MUL_3` is a generic function block (FB) for the 4diac IDE, used to perform arithmetic multiplication with three input values. It is based on the use of unidirectional adapters (`adapter::types::unidirectional::AS`), which enables clean structuring and encapsulation of data and control flows in IEC 61499 applications.

Interface Structure

Event Inputs

This function block does not have direct event inputs. Control and event processing are handled implicitly via the adapter interfaces.

Event Outputs

This function block does not have direct event outputs. Event forwarding is implicit via the adapter interfaces.

Data Inputs

This function block has no direct data inputs. Data is transferred via the adapter interface sockets.

Data Outputs

This function block has no direct data outputs. Data output is via the adapter interface plug.

Adapters

All communication for this function block is handled via adapters:

- **Sockets (Input Adapters):**
- **IN1** (Type: `adapter::types::unidirectional::AS`): The first input value (multiplicand 1) for multiplication.
- **IN2** (Type: `adapter::types::unidirectional::AS`): The second input value (multiplicand 2) for multiplication.
- **IN3** (Type: `adapter::types::unidirectional::AS`): The third input value (multiplicand 3) for the multiplication.
- **Plugs (Output Adapters):**
- **OUT** (Type: `adapter::types::unidirectional::AS`): The output adapter that provides the result of the multiplication.

Functionality

The function block `AS_MUL_3` multiplies the values received via the input adapters `IN1`, `IN2`, and `IN3`. As soon as values at the inputs change or a corresponding trigger event is received via the adapters, the calculation is performed and the result is passed to the output adapter `OUT`.

The mathematical formula is:

$$\text{OUT} = \text{IN1} \times \text{IN2} \times \text{IN3} \tag{2.76}$$

Technical Features

- **Generic Type:** The component is defined as a generic type (`GEN_AS_MUL`). This allows for flexible adaptation to different numeric data types (e.g., `INT`, `REAL`, `LREAL`) supported by the underlying adapter type.
- **Adapter-Based Architecture:** By using unidirectional adapters (`AS`), the cabling effort in the 4diac IDE is drastically reduced, as event and data lines are bundled into a single connection.
- **Adapter-Based Architecture:** —

State Overview

This function block behaves like a classic stateless computation block. Execution is triggered by incoming events on the sockets (`IN1`, `IN2`, `IN3`). After successful calculation of the product, the output event is emitted directly via the plug `OUT` along with the calculated value.

–

Application Scenarios

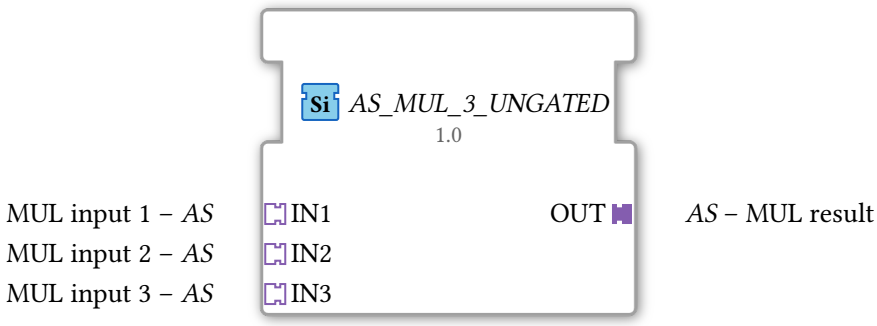
- **Sensor Scaling and Calibration:** Calculation of corrected measured values where a raw value must be multiplied by two different correction factors.
- **Volume Calculations:** Multiplication of three dimensions (length × width × height) to determine a volume in process engineering.
- **Multi-Stage Gain Control:** Cascaded signal amplification in control engineering.

Comparison with Similar Function Blocks

Compared to standard multiplication function blocks (such as `MUL`), which use separate event and data lines (e.g., `REQ`/`CNF` and standard data types), `AS_MUL_3`, thanks to its encapsulation in adapters, offers a significantly cleaner visual representation in the 4diac IDE's Application Editor. Manually linking "With" connections between events and data is no longer necessary.

–

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

`AS_MUL_3` is an efficient, modular, and reusable function block for arithmetic triple multiplication. It is ideally suited for modern, adapter-based software architectures within IEC 61499 and contributes to the clarity of complex control applications.

AS_MUL_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AS_MUL_3`. AS_MUL_4

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AS_MUL_4` is a generic function block (Generic FB) for IEC 61499, designed for the arithmetic multiplication of four input values. Instead of traditional data and event pins, this block uses adapter connections (`AS` - unidirectional) to transmit data and the associated execution control in encapsulated form. This results in a cleaner design in the 4diac IDE, as the number of visible connection lines is drastically reduced.

Interface Structure

Event Inputs

This function block does not have direct, independent event inputs. Event control is handled entirely via the connected adapters.

Event Outputs

This function block does not have direct, independent event outputs. Event control for subsequent function blocks is transmitted via the output adapter.

Data Inputs

There are no direct data inputs. Data is transferred via the input adapters.

Data Outputs

There are no direct data outputs. The result is provided via the output adapter.

Adapters

This function block is based entirely on adapter-based communication.

Sockets (Inputs)

- **IN1** (Type: `adapter::types::unidirectional::AS`): First multiplicand (Input 1).
- **IN2** (Type: `adapter::types::unidirectional::AS`): Second multiplicand (Input 2).
- **IN3** (Type: `adapter::types::unidirectional::AS`): Third multiplicand (Input 3).
- **IN4** (Type: `adapter::types::unidirectional::AS`): Fourth multiplicand (Input 4).

Plugs (Connectors / Outputs)

- **OUT** (Type: `adapter::types::unidirectional::AS`): Result of the multiplication (`IN1 * IN2 * IN3 * IN4`).

Functionality

As soon as new values or a corresponding trigger event are received via the adapter sockets, the function block performs the arithmetic multiplication of the four input values:

$$ OUT = IN1 × IN2 × IN3 × IN4

The result and the corresponding output event are then passed on to the subsequent logic elements via the adapter plug `OUT`.

Technical Features

- **Generic Character:** By assigning it to the generic class `GEN_AS_MUL`, the function block can flexibly adapt to various numeric data types (e.g., `INT`, `REAL`, `LREAL`), provided the connected adapters of type `AS` use the same data type.
- **Unidirectional Adapters:** Using the type `adapter::types::unidirectional::AS` ensures that the data flow is clear and direct from the inputs to the output.
- **Compact Design:** Encapsulating data and event channels in adapters keeps the application diagram in 4diac clear and concise.
-

State Overview

Since `AS_MUL_4` is a mathematical, stateless function block, no complex internal state diagram (ECC) exists.

- **Ready / Idle:** The block waits for incoming events at sockets `IN1` to `IN4`.
- **Calculation:** Upon receiving a trigger event, the values are updated, multiplied, and directly passed to `OUT`.

–

Application Scenarios

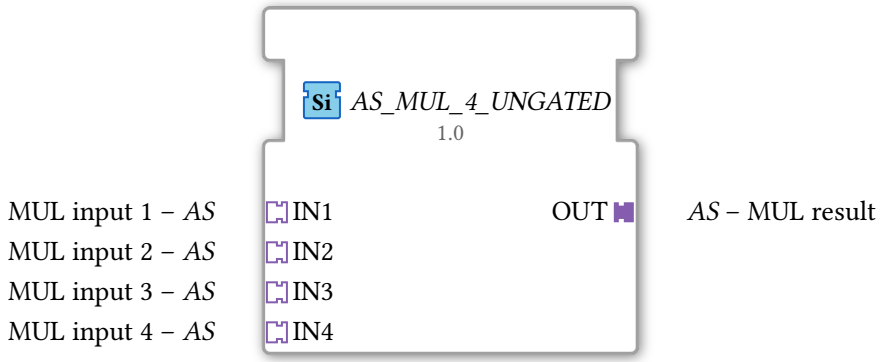
- **Scaling of Measured Values:** Multiplying a sensor value by several calibration and correction factors.
- **Volume Calculations:** Calculating a volume from three dimensions (length × width × height) multiplied by a density factor.
- **Cascaded Gainers:** Calculation of total loop gains in control engineering where four different gain factors need to be multiplied.

Comparison with Similar Components

- **Standard `MUL` component (IEC 61131-3):** This requires separate data lines for each value and at least one trigger event (REQ/CNF). `AS_MUL_4` simplifies this by using adapters, requiring only five connections (4 input adapters, 1 output adapter).

- **AS_MUL_2 / AS_MUL_3:** Offer the same adapter-based functionality but are limited to two or three input values, respectively. AS_MUL_4 eliminates the need for additional intermediate steps and temporary auxiliary variables when combining four factors.
-

Change Detection



The result is only written to the output plug (OUT) and its adapter event only sent if the newly computed value differs from the value currently held on OUT. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AS_MUL_4 is a highly efficient, clear, and modern function block for arithmetic calculations in IEC 61499. The consistent use of unidirectional adapters keeps the application design uncluttered while maintaining the full flexibility of a generic data type.

AS_MUL_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AS_MUL_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The AS_MUL_4_UNGATED is a highly efficient, clear, and modern function block for arithmetic calculations in IEC 61499. The consistent use of unidirectional adapters keeps the application design uncluttered while maintaining the full flexibility of a generic data type.

AS_SUB_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block AS_SUB_2 is a generic function block (Generic FB) for the 4diac-ide development environment. It performs an arithmetic subtraction ($OUT = IN1 - IN2$).

Unlike classic arithmetic blocks that work directly with standard data and event interfaces, this block uses unidirectional adapter connections to encapsulate data and control events. This enables structured and clear wiring in complex IEC 61499 applications.

Interface Structure

Event Inputs

The function block does not have direct, independent event inputs. Event control is handled entirely via the connected adapters.

Event Outputs

The function block does not have direct, independent event outputs. Events are forwarded via the output adapter.

Data Inputs

No direct data inputs are defined on the function block. Input data is provided via the adapter interfaces.

Data Outputs

No direct data outputs are defined on the function block. The result is passed via the output adapter.

Adapters

All communication of the function block is implemented via adapters:

- **Sockets (Input Adapters):**
- IN1 (Type: adapter::types::unidirectional::AS): The first input (minuend) for subtraction.
- IN2 (Type: adapter::types::unidirectional::AS): The second input (subtrahend) for subtraction.
- **Plugs (Output Adapters):**

- `OUT` (Type: `adapter::types::unidirectional::AS`): The result (difference) of the arithmetic subtraction.

Functionality

As soon as valid values and the corresponding trigger events are present at the input adapters `IN1` and `IN2`, the function block performs the calculation.

The mathematical operation is:

$$\text{Result} = \text{Value of } \ IN1 - \text{Value of } \ IN2 \tag{2.78}$$

The result of the calculation and the corresponding output event are then forwarded to subsequent function blocks via the output adapter `OUT`. Since it is a generic function block (`GenericClassName="GEN_AS_SUB"`), it is flexible with respect to the underlying data types, provided these are supported by the adapter type.

Technical Features

- **Generic Behavior:** By declaring it as a generic function block, it can be used for various numeric data types (e.g., INT, REAL, LREAL), depending on the definition of the adapter used, `adapter::types::unidirectional::AS`.
- **Compact Structure:** The use of adapters significantly reduces visual complexity in the 4diac Application Editor, as event and data lines are bundled into a single adapter connection.

Unidirectional Data Flow: The adapters used have a strictly unidirectional signal flow (from the sockets to the plug).

State Overview

The execution logic is typically triggered by events on the input adapters:

1. **Idle State:** The block waits for an event on `IN1` or `IN2`.
2. **Calculation:** Upon receiving a trigger, the data is read from the adapters, and the difference is calculated.
3. **Dispatch:** The result is written to the output adapter, and the output event on `OUT` is triggered. The module returns to standby mode.

Application Scenarios

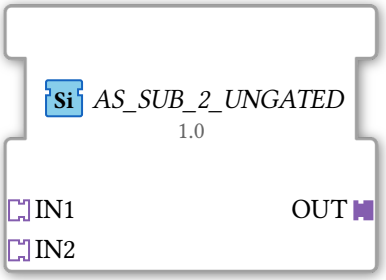
- **Measurement Correction:** Subtraction of zero-point errors or offsets in analog sensor values.
- **Setpoint-Actual Comparison:** Calculation of the control deviation ($e = w - x$) in control loops where setpoint and actual values are transferred via standardized adapter structures.
- **Level and Quantity Calculation:** Determination of differential quantities in process plants.

Comparison with Similar Function Blocks

Compared to a standard subtraction function block (e.g., `SUB` from the IEC 61131-3 library), which uses explicit inputs like `REQ`, `IN1`, and `IN2`, the `AS_SUB_2` offers significantly higher modularity due to its encapsulation in adapters. It is particularly suitable for advanced software architectures in IEC 61499, where data and signal flows are to be combined as logical units (interfaces).

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.



Conclusion

The `AS_SUB_2` is a highly efficient, reusable, and clearly structured function block for implementing subtraction tasks. Its strength lies in the consistent use of adapters, which leads to cleaner software designs and improved maintainability within the 4diac-ide.

AS_SUB_2_UNGATED

i UNGATED variant: This block is the ungated version of AS_SUB_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change.

This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

All communication of the function block is implemented via adapters:

- **Sockets (Input Adapters):**
- `IN1` (Type: `adapter::types::unidirectional::AS`): The first input (minuend) for subtraction.
- `IN2` (Type: `adapter::types::unidirectional::AS`): The second input (subtrahend) for subtraction.
- **Plugs (Output Adapters):**
- `OUT` (Type: `adapter::types::unidirectional::AS`): The result (difference) of the arithmetic subtraction.

Functionality

As soon as valid values and the corresponding trigger events are present at the input adapters `IN1` and `IN2`, the function block performs the calculation.

The mathematical operation is:

$$\text{Result} = \text{Value of } \ IN1 - \text{Value of } \ IN2 \tag{2.79}$$

The result of the calculation and the corresponding output event are then forwarded to subsequent function blocks via the output adapter `OUT`. Since it is a generic function block

(`GenericClassName="GEN_AS_SUB"`), it is flexible with respect to the underlying data types, provided these are supported by the adapter type.

Technical Features

- **Generic Behavior:** By declaring it as a generic function block, it can be used for various numeric data types (e.g., INT, REAL, LREAL), depending on the definition of the adapter used, `adapter::types::unidirectional::AS`.
- **Compact Structure:** The use of adapters significantly reduces visual complexity in the 4diac Application Editor, as event and data lines are bundled into a single adapter connection.

Unidirectional Data Flow: The adapters used have a strictly unidirectional signal flow (from the sockets to the plug).

State Overview

The execution logic is typically triggered by events on the input adapters:

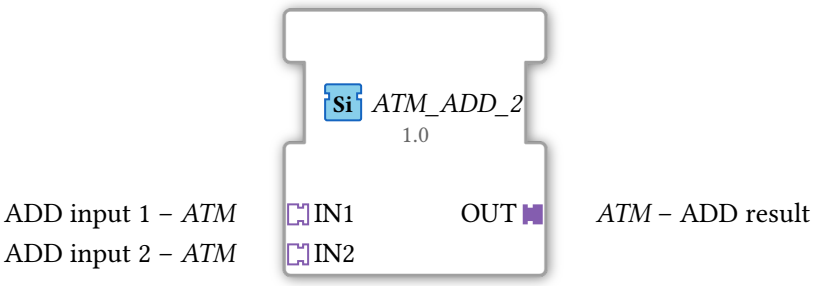
1. **Idle State:** The block waits for an event on `IN1` or `IN2`.
2. **Calculation:** Upon receiving a trigger, the data is read from the adapters, and the difference is calculated.
3. **Dispatch:** The result is written to the output adapter, and the output event on `OUT` is triggered. The module returns to standby mode.

Application Scenarios

- **Measurement Correction:** Subtraction of zero-point errors or offsets in analog sensor values.
- **Setpoint-Actual Comparison:** Calculation of the control deviation ($e = w - x$) in control loops where setpoint and actual values are transferred via standardized adapter structures.
- **Level and Quantity Calculation:** Determination of differential quantities in process plants.

Comparison with Similar Function Blocks

Compared to a standard subtraction function block (e.g., `SUB` from the IEC 61131-3 library), which uses explicit inputs like `REQ`, `IN1`, and `IN2`, the `AS_SUB_2_UNGATED` offers significantly higher modularity due to its encapsulation in adapters. It is particularly suitable for advanced software architectures in IEC 61499, where data and signal flows are to be combined as logical units (interfaces).



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AS_SUB_2_UNGATED` is a highly efficient, reusable, and clearly structured function block for implementing subtraction tasks. Its strength lies in the consistent use of adapters, which leads to cleaner software designs and improved maintainability within the 4diac-ide.

ATM_ADD_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ATM_ADD_2** is used to calculate the arithmetic addition of two time values (type `TIME`). It is designed as a generic function block and implements the basic arithmetic operation via adapter interfaces. The block is platform-independent and complies with the IEC 61499 standard.

Interface Structure

Event Inputs

Adapters

Name	Direction	Type	Comment
`IN1`	Socket	`adapter::types::unidirectional::ATM`	ADD input 1
`IN2`	Socket	`adapter::types::unidirectional::ATM`	ADD input 2
`OUT`	Plug	`adapter::types::unidirectional::ATM`	ADD result

The adapters are of type `unidirectional::ATM` and enable type-safe connections with other function blocks that support the same adapter type.

Functionality

The function block sums the time values received via adapters `IN1` and `IN2` and provides the result at adapter `OUT`. The starting point of the summation is the identity value `TIME#0s`, so that with only one input actually connected, its value is passed through unchanged. The function block operates generically – the calculation is re-executed on every event at one of the input adapters.

Technical Features

- **Generic Structure** – The function block uses a generic class name (`GEN_ATM_ADD`) at runtime, defined by the attribute `eclipse4diac::core::GenericClassName`. The same class covers the arities `ATM_ADD_2`, `ATM_ADD_3`, and `ATM_ADD_4` via the GenericClassName mechanism.
- **Adapter-Based** – Instead of individual data inputs and outputs, all signals are routed via unidirectional adapters.
- **Package Information** – The function block is organized in the package `adapter::iec61131::arithmetic`.
- **No State Logic** – The addition is stateless; there is no internal state machine.

State Overview

The function block does not have a state machine. The calculation is purely event-driven – on any event at one of the input adapters, the sum is recalculated.

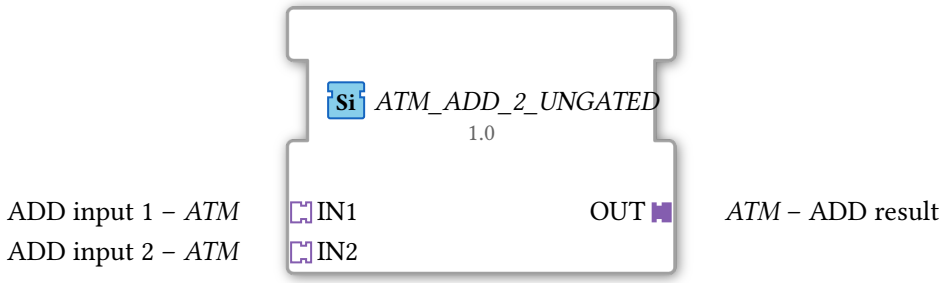
Application-Specific Scenarios

- **Time accumulation** – Summing multiple delay or runtime values into a total duration.
- **Control Engineering** – Combining two dynamically determined time values, e.g., base time plus a surcharge.
- **Generic Library Function Blocks** – Use as the adapter-based counterpart to the classic `ADD` function, specialized for `TIME`.

Comparison with Similar Function Blocks

Compared to `AR_ADD_2` (addition of two `REAL` values via adapters), `ATM_ADD_2` is specialized for the `TIME` data type. Unlike `AR_MULTIME/ATM_AR_MULTIME`, which multiply a time value by a numeric factor, `ATM_ADD_2` adds two values of the same kind.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

`ATM_ADD_2` is a compact, generic function block for adding two time values using adapter interfaces. It is particularly suitable for applications where multiple durations need to be combined into a total duration.

ATM_ADD_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ATM_ADD_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Conclusion

`ATM_ADD_4_UNGATED` is a compact, generic function block for adding two time values using adapter interfaces. It is particularly suitable for applications where multiple durations need to be combined into a total duration.

ATM_AR_DIVTIME

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_AR_DIVTIME** divides a time value (type TIME) by a numeric value – the fully adapter-based variant of AR_DIVTIME. Unlike AR_DIVTIME, the dividend (IN1) is also supplied via an adapter (type `ATM`) instead of a fixed data input. The block is classified as a standard arithmetic function according to IEC 61131-3.

Interface Structure

Event Inputs

None – the block has no classic event inputs; triggering happens exclusively via the adapter sockets.

Event Outputs

No explicit event outputs in the interface list. The result is provided via the output adapter **OUT**, which sends an event (E1) once the calculation is complete.

Data Inputs

None.

Data Outputs

None. The division result is output via the output adapter **OUT** as a data value (D1).

Adapters

- **IN1** (Adapter, type `adapter::types::unidirectional::ATM`): Time value to be divided (dividend).
- **IN2** (Adapter, type `adapter::types::unidirectional::AR`): Divisor.
- **OUT** (Adapter, type `adapter::types::unidirectional::ATM`): Output for the division result (TIME).

Functionality

The function block encapsulates the functionality of the internal function block **F_DIVTIME** (type `iec61131::arithmetic::F_DIVTIME`). An event at **IN1.E1** or **IN2.E1** triggers the division: the internal function block divides **IN1.D1** (TIME) by **IN2.D1** (numeric value) and outputs the result to **OUT.D1**. An event is then sent to **OUT.E1**.

Technical Features

- **Fully adapter-based:** Unlike `AR_DIVTIME`, which expects IN1 as a classic data input, `ATM_AR_DIVTIME` implements both operands as adapter sockets (IN1 of type `ATM`, IN2 of type `AR`).
- **Standard compliance:** The function block meets the requirements of IEC 61131-3 (classification: standard arithmetic function).

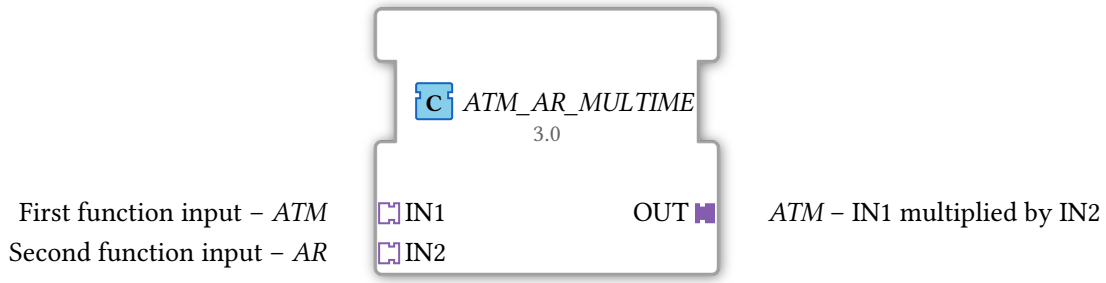
- **Internal encapsulation:** The actual calculation is performed by the reusable function block F_DIVTIME.

State Overview

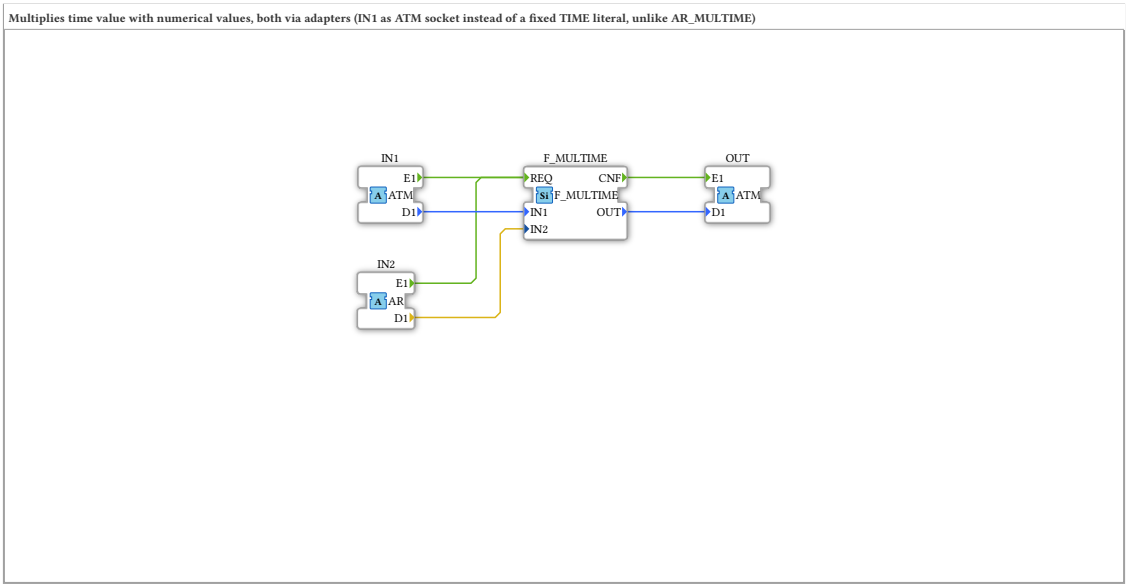
The function block does not have an explicit state machine. Event-driven processing is deterministic: waiting for an event at IN1.E1 or IN2.E1, executing the division, sending the result.

Application Scenarios

- Splitting time values where both the time value and the divisor are already available as adapter connections from upstream blocks.
- Modular networks that consistently rely on adapters instead of classic data wiring.



Comparison with Similar Function Blocks



- **AR_DIVTIME:** The mixed variant with IN1 as a classic data input instead of an adapter socket.
- **ATM_AR_MULTIME:** Multiplies instead of dividing, otherwise structurally identical.

Conclusion

`ATM_AR_DIVTIME` provides a fully adapter-based division of time values by numeric factors and is particularly suitable for networks that are built consistently around adapter connections.

ATM_AR_MULTIME

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_AR_MULTIME** multiplies a time value (type TIME) by a numeric value – the fully adapter-based variant of AR_MULTIME. Unlike AR_MULTIME, the time value (IN1) is also supplied via an adapter (type `ATM`) instead of a fixed data input. The block is classified as a standard arithmetic function according to IEC 61131-3.

Interface Structure

Event Inputs

None – the block has no classic event inputs; triggering happens exclusively via the adapter sockets.

Event Outputs

No explicit event outputs in the interface list. The result is provided via the output adapter **OUT**, which sends an event (E1) once the calculation is complete.

Data Inputs

None.

Data Outputs

None. The multiplication result is output via the output adapter **OUT** as a data value (D1).

Adapters

- **IN1** (Adapter, type `adapter::types::unidirectional::ATM`): First function input – the time value to be multiplied.
- **IN2** (Adapter, type `adapter::types::unidirectional::AR`): Second function input – the numeric multiplier.
- **OUT** (Adapter, type `adapter::types::unidirectional::ATM`): Output for the multiplied result (TIME).

Functionality

The function block encapsulates the functionality of the internal function block **F_MULTIME** (type `iec61131::arithmetic::F_MULTIME`). An event at **IN1.E1** or **IN2.E1** triggers the multiplication: the internal function block multiplies **IN1.D1** (TIME) by **IN2.D1** (numeric value) and outputs the result to **OUT.D1**. An event is then sent to **OUT.E1**.

Technical Features

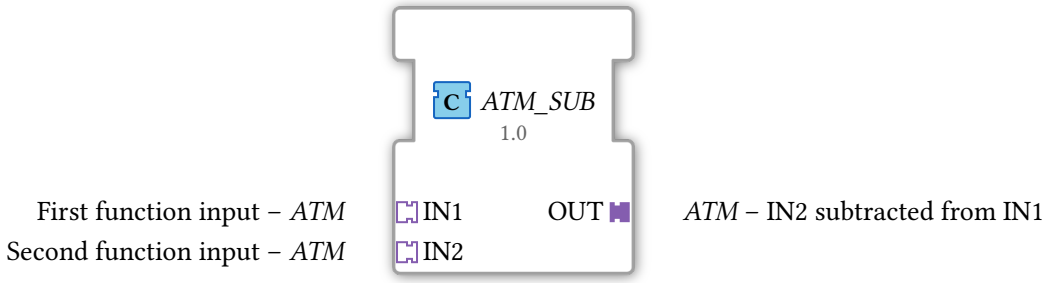
- **Fully adapter-based:** Unlike `AR_MULTIME`, which expects IN1 as a classic data input, `ATM_AR_MULTIME` implements both operands as adapter sockets (IN1 of type `ATM`, IN2 of type `AR`).
- **Standard compliance:** The function block meets the requirements of IEC 61131-3 (classification: standard arithmetic function).
- **Internal encapsulation:** The actual calculation is performed by the reusable function block F_MULTIME.

State Overview

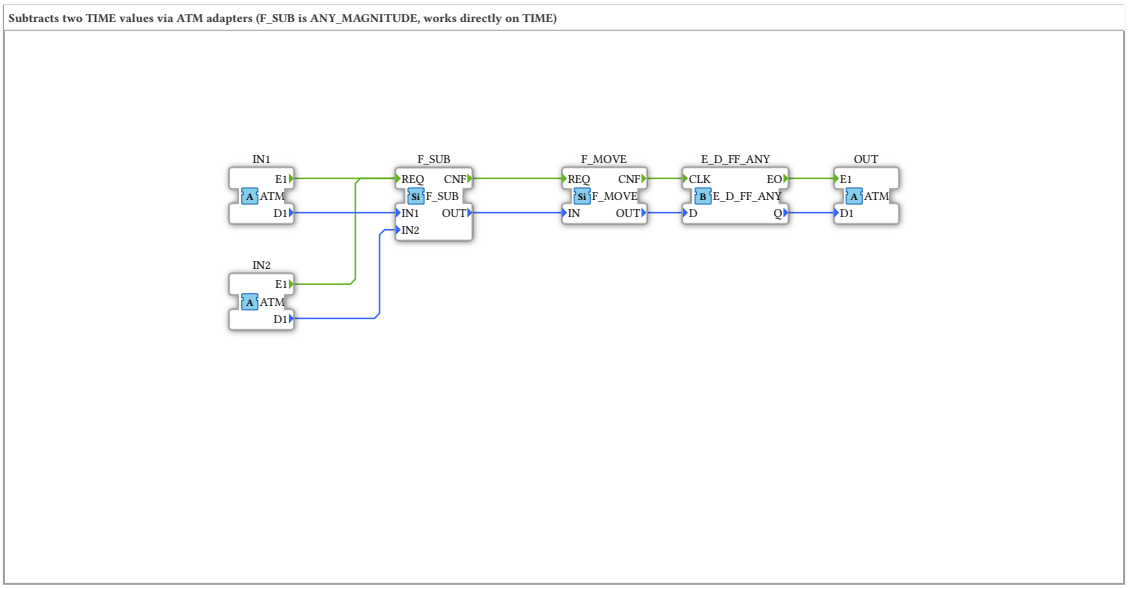
The function block does not have an explicit state machine. Event-driven processing is deterministic: waiting for an event at IN1.E1 or IN2.E1, executing the multiplication, sending the result.

Application Scenarios

- Scaling time values where both the time value and the factor are already available as adapter connections from upstream blocks.
- Modular networks that consistently rely on adapters instead of classic data wiring.



Comparison with Similar Function Blocks



- **AR_MULTIME:** The mixed variant with IN1 as a classic data input instead of an adapter socket.
- **ATM_AR_DIVTIME:** Divides instead of multiplying, otherwise structurally identical.

Conclusion

`ATM_AR_MULTIME` provides a fully adapter-based multiplication of time values by numeric factors and is particularly suitable for networks that are built consistently around adapter connections.

ATM_SUB

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ATM_SUB** subtracts two time values (type TIME) via fully adapter-based interfaces: `IN2` is subtracted from `IN1`, and the result is written to the output adapter only on an actual value change. Unlike the generic `ATM_ADD_*` blocks, ATM_SUB is implemented as a hand-wired composite FB that maps change detection explicitly through its own sub-blocks.

Interface Structure

Event Inputs

None – triggering happens exclusively via the adapter sockets `IN1`/`IN2`.

Event Outputs

No explicit event outputs in the interface list. The result is provided via the output adapter **OUT**, whose event (E1) is only sent on an actual value change.

Data Inputs

None.

Data Outputs

None. The subtraction result is output via the output adapter **OUT** as a data value (D1).

Adapters

- **IN1** (Adapter, type `adapter::types::unidirectional::ATM`): Minuend.
- **IN2** (Adapter, type `adapter::types::unidirectional::ATM`): Subtrahend.
- **OUT** (Adapter, type `adapter::types::unidirectional::ATM`): Result of `IN1 - IN2`.

Functionality

An event at **IN1.E1** or **IN2.E1** internally triggers the function block **F_SUB** (type `iec61131::arithmetic::F_SUB`), which computes `IN1.D1 - IN2.D1`. The result then passes through **F_MOVE** (type `iec61131::selection::F_MOVE`, hardwired with `DataType="TIME"`) into an **E_D_FF_ANY** block (type `iec61499::events::E_D_FF_ANY`). This block compares the new value with the last stored one and only lets the event through to **OUT.E1** if the value has actually changed – the new value is written to **OUT.D1** in every case.

Technical Features

- **Explicit change detection as a composite structure:** Unlike the generic `GEN_ATM_*` blocks, which implement change detection in C++, ATM_SUB maps it via the `F_SUB → F_MOVE → E_D_FF_ANY` chain inside the FBNetwork.
- **F_MOVE as a type anchor:** The `F_MOVE` block carries the `DataType="TIME"` attribute, pinning the generic `ANY` data path to `TIME` before it is fed into `E_D_FF_ANY`.
- **Fully adapter-based:** Both operands and the result are implemented as `ATM` adapters; there are no classic data inputs/outputs.

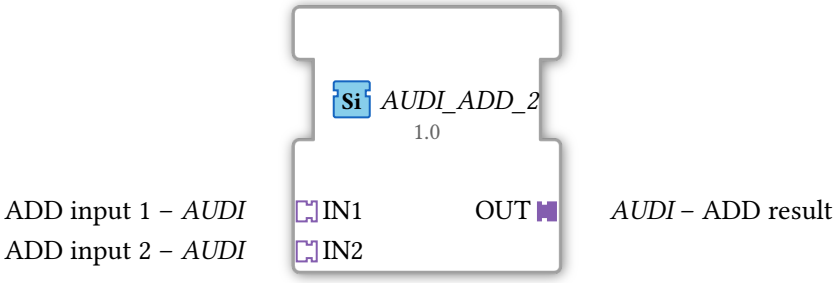
State Overview

The block implicitly holds the last output value in the internal `E_D_FF_ANY` storage:

- **Wait** for an event at IN1.E1 or IN2.E1
- **Compute** IN1 – IN2 via F_SUB
- **Compare** against the value stored in E_D_FF_ANY
- **Output**: OUT.D1 is always updated, OUT.E1 is only sent on an actual change

Application Scenarios

- Calculating remaining durations or differences between two time values, e.g., target minus actual time.
- Reducing downstream event load when the result does not change across multiple cycles.



Comparison with Similar Function Blocks

- **ATM_ADD_2/3/4:** Add instead of subtracting; implemented as generic `GEN_ATM_ADD` blocks (change detection in C++, not a visible FBNetwork).
- **F_SUB:** The direct, adapter-free subtraction block without its own change detection, used internally by ATM_SUB.

Conclusion

`ATM_SUB` provides a fully adapter-based subtraction of two time values with explicit, FBNetwork-visible change detection. It is particularly suitable wherever differences between time values are needed and unnecessary follow-up events for an unchanged result should be avoided.

AUDI_ADD_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUDI_ADD_2** performs an arithmetic addition of two input values and outputs the result. The block is generic and uses a standardized adapter interface of type `AUDI`. This allows it to be used for different data types (e.g., integers, floating-point numbers) without requiring modification of the function block itself.

Interface Structure

Event Inputs
None.

Event Outputs
None.

Data Inputs
None.

Data Outputs
None.

Adapter

Type	Direction	Name	Comment
`adapter::types::unidirectional::AUDI`	Socket (Input)	**IN1**	ADD input 1
`adapter::types::unidirectional::AUDI`	Socket (Input)	**IN2**	ADD input 2
`adapter::types::unidirectional::AUDI`	Plug (Output)	**OUT**	ADD result

The three adapters are all of the same type, `AUDI`. This adapter type encapsulates the actual data value (e.g., a numerical value) and enables unidirectional data transfer from the socket to the plug. The addition is performed between the values of `IN1` and `IN2`; The result is provided to `OUT`.

Functionality
The function block **AUDI_ADD_2** does not have traditional data inputs or events. Instead, it communicates exclusively via adapters. As soon as both input adapters (`IN1` and `IN2`) contain valid values, the sum `IN1 + IN2` is calculated internally, and the resulting value is output via the output adapter `OUT`.

The function block is generic: The actual data type used is determined by the adapter configuration and the generic attributes (`GenericClassName`, `TypeHash`). This allows the use of different numeric data types (e.g., `INT`, `REAL`, `LREAL`) without requiring multiple instantiations of the function block itself.

Technical Features
- **Pure Adapter Interface**: No events or direct data inputs/outputs – all communication occurs via adapters.
- **Generic Execution**: The attributes `eclipse4diac::core::GenericClassName` and `eclipse4diac::core::TypeHash` allow the function block to be specialized for different data types at runtime.
- **Unidirectional Adapters**: The adapters used, of type `AUDI`, are unidirectional, meaning they only transmit values in one direction (socket → plug).
- – **No State Control**: The function block (FB) contains no Execution Control Chart (ECC) and operates without events; the calculation is performed immediately upon receipt of the input values.

State Overview
The **AUDI_ADD_2** function block has no states (no ECC). The addition is performed without delay when valid input values are present.

Application Scenarios
- **Arithmetic Processing in Adapter-Based Systems**: If an architecture consistently relies on adapters, this FB offers a clean way to add two numerical values.
- **Generic Calculations**: Thanks to its generic design, the FB can be used in algorithms that work with different data types (e.g., mixed integer and floating-point environments).
- **Data Flow Systems**: In purely data flow-oriented applications where no events are required, the FB integrates seamlessly.

Comparison with Similar Function Blocks

- **Classic ADD Function Blocks (e.g., `ADD` from IEC 61131-3)**: These typically have concrete data inputs and outputs as well as event control. The `AUDI_ADD_2` replaces this with an adapter interface, enabling a higher level of abstraction and encapsulation.
- **Generic Adders (e.g., `GEN_ADD`)**: Such function blocks are also generic but often use direct data ports. The `AUDI_ADD_2` is specifically optimized for adapter-based interfaces.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The **AUDI_ADD_2** is a specialized, generic addition function block for adapter-based 4diac IDE environments. By eliminating traditional ports and utilizing the `AUDI` adapter type, it is particularly well-suited for data flow-oriented and highly modularized control applications. Its generic design increases reusability across different data types.

Adapter

Type	Direction	Name	Comment
`adapter::types::unidirectional::AUDI`	Socket (Input)	**IN1**	ADD input 1
`adapter::types::unidirectional::AUDI`	Socket (Input)	**IN2**	ADD input 2
`adapter::types::unidirectional::AUDI`	Plug (Output)	**OUT**	ADD result

The three adapters are all of the same type, `AUDI`. This adapter type encapsulates the actual data value (e.g., a numerical value) and enables unidirectional data transfer from the socket to the plug. The addition is performed between the values of `IN1` and `IN2`; The result is provided to `OUT`.

Functionality

The function block **AUDI_ADD_2_UNGATED** does not have traditional data inputs or events. Instead, it communicates exclusively via adapters. As soon as both input adapters (`IN1` and `IN2`) contain valid values, the sum `IN1 + IN2` is calculated internally, and the resulting value is output via the output adapter `OUT`.

The function block is generic: The actual data type used is determined by the adapter configuration and the generic attributes (`GenericClassName`, `TypeHash`). This allows the use of different numeric data types (e.g., `INT`, `REAL`, `LREAL`) without requiring multiple instantiations of the function block itself.

Technical Features

- **Pure Adapter Interface**: No events or direct data inputs/outputs – all communication occurs via adapters.
- **Generic Execution**: The attributes `eclipse4diac::core::GenericClassName` and `eclipse4diac::core::TypeHash` allow the function block to be specialized for different data types at runtime.
- **Unidirectional Adapters**: The adapters used, of type `AUDI`, are unidirectional, meaning they only transmit values in one direction (socket → plug).
- – **No State Control**: The function block (FB) contains no Execution Control Chart (ECC) and operates without events; the calculation is performed immediately upon receipt of the input values.

State Overview

The **AUDI_ADD_2_UNGATED** function block has no states (no ECC). The addition is performed without delay when valid input values are present.

Application Scenarios

- **Arithmetic Processing in Adapter-Based Systems**: If an architecture consistently relies on adapters, this FB offers a clean way to add two numerical values.
- **Generic Calculations**: Thanks to its generic design, the FB can be used in algorithms that work with different data types (e.g., mixed integer and floating-point environments).
- **Data Flow Systems**: In purely data flow-oriented applications where no events are required, the FB integrates seamlessly.

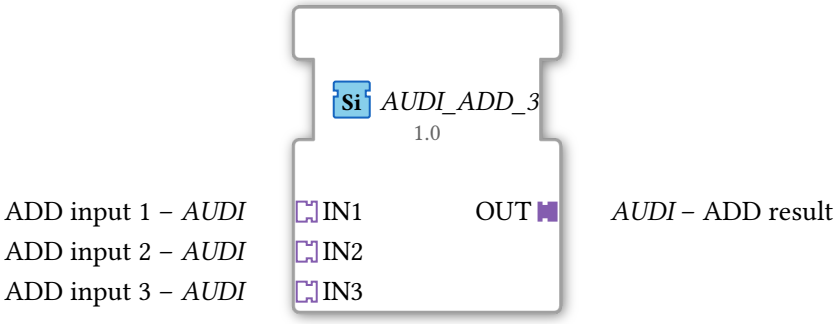
Comparison with Similar Function Blocks

- **Classic ADD Function Blocks (e.g., `ADD` from IEC 61131-3)**: These typically have concrete data inputs and outputs as well as event control. The `AUDI_ADD_2_UNGATED` replaces this with an adapter interface, enabling a higher level of abstraction and encapsulation.
- **Generic Adders (e.g., `GEN_ADD`)**: Such function blocks are also generic but often use direct data ports. The `AUDI_ADD_2_UNGATED` is specifically optimized for adapter-based interfaces.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The **AUDI_ADD_2_UNGATED** is a specialized, generic addition function block for adapter-based 4diac IDE environments. By eliminating traditional ports and utilizing the `AUDI` adapter type, it is particularly well-suited for data flow-oriented and highly modularized control applications. Its generic design increases reusability across different data types.

AUDI_ADD_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUDI_ADD_3` performs an arithmetic addition of three input values. It is a generic block that receives the values via adapter interfaces and outputs the result via another adapter. The function block is designed as part of the 4diac IDE for IEC 61499-2.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No direct data inputs available. The input values are provided via the adapter interfaces.

Data Outputs

No direct data outputs available. The result is provided via the adapter output.

Adapter

Name	Type	Direction	Comment
IN1	`adapter::types::unidirectional::AUDI`	Socket (Input)	ADD input 1
IN2	`adapter::types::unidirectional::AUDI`	Socket (Input)	ADD input 2
IN3	`adapter::types::unidirectional::AUDI`	Socket (Input)	ADD input 3
OUT	`adapter::types::unidirectional::AUDI`	Plug (Output)	ADD result

Functionality

The function block adds the three values received via the adapters `IN1`, `IN2`, and `IN3`. The result is continuously output via the adapter `OUT`. Since this is a generic function block, the specific data type of the addition is determined at runtime by the attributes `eclipse4diac::core::GenericClassName` and `eclipse4diac::core::TypeHash`.

Technical Features

- The function block is stateless (purely combinatorial) – no ECC is required.
- It uses the Eclipse 4diac generic type system to enable flexible reusability for various arithmetic data types (e.g., INT, REAL, LREAL).
- The connection is established exclusively via adapters of type `adapter::types::unidirectional::AUDI`, which provide a standardized unidirectional interface for arithmetic operations.

State Overview

The function block (FB) does not have a state machine (no ECC elements in the XML). Its behavior is purely data-driven: The output is recalculated whenever an input value changes.

Application Scenarios

- **Summation of Measured Values:** Summing three analog sensor values (e.g., temperatures).
- **Mixing Calculation:** Adding three quantities or volume flows in process engineering.
- **Generic Addition:** Used in libraries where the data type is defined during project planning.

Comparison with Similar Function Blocks

- **ADD_2:** Performs an addition of two values – `AUDI_ADD_3` extends this to three inputs.
- **ADD_4:** Adds four values – `AUDI_ADD_3` specifies three inputs.
- **MUL_3:** Multiplies three values – unlike addition.

All of the above blocks use the same adapter concept and are generic.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AUDI_ADD_3` is a flexible, generic function block for adding three values. Its pure adapter interface and stateless nature make it easy to use and ideal for modular automation solutions based on IEC 61499.

AUDI_ADD_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUDI_ADD_4` is a generic function block for calculating the arithmetic addition of four input values. It is implemented as a purely adapter-based function block without event or data interfaces. The use of adapters enables flexible coupling with other function blocks that use the same adapter type, `adapter::types::unidirectional::AUDI`.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

The function block has no direct data inputs. The values to be added are provided via adapter inputs.

Data Outputs

The function block has no direct data outputs. The result is passed on via an adapter output.

Adapter

Name	Direction	Type	Description
`IN1`	Socket (Input)	`adapter::types::unidirectional::AUDI`	First Addend
`IN2`	Socket (Input)	`adapter::types::unidirectional::AUDI`	Second Addend
`IN3`	Socket (Input)	`adapter::types::unidirectional::AUDI`	Third Addend
`IN4`	Socket (Input)	`adapter::types::unidirectional::AUDI`	Fourth Addend
`OUT`	Plug (Output)	`adapter::types::unidirectional::AUDI`	Result of the Addition

Functionality

The function block waits for valid values at the adapter inputs `IN1` through `IN4`. As soon as all four inputs provide a value, the sum `IN1 + IN2 + IN3 + IN4` is calculated and output via the `OUT` adapter. The actual data type specification is defined by the generic attribute `eclipse4diac::core::GenericClassName`, which is set to `'GEN_AUDI_ADD'`. This allows the function block to be instantiated for various numeric data types (e.g., INT, REAL, LREAL), provided the adapter type used, `AUDI`, supports them.

Technical Features

- **Pure Adapter Function Block**: The function block does not exchange events. Synchronization occurs implicitly through the connected adapter links.
- **Generic Data Type**: The specific data type is defined at runtime via the attributes `GenericClassName` and `TypeHash`. This enables a reusable implementation without changing the logic.
- **No State Machines**: The function block does not contain an ECC (Execution Control Chart) – addition is performed continuously or on demand by the data flow.

State Overview

The function block has no explicit states. The processing is data-driven: As soon as all four input values are available, the result is calculated and output.

Application Scenarios

- **Averaging**: In combination with a downstream division block, the sum can be used to calculate an average.
- **Summation of Measured Values**: For summing four analog input signals (e.g., temperature, pressure, flow rate) in an automation solution.
- **Cascaded Addition**: Multiple `AUDI_ADD_4` blocks can be cascaded to process a larger number of summands.

Comparison with Similar Blocks

- **`ADD` (Standard 61499)**: A typical ADD block has event inputs and data inputs/outputs. The `AUDI_ADD_4`, on the other hand, is entirely adapter-based and has no events, which necessitates stronger coupling between function blocks via adapters.
- **`AUDI_ADD_2`**: A hypothetical function block with only two adapter inputs – `AUDI_ADD_4` extends this to four summands.
- **Generic Function Blocks**: The attribute `GenericClassName` makes this function block similar to the generic approach of IEC 61499, where the data type is only determined at runtime.
- **`AUDI_ADD_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AUDI_ADD_4` is a flexible, pure adapter function block for adding four values. Thanks to its generic design, it is suitable for various numeric data types and can be used in modular automation projects that rely on adapter-based communication. Eliminating events simplifies handling in data-driven systems, but requires correct adapter cabling.

AUDI_DIV_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block (FB) **AUDI_DIV_2** is used to perform arithmetic division. It is a generic function block (`GEN_AUDI_DIV`) that can flexibly work with various data types within the adapter structure. Unlike classic mathematical function blocks, which have dedicated data inputs, this block uses adapter connections to encapsulate signals and control flows.

Interface Structure

The function block does not have any direct, classic event or data inputs on its surface. All communication is handled via adapters.

```
      +--------------------------------------+
| AUDI_DIV_2 | | | [IN1] =|=======================================>|=OUT | (unidirectional::AUDI) (unidirect..) | [IN2] =|=======================================>| | (unidirectional::AUDI) |
```

Event Inputs

No direct event inputs are available. Event control is handled via the adapters.

Event Outputs

No direct event outputs are available. Event control is handled via the adapters.

Data Inputs

No direct data inputs are available.

Data Outputs

No direct data outputs are available.

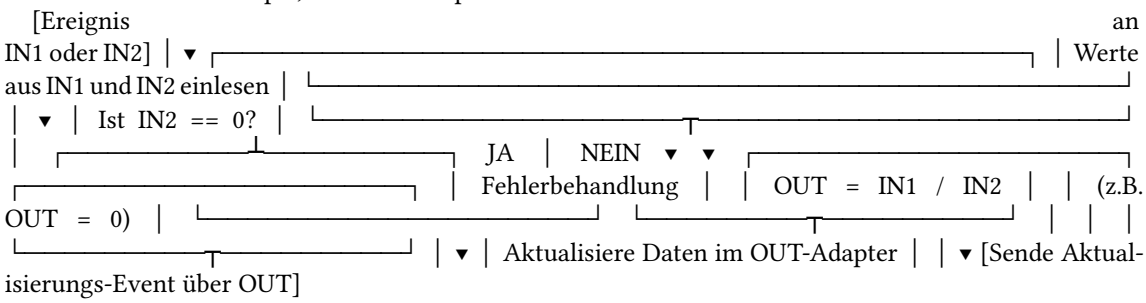
Adapters

Type	Name	Adapter Type	Description
Socket (Female)	`IN1`	`adapter::types::unidirectional::AUDI`	First input value for division (dividend).
Socket (Female)	`IN2`	`adapter::types::unidirectional::AUDI`	Second input value for the division (divisor).
Plug (connector)	`OUT`	`adapter::types::unidirectional::AUDI`	Result of the division (quotient).

Functionality

The function block calculates the quotient of the values provided via the adapters `IN1` and `IN2`:

$$\mathrm{OUT} = \frac{\mathrm{IN1}}{\mathrm{IN2}} \tag{2.80}$$



Since the interfaces are implemented as unidirectional `AUDI` adapters, an update of the input values at `IN1` or `IN2` (via the event channels integrated into the adapter) triggers the calculation in the function block. The result is then immediately signaled via the event encapsulated in the `OUT` adapter and passed on to subsequent function blocks.

Technical Features

- **Generic Type:** The function block is declared as `GEN_AUDI_DIV` via the attribute `eclipse4diac::core::GenericClassName`. This enables automatic type adaptation to the specific data structures used within the `AUDI` adapters.
- **Clean Wiring:** Encapsulating data and event signals in adapters minimizes the visual "spaghetti code" problem in 4diac-ide.
- **Error Handling (Division by Zero):** Since this is a generic division, the underlying runtime environment (e.g., forte) catches division by zero to prevent the controller from crashing. In such a case, the output is typically set to a default value (e.g., `0` or `NaN`/`Infinity`, depending on the data type).

State Overview

Execution follows a simple, event-driven pattern:

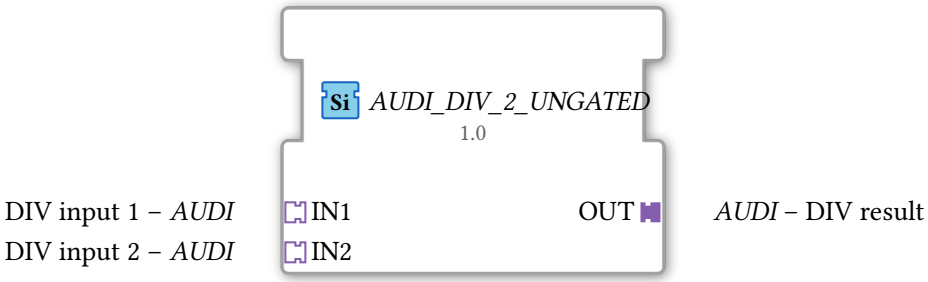
Application Scenarios

- **Scaling and Normalization Tasks:** Division of measured values transmitted in standardized `AUDI` data structures.
- **Ratio Calculations:** Determining ratios in the process industry (e.g., flow ratios of two media).
- **Signal Processing:** Modular use in control architectures where strict separation through adapter structures is required.

Comparison with Similar Components

Component Type	Interface Type	Wiring Effort	Flexibility
Standard `DIV`	Individual Pins (REQ, IN1, IN2, OUT, CNF)	High (many lines)	Low (fixed data types per instance)
`AUDI_DIV_2`	Adapter (`IN1`, `IN2`, `OUT`)	Very low	High (generic adaptation via adapter)

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AUDI_DIV_2` is a modern, adapter-based function block for IEC 61499. It is ideally suited for complex projects in the 4diac-ide where clarity, encapsulation, and easy maintainability of the application diagram are paramount.

AUDI_DIV_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUDI_DIV_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Introduction

The function block (FB) **AUDI_DIV_2_UNGATED** is used to perform arithmetic division. It is a generic function block (`GEN_AUDI_DIV`) that can flexibly work with various data types within the adapter structure. Unlike classic mathematical function blocks, which have dedicated data inputs, this block uses adapter connections to encapsulate signals and control flows.

Interface Structure

The function block does not have any direct, classic event or data inputs on its surface. All communication is handled via adapters.

+----------+
| AUDI_DIV_2_UNGATED | | | [IN1] =|=========>|=OUT | (unidirectional::AUDI) (unidirect..) | [IN2] =|=========>| | (unidirectional::AUDI) |

Event Inputs

No direct event inputs are available. Event control is handled via the adapters.

Event Outputs

No direct event outputs are available. Event control is handled via the adapters.

Data Inputs

No direct data inputs are available.

Data Outputs

No direct data outputs are available.

Adapters

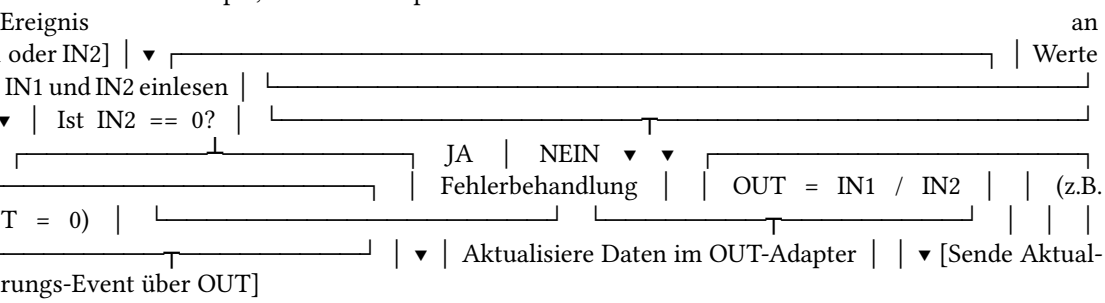
Type	Name	Adapter Type	Description
Socket (Female)	`IN1`	`adapter::types::unidirectional::AUDI`	AUDI input value for division (dividend).

Socket (Female)	`IN2`	`adapter::types::unidirectional::AUDI`	Second input value for the division (divisor).
Plug (connector)	`OUT`	`adapter::types::unidirectional::AUDI`	Result of the division (quotient).

Functionality

The function block calculates the quotient of the values provided via the adapters `IN1` and `IN2`:

$$\mathrm{OUT} = \frac{\mathrm{IN1}}{\mathrm{IN2}} \tag{2.81}$$



Since the interfaces are implemented as unidirectional `AUDI` adapters, an update of the input values at `IN1` or `IN2` (via the event channels integrated into the adapter) triggers the calculation in the function block. The result is then immediately signaled via the event encapsulated in the `OUT` adapter and passed on to subsequent function blocks.

Technical Features

- **Generic Type:** The function block is declared as `GEN_AUDI_DIV` via the attribute `eclipse4diac::core::GenericClassName`. This enables automatic type adaptation to the specific data structures used within the `AUDI` adapters.
- **Clean Wiring:** Encapsulating data and event signals in adapters minimizes the visual "spaghetti code" problem in 4diac-ide.
- **Error Handling (Division by Zero):** Since this is a generic division, the underlying runtime environment (e.g., forte) catches division by zero to prevent the controller from crashing. In such a case, the output is typically set to a default value (e.g., `0` or `NaN`/`Infinity`, depending on the data type).

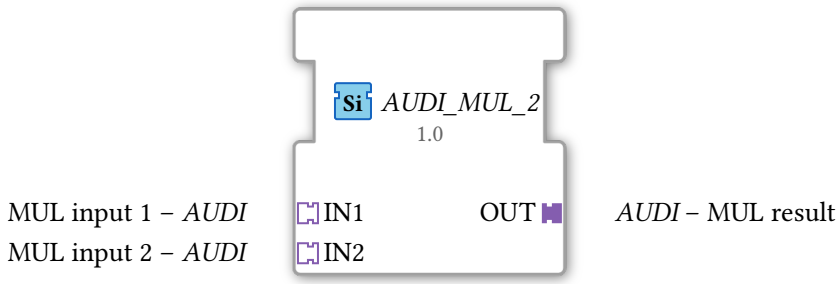
`AUDI_DIV_2_UNGATED`	Adapter (`IN1`, `IN2`, `OUT`)	Very low	High (generic adaptation via adapter)



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AUDI_DIV_2_UNGATED` is a modern, adapter-based function block for IEC 61499. It is ideally suited for complex projects in the 4diac-ide where clarity, encapsulation, and easy maintainability of the application diagram are paramount.

AUDI_MUL_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUDI_MUL_2` is a generic function block for calculating the arithmetic product of two numeric values. It receives its operands via two input adapters and outputs the result via one output adapter. Its generic design allows the use of different data types (e.g., integers, floating-point numbers), which are defined by the specific adapter type.

Interface Structure

Event Inputs

No direct event inputs are available. Control is integrated into the input adapters `IN1` and `IN2`.

Event Outputs

No direct event outputs are available. Control is integrated into the output adapter `OUT`.

Data Inputs

No direct data ports. The input values are transmitted via the adapters `IN1` and `IN2`.

Data Outputs

No direct data ports. The result is output via the adapter `OUT`.

Adapters

Direction	Name	Type	Description
Socket (Input)	`IN1`	`adapter::types::unidirectional::AUDI`	First Multiplication Operand
Socket (Input)	`IN2`	`adapter::types::unidirectional::AUDI`	Second Multiplication Operand
Plug (Output)	`OUT`	`adapter::types::unidirectional::AUDI`	Product of the two input values

Note: The adapter type `AUDI` is a unidirectional, typed adapter that encapsulates the actual numerical value.

Functionality

The function block performs the multiplication `OUT = IN1 * IN2` as soon as both input values are available via the adapters. Since no events are present, the processing is purely data-driven: As soon as the socket adapters `IN1` and `IN2` provide valid values, the product is calculated and output via the plug adapter `OUT`.

The function block is designed generically. The specific data type (e.g., `REAL`, `INT`, `LINT`) is determined by the adapter type used. Multiplication is performed using the operation defined for that type.

- **Adapter-Based Communication:** The function block does not use traditional event/data ports, but exclusively adapters. This enables loose coupling and reuse in different contexts.
- **Generic Design:** The attributes `eclipse4diac::core::GenericClassName` and `eclipse4diac::core::TypeHash` identify the function block as generic. The actual data type is only defined in the specific project, e.g., by typing the adapter.
- **No Execution Control Chart (ECC):** Since no events exist, a state machine is not required. Processing occurs continuously with valid data.

This function block has no states or ECC state diagrams. Execution is determined solely by the data flow.

- Arithmetic calculations in industrial control applications where the multiplication of two values is required (e.g., scaling, unit conversion).
- Use in complex function blocks where operands are obtained from other components via adapters.
- Replacement for classic MUL function blocks when loose coupling via adapters is desired.
- **Classic MUL FB** (with event/data ports): Operates in an event-driven manner and requires explicit data inputs/outputs. `AUDI_MUL_2`, on the other hand, uses adapters, which allows for more flexible interconnection.
- **Other generic arithmetic function blocks** (e.g., `AUDI_ADD_2`): Same structure, but with a different operation. The adapter interface remains identical, ensuring easy interchangeability.

AUDI_MUL_2` is a generic, adapter-based multiplication function block for IEC 61499 applications. By eliminating events and using typed adapters, it is particularly well-suited for dataflow-oriented and loosely coupled systems. Its generic design allows it to be used with various numeric data types without requiring modification of the function block itself.

AUDI_MUL_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUDI_MUL_3** is a generic function block for multiplying three input values. The values are provided via unidirectional adapters of type **AUDI**, and the result is output via a similar adapter. The function block is designed for use in IEC 61499-based control systems.

Interface Structure

Event Inputs

Not present – all data transmission is adapter-based without explicit event control.

Event Outputs

Not present.

Data Inputs

Not present – the input values are provided via **Sockets IN1, IN2, and IN3** as adapters.

Data Outputs

Not present – the result is output via **Plug OUT** as an adapter.

Adapter

Name	Direction	Type	Description
IN1	Socket (Input)	`adapter::types::unidirectional::AUDI`	First multiplication factor.
IN2	Socket (Input)	`adapter::types::unidirectional::AUDI`	Second multiplication factor.
IN3	Socket (Input)	`adapter::types::unidirectional::AUDI`	Third multiplication factor.
OUT	Plug (Output)	`adapter::types::unidirectional::AUDI`	Result of multiplication `IN1 * IN2 * IN3`.

Functionality

The function block **AUDI_MUL_3** performs an arithmetic multiplication of the three values provided via the adapters **IN1, IN2, and IN3**. The product is calculated continuously and made available via the adapter **OUT**. The underlying data type **AUDI** is defined generically (via the attribute `eclipse4diac::core::GenericClassName`) and can be replaced by a specific numeric type (e.g., INT, REAL) at configuration time. Explicit triggering by events is not required, as the adapters handle the data transfer independently.

Technical Features

- **Generic Data Type**: The function block is designed as a generic block (`GenericClassName = 'GEN_AUDI_MUL'`). The adapter type used, **AUDI**, can be replaced by any numeric data type, as long as the same type is used on all adapters.
- **Adapter-based interface**: Instead of discrete data and event ports, the function block communicates exclusively via unidirectional adapters. This enables flexible chaining with other function blocks of the same adapter type.
- **No explicit state logic**: The function block does not require an internal state machine – multiplication is purely data flow-driven.

State overview

The **AUDI_MUL_3** does not have an explicit state machine. The output **OUT** always corresponds to the current product of the three inputs. As soon as valid data is present at all sockets, the result is calculated without delay.

Application scenarios

- **Multidimensional calculations**: Combining several physical quantities that need to be multiplied (e.g., volume from length, width, and height).
- **Signal scaling**: Multiplying a sensor value by two calibration factors.
- **Nested arithmetic**: Use as part of a larger calculation chain where the product of three inputs is required.

Comparison with Similar Function Blocks

- **AUDI_MUL_2**: Performs the multiplication of only two inputs. **AUDI_MUL_3** extends this functionality to three factors.
- **AUDI_ADD_3**: Performs the addition of three values, while **AUDI_MUL_3** performs multiplication – both use the same adapter structure.
- **Conventional IEC 61499 Function Blocks**: Typical multifunction blocks often use separate data and event ports. The adapter-based approach simplifies typing and reusability in generic frameworks.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AUDI_MUL_3 is a compact, generic function block for multiplying three values. Its adapter-driven interface and generic typing make it ideal for modular, reusable control applications. Its simple, data-flow-oriented approach without state machines makes it intuitive to use and extensible.

AUDI_MUL_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUDI_MUL_4** performs an arithmetic multiplication based on four input values. It is a generic function block (FB) that operates via adapter interfaces with a unidirectional data structure of type `adapter::types::unidirectional::AUDI`. The block is specified according to IEC 61499-2 and is used particularly in automation solutions where scalable multiplication of multiple input variables is required.

Interface Structure

Event Inputs

The block does not have traditional event inputs. Control is integrated into the input adapters.

Event Outputs

The block does not have traditional event outputs. Control is integrated into the output adapter.

Data Inputs

The block does not have any traditional data inputs. All input values are provided via adapter interfaces.

Data Outputs

This function block does not have traditional data outputs. The multiplication result is output via an adapter plug.

Adapter

Type	Name	Direction	Comment
`adapter::types::unidirectional::AUDI`	IN1	Input (Socket)	MUL input 1
`adapter::types::unidirectional::AUDI`	IN2	Input (Socket)	MUL input 2
`adapter::types::unidirectional::AUDI`	IN3	Input (Socket)	MUL input 3
`adapter::types::unidirectional::AUDI`	IN4	Input (Socket)	MUL input 4
`adapter::types::unidirectional::AUDI`	OUT	Output (Plug)	MUL result

The adapter `AUDI` is defined as a unidirectional data type and transports the respective numerical values as well as the result.

Functionality

The function block (FB) multiplies the values applied to the four adapters **IN1**, **IN2**, **IN3**, and **IN4** and provides the product at the output adapter **OUT**. Processing is asynchronous, occurring as soon as all required input data is available. The function block is designed as a generic FB, meaning the data type used can be specified at runtime or during deployment via the attribute `eclipse4diac::core::GenericClassName`. By default, the name `'GEN_AUDI_MUL'` is used.

- **Generic Implementation**: The function block (FB) is generic and can be adapted to various numeric data types (e.g., INT, REAL, LREAL). Specific implementation is achieved via the class attribute.
- **Adapter-Based Communication**: Adapters are used instead of direct inputs/outputs. This allows for flexible data encapsulation and enables reuse in different contexts.
- **Type Hash**: The attribute value `eclipse4diac::core::TypeHash` is empty and can be supplemented at runtime with the actual hash of the data type used.
- **No State Machines**: The FB does not have an event-driven state machine (ECM), as multiplication is purely data-driven.

Not applicable – the function block operates without a state machine. Multiplication is triggered by the availability of input data.

- **Process Automation**: Multiplication of four analog measurements (e.g., flow rate, pressure, temperature, density) to calculate a mass flow correction.
- **Machine Control**: Calculation of total loads or torques from multiple individual variables.
- **Data Preprocessing**: Scaling or weighting of sensor data in a higher-level control system.
- **Image Processing**: Combination of multiple channels (e.g., red, green, blue, intensity) through multiplication.

Unlike classic IEC 61131 multiplication function blocks (e.g., `MUL` with fixed data types), `AUDI_MUL_4` offers a generic, adapter-based interface that enables flexible reuse. Other multipliers, such as `MUL_2` or `AUDI_MUL_2`, process only two inputs, while `AUDI_MUL_4` multiplies four inputs simultaneously. Function blocks with event-driven processing (e.g., `MUL_E`) require additional triggers, whereas this function block operates purely data-driven.

The function block **AUDI_MUL_4** is a specialized, generic multiplication block for four input values. Its use of adapters and generic design make it particularly suitable for modular, reusable automation solutions where flexibility and scalability are paramount. The simple, event-free interface facilitates integration into data-driven architectures.

AUDI_SUB_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block (FB) `AUDI_SUB_2` is a generic function block for performing arithmetic subtraction. It is based on the generic class `GEN_AUDI_SUB` and uses unidirectional adapters of type `AUDI` for structured and event-driven data transmission. This achieves clean encapsulation of data and events, reducing the complexity of wiring in IEC 61499 applications.

Interface Structure

Since the block is entirely based on adapters, it does not have any traditional, directly visible event or data pins at the top level. All communication is handled via the adapters.

Event Inputs

No direct event inputs are available. Event control is encapsulated within the adapters.

Event Outputs

No direct event outputs are available. Event control is encapsulated within the adapters.

Data Inputs

No direct data inputs are available. Data transmission occurs via the adapter interfaces.

Data Outputs

No direct data outputs are available. Data transmission occurs via the adapter interfaces.

Adapters

Sockets (Input Adapters / Sockets)

- **IN1** (Type: `adapter::types::unidirectional::AUDI`):
- First input for subtraction (minuend).
- **IN2** (Type: `adapter::types::unidirectional::AUDI`):
- Second input for subtraction (subtrahend).

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AUDI`):
- Output of the function block that provides the result of the subtraction (difference).

–

Functionality

The function block calculates the mathematical difference between the two values provided via the input adapters according to the following principle:

$$\mathrm{OUT} = \mathrm{IN1} - \mathrm{IN2} \tag{2.82}$$

As soon as values at the input adapters `IN1` or `IN2` change and a corresponding trigger event is received via the adapter, the calculation is performed internally. The result and the associated update event are then forwarded via the output adapter `OUT`.

Technical Features

- **Generic Implementation:** The `eclipse4diac::core::GenericClassName = 'GEN_AUDI_SUB'` attribute makes the function block flexible. Depending on the implementation of the underlying adapter, it can support various data types.
- **Encapsulation by Adapter:** Using the unidirectional adapter `AUDI` bundles data and event lines. This significantly improves clarity in the 4diac application editor, as fewer lines need to be drawn.

–

State Overview

The function block behaves like a stateless mathematical operator. There is no internal state loop (ECC states in the classical sense) that is maintained for an extended period. Each activation by an event at the inputs leads to a direct calculation and update of the output.

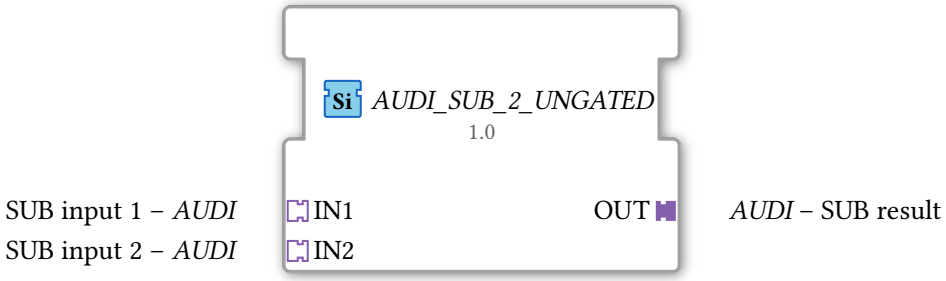
Application Scenarios

- **Signal Processing:** Subtraction of sensor values (e.g., offset compensation or calculation of differential pressures/temperatures) in systems that are consistently based on the `AUDI` adapter architecture.
- **Control Engineering:** Calculation of the control error ($e = w - x$) by subtracting the actual value from the setpoint.

Comparison with Similar Components

- **Standard SUB Component (IEC 61131-3 / IEC 61499):** A classic `SUB` component has dedicated data inputs (`IN1`, `IN2`), a data output (`OUT`), and event inputs and outputs (e.g., `REQ` / `CNF`). The `AUDI_SUB_2`, on the other hand, bundles these signals in adapters, which improves reusability and modularity in complex architectures.
- **AUDI_ADD_2:** The counterpart for addition. Uses the same adapter interface, but adds the input values ($IN1 + IN2$).

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AUDI_SUB_2` is a specialized, yet flexible, function block for subtraction due to its generic nature. It is ideally suited for service-oriented architectures within 4diac, where a unified interface concept using unidirectional adapters is paramount.

AUDI_SUB_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUDI_SUB_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

The function block calculates the mathematical difference between the two values provided via the input adapters according to the following principle:

$$\mathrm{OUT} = \mathrm{IN1} - \mathrm{IN2} \tag{2.83}$$

As soon as values at the input adapters `IN1` or `IN2` change and a corresponding trigger event is received via the adapter, the calculation is performed internally. The result and the associated update event are then forwarded via the output adapter `OUT`.

Technical Features

- **Generic Implementation:** The `eclipse4diac::core::GenericClassName = 'GEN_AUDI_SUB'` attribute makes the function block flexible. Depending on the implementation of the underlying adapter, it can support various data types.
- **Encapsulation by Adapter:** Using the unidirectional adapter `AUDI` bundles data and event lines. This significantly improves clarity in the 4diac application editor, as fewer lines need to be drawn.

–

State Overview

The function block behaves like a stateless mathematical operator. There is no internal state loop (ECC states in the classical sense) that is maintained for an extended period. Each activation by an event at the inputs leads to a direct calculation and update of the output.

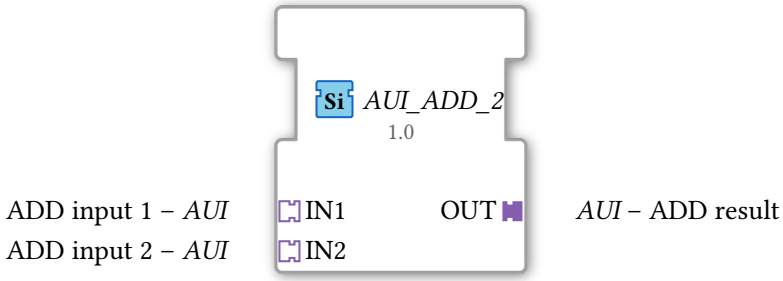
Application Scenarios

- **Signal Processing:** Subtraction of sensor values (e.g., offset compensation or calculation of differential pressures/temperatures) in systems that are consistently based on the `AUDI` adapter architecture.
- **Control Engineering:** Calculation of the control error ($e = w - x$) by subtracting the actual value from the setpoint.

Comparison with Similar Components

- **Standard SUB Component (IEC 61131-3 / IEC 61499):** A classic `SUB` component has dedicated data inputs (`IN1`, `IN2`), a data output (`OUT`), and event inputs and outputs (e.g., `REQ` / `CNF`). The

AUDI_SUB_2_UNGATED, on the other hand, bundles these signals in adapters, which improves reusability and modularity in complex architectures.
- **AUDI_ADD_2:** The counterpart for addition. Uses the same adapter interface, but adds the input values ($IN1 + IN2$).



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The AUDI_SUB_2_UNGATED is a specialized, yet flexible, function block for subtraction due to its generic nature. It is ideally suited for service-oriented architectures within 4diac, where a unified interface concept using unidirectional adapters is paramount.

AUI_ADD_2

No image available

• – ◦ • – ◦ • – ◦ •

Introduction

The function block AUI_ADD_2 is a generic function block (Generic FB) designed to perform arithmetic addition. It uses unidirectional adapters of type AUI (Adapter Unidirectional Interface) to add two input values and output the result. Because it is a generic block based on the class GEN_AUI_ADD, it can be flexibly used for various data types supported by the corresponding adapters.

Interface Structure

Since this function block is entirely based on adapters, it has no direct, discrete data or event channels at the top level. All communication and control are handled via the adapter interfaces.

Event Inputs

No direct event inputs available (control is handled via the connected adapters).

Event Outputs

No direct event outputs available (forwarding is handled via the connected adapters).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

- **Sockets (Input Adapters):**
- **IN1** (Type: adapter::types::unidirectional::AUI): First input (addend) for arithmetic addition.
- **IN2** (Type: adapter::types::unidirectional::AUI): Second input (addend) for arithmetic addition.
- **Plugs (Output Adapters):**
- **OUT** (Type: adapter::types::unidirectional::AUI): Output for the result of the addition (IN1 + IN2).

Functionality

As soon as values are present at the input adapters `IN1` and `IN2`, or a corresponding update event is triggered via the adapters, the function block performs the addition.

The mathematical operation is:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} \tag{2.84}$$

The result and the associated output event are immediately passed on to the subsequent function blocks via the output adapter `OUT`.

By defining it as a generic building block (`GEN_AUI_ADD`), the internal addition logic dynamically adapts to the data types of the connected adapters (e.g., integer or floating-point types).

Technical Features

- **Generic Design:** The building block is classified as `GEN_AUI_ADD` via the attribute `eclipse4diac::core::GenericClassName`. This enables high reusability for different numeric data types.
- **Adapter Encapsulation:** The use of the unidirectional adapter `AUI` ensures a very clean design in the 4diac application editor, as event and data flows are bundled in a single connection.
- **Unidirectional Flow:** The interfaces are designed as purely unidirectional connections, which dictates a clear direction of signal and data flow from the sockets (`IN1`, `IN2`) to the plug (`OUT`).

State Overview

The module does not have a complex internal state machine (ECC). Processing is event-driven and stateless (combinatorial) based on the triggers received via the adapters.

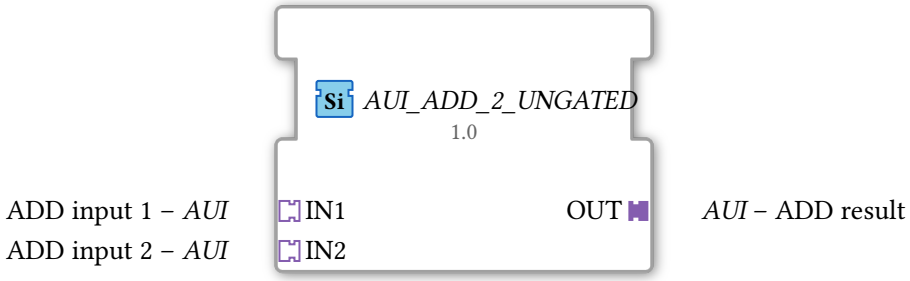
Application Scenarios

- **Signal Addition:** Combining two sensor values (e.g., to calculate a total volumetric flow rate from two individual flow meters).
- **Setpoint Offset:** Applying a constant or variable correction value (offset) to an existing control parameter.
- **Structured Signal Processing:** For use in more complex control loops within IEC 61499 where a clean, adapter-based wiring style is preferred.

Comparison with Similar Components

Compared to standard IEC 61131-3 addition components (such as a classic `ADD` component with discrete inputs), the `AUI_ADD_2` eliminates the need for separate wiring of REQ/CNF events and the actual data lines. This reduces the potential for errors when manually creating event-data associations (WITH connections).

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AUI_ADD_2` is a highly efficient, modular component for mathematical addition in modern IEC 61499 systems. Through the consistent use of adapters, he promotes a clear, error-resistant and easily maintainable application design in the 4diac IDE.

AUI_ADD_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_ADD_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUI_ADD_2_UNGATED` is a generic function block (Generic FB) designed to perform arithmetic addition. It uses unidirectional adapters of type `AUI` (Adapter Unidirectional Interface) to add two input values and output the result. Because it is a generic block based on the class `GEN_AUI_ADD`, it can be flexibly used for various data types supported by the corresponding adapters.

Interface Structure

Since this function block is entirely based on adapters, it has no direct, discrete data or event channels at the top level. All communication and control are handled via the adapter interfaces.

Event Inputs

No direct event inputs available (control is handled via the connected adapters).

Event Outputs

No direct event outputs available (forwarding is handled via the connected adapters).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

- **Sockets (Input Adapters):**
- **IN1** (Type: `adapter::types::unidirectional::AUI`): First input (addend) for arithmetic addition.
- **IN2** (Type: `adapter::types::unidirectional::AUI`): Second input (addend) for arithmetic addition.
- **Plugs (Output Adapters):**
- **OUT** (Type: `adapter::types::unidirectional::AUI`): Output for the result of the addition (`IN1 + IN2`).

Functionality

As soon as values are present at the input adapters `IN1` and `IN2`, or a corresponding update event is triggered via the adapters, the function block performs the addition.

The mathematical operation is:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} \tag{2.85}$$

The result and the associated output event are immediately passed on to the subsequent function blocks via the output adapter `OUT`.

By defining it as a generic building block (`GEN_AUI_ADD`), the internal addition logic dynamically adapts to the data types of the connected adapters (e.g., integer or floating-point types).

Technical Features

- **Generic Design:** The building block is classified as `GEN_AUI_ADD` via the attribute `eclipse4diac::core::GenericClassName`. This enables high reusability for different numeric data types.

- **Adapter Encapsulation:** The use of the unidirectional adapter `AUI` ensures a very clean design in the 4diac application editor, as event and data flows are bundled in a single connection.
- **Unidirectional Flow:** The interfaces are designed as purely unidirectional connections, which dictates a clear direction of signal and data flow from the sockets (`IN1`, `IN2`) to the plug (`OUT`).

State Overview

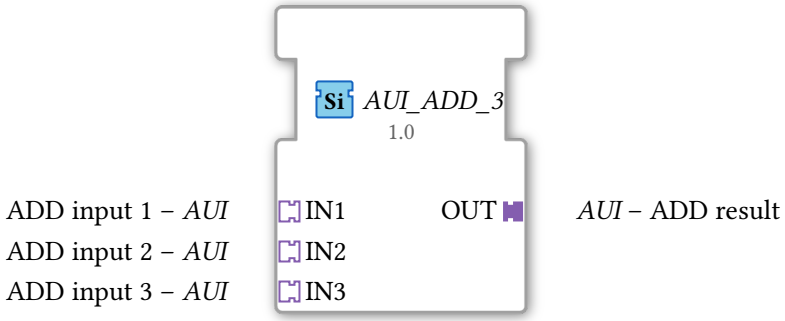
The module does not have a complex internal state machine (ECC). Processing is event-driven and stateless (combinatorial) based on the triggers received via the adapters.

Application Scenarios

- **Signal Addition:** Combining two sensor values (e.g., to calculate a total volumetric flow rate from two individual flow meters).
- **Setpoint Offset:** Applying a constant or variable correction value (offset) to an existing control parameter.
- **Structured Signal Processing:** For use in more complex control loops within IEC 61499 where a clean, adapter-based wiring style is preferred.

Comparison with Similar Components

Compared to standard IEC 61131-3 addition components (such as a classic `ADD` component with discrete inputs), the `AUI_ADD_2_UNGATED` eliminates the need for separate wiring of REQ/CNF events and the actual data lines. This reduces the potential for errors when manually creating event-data associations (WITH connections).



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AUI_ADD_2_UNGATED` is a highly efficient, modular component for mathematical addition in modern IEC 61499 systems. Through the consistent use of adapters, he promotes a clear, error-resistant and easily maintainable application design in the 4diac IDE.

AUI_ADD_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUI_ADD_3` is a generic arithmetic function block for the IEC 61499 development environment (4diac-ide). Its primary function is to add three input values, which are passed via standardized, unidirectional adapter interfaces. The result of the addition is also output via a corresponding adapter. By encapsulating data and control events in adapters, wiring in the application editor is significantly simplified, and the clarity of the system design is improved.

Interface Structure

The interfaces of `AUI_ADD_3` are based entirely on adapters to ensure a clean signal structure.

Event Inputs

No direct event inputs are defined. Event control is handled implicitly via the input adapters (sockets).

Event Outputs

No direct event outputs are defined. Event forwarding is handled implicitly via the output adapter (plug).

Data Inputs

No direct data inputs are defined. Data is provided via the input adapters.

Data Outputs

No direct data outputs are defined. The result is provided via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AUI`): First input value (addend 1) for arithmetic addition.
- **IN2** (Type: `adapter::types::unidirectional::AUI`): Second input value (addend 2) for arithmetic addition.
- **IN3** (Type: `adapter::types::unidirectional::AUI`): Third input value (addend 3) for arithmetic addition.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AUI`): Output for the calculated result (sum of `IN1 + IN2 + IN3`).

Functionality

The function block performs three-digit addition according to the following mathematical formula:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} \tag{2.86}$$

As soon as an update event arrives at one of the input adapters (`IN1`, `IN2`, or `IN3`), the function block reads the current values of all three inputs. It then calculates the sum and provides the result at the output adapter `OUT`. Simultaneously, the corresponding update event is passed on via the `OUT` adapter to inform subsequent function blocks of the new value.

Since this is a generic function block (`GEN_AUI_ADD`), the supported data type (e.g., `INT`, `REAL`, `LREAL`) depends on the specific implementation and definition of the adapter type used, `AUI`.

Technical Features

- **Generic Function Block:** The attribute `eclipse4diac::core::GenericClassName = 'GEN_AUI_ADD'` allows the function block to be used flexibly for various numeric data types, provided the adapters used support this.
- **Compact Design:** By using adapters instead of separate event and data ports, the visual "spaghetti code" problem in 4diac systems is minimized.

- **Generic Function Block:** * **Unidirectional Communication:** The use of unidirectional adapters (`unidirectional::AUI`) ensures that the data flow is clearly defined from the inputs to the output.

State Overview

The function block operates in an event-driven and stateless (i.e., purely reactive) manner:

1. **Wait State:** The function block waits for a trigger event at one of the sockets (`IN1`, `IN2`, `IN3`).
2. **Calculation:** Upon receiving an event, the data values are read and added.
3. **Output:** The calculated value is written to the plug `OUT`, and the trigger event is fired.
4. **Return:** The block immediately returns to standby mode.

Application Scenarios

- **Sensor Value Aggregation:** Addition of three analog measured values (e.g., three temperature sensors to determine total heat or three flow meters).

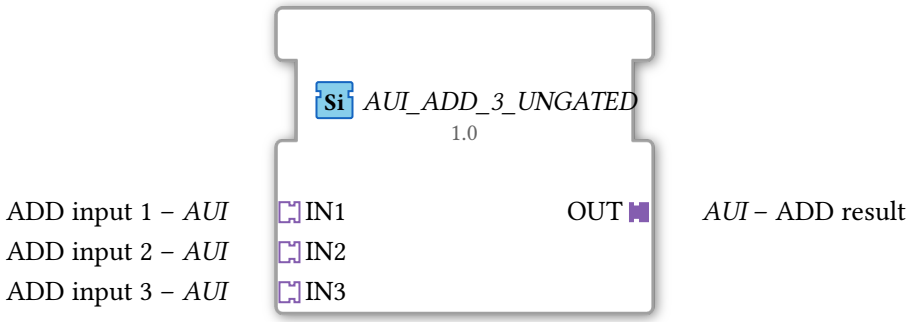
- **Setpoint Generation:** Combining the base setpoint, manual offset, and automatic correction value in process engineering.
- **Power Calculation:** Summing the active power of three individual phases of an electrical network to obtain a total power value.

Comparison with Similar Blocks

- **Standard ADD Block (IEC 61131-3):** A classic `ADD` block has discrete inputs for data and events. `AUI_ADD_3` logically groups these in adapters, which increases reusability and clarity.
- **AUI_ADD_2 (Dual Adder):** While a dual adder would require cascading two function blocks to sum three values, `AUI_ADD_3` accomplishes this in a single step. This saves resources and reduces system latency.

- `AUI_ADD_3_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AUI_ADD_3` is an efficient auxiliary function block for arithmetic operations in modern IEC 61499 control applications. Its consistent use of the adapter concept allows it to integrate seamlessly into service-oriented and modular software architectures, contributing to reduced complexity in graphical programming.

AUI_ADD_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_ADD_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). • – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUI_DIV_2` is a generic function block for performing an arithmetic division of two input values. The block uses an adapter-based concept, where data and event streams are bundled in unidirectional adapters. This enables clean, modularized, and clear modeling within IEC 61499 applications in 4diac.

Interface Structure

Event Inputs

No direct event inputs are defined. Event control is implicit via the adapter interfaces.

Event Outputs

No direct event outputs are defined. Event control is implicit via the adapter interfaces.

Data Inputs

No direct data inputs are defined. Data is transferred via the input adapters.

Data Outputs

No direct data outputs are defined. Data is transferred via the output adapter.

Adapters

- **IN1** (Type: `adapter::types::unidirectional::AUI`):

The first input adapter. It provides the dividend (numerator) for the division operation and the associated trigger events.

- **IN2** (Type: `adapter::types::unidirectional::AUI`):

The second input adapter. It provides the divisor (denominator) for the division operation and the associated trigger events.

- **OUT** (Type: `adapter::types::unidirectional::AUI`):

The output adapter. It outputs the result of the division (quotient) and the corresponding calculation event.

Plugs (Ausgangs-Schnittstellen)

Sockets (Eingangs-Schnittstellen)

Functionality

The function block performs the mathematical operation `OUT = IN1 / IN2`.

As soon as a corresponding trigger event is registered at the input adapters (`IN1` or `IN2`), the function block reads the current values from the adapters, calculates the quotient, and outputs it along with an output event via the adapter `OUT`.

Since it is a generic function block (GEN_AUI_DIV), the function block can adapt to different numeric data types (e.g., INT, REAL, LREAL) depending on the implementation and system configuration, provided the underlying adapters support the same data type.

- **Generic Type:** The attribute GenericClassName with the value 'GEN_AUI_DIV' allows the function block to be used flexibly and is not restricted to a specific data type.
- **Interface Encapsulation:** The use of unidirectional adapters (AUI) significantly reduces wiring effort in the 4diac IDE, as event and data lines are bundled into a single connection.
- **Division by Zero:** When using this function block, it must be ensured that the value of IN2 is not zero to avoid runtime errors or infinite values (NaN/Inf) in the control system.

2.2 · Status Overview

1. **Waiting State (IDLE):** The function block waits for incoming events via the adapters IN1 or IN2.
2. **Calculation (EVALUATE):** After receiving an event, the data from the adapters is read and the division is performed.
3. **Output (DISPATCH):** The result and the associated event are provided via the adapter OUT.

- **Scaling of Sensor Values:** Division of raw values by scaling factors in modular control architectures.
- **Calculation of Averages:** Use in mathematical computing networks where data streams are transmitted in a structured manner via adapters.
- **Signal Processing:** Reduction of signal strength or frequency divisions in distributed systems.

Compared to a classic standard DIV function block (e.g., from the IEC 61131-3 standard library), which uses individual pins for REQ, CNF, IN1, IN2, and OUT, the AUI_DIV_2 offers a significantly cleaner visual representation in the function block diagram. Encapsulation in adapters minimizes the potential for errors when manually wiring event-to-data mappings.

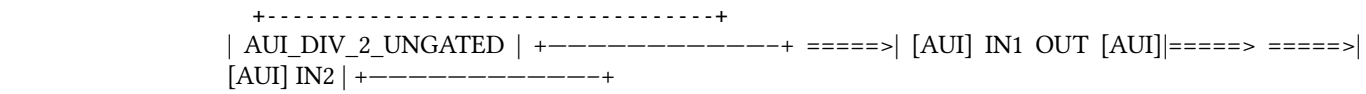
The AUI_DIV_2 is a modern, modular, and reusable function block for division. Through the consistent use of unidirectional adapters, it is ideally suited for complex, distributed control applications in 4diac where clarity and easy maintainability of the code are paramount.

Technical Features

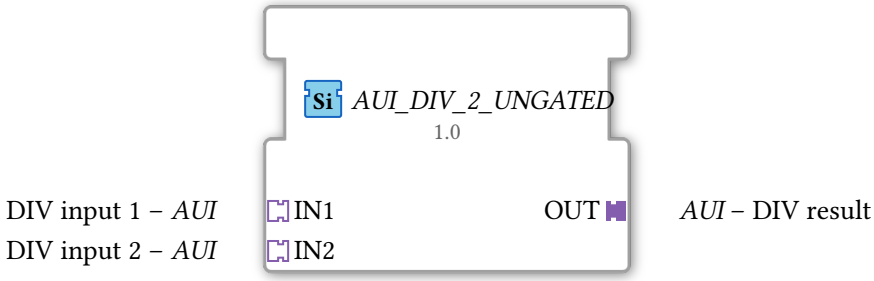
State Overview

Application Scenarios

Comparison with Similar Function Blocks



Change Detection



The result is only written to the output plug (OUT) and its adapter event only sent if the newly computed value differs from the value currently held on OUT. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AUI_DIV_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AUI_DIV_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. Introduction

The function block `AUI_DIV_2_UNGATED` is a generic function block for performing an arithmetic division of two input values. The block uses an adapter-based concept, where data and event streams are bundled in unidirectional adapters. This enables clean, modularized, and clear modeling within IEC 61499 applications in 4diac.

Interface Structure

Event Inputs

No direct event inputs are defined. Event control is implicit via the adapter interfaces.

Event Outputs

No direct event outputs are defined. Event control is implicit via the adapter interfaces.

Data Inputs

No direct data inputs are defined. Data is transferred via the input adapters.

Data Outputs

No direct data outputs are defined. Data is transferred via the output adapter.

Adapters

- **IN1** (Type: `adapter::types::unidirectional::AUI`):

The first input adapter. It provides the dividend (numerator) for the division operation and the associated trigger events.

- **IN2** (Type: `adapter::types::unidirectional::AUI`):

The second input adapter. It provides the divisor (denominator) for the division operation and the associated trigger events.

- **OUT** (Type: `adapter::types::unidirectional::AUI`):

The output adapter. It outputs the result of the division (quotient) and the corresponding calculation event.

Plugs (Ausgangs-Schnittstellen)

Sockets (Eingangs-Schnittstellen)

Functionality

The function block performs the mathematical operation `OUT = IN1 / IN2`.

As soon as a corresponding trigger event is registered at the input adapters (`IN1` or `IN2`), the function block reads the current values from the adapters, calculates the quotient, and outputs it along with an output event via the adapter `OUT`.

Since it is a generic function block (`GEN_AUI_DIV`), the function block can adapt to different numeric data types (e.g., INT, REAL, LREAL) depending on the implementation and system configuration, provided the underlying adapters support the same data type.

- **Generic Type:** The attribute `GenericClassName` with the value `'GEN_AUI_DIV'` allows the function block to be used flexibly and is not restricted to a specific data type.

- **Interface Encapsulation:** The use of unidirectional adapters (`AUI`) significantly reduces wiring effort in the 4diac IDE, as event and data lines are bundled into a single connection.
- **Division by Zero:** When using this function block, it must be ensured that the value of `IN2` is not zero to avoid runtime errors or infinite values (NaN/Inf) in the control system.

2.3 · Status Overview

1. **Waiting State (IDLE):** The function block waits for incoming events via the adapters `IN1` or `IN2`.
2. **Calculation (EVALUATE):** After receiving an event, the data from the adapters is read and the division is performed.
3. **Output (DISPATCH):** The result and the associated event are provided via the adapter `OUT`.

- **Scaling of Sensor Values:** Division of raw values by scaling factors in modular control architectures.
- **Calculation of Averages:** Use in mathematical computing networks where data streams are transmitted in a structured manner via adapters.
- **Signal Processing:** Reduction of signal strength or frequency divisions in distributed systems.

Compared to a classic standard DIV function block (e.g., from the IEC 61131-3 standard library), which uses individual pins for `REQ`, `CNF`, `IN1`, `IN2`, and `OUT`, the `AUI_DIV_2_UNGATED` offers a significantly cleaner visual representation in the function block diagram. Encapsulation in adapters minimizes the potential for errors when manually wiring event-to-data mappings.

The `AUI_DIV_2_UNGATED` is a modern, modular, and reusable function block for division. Through the consistent use of unidirectional adapters, it is ideally suited for complex, distributed control applications in 4diac where clarity and easy maintainability of the code are paramount.

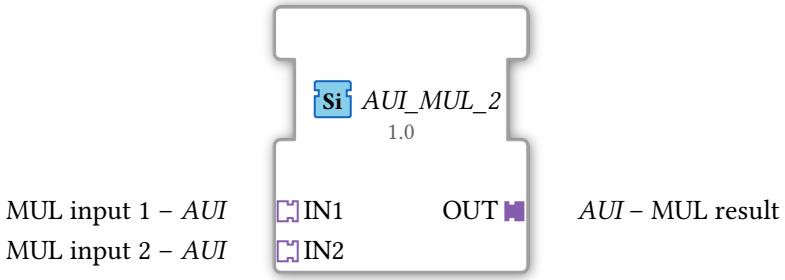
State Overview

Application Scenarios



Comparison with Similar Function Blocks

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AUI_MUL_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUI_MUL_2` is a generic arithmetic function block for the 4diac-ide development environment, used to perform the multiplication of two input values.

The special feature of this block lies in its adapter-based architecture. Instead of classic, individual data and event lines, this block uses unidirectional adapters (`AUI`) to transmit data and the associated control events in encapsulated form. This significantly reduces the visual complexity of control applications.

Interface Structure

Event Inputs
No direct event inputs are available. Event control is handled entirely via the input adapters.

Event Outputs
No direct event outputs are available. Event forwarding is handled entirely via the output adapter.

Data Inputs
No direct data inputs available.

Data Outputs
No direct data outputs available.

Adapters
- **`IN1` (Type: `adapter::types::unidirectional::AUI` - Socket):**

The first input adapter, providing the first multiplication factor.

- **`IN2` (Type: `adapter::types::unidirectional::AUI` - Socket):**

The second input adapter, providing the second multiplication factor.

- **`OUT` (Type: `adapter::types::unidirectional::AUI` - Plug):**

The output adapter that outputs the calculated product of the two input values along with the corresponding update event.

Functionality
As soon as an event is triggered at one of the input adapters (`IN1` or `IN2`) indicating the presence of a new value, the function block reads the current values from both adapters.

The calculation is performed using the classic mathematical formula:
`OUT = IN1 * IN2`
After successful calculation, the result is passed to the output adapter `OUT`, and an output event is simultaneously triggered to inform subsequent function blocks about the presence of a new value.

Technical Features
- **Generic Behavior:** The function block is linked to the value `'GEN_AUI_MUL'` via the compiler attribute `GenericClassName`. This means that the function block can operate independently of the data type (e.g., for `INT`, `REAL`, `LREAL`, etc.), depending on the specific data type defined by the connected adapters.
- **Efficient Wiring:** By encapsulating the function block in `AUI` adapters (Unidirectional Interface Adapters), the number of connections in the function plan is drastically reduced, as data and event flows are combined.
-

State Overview
The function block operates purely event-driven and stateless (reactively):

1. **Standby State:** The block waits for incoming events via `IN1` or `IN2`.
2. **Calculation Phase:** An incoming event triggers the internal multiplication of the current adapter data.
3. **Output Phase:** The calculated product is applied to `OUT`, and the output event is triggered. The block immediately returns to the standby state.

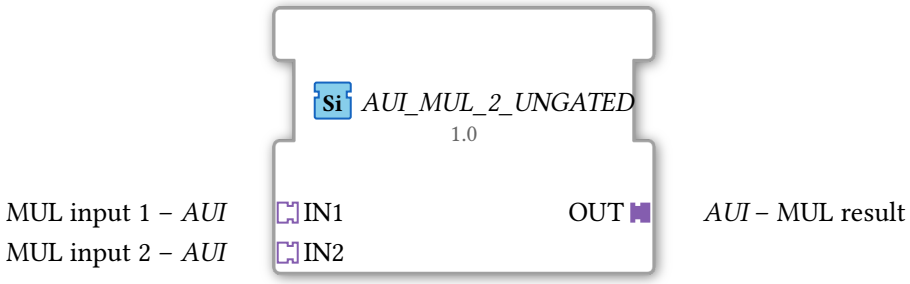
–

Application Scenarios
- **Measurement Scaling:** Multiplication of an analog sensor value (e.g., voltage) by a scaling factor to calculate the actual physical value.
- **Power Calculation:** Continuous multiplication of current (I) and voltage (U) to determine the current active power (P). * **Signal Amplification:** Application in signal processing for simple level adjustment.

Comparison with Similar Components

- **Standard `MUL` component (IEC 61131-3):** A standard multiplication component requires separate pins for each data signal as well as for the execution control (`REQ`/`CNF`). `AUI_MUL_2` solves this more elegantly and compactly using adapter connections.
- **Multi-Input Multipliers (`MUL_3`, `MUL_4`):** While function blocks like `AUI_MUL_2` are fixed to two inputs, multi-input function blocks allow the multiplication of three or more factors in a single step, but are more complex.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AUI_MUL_2` is a highly modular and modern function block for the 4diac-ide. Through the consistent use of unidirectional adapters, it promotes clean software design in distributed control systems according to IEC 61499, without sacrificing flexibility in the data types it can process.

AUI_MUL_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_MUL_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

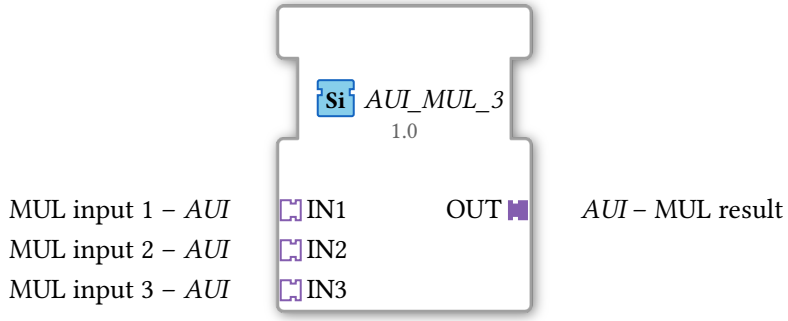
–

Application Scenarios

- **Measurement Scaling:** Multiplication of an analog sensor value (e.g., voltage) by a scaling factor to calculate the actual physical value.
- **Power Calculation:** Continuous multiplication of current (I) and voltage (U) to determine the current active power (P). * **Signal Amplification:** Application in signal processing for simple level adjustment.

Comparison with Similar Components

- **Standard `MUL` component (IEC 61131-3):** A standard multiplication component requires separate pins for each data signal as well as for the execution control (`REQ`/`CNF`). `AUI_MUL_2_UNGATED` solves this more elegantly and compactly using adapter connections.
- **Multi-Input Multipliers (`MUL_3`, `MUL_4`):** While function blocks like `AUI_MUL_2_UNGATED` are fixed to two inputs, multi-input function blocks allow the multiplication of three or more factors in a single step, but are more complex.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AUI_MUL_2_UNGATED` is a highly modular and modern function block for the 4diac-ide. Through the consistent use of unidirectional adapters, it promotes clean software design in distributed control systems according to IEC 61499, without sacrificing flexibility in the data types it can process.

AUI_MUL_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUI_MUL_3` is used for the mathematical multiplication of three input values. It is a generic function block (Generic FB) based on the higher-level class `GEN_AUI_MUL`. The special feature of this block lies in the use of unidirectional adapters of type `AUI` (Adapter Unidirectional Interface), which encapsulate both the data and the associated events. This ensures a clear and modular structure within 4diac applications.

Interface Structure

Event Inputs

This function block does not have direct, dedicated event inputs. Event control is handled entirely via the connected adapters.

Event Outputs

This function block does not have direct, dedicated event outputs. Event forwarding is handled via the output adapter.

Data Inputs

There are no direct data inputs. Data is transferred via the input adapters.

Data Outputs

There are no direct data outputs. Data output is handled via the output adapter.

Adapters

Sockets (Input Interfaces)

- **IN1** (Type: `adapter::types::unidirectional::AUI`): First multiplicand.
- **IN2** (Type: `adapter::types::unidirectional::AUI`): Second multiplicand.
- **IN3** (Type: `adapter::types::unidirectional::AUI`): Third multiplicand.

Plugs (Output Interface)

- **OUT** (Type: `adapter::types::unidirectional::AUI`): Result of the multiplication ($OUT = IN1 \cdot IN2 \cdot IN3$).

Functionality

As soon as a new event is signaled at one of the input adapters (`IN1`, `IN2`, or `IN3`), the function block reads the current values of the three inputs.

The arithmetic multiplication is calculated as follows:

$$Result = Value(IN1) \cdot Value(IN2) \cdot Value(IN3) \tag{2.88}$$

The result is passed to the output adapter `OUT`, and a corresponding output event is triggered via this adapter to inform subsequent function blocks of the update.

Since the function block is declared as generic (`GEN_AUI_MUL`), it adapts flexibly to the data types of the connected adapters (e.g., `INT`, `REAL`, `LREAL`), as long as these are supported by the adapter type used.

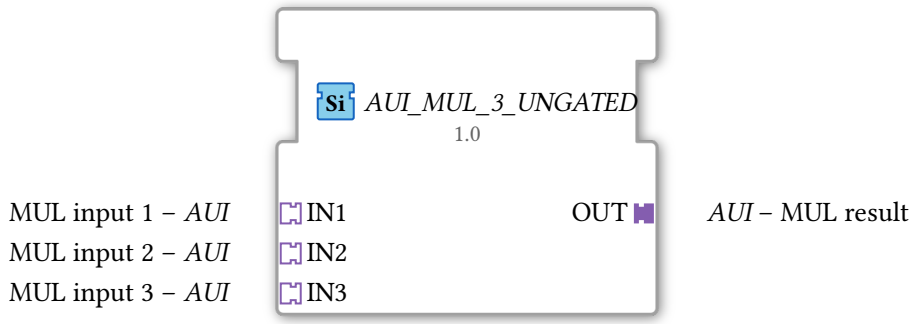
Technical Features

- **Generic Type:** By defining it as a generic function block, it can be flexibly used for various numeric data types without having to create a separate function block for each type.
- **Encapsulation by Adapters:** The use of the unidirectional `AUI` adapters significantly reduces the number of visible connection lines in the 4diac editor, as data and trigger events are bundled in a single connection.

–

State Overview

The function block operates purely event-driven:



1. **Wait State:** The function block waits for a trigger event on one of the sockets (`IN1`, `IN2`, `IN3`).
2. **Calculation:** After an event occurs, the data is read and multiplied.

– 3. **Output:** The result is applied to the plug `OUT`, the plug's send event is triggered, and the function block returns to standby mode.

Application Scenarios

- **Volume Calculation:** Calculation of a three-dimensional volume (length \cdot \cdot \bdot \cdot \bdot \bdot \b

frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUI_MUL_4` is a generic block for performing an arithmetic multiplication of four input values. It uses unidirectional adapters of type `AUI` (Adapter Unit Interface) to transmit data and associated events in a bundled manner. This enables clean and clear modeling in the 4diac-ide.

Interface Structure

Event Inputs

There are no direct event inputs. Event control is handled via the adapter interfaces.

Event Outputs

There are no direct event outputs. Event control is handled via the adapter interfaces.

Data Inputs

There are no direct data inputs.

Data Outputs

There are no direct data outputs.

Adapters

Sockets (Inputs)

- **IN1** (Type: `adapter::types::unidirectional::AUI`): First multiplicand.
- **IN2** (Type: `adapter::types::unidirectional::AUI`): Second multiplicand.
- **IN3** (Type: `adapter::types::unidirectional::AUI`): Third multiplicand.
- **IN4** (Type: `adapter::types::unidirectional::AUI`): Fourth multiplicand.

Plugs (Outputs)

- **OUT** (Type: `adapter::types::unidirectional::AUI`): Output for the result of the multiplication ($OUT = IN1 \cdot IN2 \cdot IN3 \cdot IN4$).

Functionality

As soon as a new event is signaled at one of the input adapters (`IN1` to `IN4`), the function block reads the current values of the four inputs. These values are multiplied together:

$$\text{Result} = \text{Value of IN1} \cdot \text{Value of IN2} \cdot \text{Value of IN3} \cdot \text{Value of IN4} \tag{2.90}$$

The calculated result is passed to the output adapter `OUT`, and a corresponding update event is output via this plug.

Technical Features

- **Generic Module:** The module is based on the generic class `GEN_AUI_MUL`. This allows for flexible adaptation to different data types within the adapter type used.
- **Using Adapters:** By encapsulating data and events in unidirectional adapters (`AUI`), the number of connection lines in the 4diac-ide application editor is drastically reduced, significantly improving the clarity of complex applications.

State Overview

The function block operates purely event-driven and has no internal state that persists beyond the duration of a calculation cycle (stateless/static function block).

- **Wait State:** The function block waits for an update event at one of the sockets (`IN1` to `IN4`).
- **Calculation:** After an event arrives, the multiplication is performed.
- **Output:** The result is created at `OUT`, an event is triggered at the plug, and the function block immediately returns to the wait state.

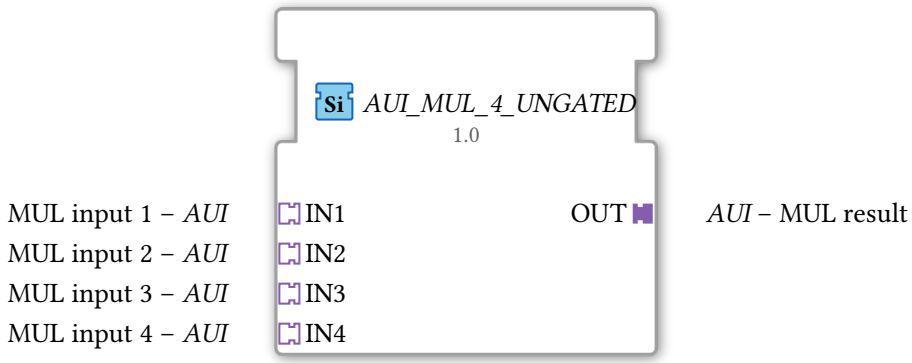
Application Scenarios

- **Signal Scaling:** Cascaded scaling of measured values where a raw value must be multiplied by several correction and calibration factors.
- **Signal Scaling:** * **Power Calculation:** Multiplication of various physical quantities to determine a target value (e.g., calculating total power from different factors).
- **Modular Control Concepts:** Applications where structured data transfers are implemented using standardized adapter interfaces.

Comparison with Similar Function Blocks

- **Standard MUL Function Blocks (IEC 61131-3):** Classic multipliers work with direct elementary data types (such as `REAL` or `INT`) and require separate event inputs (`REQ`) and event outputs (`CNF`). `AUI_MUL_4` simplifies this by encapsulating the data in adapters.
- **AUI_MUL_2 / AUI_MUL_3:** Similar function blocks with fewer inputs. The function block `AUI_MUL_4` is particularly suitable when exactly four factors need to be multiplied without having to chain multiple multiplication blocks together (which saves resources and latency in the execution model).

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The function block `AUI_MUL_4` represents an efficient and clean solution for arithmetic multiplications of four factors within an adapter-based 4diac architecture. It promotes the modular design and clarity of the IEC 61499 application.

AUI_MUL_4_UNGATED

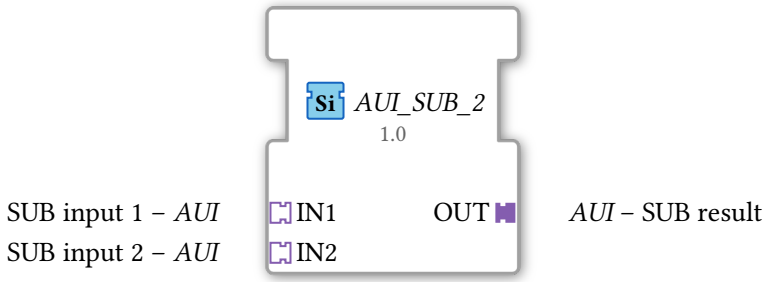
- **Standard MUL Function Blocks (IEC 61131-3):** Classic multipliers work with direct elementary data types (such as `REAL` or `INT`) and require separate event inputs (`REQ`) and event outputs (`CNF`). `AUI_MUL_4_UNGATED` simplifies this by encapsulating the data in adapters.
- **AUI_MUL_2 / AUI_MUL_3:** Similar function blocks with fewer inputs. The function block `AUI_MUL_4_UNGATED` is particularly suitable when exactly four factors need to be multiplied without having to chain multiple multiplication blocks together (which saves resources and latency in the execution model).



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The function block `AUI_MUL_4_UNGATED` represents an efficient and clean solution for arithmetic multiplications of four factors within an adapter-based 4diac architecture. It promotes the modular design and clarity of the IEC 61499 application.

AUI_SUB_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUI_SUB_2` is used to perform arithmetic subtraction within an IEC 61499 application. It is a generic function block (FB) specifically designed for interaction with adapter interfaces. It allows subtraction operations to be implemented modularly and in a structured manner via standardized adapter connections, instead of using discrete individual wires for data and events.

Interface Structure

Event Inputs

This function block does not have direct event inputs. Event control is handled internally via the connected adapters.

Event Outputs

This function block does not have direct event outputs. Event forwarding is encapsulated via the output adapter.

Data Inputs

There are no direct data inputs. Data is transferred via the input adapters.

Data Outputs

There are no direct data outputs. The result is provided via the output adapter.

Adapters

Sockets (Inputs)

- **IN1** (Type: `adapter::types::unidirectional::AUI`):

First input adapter for subtraction. This represents the minuend (value from which the subtraction is made).

- **IN2** (Type: `adapter::types::unidirectional::AUI`):

Second input adapter for subtraction. This represents the subtrahend (value being subtracted).

Plugs (Inputs / Outputs)

- **OUT** (Type: `adapter::types::unidirectional::AUI`):

Output adapter that provides the result of the subtraction (the difference) for further use.

–

Functionality

The function block performs the basic mathematical operation of subtraction on the values received via the adapters:

$$\mathrm{OUT} = \mathrm{IN1} - \mathrm{IN2} \tag{2.92}$$

As soon as a change in value is signaled at the input adapters `IN1` or `IN2` (triggered by the event-driven nature of the underlying `AUI` adapter), the function block calculates the difference and outputs the result, along with a corresponding update event, via the output adapter `OUT`.

Technical Features

- **Generic Type:** The function block is based on the generic class `GEN_AUI_SUB`. This allows for flexible handling of different data types, provided they are supported by the underlying adapter type `AUI` (Analog User Interface / Unidirectional).
- **Encapsulation:** By using unidirectional adapters, signal flows and their associated trigger events are neatly bundled. This significantly simplifies application design in the 4diac IDE and reduces the number of visible connection lines.

–

State Overview

The function block itself does not manage a complex internal state (stateless in the sense of a state machine). Its execution is purely reactive:

1. **Waiting:** The function block waits for an update event at `IN1` or `IN2`.

Encapsulation: 2. **Calculation:** After an event occurs, the data values are read and the subtraction is performed.

1. **Output:** The new difference value is applied to `OUT`, and the adapter's output event is triggered.

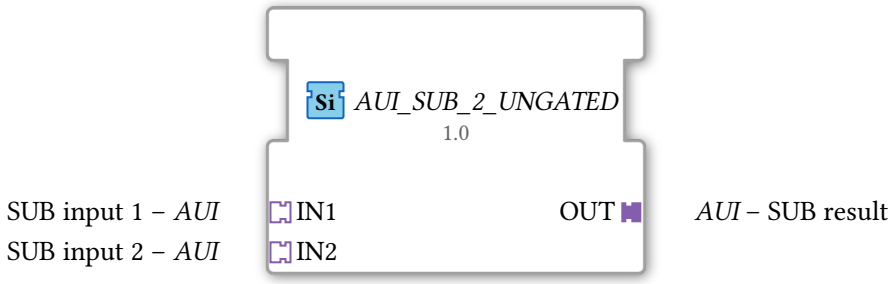
Application Scenarios

- **Differential Pressure/Differential Temperature Measurement:** Calculation of the deviation between two analog sensors whose values are already available as structured adapter signals.
- **Setpoint-Actual Value Comparison:** Subtraction of an actual value from a setpoint to determine the control deviation in control loops.
- **Zero Point Compensation (Offset Calculation):** Subtraction of a static or dynamic offset value (via `IN2`) from a raw signal (via `IN1`).
-

Comparison with Similar Building Blocks

Compared to a standard subtraction block (such as the classic `SUB` block from the IEC 61131-3 library), the `AUI_SUB_2` does not require explicit wiring of separate event and data ports (e.g., `REQ`, `IN1`, and `IN2`). All the logic for value transfer and updates is encapsulated in the `AUI` adapter. This makes the `AUI_SUB_2` easier to maintain and more robust against wiring errors in complex system architectures.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AUI_SUB_2` is a highly efficient, clear, and modern function block for performing subtractions. Through the consistent use of adapters, it integrates seamlessly into service-oriented and modularized control concepts and contributes to a clean software design in the 4diac IDE.

AUI_SUB_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_SUB_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUI_SUB_2_UNGATED` is used to perform arithmetic subtraction within an IEC 61499 application. It is a generic function block (FB) specifically designed for interaction with adapter interfaces. It allows subtraction operations to be implemented modularly and in a structured manner via standardized adapter connections, instead of using discrete individual wires for data and events.

Interface Structure

Event Inputs

This function block does not have direct event inputs. Event control is handled internally via the connected adapters.

Event Outputs

This function block does not have direct event outputs. Event forwarding is encapsulated via the output adapter.

Data Inputs

There are no direct data inputs. Data is transferred via the input adapters.

Data Outputs

There are no direct data outputs. The result is provided via the output adapter.

Adapters

Sockets (Inputs)

- **IN1** (Type: `adapter::types::unidirectional::AUI`):

First input adapter for subtraction. This represents the minuend (value from which the subtraction is made).

- **IN2** (Type: `adapter::types::unidirectional::AUI`):

Second input adapter for subtraction. This represents the subtrahend (value being subtracted).

Plugs (Inputs / Outputs)

- **OUT** (Type: `adapter::types::unidirectional::AUI`):

Output adapter that provides the result of the subtraction (the difference) for further use.
–

Functionality

The function block performs the basic mathematical operation of subtraction on the values received via the adapters:

$$\mathrm{OUT} = \mathrm{IN1} - \mathrm{IN2} \tag{2.93}$$

As soon as a change in value is signaled at the input adapters `IN1` or `IN2` (triggered by the event-driven nature of the underlying `AUI` adapter), the function block calculates the difference and outputs the result, along with a corresponding update event, via the output adapter `OUT`.

Technical Features

- **Generic Type:** The function block is based on the generic class `GEN_AUI_SUB`. This allows for flexible handling of different data types, provided they are supported by the underlying adapter type `AUI` (Analog User Interface / Unidirectional).
- **Encapsulation:** By using unidirectional adapters, signal flows and their associated trigger events are neatly bundled. This significantly simplifies application design in the 4diac IDE and reduces the number of visible connection lines.

–

State Overview

The function block itself does not manage a complex internal state (stateless in the sense of a state machine). Its execution is purely reactive:

1. **Waiting:** The function block waits for an update event at `IN1` or `IN2`.

Encapsulation: 2. **Calculation:** After an event occurs, the data values are read and the subtraction is performed.

1. **Output:** The new difference value is applied to `OUT`, and the adapter's output event is triggered.

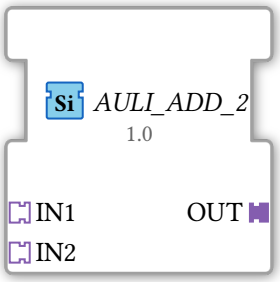
Application Scenarios

- **Differential Pressure/Differential Temperature Measurement:** Calculation of the deviation between two analog sensors whose values are already available as structured adapter signals.
- **Setpoint-Actual Value Comparison:** Subtraction of an actual value from a setpoint to determine the control deviation in control loops.
- **Zero Point Compensation (Offset Calculation):** Subtraction of a static or dynamic offset value (via `IN2`) from a raw signal (via `IN1`).
-

Comparison with Similar Building Blocks

Compared to a standard subtraction block (such as the classic `SUB` block from the IEC 61131-3 library), the `AUI_SUB_2_UNGATED` does not require explicit wiring of separate event and data ports (e.g., `REQ`, `IN1`, and `IN2`). All the logic for value transfer and updates is encapsulated in the `AUI` adapter. This makes the `AUI_SUB_2_UNGATED` easier to maintain and more robust against wiring errors in complex system architectures.

Change Detection



This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AUI_SUB_2_UNGATED` is a highly efficient, clear, and modern function block for performing subtractions. Through the consistent use of adapters, it integrates seamlessly into service-oriented and modularized control concepts and contributes to a clean software design in the 4diac IDE.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AULI_ADD_2` is a generic arithmetic block for the IEC 61499 environment (4diac-ide). It performs the mathematical addition of two input values transmitted via standardized, unidirectional adapters. The calculated result is passed to a corresponding output adapter.

The block does not have any classic, discrete event or data inputs at the top level. All communication and value transmissions are handled via adapters.

Interface Structure

Event Inputs

No direct event inputs are available. (Event control is encapsulated within the adapters).

Event Outputs

No direct event outputs are available. (Event control is encapsulated within the adapters).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AULI`):

The first addend for the addition operation.

- **IN2** (Type: `adapter::types::unidirectional::AULI`):

The second addend for the addition operation.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AULI`):

The result of the addition ($OUT = IN1 + IN2$).

Functionality

The function block `AULI_ADD_2` performs a classic addition operation. As soon as values change at the input adapters `IN1` or `IN2`, or a corresponding update event is triggered via the adapters, the function block calculates the sum of the transmitted values:

$$Result = Value(IN1) + Value(IN2) \tag{2.94}$$

This result, along with the associated update event, is then forwarded to subsequent function blocks via the output plug `OUT`.

- **Generic Nature:** The function block is declared as qzmsdocs0000010qz via the attribute `GenericClassName`. This allows for flexible typing depending on the specific implementation of the `AULI` adapter data used.
- **Adapter Encapsulation:** Using adapters of type `unidirectional::AULI` reduces the complexity of control circuit diagrams because data and associated trigger events are bundled in a single connection.

Since this function block is a purely functional/mathematical coupler, it typically does not have a complex internal state machine (ECC). Its execution is purely data- or event-driven based on the incoming adapter signals:

1. **Idle State:** The function block waits for signal updates at `IN1` or `IN2`.
2. **Evaluate:** When an event is received at one of the sockets, the data values are added.
3. **Output (Propagate):** The added value is output via the plug `OUT`, triggering the corresponding event.

- **Measurement Aggregation:** Addition of two analog process values (e.g., two parallel flow sensors to determine the total flow rate).
- **Setpoint Offset:** Applying a correction value or offset (via `IN2`) to a primary setpoint (via `IN1`).
- **Signal Bundling:** Structured mathematical signal processing in complex plant control systems using standardized adapter interfaces to reduce wiring effort.

2.4 · Comparison with Similar Components

Compared to a standard add-in component (such as the IEC 61131-3 compliant `ADD` component), which uses discrete pins for `REQ`, `CNF`, `IN1`, `IN2`, and `OUT`, the `AULI_ADD_2` eliminates the need for explicit wiring of control flows (events) and data lines. This significantly improves clarity in the 4diac development environment, as only a single adapter line needs to be drawn per signal source.

The `AULI_ADD_2` is a highly efficient, modular auxiliary component for analog signal processing. Through the consistent use of unidirectional adapters, it facilitates the design of cleanly structured and maintainable control applications according to the IEC 61499 standard.

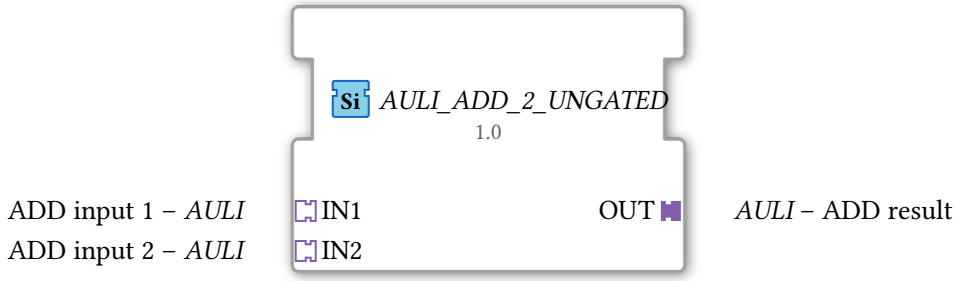
Technical Features

State Overview

Application Scenarios

Comparison with Similar Function Blocks

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AULI_ADD_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AULI_ADD_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Conclusion

AULI_ADD_3

(Image of the function block temporarily unavailable)

• – ◦ • – ◦ • – ◦ •

Introduction

The `AULI_ADD_3` function block is a generic arithmetic function block for IEC 61499 systems, specifically designed for adding three input values. Unlike traditional mathematical function blocks, this block uses `AULI` (unidirectional) adapter connections to transmit data and associated control signals in a bundled manner. This significantly reduces wiring complexity within the development environment (4diac IDE).

Interface Structure

Event Inputs

No direct event inputs are defined. Event-based control is handled implicitly via the connected adapters (`Sockets`).

Event Outputs

No direct event outputs are defined. Event forwarding is encapsulated via the output adapter (`Plug`).

Data Inputs

No direct data inputs are available. Data transfer occurs via the adapter interfaces.

Data Outputs

No direct data outputs are available. The calculation result is provided via the output adapter.

Adapters

Sockets (Input Adapters)

The sockets serve as receivers for the values to be added.

- **IN1** (Type: `adapter::types::unidirectional::AULI`): First addend of the arithmetic addition.
- **IN2** (Type: `adapter::types::unidirectional::AULI`): Second addend of the arithmetic addition.
- **IN3** (Type: `adapter::types::unidirectional::AULI`): Third addend of the arithmetic addition.

Plugs (Output Adapters)

The plug serves as a transmitter for the calculated result.

- **OUT** (Type: `adapter::types::unidirectional::AULI`): Output for the result of the addition ($IN1 + IN2 + IN3$).

Functionality

As soon as new data is signaled at the input adapters (`IN1`, `IN2`, `IN3`), the function block performs the mathematical addition.

The underlying formula is:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} \tag{2.96}$$

The calculated result is immediately passed to the output adapter `OUT` and is available to subsequent function blocks. Since these are unidirectional adapters, the data stream flows exclusively from the sockets to the plug.

–

Technical Features

- **Generic Function Block:** The function block is declared as a generic type in the 4diac IDE (`GenericClassName = 'GEN_AULI_ADD'`). This enables flexible processing of various data types (e.g., INT, REAL, LREAL), supported by the definition of the `AULI` adapter.
- **Adapter Encapsulation:** Using adapters instead of standard data and event channels makes the system design more modular and transparent.
- **Resource Efficiency:** Computations are performed directly based on adapter events, ensuring high-performance execution.

State Overview

The function block operates as a stateless (or purely event-driven) arithmetic block:

1. **Ready (Idle):** The block waits for value changes or trigger signals at the input adapters `IN1`, `IN2`, or `IN3`.

Resource Efficiency: Computations are performed directly based on adapter events, ensuring high performance.

The function block operates as a stateless (or purely event-driven) arithmetic block:

Ready (Idle): The block waits for value changes or trigger signals at the input adapters `IN1`, `IN2`, or `IN3`. 2. **Evaluation:** After a signal arrives, the values are read and summed.

1. **Output:** The sum is passed to `OUT`, and the corresponding event in the adapter is triggered. The function block immediately returns to the *Ready* state.

Application Scenarios

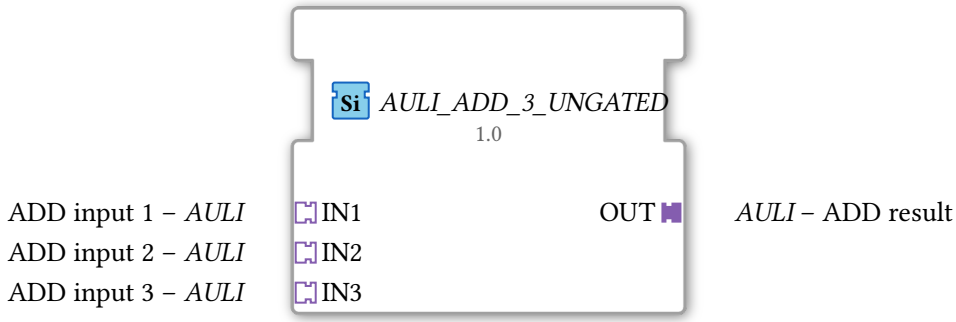
- **Measurement Summing:** Summarizing three analog measurements (e.g., three partial currents to determine the total current) in process automation.
- **Setpoint Generation:** Adding base setpoints with two different correction or offset values.
- **Structured Data Processing:** Used in complex IEC 61499 control applications where consistent use of adapters is required to improve clarity.

Comparison with Similar Components

- **Standard Adder (IEC 61131-3):** The classic `ADD` component requires explicit `REQ` and `CNF` event lines, as well as individual data lines. `AULI_ADD_3` replaces these with just four adapter connections, which simplifies the visual programming interface.
- **Cascaded Adders (e.g., 2x `AULI_ADD_2`):** To add three values with classic two-way adders, two components would have to be connected in series. `AULI_ADD_3` eliminates the need for an entire function block and the associated intermediate wiring.

•

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AULI_ADD_3` is a practical and modern function block for structured programming in 4diac. Thanks to the consistent use of the unidirectional `AULI` adapter, it is ideally suited for clean, clear, and maintainable architectures in distributed control systems according to the IEC 61499 standard.

AULI_ADD_3_UNGATED

i UNGATED variant: This block is the ungated version of `AULI_ADD_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. AULI_ADD_4

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AULI_ADD_4` is a generic function block (FB) designed for the mathematical addition of four values. The unique feature of this block lies in its use of adapters of type `AULI` (unidirectional). By encapsulating data and event transmission within adapters, the block enables clear and modular wiring within IEC 61499 applications in the 4diac IDE.

Interface Structure

Event Inputs

There are no direct event inputs. Event control is implicit via the connected adapter sockets.

Event Outputs

There are no direct event outputs. Event control is implicit via the connected adapter plug.

Data Inputs

There are no direct data inputs. Data is transferred via the input adapters.

Data Outputs

There are no direct data outputs. Data is output via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AULI`): First addend for the addition operation.
- **IN2** (Type: `adapter::types::unidirectional::AULI`): Second addend for the addition operation.
- **IN3** (Type: `adapter::types::unidirectional::AULI`): Third addend for the addition operation.
- **IN4** (Type: `adapter::types::unidirectional::AULI`): Fourth addend for the addition operation.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AULI`): Contains the result of the addition (`IN1 + IN2 + IN3 + IN4`) and the corresponding output event.

Functionality

As soon as a new value event is signaled at one or more of the input adapters (`IN1` to `IN4`), the function block reads the current values from all four adapters. These values are added mathematically:

$$\text{Result} = \text{Value}_{IN1} + \text{Value}_{IN2} + \text{Value}_{IN3} + \text{Value}_{IN4} \tag{2.98}$$

The calculated result is passed to the output adapter `OUT`, and simultaneously, the corresponding event is triggered at the output plug to inform subsequent function blocks about the value update.

Technical Features

- **Generic Function Block:** The function block is based on the generic class `GEN_AULI_ADD`. This means that it can flexibly respond to different data types within the `AULI` adapter structure.
- **Unidirectional Adapters:** Unidirectional adapters (`unidirectional::AULI`) are used. This simplifies data flow, as information and events flow exclusively in one direction (from inputs to output).
- **Reduced wiring effort:** By using adapters, event and data lines do not need to be run separately. A single adapter channel bundles all relevant signals.

State overview

The function block behaves in an event-driven and stateless manner (i.e., it has no internal memory for historical values):

1. **Wait state:** The function block waits for an event at one of the inputs (`IN1` to `IN4`).
2. **Calculation:** When an event arrives, the data from all four inputs are summed.
3. **Output:** The calculated value is applied to `OUT`, and the output event is triggered. The function block immediately returns to the wait state.

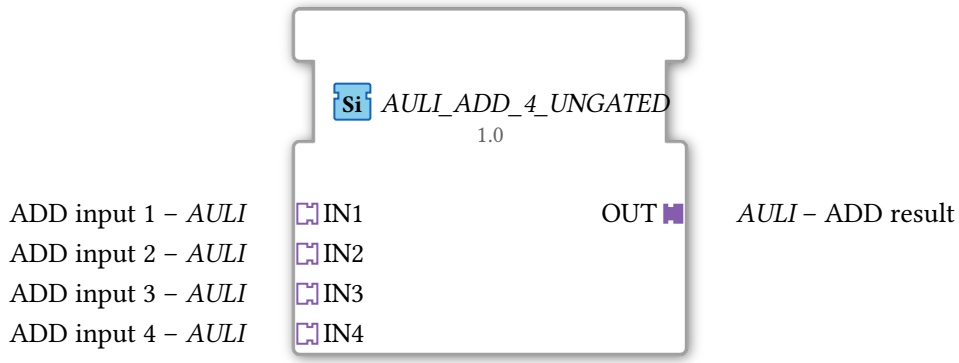
Application Scenarios

- **Measurement Summing:** Summarizing four individual sensor values (e.g., energy measurements from four consumers, flow rates from four pipes) into a single total value.
- **Average Preparation:** Pre-summing four data points before subsequent division to calculate the average.
- **Modular Control Architectures:** Use in complex systems where signals are already standardized as `AULI` adapters.

Comparison with Similar Function Blocks

- **Standard ADD Function Blocks (e.g., `ADD` from IEC 61131-3):** These use direct data and event ports (such as `REQ`, `CNF`, `IN1`, `IN2`). `AULI_ADD_4`, on the other hand, completely encapsulates these interfaces in adapters, resulting in a cleaner control flow diagram.
- **AULI_ADD_2:** A similar function block, but with only two inputs. `AULI_ADD_4` eliminates the need to cascade multiple individual addition function blocks when adding four values.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AULI_ADD_4` function block is a highly efficient, clear, and modern block for arithmetic operations in IEC 61499. Through the consistent use of the `AULI` adapter structure, it significantly reduces the number of connection lines in the 4diac IDE application editor and is ideally suited for modular automation solutions.

AULI_ADD_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AULI_ADD_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AULI_ADD_4_UNGATED` function block is a highly efficient, clear, and modern block for arithmetic operations in IEC 61499. Through the consistent use of the `AULI` adapter structure, it significantly reduces the number of connection lines in the 4diac IDE application editor and is ideally suited for modular automation solutions.

AULI_DIV_2

No image available

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AULI_DIV_2` is a generic function block (Generic FB) designed to perform arithmetic division (DIV). It is based on the IEC 61499 standard and utilizes the concept of adapters to efficiently transfer data and the associated control logic. The block is defined in the namespace `adapter::iec61131::arithmetic` and uses the generic class `GEN_AULI_DIV`.

Interface Structure

Event Inputs

This function block does not have direct, dedicated event inputs. Signal flow control and event processing are handled entirely via the connected adapters.

Event Outputs

This function block does not have direct, dedicated event outputs. Event forwarding is handled via the output adapter.

Data Inputs

There are no direct data inputs. The values for the calculation are provided via the input adapters.

Data Outputs

There are no direct data outputs. The calculation result is provided via the output adapter.

Adapters

All communication for this function block is implemented via adapters of type `AULI` (unidirectional):

- **IN1 (Socket)**:
- **Type**: `adapter::types::unidirectional::AULI`
- **Description**: First input of the division (dividend/counter).

- **IN2 (Socket)**:

Type: `adapter::types::unidirectional::AULI`
Description: Second input for division (divisor/denominator).
OUT (Plug):
Type: `adapter::types::unidirectional::AULI`
Description: Output that provides the result of the division (quotient).

Functionality

This module performs a mathematical division of the input values provided via the adapters. The formula is:

$$\mathrm{OUT} = \frac{\mathrm{IN1}}{\mathrm{IN2}} \tag{2.100}$$

Since this is a generic function block (`GEN_AULI_DIV`), it can adapt to various numeric data types at runtime or during instantiation in the 4diac IDE, provided these are supported by type `AULI`. The calculation is typically triggered by an update event on one of the input adapters (`IN1` or `IN2`). The result is then provided at the output adapter `OUT` along with a corresponding output event.

- **Generic Nature**: The attribute `GenericClassName` with the value `'GEN_AULI_DIV'` makes the function block flexible and not rigidly tied to a single data type (such as only `REAL` or `INT`).
- **Encapsulation via Adapters**: Since no traditional event and data ports are used, the visual design in the function block diagram (FBD) remains very clear. The logical relationship between data and triggers is encapsulated in the `AULI` adapter.
- **Unidirectional Adapters**: The use of `unidirectional::AULI` indicates that the information flow is strictly unidirectional (from the sockets to the function block and from the function block to the plug).

Since this function block is a basic arithmetic function block, it typically exhibits simple, stateless behavior (i.e., it behaves like a classic Execution Control Chart (ECC) with a default state that reacts to input events):

Technical Features

1. **Waiting for Event**: The function block waits for an update event at `IN1` or `IN2`.
2. **Calculation**: Upon receiving an event, the division is performed.
3. **Result Transfer**: The calculated value is assigned to `OUT`, and the corresponding output event is triggered at the plug.
4. **Return**: The function block returns to the wait state.

State Overview

Note on Division by Zero: Depending on the implementation of the runtime environment for the generic type `GEN_AULI_DIV`, mechanisms to prevent division by zero (e.g., outputting `NaN`, infinity, or intercepting via the adapter status) should be considered.

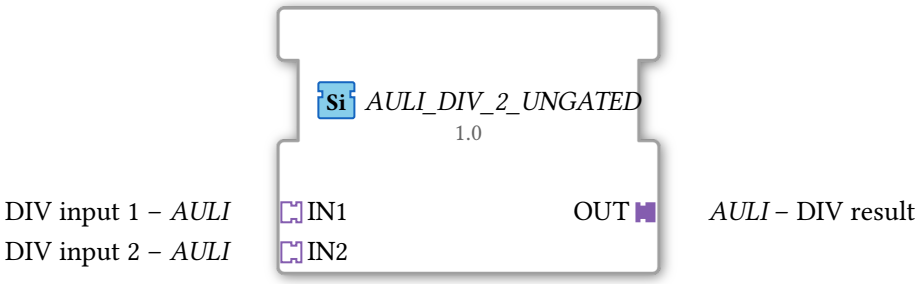
Application Scenarios

- **Sensor Value Scaling**: Division of raw analog values by a scaling factor for conversion to physical units.
- **Ratio Measurement**: Calculation of ratios in process automation (e.g., flow rate ratio of two media).
- **Averaging**: Use in computational networks where total values need to be divided by a number.
- **Structured Architectures**: Use in systems that consistently rely on adapter-based communication to minimize the number of visible connection lines in the system model.

Comparison with Similar Function Blocks

- **Standard `DIV` component**: A classic IEC 61131-3 / IEC 61499 `DIV` component uses direct data inputs (`IN1`, `IN2`) and event ports (`REQ`, `CNF`). The `AULI_DIV_2`, on the other hand, bundles these signals in adapters, which significantly simplifies wiring for complex signal structures.
- **Standard `DIV` component**: A classic IEC 61131-3 / IEC 61499 `DIV` component uses direct data inputs (`IN1`, `IN2`) and event ports (`REQ`, `CNF`). The `AULI_DIV_2`, however, bundles these signals in adapters, which significantly simplifies wiring for complex signal structures.
- – **Other AULI Arithmetic Blocks** (e.g., `AULI_ADD`, `AULI_SUB`): These use the same interface philosophy with sockets and plugs, but perform different mathematical operations.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AULI_DIV_2` is a modern, modular function block for arithmetic division in Eclipse 4diac. Through the consistent use of unidirectional adapters, it promotes clean and well-organized software design in distributed control systems according to IEC 61499 by elegantly bundling data and control events.

AULI_DIV_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AULI_DIV_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AULI_DIV_2_UNGATED` is a generic function block (Generic FB) designed to perform arithmetic division (DIV). It is based on the IEC 61499 standard and utilizes the concept of adapters to efficiently transfer data and the associated control logic. The block is defined in the namespace `adapter::iec61131::arithmetic` and uses the generic class `GEN_AULI_DIV`.

Interface Structure

Event Inputs

This function block does not have direct, dedicated event inputs. Signal flow control and event processing are handled entirely via the connected adapters.

Event Outputs

This function block does not have direct, dedicated event outputs. Event forwarding is handled via the output adapter.

Data Inputs

There are no direct data inputs. The values for the calculation are provided via the input adapters.

Data Outputs

There are no direct data outputs. The calculation result is provided via the output adapter.

Adapters

All communication for this function block is implemented via adapters of type `AULI` (unidirectional):

- **IN1 (Socket)**:
- **Type**: `adapter::types::unidirectional::AULI`

- **Description**: First input of the division (dividend/counter).
- **IN2 (Socket)**:

Type: `adapter::types::unidirectional::AULI`
Description: Second input for division (divisor/denominator).
OUT (Plug):
Type: `adapter::types::unidirectional::AULI`
Description: Output that provides the result of the division (quotient).

Functionality

This module performs a mathematical division of the input values provided via the adapters. The formula is:

$$\text{OUT} = \frac{\text{IN1}}{\text{IN2}} \tag{2.101}$$

Since this is a generic function block (`GEN_AULI_DIV`), it can adapt to various numeric data types at runtime or during instantiation in the 4diac IDE, provided these are supported by type `AULI`. The calculation is typically triggered by an update event on one of the input adapters (`IN1` or `IN2`). The result is then provided at the output adapter `OUT` along with a corresponding output event.

- **Generic Nature**: The attribute `GenericClassName` with the value `'GEN_AULI_DIV'` makes the function block flexible and not rigidly tied to a single data type (such as only `REAL` or `INT`).
- **Encapsulation via Adapters**: Since no traditional event and data ports are used, the visual design in the function block diagram (FBD) remains very clear. The logical relationship between data and triggers is encapsulated in the `AULI` adapter.
- **Unidirectional Adapters**: The use of `unidirectional::AULI` indicates that the information flow is strictly unidirectional (from the sockets to the function block and from the function block to the plug).

Since this function block is a basic arithmetic function block, it typically exhibits simple, stateless behavior (i.e., it behaves like a classic Execution Control Chart (ECC) with a default state that reacts to input events):

Technical Features

1. **Waiting for Event**: The function block waits for an update event at `IN1` or `IN2`.
2. **Calculation**: Upon receiving an event, the division is performed.
3. **Result Transfer**: The calculated value is assigned to `OUT`, and the corresponding output event is triggered at the plug.
4. **Return**: The function block returns to the wait state.

State Overview

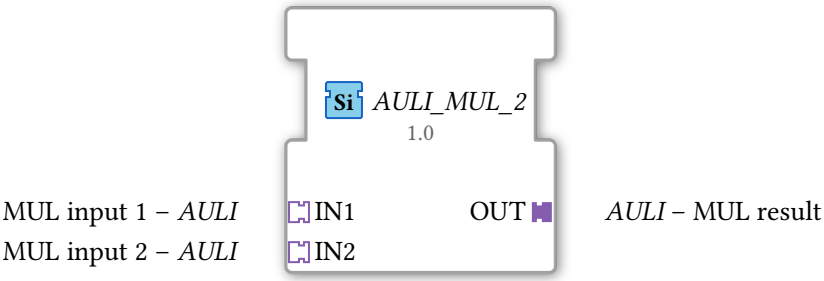
Note on Division by Zero: Depending on the implementation of the runtime environment for the generic type `GEN_AULI_DIV`, mechanisms to prevent division by zero (e.g., outputting `NaN`, infinity, or intercepting via the adapter status) should be considered.

Application Scenarios

- **Sensor Value Scaling**: Division of raw analog values by a scaling factor for conversion to physical units.
- **Ratio Measurement**: Calculation of ratios in process automation (e.g., flow rate ratio of two media).
- **Averaging**: Use in computational networks where total values need to be divided by a number.
- **Structured Architectures**: Use in systems that consistently rely on adapter-based communication to minimize the number of visible connection lines in the system model.

Comparison with Similar Function Blocks

- **Standard `DIV` component**: A classic IEC 61131-3 / IEC 61499 `DIV` component uses direct data inputs (`IN1`, `IN2`) and event ports (`REQ`, `CNF`). The `AULI_DIV_2_UNGATED`, on the other hand, bundles these signals in adapters, which significantly simplifies wiring for complex signal structures.
- **Standard `DIV` component**: A classic IEC 61131-3 / IEC 61499 `DIV` component uses direct data inputs (`IN1`, `IN2`) and event ports (`REQ`, `CNF`). The `AULI_DIV_2_UNGATED`, however, bundles these signals in adapters, which significantly simplifies wiring for complex signal structures.
- – **Other AULI Arithmetic Blocks** (e.g., `AULI_ADD`, `AULI_SUB`): These use the same interface philosophy with sockets and plugs, but perform different mathematical operations.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AULI_DIV_2_UNGATED` is a modern, modular function block for arithmetic division in Eclipse 4diac. Through the consistent use of unidirectional adapters, it promotes clean and well-organized software design in distributed control systems according to IEC 61499 by elegantly bundling data and control events.

AULI_MUL_2

No image available

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AULI_MUL_2` is used to perform an arithmetic multiplication of two values. It is a generic function block (`GEN_AULI_MUL`) whose interfaces are implemented entirely via adapters of type `AULI` (unidirectional). This allows for clean encapsulation of data and events and reduces the wiring effort within the 4diac IDE.

Interface Structure

Event Inputs

There are no direct event inputs. Event control is handled implicitly via the adapter interfaces.

Event Outputs

There are no direct event outputs. Event control is implicit via the adapter interfaces.

Data Inputs

There are no direct data inputs. Data is transferred via the input adapters.

Data Outputs

There are no direct data outputs. Data is output via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AULI`):
- First input value (multiplicand) for multiplication.
- **IN2** (Type: `adapter::types::unidirectional::AULI`):
- Second input value (multiplier) for multiplication.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AULI`):
- Result of the multiplication ($OUT = IN1 \times IN2$).

Functionality

As soon as new data is signaled at the input adapters `IN1` or `IN2`, the function block performs the multiplication of the two values:

$$OUT = IN1 \times IN2$$

The result and the corresponding update event are then output via the output adapter `OUT`. Since this is a generic function block, the exact data type depends on the definition of the `AULI` adapter used (e.g., REAL, INT, LREAL).

Technical Features

- **Generic Function Block:** The type is declared as `GEN_AULI_MUL`, which allows for flexible reusability for various numeric data types, provided they are supported by the adapter type.
- **Adapter Encapsulation:** By using unidirectional adapters (`AULI`), data and the associated trigger event are bundled in a single connection. This prevents "spaghetti code" and loose event-data pairs in the function plan.
- **Package Membership:** The function block is organized in the `adapter::iec61131::arithmetic` namespace.
-

State Overview

Since this is a purely computational function block (arithmetic function), it does not have an internal state machine (ECC) in the classical sense.

1. **Waiting:** The function block waits for an update event on the adapters `IN1` or `IN2`.
2. **Calculation:** Upon receiving an event, the values from `IN1` and `IN2` are read and multiplied.
3. **Output:** The result is created on `OUT`, and the output event of the adapter is triggered. The function block immediately returns to the *Waiting* state.

Application Scenarios

- **Signal Processing:** Scaling of sensor values where a measured value needs to be multiplied by a constant or dynamic factor.
- **Control Engineering:** Calculation of manipulated variables in control loops (e.g., the proportional component of a PID controller).
- **Structured Control Architectures:** Use in complex systems where adapters are used uniformly to maintain the readability of the overall system.

–

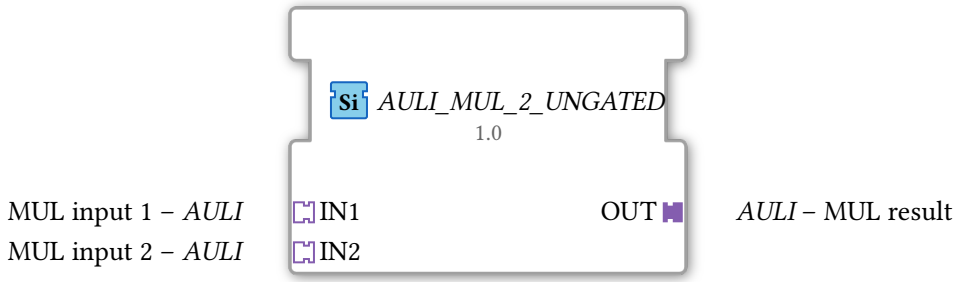
Comparison with Similar Function Blocks

Compared to a standard multiplication function block (such as the IEC 61199 `MUL` function block), the `AULI_MUL_2` offers the following advantages and disadvantages:

Feature	Standard `MUL` function block	`AULI_MUL_2`
Interfaces	Individual event and data pins	Bundled adapters (`AULI`)
Wiring Effort	High (separate event and data lines)	Minimal (only one adapter line per signal)
Flexibility	High (direct mapping of variables)	Requires the use of the `AULI` adapter type
Readability	Can become cluttered with many function blocks	Very clean and modular

---

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AULI_MUL_2 is a specialized and modern variant of a multiplication function block for IEC 61499. Due to the consistent use of adapters, it is ideally suited for demanding, modular applications where clarity and standardization are paramount.

AULI_MUL_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AULI_MUL_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. AULI_MUL_3

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AULI_MUL_3` is a generic function block (FB) designed for the arithmetic multiplication of three input values via unidirectional adapters. It is defined in the package `adapter::iec61131::arithmetic` and enables clean, adapter-based data processing within the 4diac environment.

Interface Structure

Event Inputs

This function block has no direct event inputs. Control and event processing are handled via the connected adapters.

Event Outputs

This function block has no direct event outputs. Events are forwarded via the output adapter.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AULI`): First input value (multiplicand 1) for multiplication.
- **IN2** (Type: `adapter::types::unidirectional::AULI`): Second input value (multiplicand 2) for multiplication.
- **IN3** (Type: `adapter::types::unidirectional::AULI`): Third input value (multiplicand 3) for multiplication.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AULI`): Output for the calculated product of the three input values.

Functionality

The AULI_MUL_3 function block performs a classic multiplication of the values provided by the three input adapters (IN1, IN2, and IN3). The calculation follows the mathematical formula:

$$\mathrm{OUT} = \mathrm{IN1} \times \mathrm{IN2} \times \mathrm{IN3} \tag{2.102}$$

Since this is a generic function block (GEN_AULI_MUL) based on unidirectional adapters (AULI), the values and their corresponding update events are transmitted within the adapter connections. As soon as new data is received and signaled at the inputs, the calculation is performed, and the result is output via the output adapter OUT.

Technical Features

- **Generic Type:** The function block is declared as a generic type (GenericClassName = "GEN_AULI_MUL"). This allows for flexible handling depending on the underlying data type of the adapters used.
- **Adapter Encapsulation:** By using adapters of type AULI, data and associated control flows (events) are bundled into a single connection, significantly reducing wiring complexity in the function block diagram.

Unidirectionality: The interfaces utilize a unidirectional profile, ensuring a clear flow of information from the inputs to the output.

State Overview

The function block operates in an event-driven manner and has no internal, persistent state (stateless/ combinatorial).

1. **Waiting for Update:** The function block waits for an update event at the input sockets (IN1, IN2, or IN3).
2. **Calculation:** Upon receiving an event, the current values are read and multiplied.

- ... 3. **Output:** The result is passed to the OUT plug and the corresponding output event is triggered.

Application Scenarios

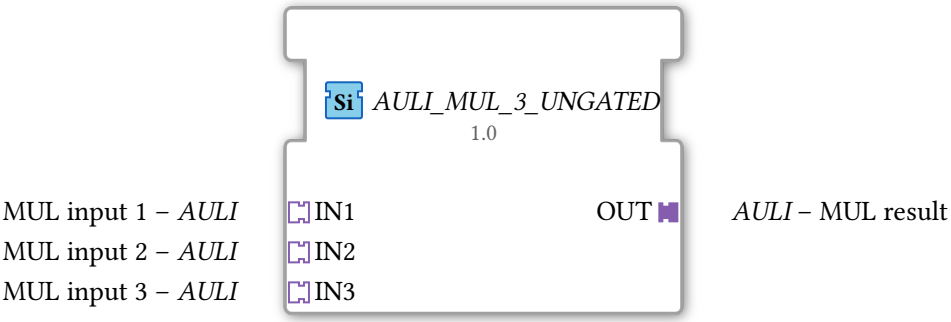
- **Volume Calculation:** Calculation of three-dimensional quantities (e.g., length × width × height) in process automation.
- **Scaling and Weighting:** Application of two consecutive scaling factors to a measured value (e.g., sensor value × calibration factor × unit conversion).
- **Power Calculation:** Three-phase or multi-stage calculations where three physical quantities must be combined multiplicatively.

Comparison with Similar Blocks

- **Standard MUL (IEC 61131-3):** The classic MUL block uses direct data and event pins. AULI_MUL_3 differs in that it has exactly three inputs, which are completely encapsulated by adapters (AULI), resulting in a more streamlined architecture.
- **AULI_MUL_2 (if present):** A hypothetical component with only two inputs. AULI_MUL_3 eliminates the need for an entire cascading component when multiplying three values.

- **AULI_MUL_3_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Change Detection



The result is only written to the output plug (OUT) and its adapter event only sent if the newly computed value differs from the value currently held on OUT. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

AULI_MUL_3 is an efficient auxiliary component for applications requiring a high degree of modularity. Through the consistent use of unidirectional adapters, it helps reduce "signal spaghetti" in complex 4diac applications and simplifies the multiplication of three variables.

AULI_MUL_3_UNGATED

i UNGATED variant: This block is the ungated version of AULI_MUL_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

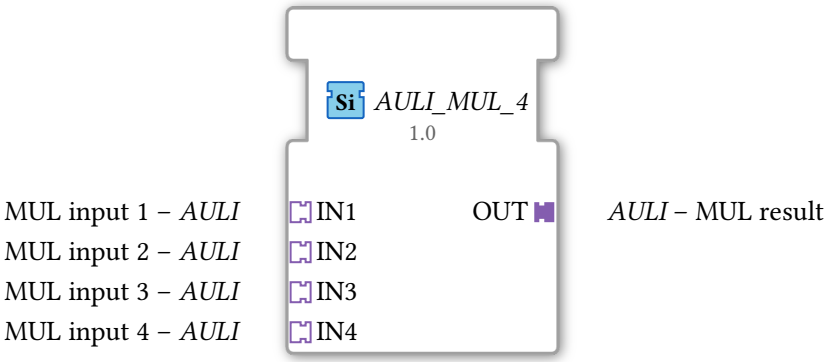
Comparison with Similar Blocks

- **Standard MUL (IEC 61131-3):** The classic `MUL` block uses direct data and event pins. `AULI_MUL_3_UNGATED` differs in that it has exactly three inputs, which are completely encapsulated by adapters (`AULI`), resulting in a more streamlined architecture.
- **AULI_MUL_2 (if present):** A hypothetical component with only two inputs. `AULI_MUL_3_UNGATED` eliminates the need for an entire cascading component when multiplying three values.

- `AULI_MUL_3`: The gated variant – updates the output only on an actual value change.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

`AULI_MUL_3_UNGATED` is an efficient auxiliary component for applications requiring a high degree of modularity. Through the consistent use of unidirectional adapters, it helps reduce “signal spaghetti” in complex 4diac applications and simplifies the multiplication of three variables.

AULI_MUL_4

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AULI_MUL_4` is a generic arithmetic block for the 4diac-ide. It is used to multiply four input values. The block uses an adapter-based interface concept to minimize the number of individual event and data connections in the application diagram and to ensure clean encapsulation.

Interface Structure

Event Inputs

There are no direct event inputs. Event control is handled entirely via the adapters.

Event Outputs

There are no direct event outputs. Event control is handled entirely via the adapters.

Data Inputs

There are no direct data inputs. Data transmission is encapsulated via the input adapters.

Data Outputs

There are no direct data outputs. Data transmission is encapsulated via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AULI`): First multiplicand.
- **IN2** (Type: `adapter::types::unidirectional::AULI`): Second multiplicand.
- **IN3** (Type: `adapter::types::unidirectional::AULI`): Third multiplicand.
- **IN4** (Type: `adapter::types::unidirectional::AULI`): Fourth multiplicand.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AULI`): Result of the multiplication.

Functionality

As soon as new values are signaled at the input adapters (`IN1` to `IN4`), the module performs the multiplication of the four values.

The mathematical formula is:

$$\text{OUT} = \text{IN1} \times \text{IN2} \times \text{IN3} \times \text{IN4} \tag{2.104}$$

Technical Features

The result and the associated processing event are then output via the output adapter `OUT`. Since these are unidirectional adapters of type `AULI`, data and trigger signals flow directly from the sockets to the plug.

State Overview

- **Generic Block:** The block is declared as a generic type (`GenericClassName = 'GEN_AULI_MUL'`). This allows for flexible adaptation to different numeric data types supported by the underlying `AULI` adapter type.
- **Adapter Encapsulation:** Using adapters instead of standard event/data pins greatly simplifies the system design (avoiding "spaghetti wiring" in the control flow).

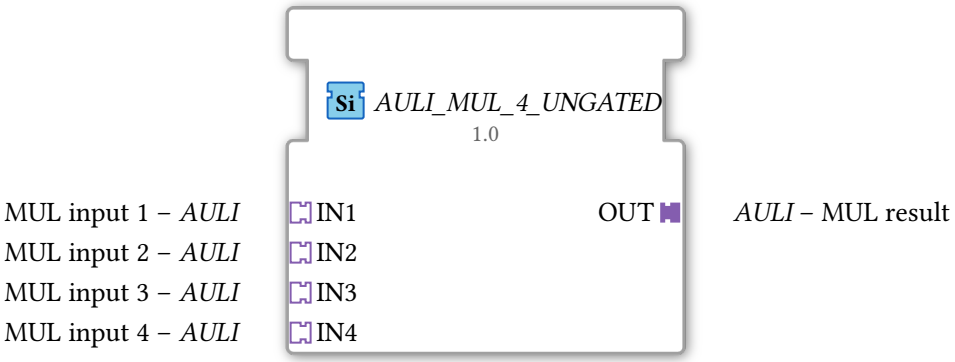
Application Scenarios

The function block is essentially stateless. Computation is purely reactive, based on the values and events present at the input adapters. No internal historical states are stored.

Comparison with Similar Function Blocks

- **Sensor Value Scaling:** Calculation of corrected measured values where a raw value must be multiplied by several calibration, correction, or conversion factors.
- **Volume and Mass Calculation:** Physical calculations in process engineering that require the product of several variables (e.g., $V = l \times b \times h$ taking into account an additional density factor).
- **Structured Signal Processing:** Use in more complex control applications where data is distributed modularly via adapter structures.
- **Structured Signal Processing:** Use in more complex control applications where data is distributed modularly via adapter structures. ## Comparison with Similar Components
- **Standard MUL Component (IEC 61131-3 / IEC 61499):** Standard multipliers typically have dedicated pins, such as `REQ`, `CNF`, as well as standard data inputs (e.g., `IN1`, `IN2`). `AULI_MUL_4` significantly simplifies interface design through the use of adapters.
- **Cascaded Dual Multipliers:** To multiply four values using standard components, three conventional `MUL` components would need to be cascaded. `AULI_MUL_4` consolidates this logic into a single function block, saving resources and improving clarity.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AULI_MUL_4` is a practical and modern function block for multiplying four numeric values using the IEC 61499 adapter concept. It is ideally suited for cleanly structured, readable, and maintainable control applications in the 4diac IDE.

AULI_MUL_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AULI_MUL_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

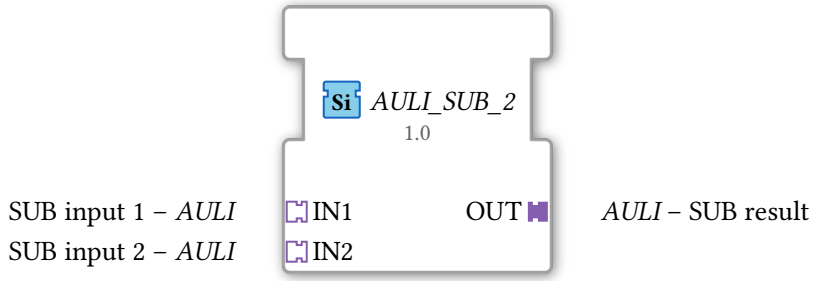
- **Structured Signal Processing:** Use in more complex control applications where data is distributed modularly via adapter structures. ## Comparison with Similar Components
- **Standard MUL Component (IEC 61131-3 / IEC 61499):** Standard multipliers typically have dedicated pins, such as `REQ`, `CNF`, as well as standard data inputs (e.g., `IN1`, `IN2`). `AULI_MUL_4_UNGATED` significantly simplifies interface design through the use of adapters.
- **Cascaded Dual Multipliers:** To multiply four values using standard components, three conventional `MUL` components would need to be cascaded. `AULI_MUL_4_UNGATED` consolidates this logic into a single function block, saving resources and improving clarity.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AULI_MUL_4_UNGATED` is a practical and modern function block for multiplying four numeric values using the IEC 61499 adapter concept. It is ideally suited for cleanly structured, readable, and maintainable control applications in the 4diac IDE.

AULI_SUB_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AULI_SUB_2` is a generic function block (Generic FB) designed to perform arithmetic subtraction (`OUT = IN1 - IN2`). Instead of traditional data and event pins, this block uses adapter interfaces of type `unidirectional::AULI`. This enables structured and modularized signal transmission in IEC 61499 applications.

Interface Structure

Event Inputs

No direct event inputs are available. Event control is handled entirely via the adapters.

Event Outputs

No direct event outputs are available. Event control is handled entirely via the adapters.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AULI`):
- Description: The first input (minuend) for subtraction.
- **IN2** (Type: `adapter::types::unidirectional::AULI`):
- Description: The second input (subtrahend) for subtraction.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AULI`):
- Description: The output (difference) of arithmetic subtraction.

Functionality

As soon as values and their corresponding events arrive via the input adapters `IN1` and `IN2`, the function block executes the mathematical operation `OUT = IN1 - IN2`.

Since this is a generic function block (`GEN_AULI_SUB`), the specific data type processing can be determined by the data types defined in the adapter (e.g., integers or floating-point numbers). The result, along with the corresponding trigger event, is forwarded via the output adapter `OUT`.

` ... —

Technical Features

- **Generic Block:** The attribute `GenericClassName` with the value `'GEN_AULI_SUB'` allows the block to be used flexibly for various data types, provided the adapters used support this.
- **Unidirectional Adapters:** Using the type `AULI` ensures a clear separation of signal flow directions (unidirectional) and drastically reduces the wiring effort in the 4diac editor.

–

State Overview

The block behaves purely combinatorially or event-driven:

1. **Waiting for Input:** The block remains in idle state until an event is signaled at one of the input adapters (`IN1` or `IN2`).

Unidirectional Adapters: 2. **Calculation:** Subtraction is performed upon signal change/event.

1. **Output:** The result is immediately transferred to the plug `OUT`, triggering the output event.

Application Scenarios

- **Target-Actual Value Comparison:** Calculation of control deviations in process engineering (e.g., `Regeldifferenz = Sollwert - Istwert`).
- **Offset Compensation:** Subtraction of zero-point errors or offsets from analog sensor values.
- **Cascaded Calculations:** Mathematical calculations in modular plant control systems where measured values are transported in a structured manner via adapters.

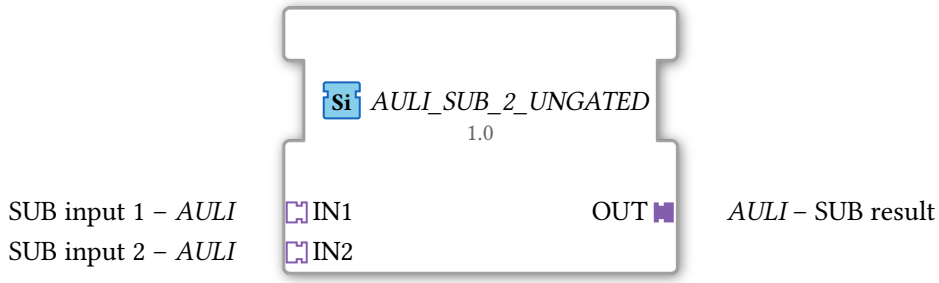
Comparison with Similar Function Blocks

Compared to a standard subtraction function block (e.g., `SUB` from the IEC 61131-3 standard library), `AULI_SUB_2` offers the following advantages:

- **Reduced Complexity:** Instead of separate lines for event (REQ/CNF) and data (IN1, IN2, OUT), the `AULI` adapters bundle all relevant information into a single connection.
- **Modularity:** The design is ideally suited for service-oriented architectures in distributed systems.

–

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AULI_SUB_2` is a robust and reusable function block for subtraction. Through the consistent use of adapters, it promotes a clean, well-organized, and maintainable application design in the 4diac IDE.

AULI_SUB_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AULI_SUB_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

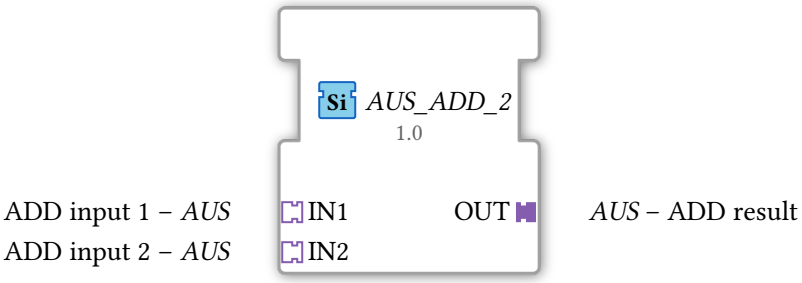
Comparison with Similar Function Blocks

Compared to a standard subtraction function block (e.g., `SUB` from the IEC 61131-3 standard library), `AULI_SUB_2_UNGATED` offers the following advantages:

- **Reduced Complexity:** Instead of separate lines for event (REQ/CNF) and data (IN1, IN2, OUT), the `AULI` adapters bundle all relevant information into a single connection.
- **Modularity:** The design is ideally suited for service-oriented architectures in distributed systems.

–



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AULI_SUB_2_UNGATED` is a robust and reusable function block for subtraction. Through the consistent use of adapters, it promotes a clean, well-organized, and maintainable application design in the 4diac IDE.

AUS_ADD_2

(Graphical representation of the function block not available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUS_ADD_2` is a generic function block (Generic FB) for performing arithmetic addition. It is used to add two input signals and output the result. The special feature of this block lies in the use of standardized, unidirectional adapters (`AUS`), which greatly simplifies and encapsulates the signal and data wiring within Eclipse 4diac.

Interface Structure

Event Inputs

This function block does not have direct event inputs. Event control is handled via the adapters.

Event Outputs

This function block does not have direct event outputs. Event control is handled via the adapters.

Data Inputs

This function block does not have direct data inputs.

Data Outputs

This function block does not have direct data outputs.

Adapters

Sockets (Input Adapters / Jacks)

- **IN1** (Type: `adapter::types::unidirectional::AUS`): The first addend of the addition.
- **IN2** (Type: `adapter::types::unidirectional::AUS`): The second addend of the addition.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AUS`): The result of the addition (sum of `IN1` and `IN2`).

Functionality

The `AUS_ADD_2` module functions as an arithmetic adder based on adapters. As soon as a new event with a data value arrives at the input adapters `IN1` or `IN2`, the function block adds the two values:

$$OUT = IN1 + IN2 \tag{2.106}$$

The result, along with the corresponding trigger event, is output via the output adapter `OUT`. Since these are unidirectional adapters, the data and control flow is exclusively from the inputs to the output.

Technical Features

- **Generic Function Block:** The attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AUS_ADD'` defines the function block as a generic type. This allows for flexible adaptation to different data types defined by the adapter structures.
- **Encapsulation:** By using adapters instead of individual event and data pins, the system design becomes clearer and less prone to wiring errors.

State Overview

Since this component is essentially a mathematical operation, it does not have a complex internal state diagram (ECC). It reacts to incoming data at adapters `IN1` and `IN2`, calculates the sum, and forwards the result directly to `OUT`.

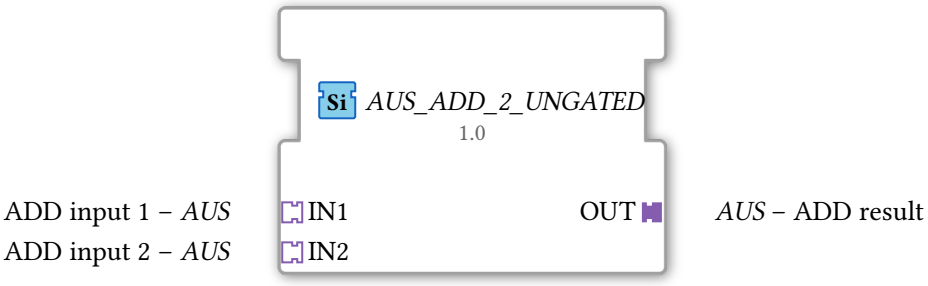
Application Scenarios

- **Measurement Processing:** Adding two sensor values or applying an offset to a measured value, which is supplied via an adapter.
- **Setpoint Calculation:** Combining base setpoints and correction values in process automation.
- – **Structured Programming:** Used in complex control systems where data and event lines are bundled in adapters to improve clarity.

Comparison with Similar Function Blocks

Compared to a standard addition function block (such as `ADD` from the IEC 61131-3 library), which has discrete data and event pins (such as `REQ`, `CNF`, `IN1`, `IN2`, `OUT`), `AUS_ADD_2` completely encapsulates these interfaces in adapters. This drastically reduces the number of visible connection lines in the 4diac editor and promotes object-oriented design.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

`AUS_ADD_2` is an efficient, generic auxiliary block for arithmetic addition in IEC 61499 applications. Its consistent use of unidirectional adapters makes it ideally suited for modern, modular software architectures in industrial automation.

AUS_ADD_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUS_ADD_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

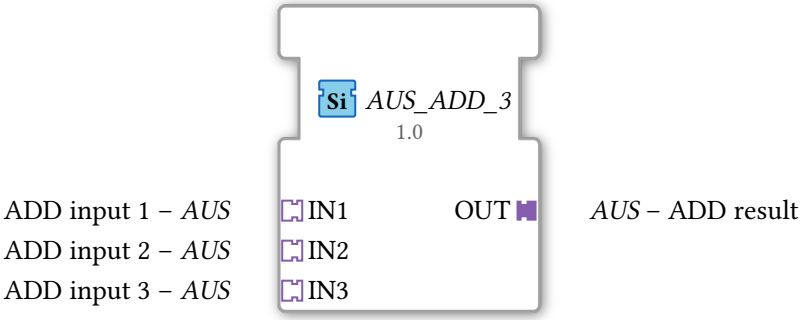
Compared to a standard addition function block (such as `ADD` from the IEC 61131-3 library), which has discrete data and event pins (such as `REQ`, `CNF`, `IN1`, `IN2`, `OUT`), `AUS_ADD_2_UNGATED` completely encapsulates these interfaces in adapters. This drastically reduces the number of visible connection lines in the 4diac editor and promotes object-oriented design.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

`AUS_ADD_2_UNGATED` is an efficient, generic auxiliary block for arithmetic addition in IEC 61499 applications. Its consistent use of unidirectional adapters makes it ideally suited for modern, modular software architectures in industrial automation.

AUS_ADD_3

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUS_ADD_3` is a generic arithmetic addition block for the 4diac IDE. It is used to add the values from three input adapters (`IN1`, `IN2`, and `IN3`) and output the result via an output adapter (`OUT`). The block uses unidirectional adapters of type `AUS` for this purpose.

Interface Structure

Event Inputs

No direct event inputs are available. Control and triggering are handled via the adapter interfaces.

Event Outputs

No direct event outputs are available. Event forwarding is handled via the adapter interfaces.

Data Inputs

No direct data inputs are available.

Data Outputs

No direct data outputs are available.

Adapters

The module communicates exclusively via adapter interfaces:
Sockets (Input Adapters):

- **IN1** (Type: `adapter::types::unidirectional::AUS`): First addend for addition.
- **IN2** (Type: `adapter::types::unidirectional::AUS`): Second addend for addition.
- **IN3** (Type: `adapter::types::unidirectional::AUS`): Third addend for addition.

Plugs (Output Adapters):

- **OUT** (Type: `adapter::types::unidirectional::AUS`): Output adapter that carries the result of the addition (`IN1 + IN2 + IN3`).

Functionality

As soon as a new event or a changed data value is signaled at one of the input adapters (`IN1`, `IN2`, or `IN3`), the function block internally performs an addition of the values.

The calculation follows the mathematical formula:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} \tag{2.108}$$

After successful calculation, the result and the associated update event are forwarded to subsequent function blocks via the output adapter `OUT`.

Technical Features

- **Generic Function Block:** The function block is based on the generic class `GEN_AUS_ADD` (attribute `eclipse4diac::core::GenericClassName`). This allows for flexible adaptation to different data types within the `AUS` adapter.
- **Adapter-Based Architecture:** By using adapters instead of standard event/data connections, the wiring effort in the function block diagram is drastically reduced, as events and data are bundled in a single channel (the adapter).
- **Unidirectional Data Flow:** The adapters used are unidirectional, which defines a clear direction of data processing from inputs to output.

State Overview

Since it is a combinational (or stateless) function block, `AUS_ADD_3` has no complex internal states (no state machine). The processing is purely event-driven:

1. **Wait State:** The function block waits for an event at one of the inputs (`IN1`, `IN2`, `IN3`).
2. **Calculation:** Upon arrival of an event, the data is read and summed.
3. **Update:** The result is written to `OUT`, and the corresponding output event is triggered on the adapter.

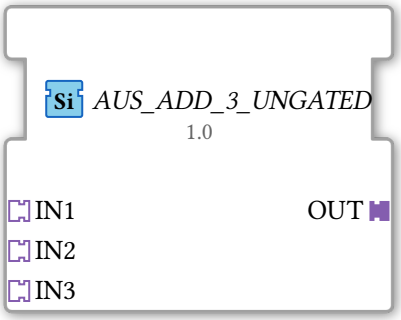
Application Scenarios

- **Measurement Unit:** Combining and summing three analog sensor values (e.g., three flow meters, temperature sensors, or current consumers) distributed throughout the system via adapter interfaces.
- **Setpoint Generation:** Adding base setpoints, correction values, and offsets in control systems.

Comparison with Similar Function Blocks

- **Standard ADD (IEC 61131-3):** Classic `ADD` function blocks use dedicated event and data lines. `AUS_ADD_3`, on the other hand, encapsulates these in adapters, resulting in cleaner software architectures.
- **OFF_ADD_2 / OFF_ADD_4:** Compared to variants with two or four inputs, this function block is specifically optimized for exactly three input channels to avoid unused interfaces in the program code.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AUS_ADD_3` is an efficient and reusable function block for adding three signals. Through the consistent use of unidirectional adapters, it promotes a modular, clear, and maintainable application design within the IEC 61499 development environment.

AUS_ADD_3_UNGATED

i UNGATED variant: This block is the ungated version of `AUS_ADD_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

AUS – ADD result

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUS_ADD_3_UNGATED` is a generic arithmetic addition block for the 4diac IDE. It is used to add the values from three input adapters (`IN1`, `IN2`, and `IN3`) and output the result via an output adapter (`OUT`). The block uses unidirectional adapters of type `AUS` for this purpose.

Interface Structure

Event Inputs

No direct event inputs are available. Control and triggering are handled via the adapter interfaces.

Event Outputs

No direct event outputs are available. Event forwarding is handled via the adapter interfaces.

Data Inputs

No direct data inputs are available.

Data Outputs

No direct data outputs are available.

Adapters

The module communicates exclusively via adapter interfaces:

Sockets (Input Adapters):

- **IN1** (Type: `adapter::types::unidirectional::AUS`): First addend for addition.
- **IN2** (Type: `adapter::types::unidirectional::AUS`): Second addend for addition.
- **IN3** (Type: `adapter::types::unidirectional::AUS`): Third addend for addition.

Plugs (Output Adapters):

- **OUT** (Type: `adapter::types::unidirectional::AUS`): Output adapter that carries the result of the addition (`IN1 + IN2 + IN3`).

Functionality

As soon as a new event or a changed data value is signaled at one of the input adapters (`IN1`, `IN2`, or `IN3`), the function block internally performs an addition of the values.

The calculation follows the mathematical formula:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} \tag{2.109}$$

After successful calculation, the result and the associated update event are forwarded to subsequent function blocks via the output adapter `OUT`.

Technical Features

- **Generic Function Block:** The function block is based on the generic class `GEN_AUS_ADD` (attribute `eclipse4diac::core::GenericClassName`). This allows for flexible adaptation to different data types within the `AUS` adapter.

- **Adapter-Based Architecture:** By using adapters instead of standard event/data connections, the wiring effort in the function block diagram is drastically reduced, as events and data are bundled in a single channel (the adapter).
- **Unidirectional Data Flow:** The adapters used are unidirectional, which defines a clear direction of data processing from inputs to output.

State Overview

Since it is a combinational (or stateless) function block, `AUS_ADD_3_UNGATED` has no complex internal states (no state machine). The processing is purely event-driven:

1. **Wait State:** The function block waits for an event at one of the inputs (`IN1`, `IN2`, `IN3`).
2. **Calculation:** Upon arrival of an event, the data is read and summed.
3. **Update:** The result is written to `OUT`, and the corresponding output event is triggered on the adapter.

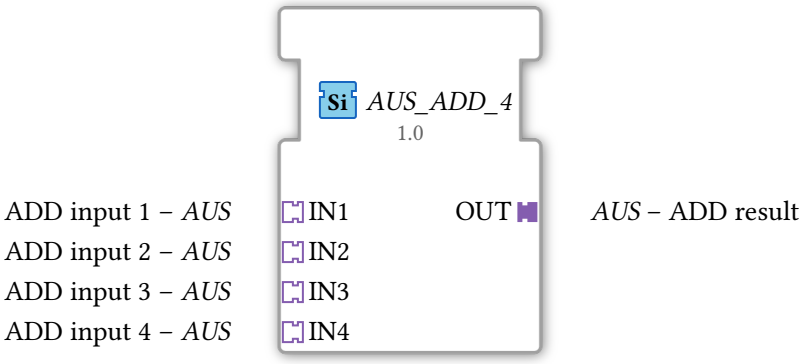
Application Scenarios

- **Measurement Unit:** Combining and summing three analog sensor values (e.g., three flow meters, temperature sensors, or current consumers) distributed throughout the system via adapter interfaces.
- **Setpoint Generation:** Adding base setpoints, correction values, and offsets in control systems.

Comparison with Similar Function Blocks

- **Standard ADD (IEC 61131-3):** Classic `ADD` function blocks use dedicated event and data lines. `AUS_ADD_3_UNGATED`, on the other hand, encapsulates these in adapters, resulting in cleaner software architectures.
- **OFF_ADD_2 / OFF_ADD_4:** Compared to variants with two or four inputs, this function block is specifically optimized for exactly three input channels to avoid unused interfaces in the program code.

Change Detection



This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AUS_ADD_3_UNGATED` is an efficient and reusable function block for adding three signals. Through the consistent use of unidirectional adapters, it promotes a modular, clear, and maintainable application design within the IEC 61499 development environment.

AUS_ADD_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUS_ADD_4` performs the arithmetic addition of four input values. It is a generic function block (FB) specifically designed for use with unidirectional adapters. By encapsulating the signals within adapters, the block enables a clean and clear structuring of data flows within IEC 61499 applications.

Interface Structure

Event Inputs

This function block does not have direct, traditional event inputs. Event control is handled implicitly via the adapter interfaces.

Event Outputs

This function block does not have direct, traditional event outputs. Event forwarding occurs via the adapter interfaces.

Data Inputs

There are no direct data inputs. Data transmission occurs exclusively via the assigned adapters.

Data Outputs

There are no direct data outputs. The result is provided via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AUS`): First addend of the addition.
- **IN2** (Type: `adapter::types::unidirectional::AUS`): Second addend of the addition.
- **IN3** (Type: `adapter::types::unidirectional::AUS`): Third addend of the addition.
- **IN4** (Type: `adapter::types::unidirectional::AUS`): Fourth addend of the addition.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AUS`): Interface for outputting the calculated addition result.

Functionality

The function block `AUS_ADD_4` receives numerical values continuously or event-driven via its four input adapters (`IN1` to `IN4`). As soon as data is present at the sockets or an update event arrives, the function block performs the arithmetic addition of the four values:

$$\text{OUT} = \text{IN1} + \text{IN2} + \text{IN3} + \text{IN4} \tag{2.110}$$

The result of this calculation is immediately passed to the output plug `OUT` and made available for subsequent program components. Since these are unidirectional connections, data flows strictly in a directed direction from the inputs to the output.

Technical Features

- **Generic Block:** By being assigned to the generic class `GEN_AUS_ADD`, the block is highly reusable and adapts flexibly to the underlying data types of the adapters.
- **Reduced Routing Complexity:** By using adapters instead of individual event and data lines, the number of connection lines in the 4diac IDE is drastically reduced, which significantly improves the readability of large application diagrams.
- **Compiler Membership:** The block is organized in the package `adapter::iec61131::arithmetic`.

State Overview

The block behaves like a combinational component (or a stateless function block). It does not store historical values between calculation cycles. Each update to one of the input adapters directly triggers the calculation and updates the output.

Application Scenarios

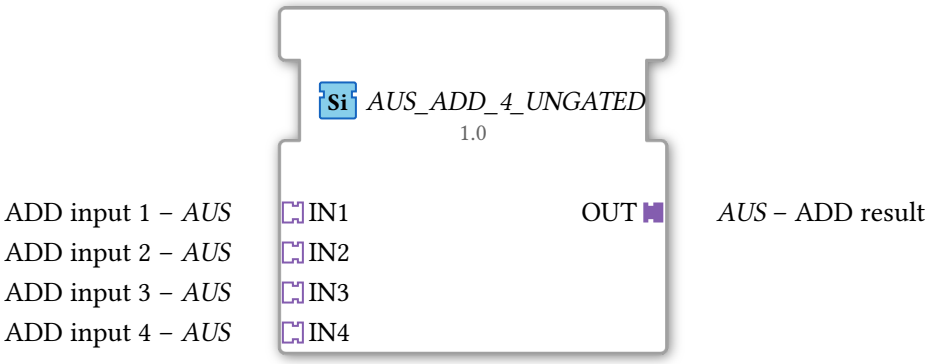
- **Signal Summation:** Combining and adding four analog sensor values (e.g., determining the total flow rate from four individual flow meters or the total power consumption of four electrical devices).
- **Average Preparation:** Summing four measurement points as a preparatory step for subsequent division to calculate the average.
- **Combinatorial Control Logic:** Aggregating weighted control signals in more complex distributed systems.

Comparison with Similar Function Blocks

Compared to a standard adder (e.g., the classic `ADD` function block from the IEC 61131-3 library), which works directly with elementary data types (such as `REAL` or `INT`), `AUS_ADD_4` relies entirely on adapter coupling. This saves time during instantiation and wiring, but requires that the source and destination signals are encapsulated in the adapter type `AUS`.

Change Detection

The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.



Conclusion

The `AUS_ADD_4` is a specialized and efficient auxiliary function block for structured application development in 4diac. It is ideally suited for cleanly structured control applications where signal processing is to be consistently implemented via adapter pipelines.

AUS_ADD_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUS_ADD_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUS_ADD_4_UNGATED` performs the arithmetic addition of four input values. It is a generic function block (FB) specifically designed for use with unidirectional adapters. By encapsulating the signals within adapters, the block enables a clean and clear structuring of data flows within IEC 61499 applications.

Interface Structure

Event Inputs

This function block does not have direct, traditional event inputs. Event control is handled implicitly via the adapter interfaces.

Event Outputs

This function block does not have direct, traditional event outputs. Event forwarding occurs via the adapter interfaces.

Data Inputs

There are no direct data inputs. Data transmission occurs exclusively via the assigned adapters.

Data Outputs

There are no direct data outputs. The result is provided via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AUS`): First addend of the addition.
- **IN2** (Type: `adapter::types::unidirectional::AUS`): Second addend of the addition.
- **IN3** (Type: `adapter::types::unidirectional::AUS`): Third addend of the addition.
- **IN4** (Type: `adapter::types::unidirectional::AUS`): Fourth addend of the addition.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AUS`): Interface for outputting the calculated addition result.

Functionality

The function block `AUS_ADD_4_UNGATED` receives numerical values continuously or event-driven via its four input adapters (`IN1` to `IN4`). As soon as data is present at the sockets or an update event arrives, the function block performs the arithmetic addition of the four values:

$$\mathrm{OUT} = \mathrm{IN1} + \mathrm{IN2} + \mathrm{IN3} + \mathrm{IN4} \tag{2.111}$$

The result of this calculation is immediately passed to the output plug `OUT` and made available for subsequent program components. Since these are unidirectional connections, data flows strictly in a directed direction from the inputs to the output.

Technical Features

- **Generic Block:** By being assigned to the generic class `GEN_AUS_ADD`, the block is highly reusable and adapts flexibly to the underlying data types of the adapters.
- **Reduced Routing Complexity:** By using adapters instead of individual event and data lines, the number of connection lines in the 4diac IDE is drastically reduced, which significantly improves the readability of large application diagrams.
- **Compiler Membership:** The block is organized in the package `adapter::iec61131::arithmetic`.

State Overview

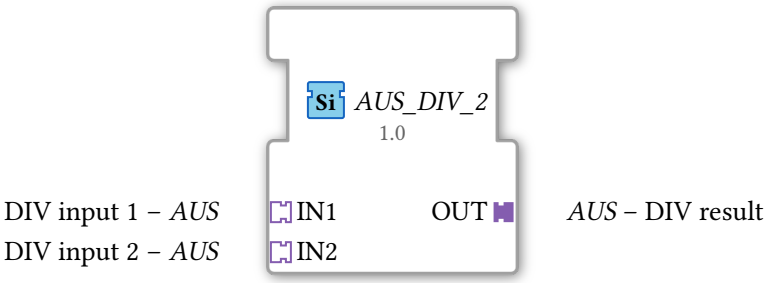
The block behaves like a combinational component (or a stateless function block). It does not store historical values between calculation cycles. Each update to one of the input adapters directly triggers the calculation and updates the output.

Application Scenarios

- **Signal Summation:** Combining and adding four analog sensor values (e.g., determining the total flow rate from four individual flow meters or the total power consumption of four electrical devices).
- **Average Preparation:** Summing four measurement points as a preparatory step for subsequent division to calculate the average.
- **Combinatorial Control Logic:** Aggregating weighted control signals in more complex distributed systems.

Comparison with Similar Function Blocks

Compared to a standard adder (e.g., the classic `ADD` function block from the IEC 61131-3 library), which works directly with elementary data types (such as `REAL` or `INT`), `AUS_ADD_4_UNGATED` relies entirely on adapter coupling. This saves time during instantiation and wiring, but requires that the source and destination signals are encapsulated in the adapter type `AUS`.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AUS_ADD_4_UNGATED` is a specialized and efficient auxiliary function block for structured application development in 4diac. It is ideally suited for cleanly structured control applications where signal processing is to be consistently implemented via adapter pipelines.

AUS_DIV_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block (FB) **AUS_DIV_2** is a generic block for performing arithmetic division (DIV). It is designed for use in IEC 61499-compliant systems (such as Eclipse 4diac). The block uses unidirectional adapters of type `AUS` to receive the input data, perform the division, and forward the result via a corresponding output adapter. Encapsulating the signals in adapters significantly simplifies the wiring within the development environment.

Interface Structure

Event Inputs

There are no direct event inputs on the block interface. Event-based control and triggering of the calculation are handled internally via the connected input adapters.

Event Outputs

There are no direct event outputs on the block interface. Calculation and update events are forwarded via the output adapter.

Data Inputs

The block has no direct elementary data inputs. All input data is passed via the adapter interfaces.

Data Outputs

The block has no direct elementary data outputs. The calculation result is provided via the output adapter.

Adapters

Type	Name	Adapter Type	Description
Socket (Input)	`IN1`	`adapter::types::unidirectional::AUS`	First input value for division (Dividend).
Socket (Input)	`IN2`	`adapter::types::unidirectional::AUS`	Second input value for the division (divisor).
Plug (Output)	`OUT`	`adapter::types::unidirectional::AUS`	Output for the result of the division (quotient).

Functionality

The function block `AUS_DIV_2` performs a classic division according to the following mathematical principle:

$$\mathrm{OUT} = \frac{\mathrm{IN1}}{\mathrm{IN2}} \tag{2.112}$$

Since it is a generic function block (identified by the attribute `GEN_AUS_DIV`), the block is not fixed to a specific data type (such as `INT` or `REAL`). The actual data type is resolved during instantiation in the 4diac IDE based on the connected adapters.

As soon as a new data event is signaled at the input adapters `IN1` or `IN2`, the function block performs the division and updates the value at the output adapter `OUT`, followed by a corresponding release event via the output plug.

- **Generic Type (`GEN_AUS_DIV`):** Enables flexible reuse for different numeric data types without the need to create separate function blocks for `INT`, `REAL`, or `LREAL`.
- **Unidirectional Adapters:** Using the `adapter::types::unidirectional::AUS` type ensures clean data and event encapsulation. This reduces visual complexity in system design (less "spaghetti code" due to loosely connected event and data lines).
- **Division by Zero:** When implementing on the target platform (runtime), it is important to consider how the function block reacts to a divisor of `0` (e.g., outputting `NaN`/`INF` for floating-point numbers or a system error for integers).

The function block does not have a complex internal state diagram (ECC). Its execution is purely transactional:

Technical Features

1. **Wait State:** The function block waits for an update event at sockets `IN1` or `IN2`.
2. **Calculation:** Upon receiving an event, the values are read and divided.
3. **Output:** The result is written to the plug `OUT` and the output event is triggered. The function block immediately returns to the wait state.

State Overview

- **Measurement Scaling:** Division of sensor values by constant factors distributed across the system via adapter structures.
- **Average Calculation:** Use in mathematical computation networks within distributed control systems.
- **Ratio Control:** Calculation of ratios (e.g., air-fuel ratio in burner controls) where the input signals are already available as standardized `AUS` adapters.

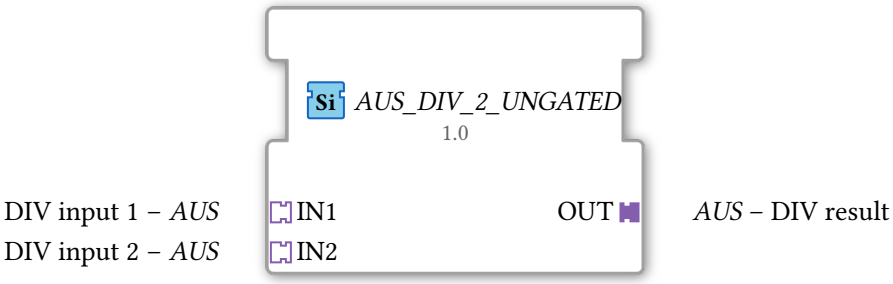
Application Scenarios

Compared to a standard integer division function block (such as the IEC 61131-3 `DIV` block), `AUS_DIV_2` offers the following advantages:

Comparison with Similar Function Blocks

- **Adapter-Based Coupling:** Standard function blocks require separate pins for data and events (REQ/CNF). `AUS_DIV_2` logically combines these in the `AUS` adapters.
- **Data Type Flexibility:** While classic function blocks are often rigidly defined for, e.g., `REAL` (e.g., `R_DIV`), this generic function block adapts to the adapter type used.
- **Adapter-Based Coupling:** Standard function blocks require separate pins for data and events (REQ/CNF). `AUS_DIV_2` logically combines these in the `AUS` adapters.
- **Data Type Flexibility:** While classic function blocks are often fixed for, e.g., `REAL` (e.g., `R_DIV`), this generic function block adapts to the adapter type used.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The function block `AUS_DIV_2` is a highly efficient, reusable auxiliary block for arithmetic calculations in modern, adapter-based IEC 61499 architectures. It significantly improves the clarity of application diagrams by consolidating the signal and event flows for mathematical divisions in standardized adapters.

AUS_DIV_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AUS_DIV_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

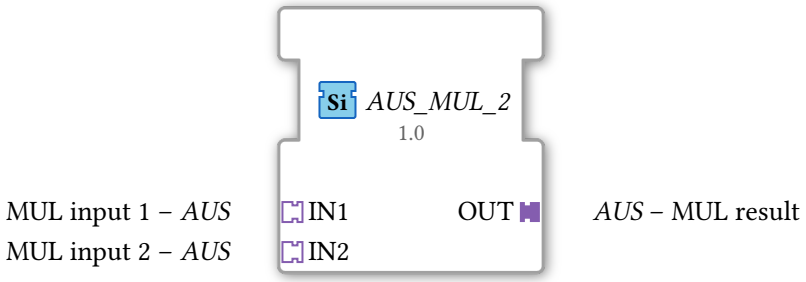
- **Adapter-Based Coupling:** Standard function blocks require separate pins for data and events (REQ/CNF). AUS_DIV_2_UNGATED logically combines these in the AUS adapters.
- **Data Type Flexibility:** While classic function blocks are often rigidly defined for, e.g., REAL (e.g., R_DIV), this generic function block adapts to the adapter type used.
- **Adapter-Based Coupling:** Standard function blocks require separate pins for data and events (REQ/CNF). AUS_DIV_2_UNGATED logically combines these in the AUS adapters.
- **Data Type Flexibility:** While classic function blocks are often fixed for, e.g., REAL (e.g., R_DIV), this generic function block adapts to the adapter type used.

Change Detection



This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The function block AUS_DIV_2_UNGATED is a highly efficient, reusable auxiliary block for arithmetic calculations in modern, adapter-based IEC 61499 architectures. It significantly improves the clarity of

application diagrams by consolidating the signal and event flows for mathematical divisions in standardized adapters.

AUS_MUL_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUS_MUL_2` is a generic arithmetic block for the 4diac IDE, used for multiplying two values. Unlike classic mathematical function blocks, this block uses an adapter-based concept for data transmission. This enables structured, modular, and clear signal wiring in complex IEC 61499 applications.

Interface Structure

Event Inputs

This function block does not have direct event inputs. Event control is handled via the connected adapters.

Event Outputs

This function block does not have direct event outputs. Event forwarding is handled via the output adapter.

Data Inputs

This function block has no direct data inputs.

Data Outputs

This function block has no direct data outputs.

Adapters

All communication (data and associated trigger events) is implemented via unidirectional adapters of type `AUS`.

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AUS`): The first multiplicand (input 1).
- **IN2** (Type: `adapter::types::unidirectional::AUS`): The second multiplicand (input 2).

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AUS`): The result of the multiplication ($IN1 \times IN2$).

–

Functionality

As soon as a new event indicating new data is signaled at the input adapters `IN1` or `IN2`, the function block internally performs the multiplication:

$$OUT = \text{IN1} \times \text{IN2} \tag{2.114}$$

The result of the calculation and the corresponding confirmation event are then passed on to subsequent function blocks via the output plug `OUT`. Since this is a generic function block (`GEN_AUS_MUL`), the internal processing adapts flexibly to the data type defined in the adapter.

Technical Features

- **Generic Nature:** The function block is declared as a generic type (`GenericClassName = 'GEN_AUS_MUL'`). This allows for flexible handling of various numeric data types (e.g., `INT`, `REAL`, `LREAL`) defined by the adapter structure.
- **Adapter Focus:** Reducing the number of traditional pins to adapters significantly minimizes the wiring effort in the function block diagram and ensures a clean, object-oriented design.
-

State Overview

The function block operates in an event-driven manner based on the state changes of the adapters:

1. **IDLE (Standby):** The function block waits for incoming values/events at sockets `IN1` and `IN2`.
2. **CALCULATION:** Upon receiving a trigger, the data values contained in the adapters are multiplied.
3. **OUTPUT:** The product is written to adapter `OUT`, and a send event is triggered. The function block returns to the *IDLE* state.

–

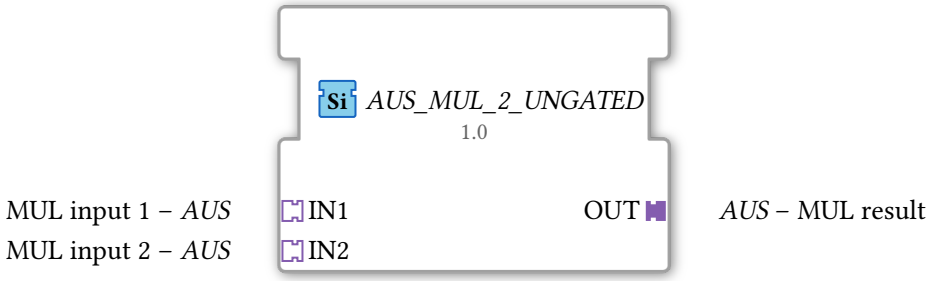
Application Scenarios

- **Measurement Scaling:** Multiplication of a raw value (e.g., from a sensor adapter) by a calibration factor.
- **Power Calculation:** Multiplication of current and voltage values read in via standardized adapter interfaces.
- **Modular Signal Processing:** Use in complex control loops where signal chains are neatly encapsulated by adapters to maintain clarity in the control diagram.

Comparison with Similar Components

Compared to the standard IEC 61131-3 multiplication component (`MUL`), which uses individual pins for `REQ`, `CNF`, and direct data inputs and outputs, `AUS_MUL_2` bundles all these signals into adapters. This prevents "cable clutter" in the function block diagram but requires that the connected signals are already in the `AUS` adapter format.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AUS_MUL_2` is a modern, robust, and reusable function block for multiplication in the 4diac IDE. Its consistent use of unidirectional adapters makes it ideally suited for service-oriented architectures and structured application designs in industrial environments.

AUS_MUL_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUS_MUL_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

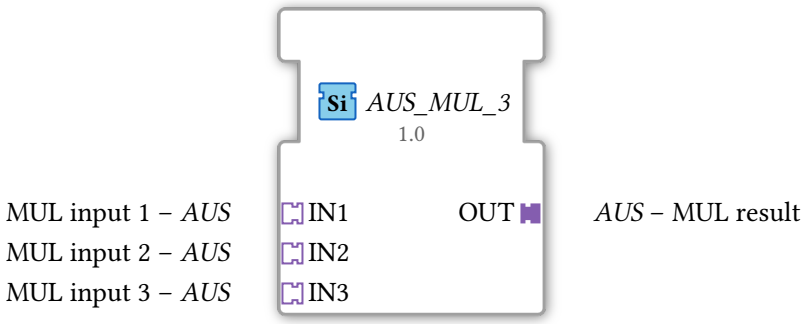
This prevents "cable clutter" in the function block diagram but requires that the connected signals are already in the `AUS` adapter format.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AUS_MUL_2_UNGATED` is a modern, robust, and reusable function block for multiplication in the 4diac IDE. Its consistent use of unidirectional adapters makes it ideally suited for service-oriented architectures and structured application designs in industrial environments.

AUS_MUL_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block (FB) `AUS_MUL_3` is used for the arithmetic multiplication of three input values. It is a generic function block (`Generic FB`) based on the use of unidirectional adapters of type `AUS`. The block calculates the product of three input values and provides the result at an output adapter.

Since this function block is entirely based on adapters, it has no direct, traditional event or data interfaces at the block level. All communication and synchronization takes place via the declared adapters.

Interface Structure

Event Inputs

No direct event inputs available. (Event control is handled via the adapter sockets).

Event Outputs

No direct event outputs available. (Event control is handled via the adapter plug).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AUS`): The first multiplicand for the arithmetic operation.
- **IN2** (Type: `adapter::types::unidirectional::AUS`): The second multiplicand for the arithmetic operation.
- **IN3** (Type: `adapter::types::unidirectional::AUS`): The third multiplicand for the arithmetic operation.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AUS`): The calculated result of the multiplication ($OUT = IN1 \times IN2 \times IN3$).

Functionality

As soon as new values are present at the input adapters (`IN1`, `IN2`, `IN3`) and a corresponding trigger event is transmitted via the adapters, the function block executes the multiplication.

The mathematical formula is:

$$\text{Result} = \text{Value of IN1} \times \text{Value of IN2} \times \text{Value of IN3} \tag{2.116}$$

The calculated result, along with a corresponding confirmation event, is passed to subsequent program components via the output plug `OUT`.

Technical Features

- **Generic Module:** The attribute `GenericClassName` with the value `'GEN_AUS_MUL'` allows for flexible use of the module. Depending on the specific implementation of the adapter type `AUS`, the function block can adapt to various data types (e.g., `INT`, `REAL`, `LREAL`).
- **Encapsulation by Adapter:** The use of unidirectional adapters (`unidirectional::AUS`) drastically reduces the routing of individual event and data lines in the 4diac IDE. This results in a cleaner and more organized application design.

State Overview

The module behaves in a purely stateless manner (i.e., it reacts to incoming adapter signals in an event-driven manner):

Application Scenarios

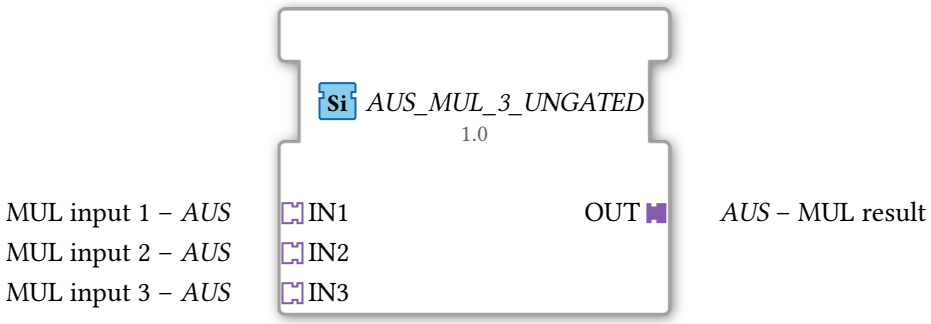
1. **Wait State:** The module waits for an update event at sockets `IN1`, `IN2`, or `IN3`.

2. **Calculation:** Upon receiving an event, the data values of the three input adapters are read and multiplied together.
3. **Output:** The result is written to plug `OUT`, and the corresponding send event of the plug is triggered.

Comparison with Similar Function Blocks

- **Scaling and Weighting:** Multiplication of a sensor value by two consecutive scaling factors (e.g., physical conversion and calibration factor).
- **Volume Calculation:** Calculating three-dimensional volume or flow rate where three parameters (e.g., length × width × height or three different rates) must be directly multiplied together.
- **Structured Signal Processing:** Used in more complex control loops that require a clean signal architecture using adapters.
- **Standard MUL Component (IEC 61131-3):** The classic `MUL` component uses direct data and event pins. The `AUS_MUL_3`, on the other hand, bundles these signals in adapters, simplifying wiring in large projects.
- **AUS_MUL_2 (Two-Input Variant):** While a hypothetical two-input variant can only multiply two factors, `AUS_MUL_3` eliminates the need for an additional cascading block when multiplying three values.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AUS_MUL_3` is a highly efficient, generic function block for multiplying three values. Its consistent use of unidirectional adapters makes it ideally suited for modern, adapter-based software architectures in the 4diac environment, as it minimizes the visual complexity of control diagrams.

AUS_MUL_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUS_MUL_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

- **IN1** (Type: `adapter::types::unidirectional::AUS`): The first multiplicand for the arithmetic operation.
- **IN2** (Type: `adapter::types::unidirectional::AUS`): The second multiplicand for the arithmetic operation.
- **IN3** (Type: `adapter::types::unidirectional::AUS`): The third multiplicand for the arithmetic operation.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AUS`): The calculated result of the multiplication ($OUT = IN1 \times IN2 \times IN3$).

Functionality

As soon as new values are present at the input adapters (`IN1`, `IN2`, `IN3`) and a corresponding trigger event is transmitted via the adapters, the function block executes the multiplication.

The mathematical formula is:

$$\text{Result} = \text{Value of IN1} \times \text{Value of IN2} \times \text{Value of IN3} \tag{2.117}$$

The calculated result, along with a corresponding confirmation event, is passed to subsequent program components via the output plug `OUT`.

Technical Features

- **Generic Module:** The attribute `GenericClassName` with the value `'GEN_AUS_MUL'` allows for flexible use of the module. Depending on the specific implementation of the adapter type `AUS`, the function block can adapt to various data types (e.g., `INT`, `REAL`, `LREAL`).
- **Encapsulation by Adapter:** The use of unidirectional adapters (`unidirectional::AUS`) drastically reduces the routing of individual event and data lines in the 4diac IDE. This results in a cleaner and more organized application design.

State Overview

The module behaves in a purely stateless manner (i.e., it reacts to incoming adapter signals in an event-driven manner):

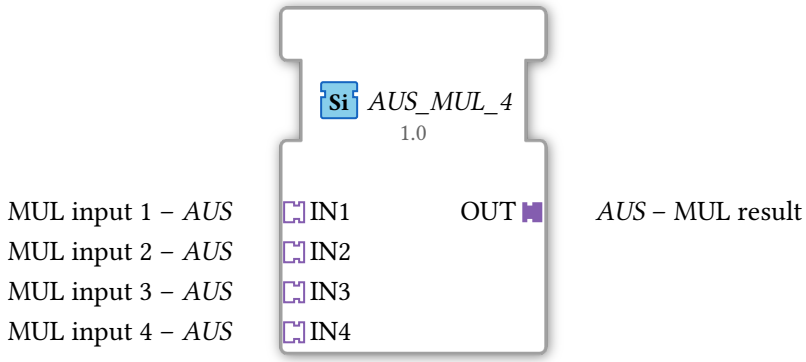
Application Scenarios

1. **Wait State:** The module waits for an update event at sockets `IN1`, `IN2`, or `IN3`.
2. **Calculation:** Upon receiving an event, the data values of the three input adapters are read and multiplied together.
3. **Output:** The result is written to plug `OUT`, and the corresponding send event of the plug is triggered.

Comparison with Similar Function Blocks

- **Scaling and Weighting:** Multiplication of a sensor value by two consecutive scaling factors (e.g., physical conversion and calibration factor).

- **Volume Calculation:** Calculating three-dimensional volume or flow rate where three parameters (e.g., length × width × height or three different rates) must be directly multiplied together.
- **Structured Signal Processing:** Used in more complex control loops that require a clean signal architecture using adapters.
- **Standard MUL Component (IEC 61131-3):** The classic `MUL` component uses direct data and event pins. The `AUS_MUL_3_UNGATED`, on the other hand, bundles these signals in adapters, simplifying wiring in large projects.
- **AUS_MUL_2 (Two-Input Variant):** While a hypothetical two-input variant can only multiply two factors, `AUS_MUL_3_UNGATED` eliminates the need for an additional cascading block when multiplying three values.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AUS_MUL_3_UNGATED` is a highly efficient, generic function block for multiplying three values. Its consistent use of unidirectional adapters makes it ideally suited for modern, adapter-based software architectures in the 4diac environment, as it minimizes the visual complexity of control diagrams.

AUS_MUL_4

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUS_MUL_4` is a generic function block (Generic FB) for performing an arithmetic multiplication (`MUL`) with up to four input values. It is based on the IEC 61499 architecture and uses unidirectional adapters to transmit data and the associated control events in a clean, encapsulated manner.

Due to its generic nature (`GEN_AUS_MUL`), the function block is flexible and can be applied to various numeric data types.

Interface Structure

Event Inputs

This function block does not have direct event inputs. Event control is handled entirely via the connected adapters.

Event Outputs

This function block does not have direct event outputs. Event control is handled entirely via the output adapter.

Data Inputs

There are no direct data inputs. Data is transferred via the input adapters.

Data Outputs

There are no direct data outputs. Data is transferred via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AUS`): First input value (multiplicand 1) for multiplication.
- **IN2** (Type: `adapter::types::unidirectional::AUS`): Second input value (multiplicand 2) for multiplication.
- **IN3** (Type: `adapter::types::unidirectional::AUS`): Third input value (multiplicand 3) for multiplication.
- **IN4** (Type: `adapter::types::unidirectional::AUS`): Fourth input value (multiplicand 4) for multiplication.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AUS`): The calculated product (result of the multiplication).

Functionality

As soon as new data values and the corresponding trigger events are present at the input adapters (`IN1` to `IN4`), the function block performs the multiplication.

The mathematical calculation follows the formula:

$$\mathrm{OUT} = \mathrm{IN1} \times \mathrm{IN2} \times \mathrm{IN3} \times \mathrm{IN4} \tag{2.118}$$

The calculated result, along with a corresponding output event, is provided via the output adapter `OUT`. Since this is a generic function block, the actual data type (e.g., `INT`, `REAL`, `LREAL`) adapts to the instantiation in the 4diac IDE.

Technical Features

- **Generic Function Block:** By defining it as `GEN_AUS_MUL`, the function block is not tied to a specific data type, which drastically increases its reusability across different projects.
- **Adapter-Based Communication:** The use of unidirectional `AUS` adapters ensures a clear application diagram, as data and event lines are bundled into a single connection. This reduces wiring errors in the development environment.

–

State Overview

The function block behaves like a classic, stateless mathematical operator (combinatorial logic). It does not store any internal states between calculation cycles. Each update of the input values via the adapters triggers a recalculation and update of the output.

Application Scenarios

- **Scaling and Calibration:** Calculation of more complex physical values where multiple factors (e.g., sensor value × calibration factor × temperature compensation × unit conversion) need to be multiplied.
- **Power Calculation:** Combination of multiple measured variables in process engineering.
- **Multi-Stage Gain Control:** Cascading of gain factors in control algorithms.

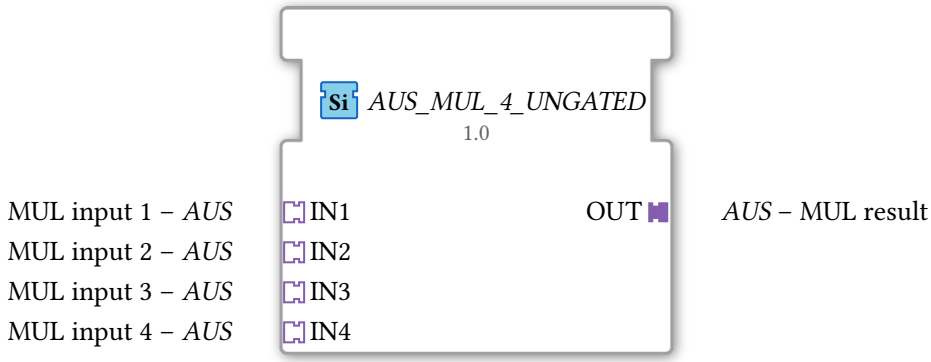
–

Comparison with Similar Components

Compared to standard multiplication components (such as the classic `MUL` of IEC 61131-3), which use separate pins for events and data, the `AUS_MUL_4` offers the following advantages:

- **Fewer Connections:** Four separate inputs and one output would require at least 10 connections (5 events, 5 data lines) in the classic model. The adapter technology reduces this to 5 adapter connections.
- **Compactness:** Cascading multiple 2x multipliers is no longer necessary, as four operands can be processed directly in a single function block.

Change Detection



The result is only written to the output plug (`OUT`) and its adapter event only sent if the newly computed value differs from the value currently held on `OUT`. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The `AUS_MUL_4` is a highly efficient and modern function block for the 4diac IDE. It combines the fundamental mathematical function of multiplication with the modern structuring advantages of IEC 61499 adapters, resulting in cleaner, more maintainable, and more transparent control applications.

AUS_MUL_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUS_MUL_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUS_MUL_4_UNGATED` is a generic function block (Generic FB) for performing an arithmetic multiplication (`MUL`) with up to four input values. It is based on the IEC 61499 architecture and uses unidirectional adapters to transmit data and the associated control events in a clean, encapsulated manner.

Due to its generic nature (`GEN_AUS_MUL`), the function block is flexible and can be applied to various numeric data types.

Interface Structure

Event Inputs

This function block does not have direct event inputs. Event control is handled entirely via the connected adapters.

Event Outputs

This function block does not have direct event outputs. Event control is handled entirely via the output adapter.

Data Inputs

There are no direct data inputs. Data is transferred via the input adapters.

Data Outputs

There are no direct data outputs. Data is transferred via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AUS`): First input value (multiplicand 1) for multiplication.
- **IN2** (Type: `adapter::types::unidirectional::AUS`): Second input value (multiplicand 2) for multiplication.
- **IN3** (Type: `adapter::types::unidirectional::AUS`): Third input value (multiplicand 3) for multiplication.
- **IN4** (Type: `adapter::types::unidirectional::AUS`): Fourth input value (multiplicand 4) for multiplication.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AUS`): The calculated product (result of the multiplication).

Functionality

As soon as new data values and the corresponding trigger events are present at the input adapters (`IN1` to `IN4`), the function block performs the multiplication.

The mathematical calculation follows the formula:

$$\mathrm{OUT} = \mathrm{IN1} \times \mathrm{IN2} \times \mathrm{IN3} \times \mathrm{IN4} \tag{2.119}$$

The calculated result, along with a corresponding output event, is provided via the output adapter `OUT`. Since this is a generic function block, the actual data type (e.g., `INT`, `REAL`, `LREAL`) adapts to the instantiation in the 4diac IDE.

Technical Features

- **Generic Function Block:** By defining it as `GEN_AUS_MUL`, the function block is not tied to a specific data type, which drastically increases its reusability across different projects.
- **Adapter-Based Communication:** The use of unidirectional `AUS` adapters ensures a clear application diagram, as data and event lines are bundled into a single connection. This reduces wiring errors in the development environment.

–

State Overview

The function block behaves like a classic, stateless mathematical operator (combinatorial logic). It does not store any internal states between calculation cycles. Each update of the input values via the adapters triggers a recalculation and update of the output.

Application Scenarios

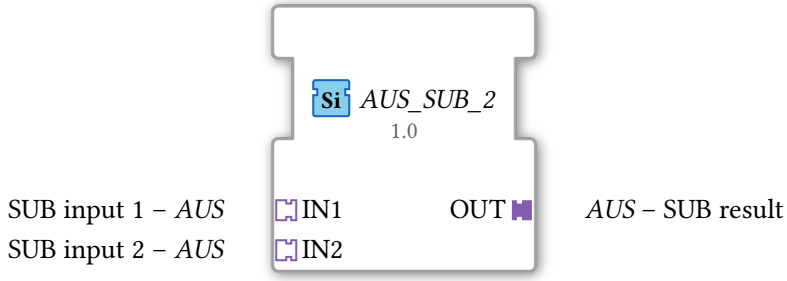
- **Scaling and Calibration:** Calculation of more complex physical values where multiple factors (e.g., sensor value × calibration factor × temperature compensation × unit conversion) need to be multiplied.
- **Power Calculation:** Combination of multiple measured variables in process engineering.
- **Multi-Stage Gain Control:** Cascading of gain factors in control algorithms.

–

Comparison with Similar Components

Compared to standard multiplication components (such as the classic `MUL` of IEC 61131-3), which use separate pins for events and data, the `AUS_MUL_4_UNGATED` offers the following advantages:

- **Fewer Connections:** Four separate inputs and one output would require at least 10 connections (5 events, 5 data lines) in the classic model. The adapter technology reduces this to 5 adapter connections.
- **Compactness:** Cascading multiple 2x multipliers is no longer necessary, as four operands can be processed directly in a single function block.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AUS_MUL_4_UNGATED` is a highly efficient and modern function block for the 4diac IDE. It combines the fundamental mathematical function of multiplication with the modern structuring advantages of IEC 61499 adapters, resulting in cleaner, more maintainable, and more transparent control applications.

AUS_SUB_2

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block (FB) `AUS_SUB_2` is a generic block for performing arithmetic subtraction operations within 4diac-based control systems. The block uses unidirectional adapters of type `AUS` to encapsulate and transmit input and output signals. Due to its generic design (compilation class `GEN_AUS_SUB`), it can be flexibly used in various control scenarios to calculate the difference between two values.

Interface Structure

Event Inputs

This function block does not have direct, dedicated event inputs. Event control is handled entirely via the adapters used.

Event Outputs

This function block does not have direct, dedicated event outputs. Event control is handled entirely via the adapters used.

Data Inputs

There are no direct, basic data inputs. Data is transferred via the input adapters.

Data Outputs

There are no direct, basic data outputs. The result is provided via the output adapter.

Adapters

Sockets (Input Adapters)

- **IN1** (Type: `adapter::types::unidirectional::AUS`): The first input (minuend) for subtraction calculation.
- **IN2** (Type: `adapter::types::unidirectional::AUS`): The second input (subtrahend) for subtraction calculation.

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AUS`): The output (difference) that provides the calculated result of the subtraction.

Functionality

The primary function of AUS_SUB_2 is arithmetic subtraction:

$$\mathrm{OUT} = \mathrm{IN1} - \mathrm{IN2} \tag{2.120}$$

Since the function block is based on adapters, it receives the values and the corresponding trigger events via the sockets IN1 and IN2. As soon as relevant data arrives via the input adapters, the mathematical operation is executed. The result of the calculation and the corresponding output event are then forwarded to the subsequent function blocks via the plug OUT.

Since this is a generic function block (GEN_AUS_SUB), the mathematical processing dynamically adapts to the data types defined in the AUS adapter.

Technical Features

- **Generic Type (GEN_AUS_SUB):** The function block is not limited to a single data type (such as only INT or REAL), but supports the data types defined by the adapter structure.
- **Unidirectional Adapters:** Using the unidirectional::AUS type ensures a clear, one-way data and signal flow. This minimizes the complexity of signal tracing within the system.
- – **Encapsulation:** By eliminating traditional event and data pins, the visual layout in the 4diac-ide Application Editor remains extremely compact and clear.

State Overview

Since this module is designed as a purely functional, stateless calculation block, it does not have a complex internal Execution Control Chart (ECC). Its execution is purely data- and event-driven, based on the interactions of the connected adapters.

Application Scenarios

- **Process Value Correction:** Subtraction of zero-point offsets or calibration values from a measured sensor value.
- **Target-Actual Value Comparison:** Calculation of the control deviation ($e = w - x$) in control loops where the signals are already available as structured adapter channels.
- **Level Calculation:** Determination of differential quantities in containers or systems by subtracting the outflow from the inflow.

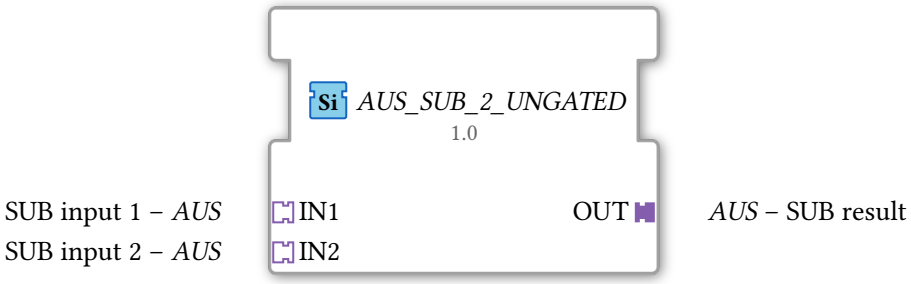
Comparison with Similar Function Blocks

Compared to a classic IEC 61131-3 SUB function block, which works directly with elementary data types, the AUS_SUB_2 offers the following advantages:

- **Reduced Wiring Effort:** Event and data lines do not need to be run separately, as they are bundled in the AUS adapter.
- **Increased Modularity:** It is ideally suited for service-oriented architectures in IEC 61499, where subsystems typically communicate via adapters.

–

Change Detection



The result is only written to the output plug (OUT) and its adapter event only sent if the newly computed value differs from the value currently held on OUT. If the result is unchanged, no adapter event is sent, avoiding redundant updates on downstream peers.

Conclusion

The AUS_SUB_2 is a specialized yet flexible subtraction function block. Through the consistent use of unidirectional adapters, it promotes a clean, structured, and clear design of control programs in the 4diac IDE.

AUS_SUB_2_UNGATED

i UNGATED variant: This block is the ungated version of AUS_SUB_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block (FB) AUS_SUB_2_UNGATED is a generic block for performing arithmetic subtraction operations within 4diac-based control systems. The block uses unidirectional adapters of type AUS to encapsulate and transmit input and output signals. Due to its generic design (compilation class GEN_AUS_SUB), it can be flexibly used in various control scenarios to calculate the difference between two values.

Interface Structure

Event Inputs

This function block does not have direct, dedicated event inputs. Event control is handled entirely via the adapters used.

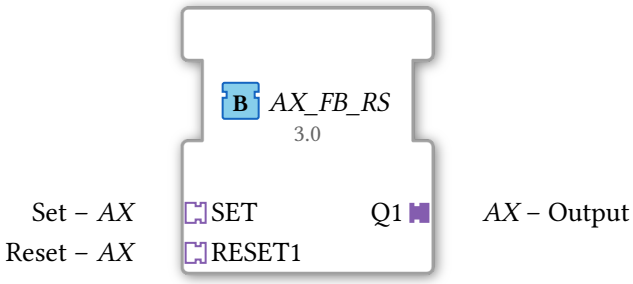
Here you will find all exercises from the iec61131-3 workspace in ascending order.



AX_FB_RS

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_FB_RS** implements a bistable flip-flop with reset dominance, based on the IEC 61131-3 standard. Unlike the standard RS block, this function block uses adapter interfaces (AX) to transmit events and data in a bundled manner. This allows for a more compact representation in control diagrams, as data and event connections are combined in a single line.

Interface Structure

Since this block is based exclusively on adapters, the classic event and data inputs/outputs are empty. Communication takes place entirely via the defined plugs and sockets.

Event Inputs

No direct event inputs available.

Event Outputs

No direct event outputs available.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

This component uses the adapter type `adapter::types::unidirectional::AX`. This adapter type typically bundles a Boolean signal (`D1`) and an associated event (`E1`).

Name	Type	Direction	Description
Q1	AX	Plug (Output)	The output of the flip-flop (status).
SET	AX	Socket (Input)	The set input. When active, the output `Q1` is set to TRUE (unless `RESET1` is active).
RESET1	AX	Socket (Input)	The reset input. When active, the output `Q1` is set to FALSE. This input has priority over `SET`.

Functionality

The **AX_FB_RS** implements the logic of an RS flip-flop with reset dominance. The internal state and the output `Q1` are calculated based on the input values of the adapters `SET` and `RESET1`.

The logical function is:
Q1 := (NOT RESET1) AND (SET OR Q1)`
The behavior can be summarized as follows:

1. **Reset:** If `RESET1.D1` is TRUE, `Q1.D1` immediately becomes FALSE, regardless of the state of `SET.D1`.
2. **Set:** If `SET.D1` is TRUE and `RESET1.D1` is FALSE, `Q1.D1` becomes TRUE.
3. **Save:** If both `SET.D1` and `RESET1.D1` are FALSE, `Q1.D1` retains its previous state.

As soon as an event (`E1`) is received at one of the input adapters (`SET` or `RESET1`), the module executes the algorithm and then fires an event at the output adapter `Q1.E1`.

Technical Features

- **Adapter Technology:** By using `AX` adapters, the module reduces visual complexity in 4diac applications, as only one connecting line needs to be drawn for the event-boolean value pair.
- **Event-Driven:** The algorithm is triggered when an event arrives via the `SET` or `RESET1` adapter.
- **Reset Dominance:** This is a safety-relevant feature. In case of a conflict (both inputs TRUE), the output safely shuts down (FALSE).

State Overview

The function block is based on a simple ECC (Execution Control Chart) with a single main state.

- **State Name:** `REQ`
- **Action:** Executes the algorithm `REQ` and sends an event via `Q1.E1`.
- **Transitions:**
- The state `REQ` has self-transitions (self-loops) that are triggered by the arrival of events at the adapters `SET.E1` or `RESET1.E1`.

This means that the function block is always ready to process input signals and respond to them immediately.

Application Scenarios

- **Motor Controls (Start/Stop):** Typical application for start (Set) and stop (Reset) buttons, where the stop button takes precedence for safety reasons (emergency stop logic).
- **Alarm Memory:** An alarm is set and remains active until it is explicitly reset (acknowledged).
- **State Markers:** Storing binary states within an adapter-based control logic.
- **Modular Systems:** Used in systems that consistently rely on adapter interfaces to avoid “spaghetti code” in the graphical representation.

⚖️ Comparison with Similar Function Blocks

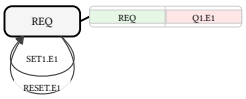
Feature	AX_FB_RS	AX_FB_SR	RS (Standard)

Dominance	**Reset Dominant** (Output FALSE at S=1, R=1)	Set Dominant (Output TRUE at S=1, R=1)	Reset Dominant
Interface	Adapter (AX)	Adapter (AX)	Boolean Event/Data Ports
Wiring	Minimalist (bundled)	Minimalist (bundled)	Classic (separate lines)

Conclusion

The **AX_FB_RS** is a modern, adapter-based implementation of the classic RS flip-flop. It is ideally suited for complex control applications in 4diac where clarity and signal encapsulation are paramount. Thanks to its integrated reset dominance, it is particularly well-suited for applications where safe shutdown takes precedence over shutdown.

Wiring | Minimalist (bundled) | Classic (separate lines) |



The **AX_FB_RS** is a modern, adapter-based implementation of the classic RS flip-flop. It is ideally suited for complex control applications in 4diac where clarity and signal encapsulation are essential. Its integrated reset dominance makes it especially suitable for applications where safe shutdown must take precedence over shutdown.

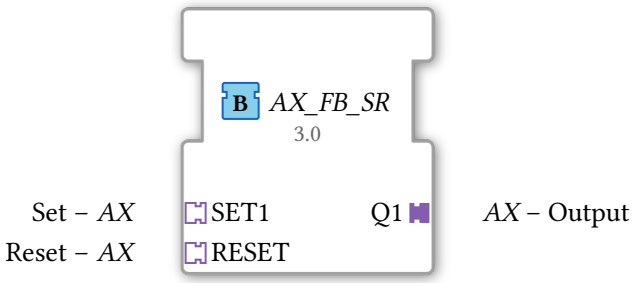
AX_FB_SR



• – ○ • – ○ • – ○ •

Introduction

The **AX_FB_SR** function block implements a bistable latch with **set dominance** (SR flip-flop). Unlike conventional IEC 61131-3 function blocks, this block does not use discrete event and data connections, but rather **adapters** for signal transmission. This allows for a more compact representation and simplified wiring in complex control applications based on the adapter concept.

The block stores a binary state. If both the set (SET) and reset (RESET) signals are active simultaneously, the set signal takes precedence (set dominance).

Interface Structure

The block communicates exclusively via adapter interfaces. Traditional discrete inputs and outputs are not present, as these are encapsulated within the adapters.

Event Inputs

No direct event inputs available (these are contained in sockets `SET1` and `RESET`).

Event Outputs

No direct event outputs available (these are contained in plug `Q1`).

Data Inputs

No direct data inputs available (these are contained in sockets `SET1` and `RESET`).

Data Outputs

No direct data outputs available (these are contained in plug `Q1`).

Adapter

Name	Type	Direction	Description
Q1	`adapter::types::unidirectional::AX`	Plug (Output)	The output adapter that provides the current state (Q) and the associated event.
SET1	`adapter::types::unidirectional::AX`	Socket (Input)	The set input adapter. A `TRUE` signal here sets the output to `TRUE`.
RESET	`adapter::types::unidirectional::AX`	Socket (Input)	The reset input adapter. A `TRUE` signal here sets the output to `FALSE` (if SET1 is not active).

Note: The adapter type `AX` typically implies a combination of a Boolean data point (`D1`) and an event (`E1`).

Functionality

The internal algorithm implements the logic of an SR flip-flop with set precedence. The logic is executed as soon as an event is received at one of the adapter inputs (`SET1.E1` or `RESET.E1`).

The logical equation is (in ST syntax):

```
Q1.D1 := SET1.D1 OR ((NOT RESET.D1) AND Q1.D1);
```

Technical Features

- **Adapter-based:** The main advantage of this function block is the reduction of connection lines in the function plan, as data and events are bundled via a single adapter connection.
- **Event-driven:** The function block reacts immediately to incoming events at the `SET1` or `RESET` adapters and forwards the result immediately.
- **State machine (ECC):** The Execution Control Chart (ECC) is minimal. It consists of a single state, `REQ`, which waits for input events and executes the algorithm `REQ`.

State Overview

The following truth table describes the behavior of the function block (where `Q_n` is the old state and `Q_n+1` is the new state):

SET1.D1	RESET.D1	Q_n (Old State)	Q_n+1 (New State)	Description
0	0	0	0	Hold State
0	0	1	1	Hold State
0	1	X	0	Reset
1	0	X	1	Set
1	1	X	1	**Set (Dominant)**

Application Scenarios

- **Adapter-Based Control Systems:** Ideal for projects that consistently utilize 4diac's adapter technology to avoid the "spaghetti code" of parallel event and data lines.
- **Start/Stop Logic:** Implementing machine controls where the "on" signal (set) has priority or where continuous activation must be ensured as long as the button is pressed.
- **Alarm Handling:** Storing alarm states that must be manually acknowledged (reset).

⚖️ **Comparison with similar components**

- **SR (Standard):** The `AX_FB_SR` is logically equivalent to the standard `SR` component of IEC 61131-3, but differs in that it uses `AX` adapters instead of discrete `BOOL` and `EVENT` pins.
- **AX_FB_RS:** This is the counterpart with **reset dominance**. With the `AX_FB_RS`, if SET and RESET are applied simultaneously, the output would go to `FALSE`.
- **E_SR:** An event-driven standard SR flip-flop without adapters.

Conclusion

The **AX_FB_SR** is a specialized component for structured, adapter-based programming in 4diac. It offers the classic functionality of a set-dominant memory element, but optimizes the graphical representation and handling by encapsulating signals in adapters. It is indispensable in applications based on modular and clearly structured interface definitions.

AD_SHL

• – ○ • – ○ • – ○ •

Introduction

The function block **AD_SHL** performs a bitwise left shift of an input value. It is designed as a generic function block that communicates via adapter interfaces and supports any integer data type (ANY_INT). The actual shift operation is implemented internally by a predefined function block `F_SHL`.

Interface Structure

Event Inputs

Event	Description	With Parameters
`UPDATE`	Updates the shift count and starts the calculation.	`N`

Event Outputs

No direct event outputs are available. The event for passing the result is handled via the adapter `OUT` (event `OUT.E1`).

Data Inputs

Name	Type	Description
`N`	`ANY_INT`	Number of bit positions to shift.

Data Outputs

No direct data outputs. The result of the shift is provided via the adapter `OUT` (data `OUT.D1`).

Adapter

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AD`	Receives the value to be shifted via the adapter channel.
Plug	`OUT`	`adapter::types::unidirectional::AD`	Provides the result of the left shift.

Functionality

The FB operates as a composite function block that delegates the actual operation to the block `F_SHL`. Internally, the following logic is implemented:

1. **Event Triggering**

- An incoming event from UPDATE or from the adapter IN.E1 triggers the input REQ of the internal block F_SHL.
- The value of N is directly passed to the input F_SHL.N.
- The data value provided via the adapter IN (IN.D1) is forwarded to the F_SHL.IN input.

1. **Calculation**

The internal function block F_SHL (type iec61131::bitwiseOperators::F_SHL) performs a bitwise left shift of the input value by the number of times specified in N.

1. **Output**

The result of the calculation (F_SHL.OUT) is transferred to the data output of the plug adapter OUT.D1. Simultaneously, the event F_SHL.CNF signals the availability of the new result to the plug adapter (OUT.E1).

The function block is event-driven: Each arrival of a valid event (either externally via UPDATE or from the socket adapter IN) triggers a complete calculation.

Technical Features

- **Adapter Interface**

Instead of fixed inputs and outputs, the function block uses adapters (IN as a socket, OUT as a plug), which enables flexible integration in various architectural contexts.

- **Generic Data Type**

The parameter N is declared as ANY_INT, allowing the function block to work with different integer types (e.g., INT, DINT, LINT), as long as the internal F_SHL supports them.

- **Combined Event Control**

Both the external event UPDATE and the event received from the socket adapter, IN.E1, can trigger the calculation. This enables both cyclic and data-driven updates.

- **Licensing**

This function block is licensed under the Eclipse Public License 2.0 and designed as a generic function block.

State Overview

This function block is implemented as a **composite network** and does not have its own internal state machine (ECC). The sequence control is entirely determined by the event connections within the network and the F_SHL function block used. An explicit state machine is not required.

Application Scenarios

- **Bit Manipulation in Control Engineering**

Shifting bit patterns for masking, scaling, or encoding signals.

- **Data Preparation in Communication Protocols**

Adapting data words by left shifting, e.g., for serial interfaces or bus systems.

- **Arithmetic Calculations**

Multiplication by powers of two by left shifting, especially in computationally critical environments.

Comparison with Similar Blocks

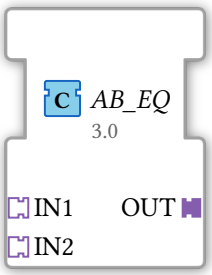
- **Direct F_SHL Block**

The internal F_SHL offers the same functionality, but without an adapter interface. AD_SHL encapsulates this block and extends it with an adapter-based connection, which facilitates reuse in modular systems.

- **Adapter-Based Arithmetic Blocks**

Similar concepts exist for other bitwise operations (e.g., AD_SHR, AD_AND). AD_SHL specifies the left shift and can be used in a library of adapter-coupled logic blocks.

Conclusion



The function block `AD_SHL` implements a bitwise left shift using an encapsulated `F_SHL` block and provides all functionality via a standardized adapter interface. Its generic design and flexible event control make it suitable for a wide range of applications in IEC 61499-based automation technology. Its composite structure makes it maintainable and easily extensible.

AB_EQ

Input value 1 -- left operand (IN1 = IN2) – *AB*
Input value 2 -- right operand (IN1 = IN2) – *AB*

AX – IN1 = IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_EQ** compares two values of type `BYTE` (8-bit bit pattern (byte)) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type BYTE, 8-bit bit pattern (byte)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – TRUE if IN1 = IN2, otherwise FALSE.

Adapters

Adapter	Type	Direction	Description
IN1	AB (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AB (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AB and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_EQ (type iec61131::comparison::F_EQ). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AB/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 ("equal to") for the BYTE data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

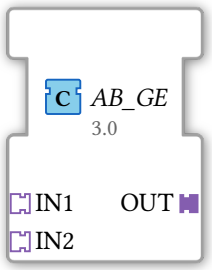
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking status register against a reference or threshold value of type BYTE.
- **Control Logic**: Triggering an action once two values of type BYTE satisfy the "equal to" condition.
- **Data Filtering**: Selecting data records or signals that satisfy a BYTE-based comparison condition.

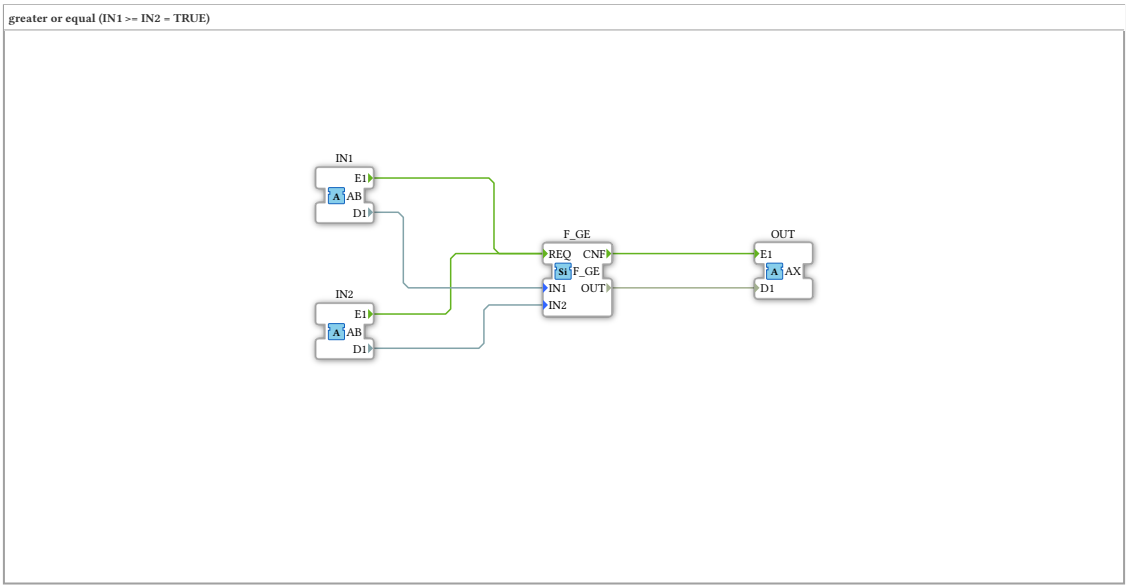
Comparison with Similar Function Blocks



- **AB_NE**: Checks for "not equal to" – the inverse function of AB_EQ.
- **AB_NE**: Checks for inequality of values.

AB_EQ is part of the complete AB comparison family (EQ/NE/GT/GE/LT/LE) for the BYTE data type.

Conclusion



AB_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the BYTE data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AB_GE

Input value 1 -- left operand (IN1 >= IN2) – *AB*
Input value 2 -- right operand (IN1 >= IN2) – *AB*

AX – IN1 >= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_GE** compares two values of type `BYTE` (8-bit bit pattern (byte)) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `BYTE`, 8-bit bit pattern (byte)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AB (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AB (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AB and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GE (type iec61131::comparison::F_GE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AB/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the BYTE data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

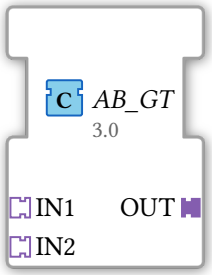
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking status register against a reference or threshold value of type BYTE.
- **Control Logic**: Triggering an action once two values of type BYTE satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a BYTE-based comparison condition.

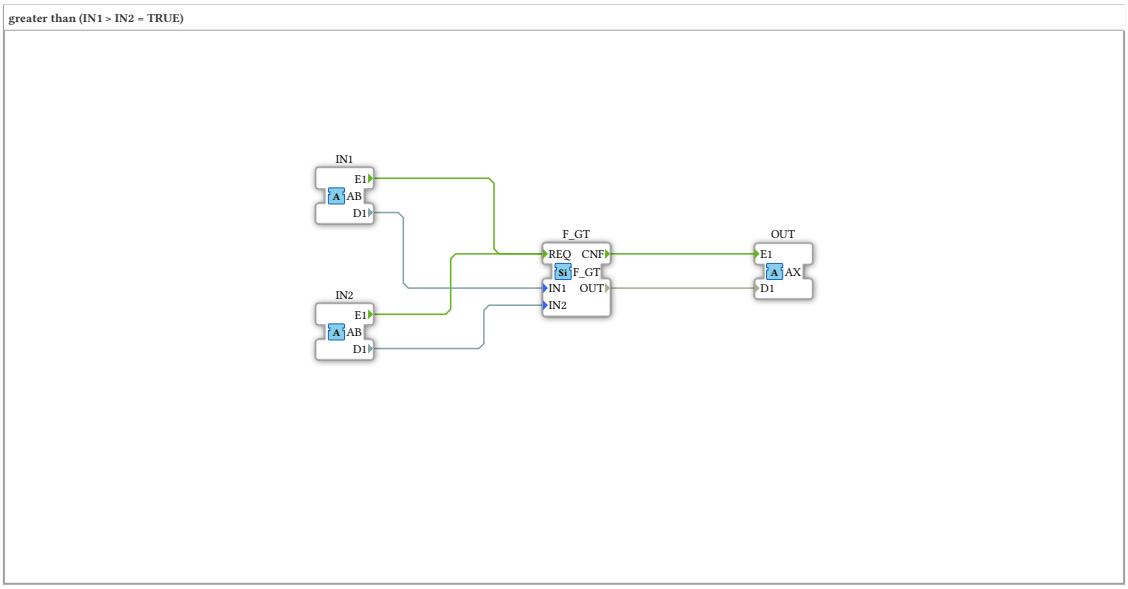
Comparison with Similar Function Blocks



- **AB_LE**: Checks for “less than or equal to” – the inverse function of AB_GE.
- **AB_EQ**: Checks for equality of values.
- **AB_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which AB_GE is the extended version.

AB_GE completes the AB comparison family with the boundary case of equality.

Conclusion



AB_GE is a simple yet important comparison block for IEC 61131-3 control applications using the BYTE data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AB_GT

Input value 1 -- left operand (IN1 > IN2) – *AB*
Input value 2 -- right operand (IN1 > IN2) – *AB*

AX – IN1 > IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AB_GT** compares two values of type `BYTE` (8-bit bit pattern (byte)) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `BYTE`, 8-bit bit pattern (byte)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AB (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AB (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AB and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GT (type iec61131::comparison::F_GT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AB/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the BYTE data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

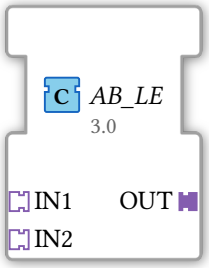
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking status register against a reference or threshold value of type BYTE.
- **Control Logic**: Triggering an action once two values of type BYTE satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a BYTE-based comparison condition.

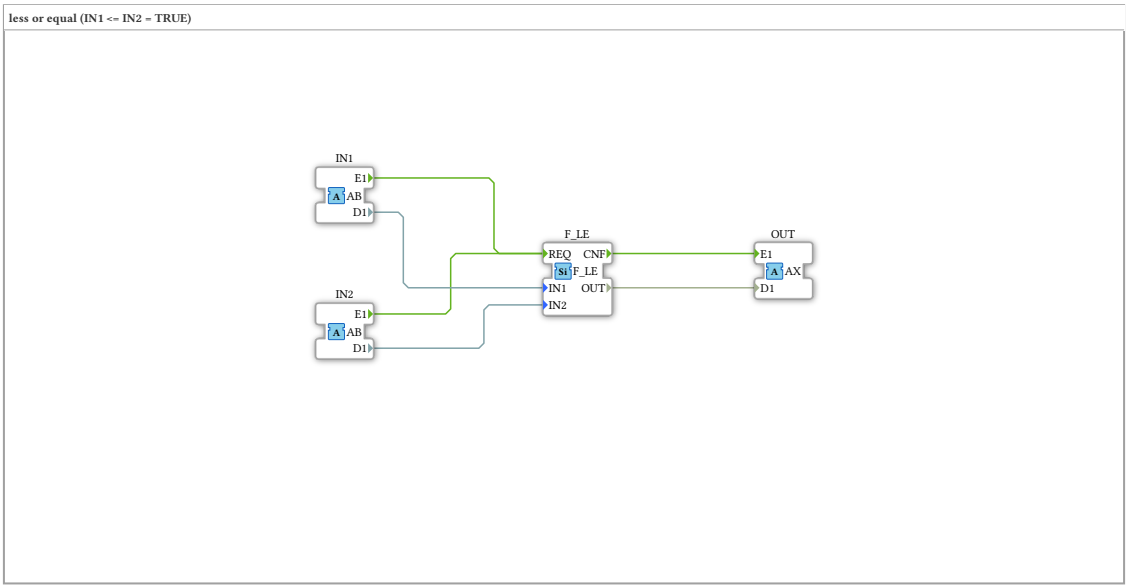
Comparison with Similar Function Blocks



- **AB_LT**: Checks for “less than” – the inverse function of AB_GT.
- **AB_EQ**: Checks for equality of values.
- **AB_GE**: Performs the “greater than or equal to” comparison – the extended version of AB_GT that includes the equality case.

AB_GT is the basic “greater than” component without the equality case, complemented by AB_GE.

Conclusion



AB_GT is a simple yet important comparison block for IEC 61131-3 control applications using the BYTE data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AB_LE

Input value 1 -- left operand (IN1 <= IN2) – *AB*
Input value 2 -- right operand (IN1 <= IN2) – *AB*

AX – IN1 <= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_LE** compares two values of type `BYTE` (8-bit bit pattern (byte)) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `BYTE`, 8-bit bit pattern (byte)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AB (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AB (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AB and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LE (type iec61131::comparison::F_LE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AB/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the BYTE data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

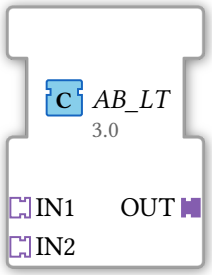
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking status register against a reference or threshold value of type BYTE.
- **Control Logic**: Triggering an action once two values of type BYTE satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a BYTE-based comparison condition.

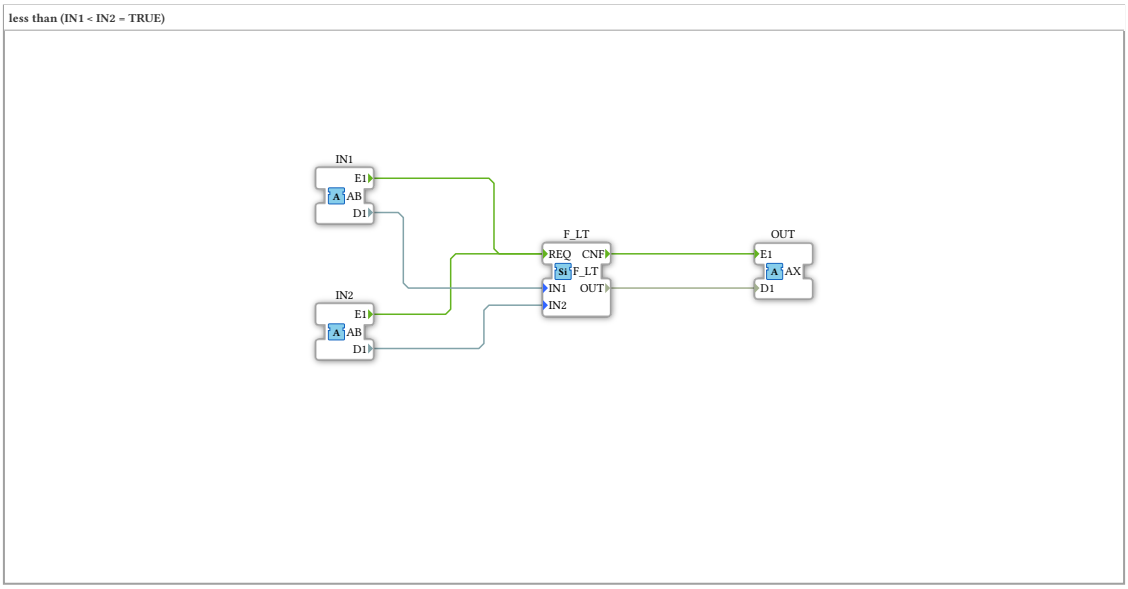
Comparison with Similar Function Blocks



- **AB_GE**: Checks for “greater than or equal to” – the inverse function of AB_LE.
- **AB_EQ**: Checks for equality of values.
- **AB_LT**: Performs the “less than” comparison – the base variant without the equality case, of which AB_LE is the extended version.

AB_LE completes the AB comparison family with the boundary case of equality.

Conclusion



AB_LE is a simple yet important comparison block for IEC 61131-3 control applications using the BYTE data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AB_LT

Input value 1 -- left operand (IN1 < IN2) – *AB*
Input value 2 -- right operand (IN1 < IN2) – *AB*

AX – IN1 < IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AB_LT** compares two values of type `BYTE` (8-bit bit pattern (byte)) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `BYTE`, 8-bit bit pattern (byte)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AB (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AB (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AB and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LT (type iec61131::comparison::F_LT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AB/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the BYTE data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

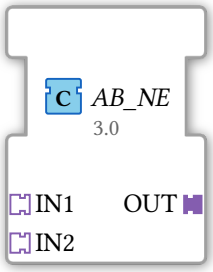
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking status register against a reference or threshold value of type BYTE.
- **Control Logic**: Triggering an action once two values of type BYTE satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a BYTE-based comparison condition.

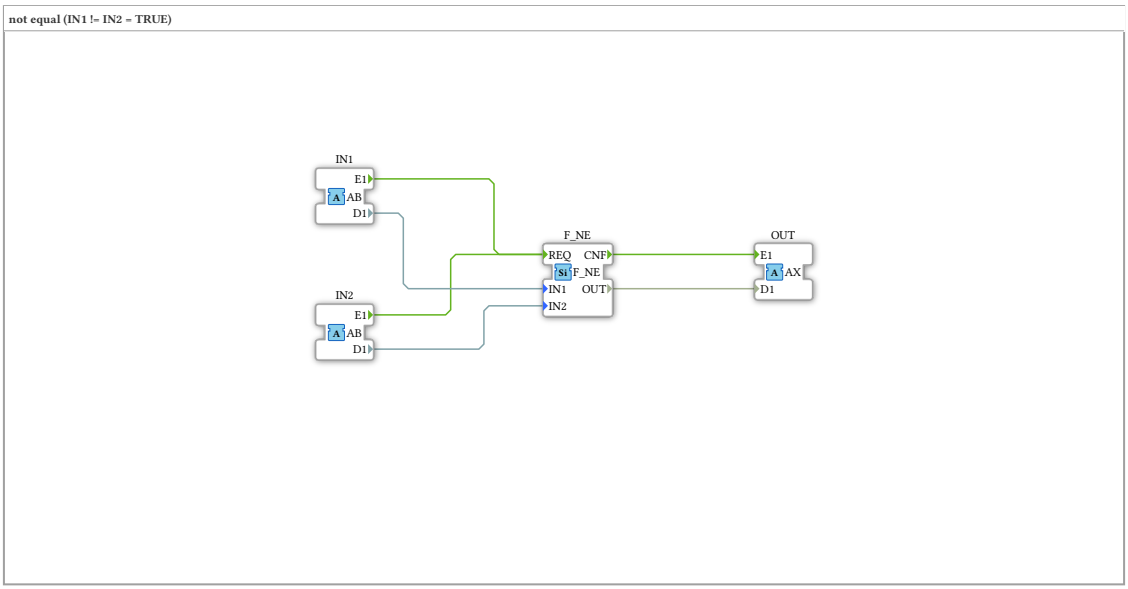
Comparison with Similar Function Blocks



- **AB_GT**: Checks for “greater than” – the inverse function of AB_LT.
- **AB_EQ**: Checks for equality of values.
- **AB_LE**: Performs the “less than or equal to” comparison – the extended version of AB_LT that includes the equality case.

AB_LT is the basic “less than” component without the equality case, complemented by AB_LE.

Conclusion



AB_LT is a simple yet important comparison block for IEC 61131-3 control applications using the BYTE data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AB_NE

Input value 1 -- left operand (IN1 != IN2) – *AB*
Input value 2 -- right operand (IN1 != IN2) – *AB*

AX – IN1 != IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_NE** compares two values of type `BYTE` (8-bit bit pattern (byte)) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `BYTE`, 8-bit bit pattern (byte)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AB (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AB (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AB and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_NE (type iec61131::comparison::F_NE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AB/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the BYTE data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

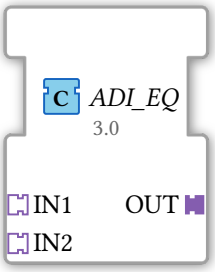
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking status register against a reference or threshold value of type BYTE.
- **Control Logic**: Triggering an action once two values of type BYTE satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a BYTE-based comparison condition.

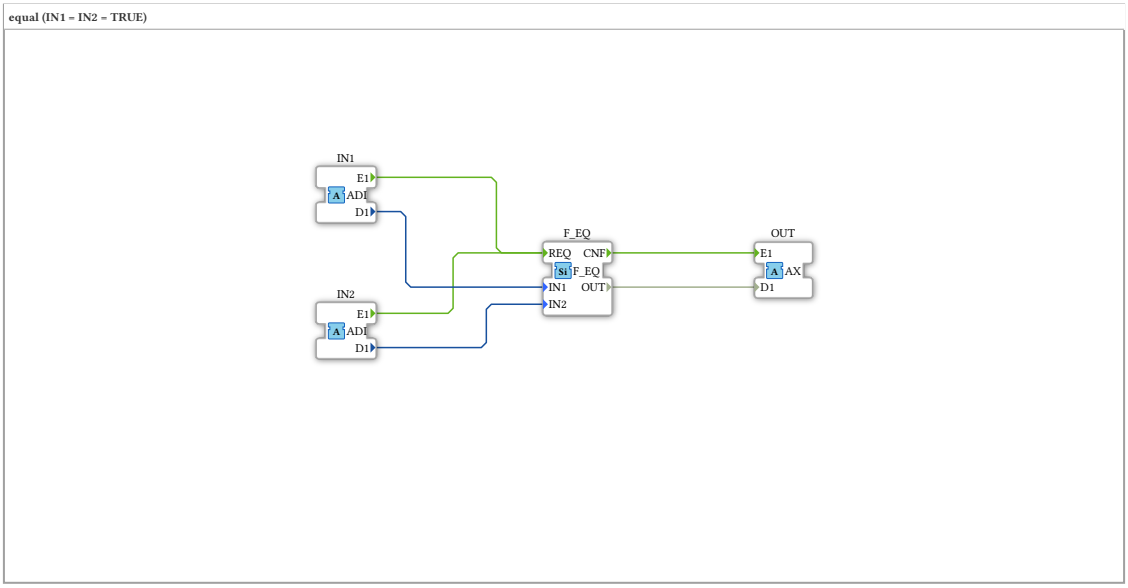
Comparison with Similar Function Blocks



- **AB_EQ**: Checks for “equal to” – the inverse function of AB_NE.
- **AB_EQ**: Checks for equality of values.

AB_NE is part of the complete AB comparison family (EQ/NE/GT/GE/LT/LE) for the BYTE data type.

Conclusion



AB_NE is a simple yet important comparison block for IEC 61131-3 control applications using the BYTE data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ADI_EQ

Input value 1 -- left operand (IN1 = IN2) – *ADI*
Input value 2 -- right operand (IN1 = IN2) – *ADI*

AX – IN1 = IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ADI_EQ** compares two values of type `DINT` (32-bit signed integer) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `DINT`, 32-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`ADI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`ADI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `ADI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_EQ` (type `iec61131::comparison::F_EQ`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`ADI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the `DINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

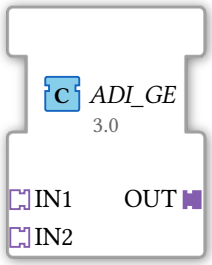
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking counter and position values against a reference or threshold value of type `DINT`.
- **Control Logic**: Triggering an action once two values of type `DINT` satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `DINT`-based comparison condition.

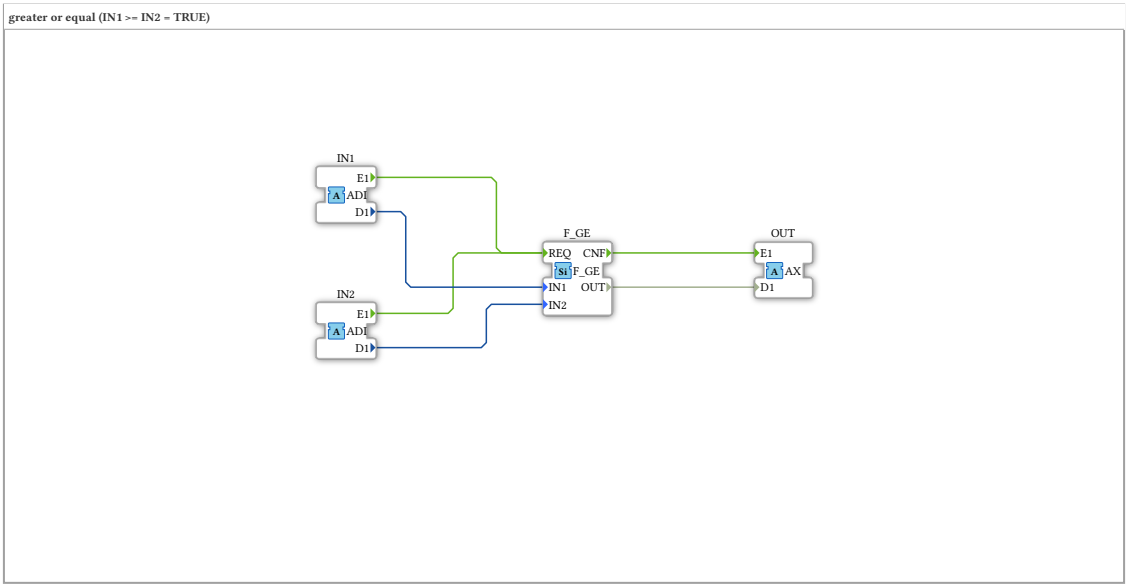
Comparison with Similar Function Blocks



- **ADI_NE**: Checks for “not equal to” – the inverse function of ADI_EQ.
- **ADI_NE**: Checks for inequality of values.

ADI_EQ is part of the complete ADI comparison family (EQ/NE/GT/GE/LT/LE) for the `DINT` data type.

Conclusion



ADI_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the `DINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ADI_GE

Input value 1 -- left operand (IN1 >= IN2) – *ADI*
Input value 2 -- right operand (IN1 >= IN2) – *ADI*

AX – IN1 >= IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ADI_GE** compares two values of type `DINT` (32-bit signed integer) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `DINT`, 32-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`ADI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`ADI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `ADI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GE` (type `iec61131::comparison::F_GE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`ADI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the `DINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

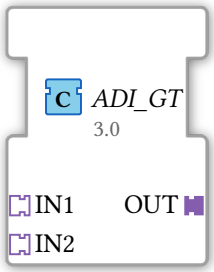
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking counter and position values against a reference or threshold value of type `DINT`.
- **Control Logic**: Triggering an action once two values of type `DINT` satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `DINT`-based comparison condition.

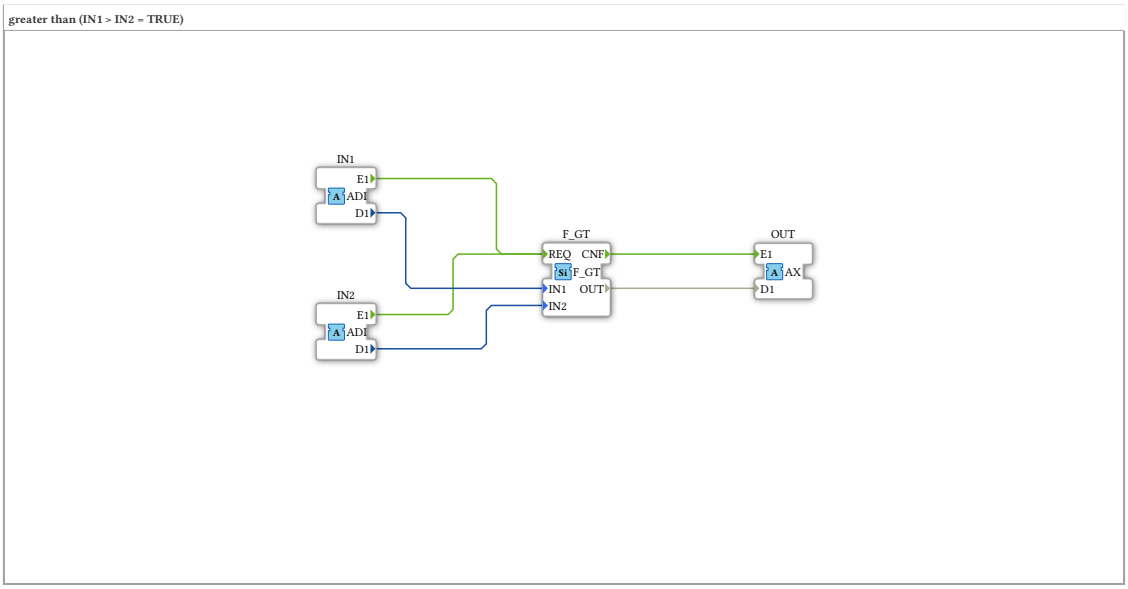
Comparison with Similar Function Blocks



- **ADI_LE**: Checks for “less than or equal to” – the inverse function of ADI_GE.
- **ADI_EQ**: Checks for equality of values.
- **ADI_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which ADI_GE is the extended version.

ADI_GE completes the ADI comparison family with the boundary case of equality.

Conclusion



ADI_GE is a simple yet important comparison block for IEC 61131-3 control applications using the `DINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ADI_GT

Input value 1 -- left operand (IN1 > IN2) – *ADI*
Input value 2 -- right operand (IN1 > IN2) – *ADI*

AX – IN1 > IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ADI_GT** compares two values of type `DINT` (32-bit signed integer) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `DINT`, 32-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	ADI (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	ADI (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters ADI and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GT (type iec61131::comparison::F_GT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (ADI/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the DINT data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

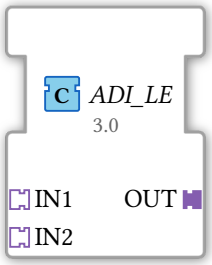
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking counter and position values against a reference or threshold value of type DINT.
- **Control Logic**: Triggering an action once two values of type DINT satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a DINT-based comparison condition.

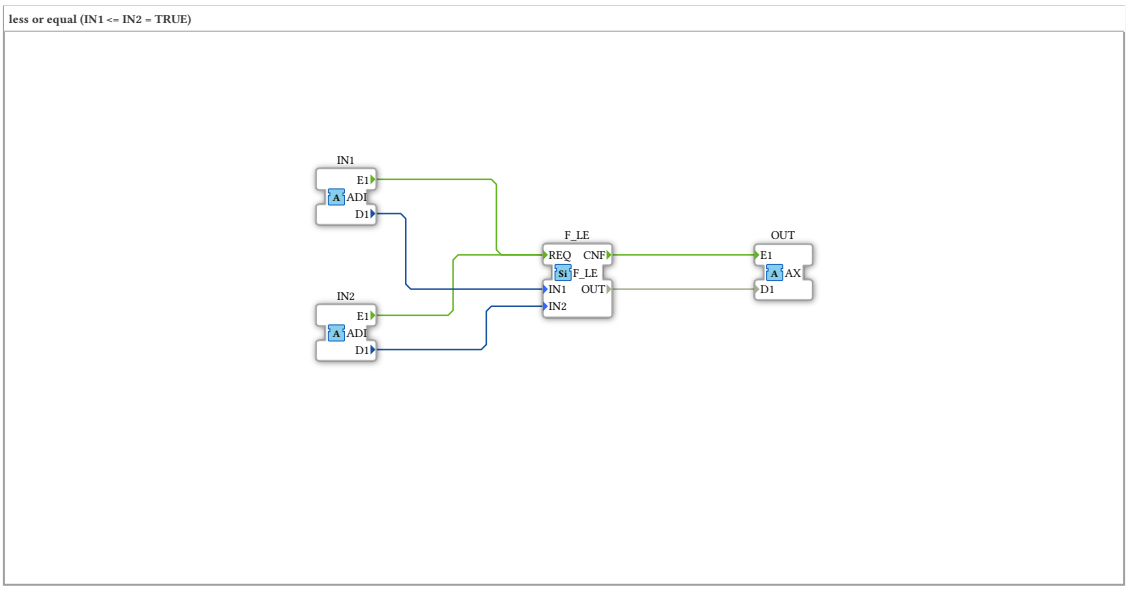
Comparison with Similar Function Blocks



- **ADI_LT**: Checks for “less than” – the inverse function of ADI_GT.
- **ADI_EQ**: Checks for equality of values.
- **ADI_GE**: Performs the “greater than or equal to” comparison – the extended version of ADI_GT that includes the equality case.

ADI_GT is the basic “greater than” component without the equality case, complemented by ADI_GE.

Conclusion



ADI_GT is a simple yet important comparison block for IEC 61131-3 control applications using the DINT data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ADI_LE

Input value 1 -- left operand (IN1 <= IN2) – *ADI*
Input value 2 -- right operand (IN1 <= IN2) – *ADI*

AX – IN1 <= IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ADI_LE** compares two values of type `DINT` (32-bit signed integer) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `DINT`, 32-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`ADI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`ADI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `ADI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LE` (type `iec61131::comparison::F_LE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`ADI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the `DINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

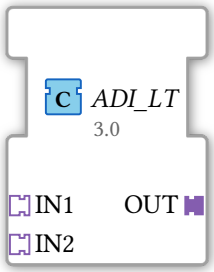
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking counter and position values against a reference or threshold value of type `DINT`.
- **Control Logic**: Triggering an action once two values of type `DINT` satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `DINT`-based comparison condition.

Comparison with Similar Function Blocks

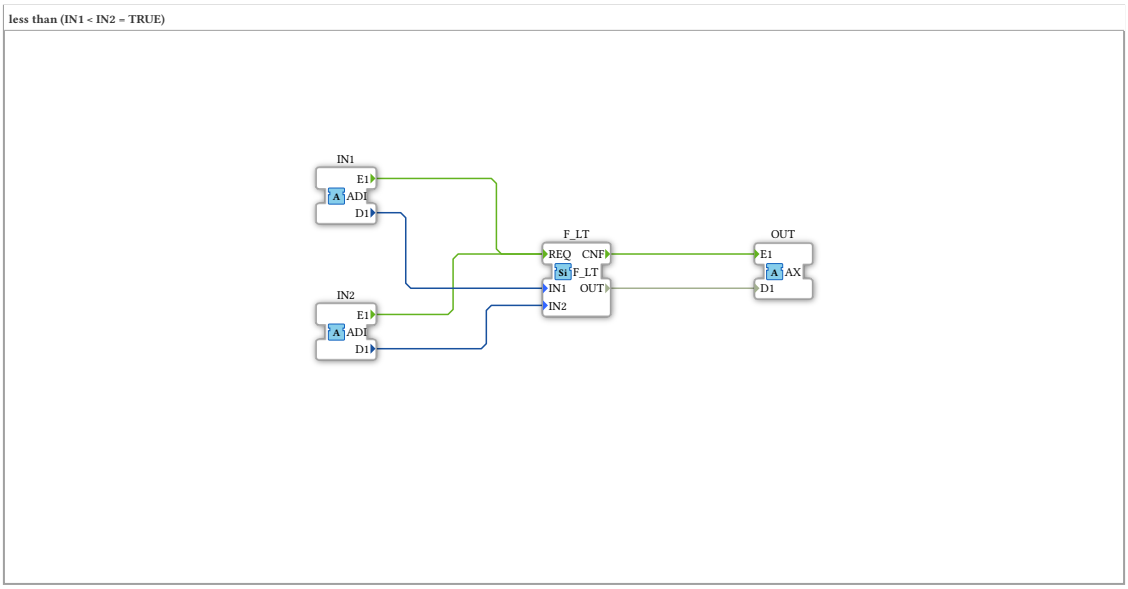


- **ADI_GE**: Checks for “greater than or equal to” – the inverse function of ADI_LE.
- **ADI_EQ**: Checks for equality of values.
- **ADI_LT**: Performs the “less than” comparison – the base variant without the equality case, of which ADI_LE is the extended version.

ADI_LE completes the ADI comparison family with the boundary case of equality.

Conclusion

ADI_LE is a simple yet important comparison block for IEC 61131-3 control applications using the `DINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.



ADI_LT

Input value 1 -- left operand (IN1 < IN2) – *ADI*

Input value 2 -- right operand (IN1 < IN2) – *ADI*

AX – IN1 < IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ADI_LT** compares two values of type `DINT` (32-bit signed integer) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `DINT`, 32-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`ADI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`ADI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `ADI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LT` (type `iec61131::comparison::F_LT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`ADI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the `DINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

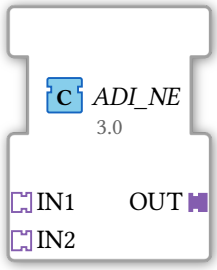
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking counter and position values against a reference or threshold value of type `DINT`.
- **Control Logic**: Triggering an action once two values of type `DINT` satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `DINT`-based comparison condition.

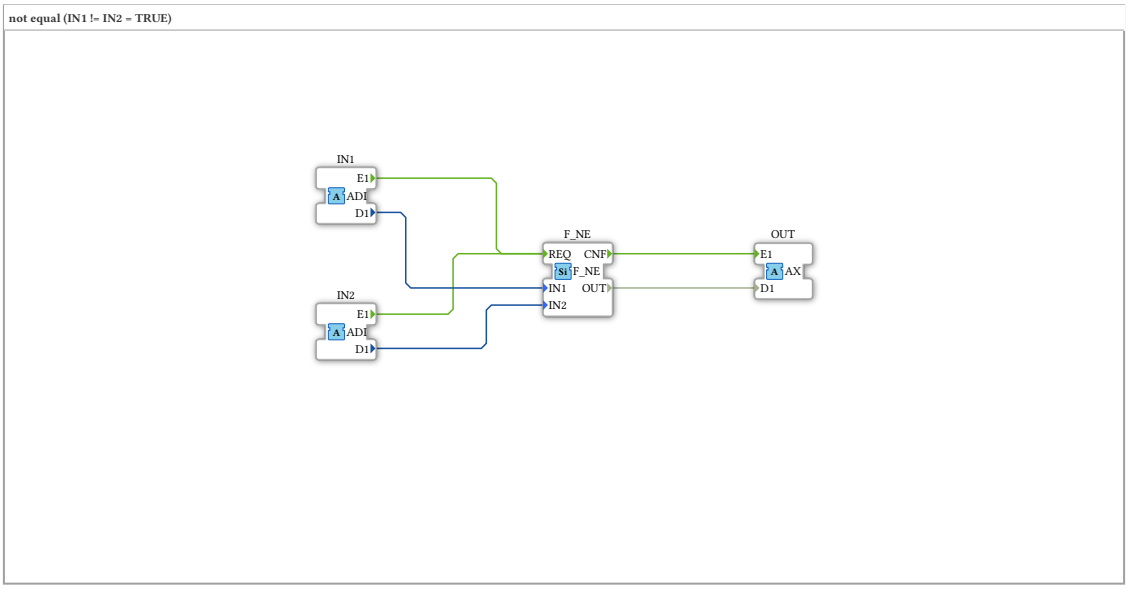
Comparison with Similar Function Blocks



- **ADI_GT**: Checks for “greater than” – the inverse function of ADI_LT.
- **ADI_EQ**: Checks for equality of values.
- **ADI_LE**: Performs the “less than or equal to” comparison – the extended version of ADI_LT that includes the equality case.

ADI_LT is the basic “less than” component without the equality case, complemented by ADI_LE.

Conclusion



ADI_LT is a simple yet important comparison block for IEC 61131-3 control applications using the `DINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ADI_NE

Input value 1 -- left operand (IN1 != IN2) – *ADI*
Input value 2 -- right operand (IN1 != IN2) – *ADI*

AX – IN1 != IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ADI_NE** compares two values of type `DINT` (32-bit signed integer) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `DINT`, 32-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`ADI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`ADI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `ADI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_NE` (type `iec61131::comparison::F_NE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`ADI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the `DINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

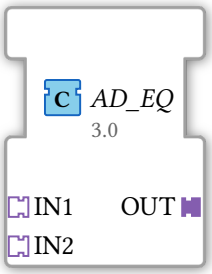
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking counter and position values against a reference or threshold value of type `DINT`.
- **Control Logic**: Triggering an action once two values of type `DINT` satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `DINT`-based comparison condition.

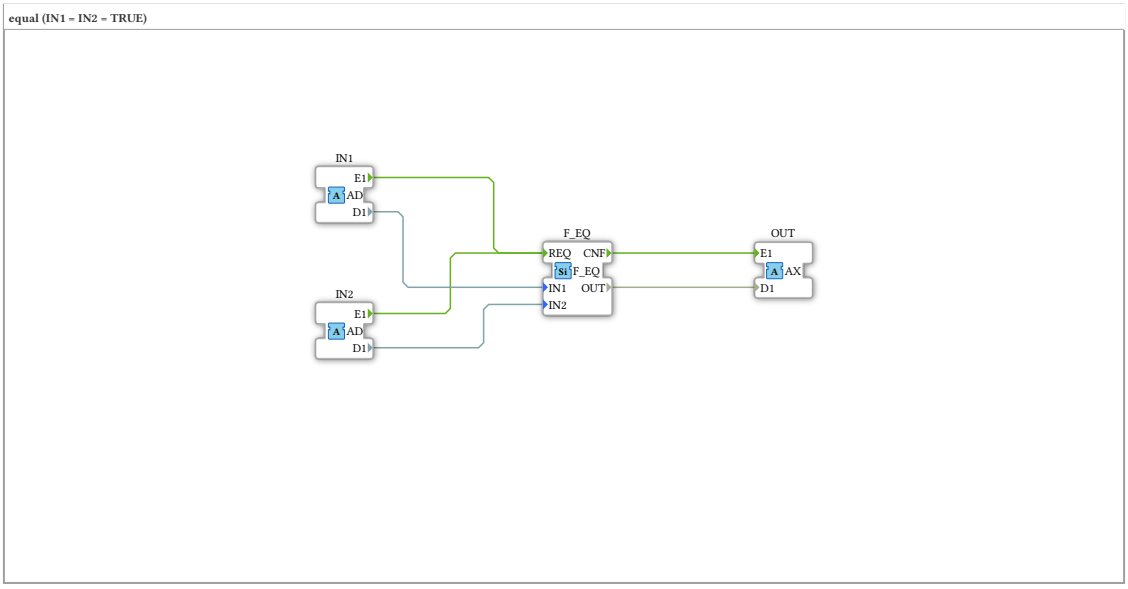
Comparison with Similar Function Blocks



- **ADI_EQ**: Checks for “equal to” – the inverse function of ADI_NE.
- **ADI_EQ**: Checks for equality of values.

ADI_NE is part of the complete ADI comparison family (EQ/NE/GT/GE/LT/LE) for the `DINT` data type.

Conclusion



ADI_NE is a simple yet important comparison block for IEC 61131-3 control applications using the `DINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AD_EQ

Input value 1 -- left operand (IN1 = IN2) – *AD*
Input value 2 -- right operand (IN1 = IN2) – *AD*

AX – IN1 = IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AD_EQ** compares two values of type `DWORD` (32-bit bit pattern (double word)) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `DWORD`, 32-bit bit pattern (double word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AD (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AD (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AD and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_EQ (type iec61131::comparison::F_EQ). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AD/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the DWORD data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

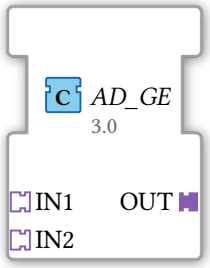
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

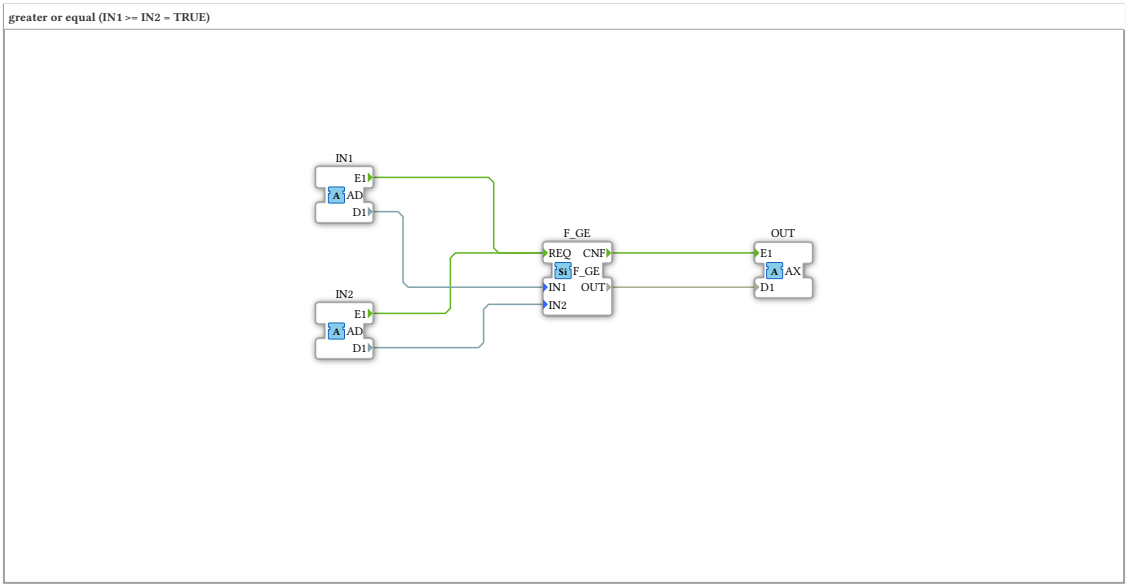
- **Limit Monitoring**: Checking bit masks against a reference or threshold value of type DWORD.
- **Control Logic**: Triggering an action once two values of type DWORD satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a DWORD-based comparison condition.

Comparison with Similar Function Blocks



- **AD_NE**: Checks for “not equal to” – the inverse function of AD_EQ.
- **AD_NE**: Checks for inequality of values.

AD_EQ is part of the complete AD comparison family (EQ/NE/GT/GE/LT/LE) for the DWORD data type.



Conclusion

AD_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the DWORD data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AD_GE

Input value 1 -- left operand (IN1 >= IN2) – *AD*
Input value 2 -- right operand (IN1 >= IN2) – *AD*
AX – IN1 >= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AD_GE** compares two values of type `DWORD` (32-bit bit pattern (double word)) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `DWORD`, 32-bit bit pattern (double word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AD (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AD (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AD and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GE (type iec61131::comparison::F_GE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AD/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the DWORD data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

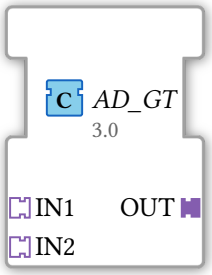
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking bit masks against a reference or threshold value of type DWORD.
- **Control Logic**: Triggering an action once two values of type DWORD satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a DWORD-based comparison condition.

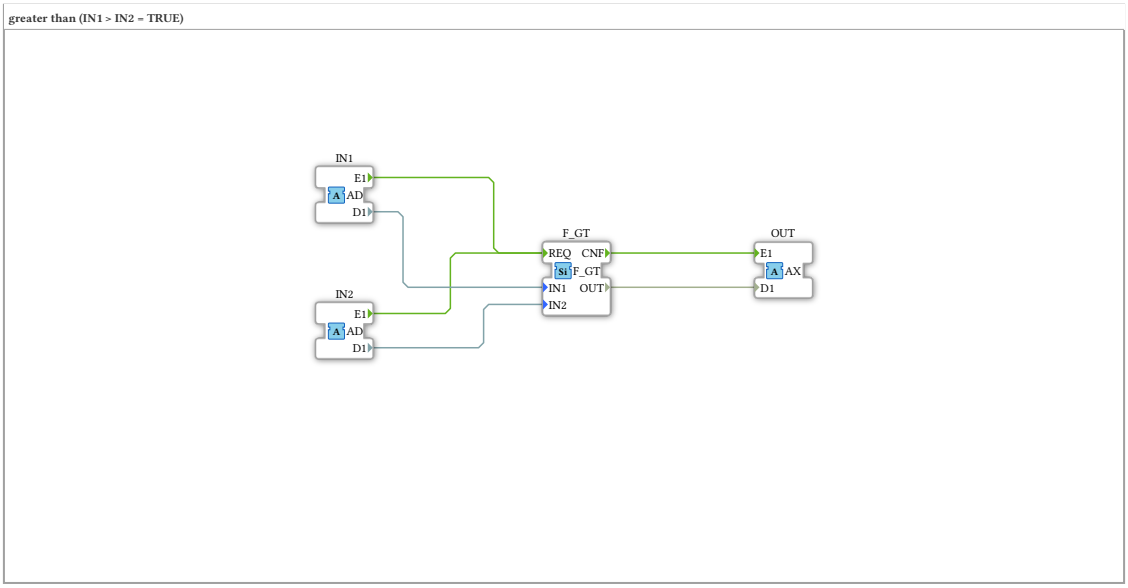
Comparison with Similar Function Blocks



- **AD_LE**: Checks for “less than or equal to” – the inverse function of AD_GE.
- **AD_EQ**: Checks for equality of values.
- **AD_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which AD_GE is the extended version.

AD_GE completes the AD comparison family with the boundary case of equality.

Conclusion



AD_GE is a simple yet important comparison block for IEC 61131-3 control applications using the DWORD data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AD_GT

Input value 1 -- left operand (IN1 > IN2) – *AD*
Input value 2 -- right operand (IN1 > IN2) – *AD*

AX – IN1 > IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AD_GT** compares two values of type `DWORD` (32-bit bit pattern (double word)) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `DWORD`, 32-bit bit pattern (double word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AD (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AD (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AD and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GT (type iec61131::comparison::F_GT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AD/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the DWORD data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

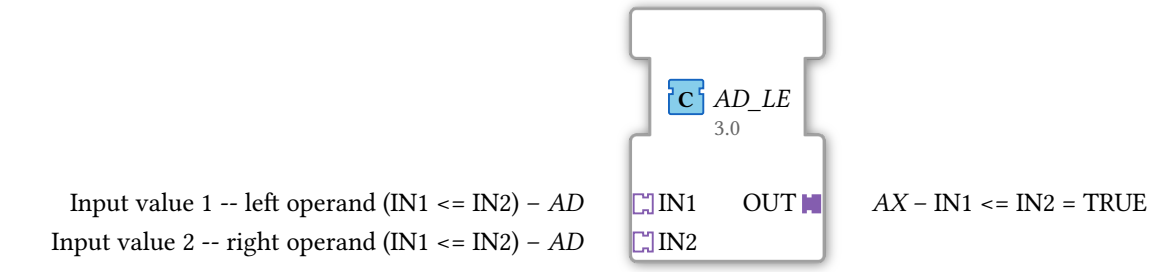
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

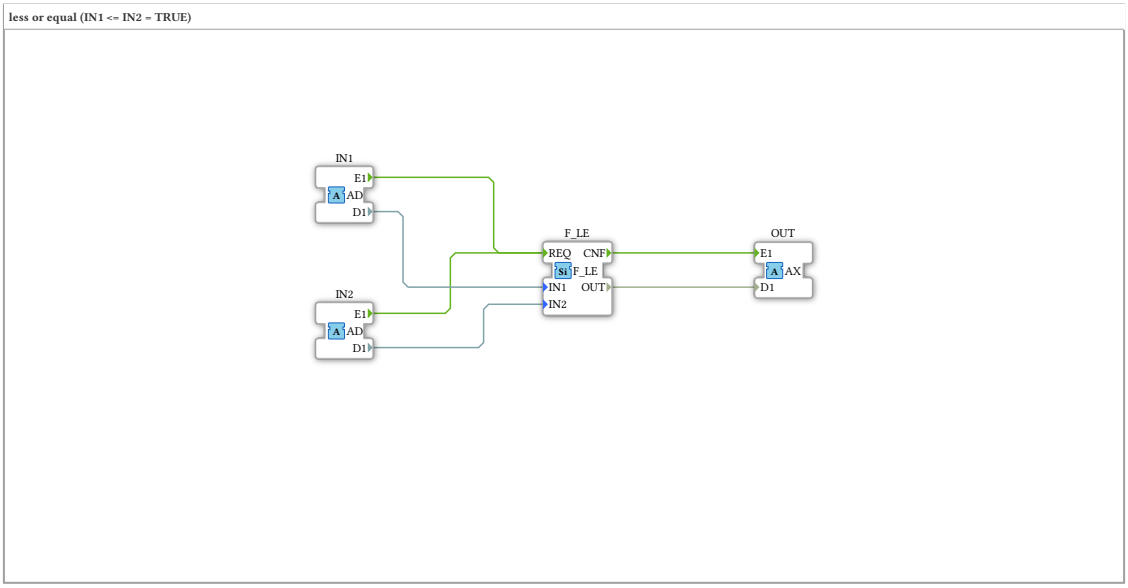
Application Scenarios

- **Limit Monitoring**: Checking bit masks against a reference or threshold value of type DWORD.
- **Control Logic**: Triggering an action once two values of type DWORD satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a DWORD-based comparison condition.

Comparison with Similar Function Blocks



- **AD_LT**: Checks for “less than” – the inverse function of AD_GT.
- **AD_EQ**: Checks for equality of values.
- **AD_GE**: Performs the “greater than or equal to” comparison – the extended version of AD_GT that includes the equality case.



AD_GT is the basic “greater than” component without the equality case, complemented by AD_GE.

Conclusion

AD_GT is a simple yet important comparison block for IEC 61131-3 control applications using the DWORD data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AD_LE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AD_LE** compares two values of type `DWORD` (32-bit bit pattern (double word)) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `DWORD`, 32-bit bit pattern (double word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AD (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AD (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AD and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LE (type iec61131::comparison::F_LE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AD/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the DWORD data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

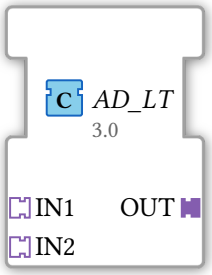
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking bit masks against a reference or threshold value of type DWORD.
- **Control Logic**: Triggering an action once two values of type DWORD satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a DWORD-based comparison condition.

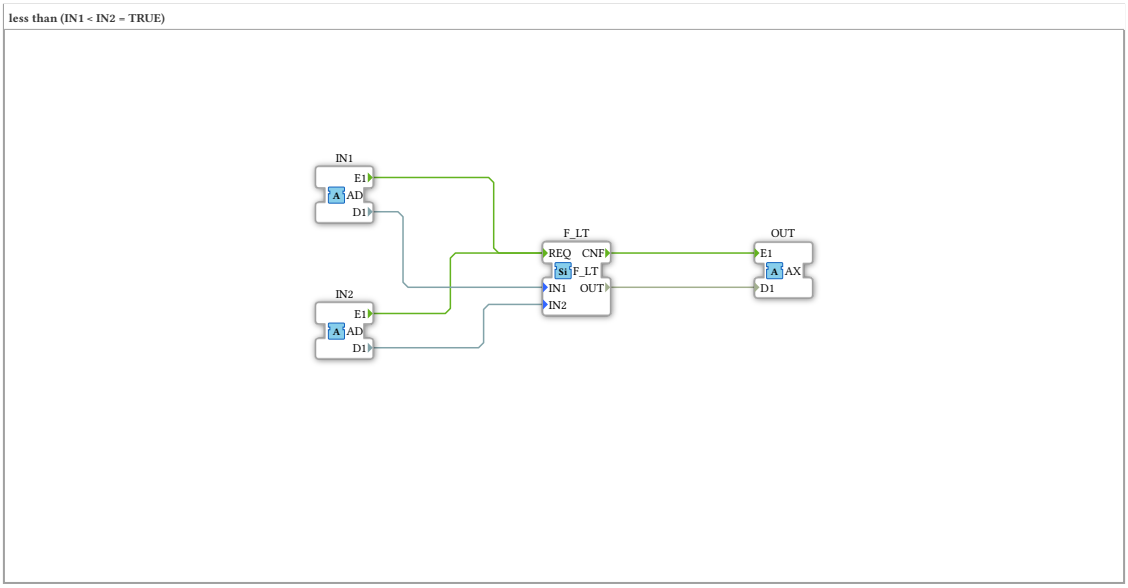
Comparison with Similar Function Blocks



- **AD_GE**: Checks for “greater than or equal to” – the inverse function of AD_LE.
- **AD_EQ**: Checks for equality of values.
- **AD_LT**: Performs the “less than” comparison – the base variant without the equality case, of which AD_LE is the extended version.

AD_LE completes the AD comparison family with the boundary case of equality.

Conclusion



AD_LE is a simple yet important comparison block for IEC 61131-3 control applications using the DWORD data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AD_LT

Input value 1 -- left operand (IN1 < IN2) – *AD*
Input value 2 -- right operand (IN1 < IN2) – *AD*

AX – IN1 < IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AD_LT** compares two values of type `DWORD` (32-bit bit pattern (double word)) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `DWORD`, 32-bit bit pattern (double word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AD (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AD (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AD and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LT (type iec61131::comparison::F_LT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AD/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the DWORD data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

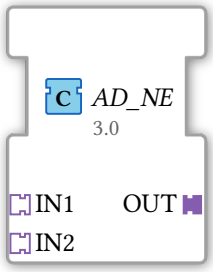
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking bit masks against a reference or threshold value of type DWORD.
- **Control Logic**: Triggering an action once two values of type DWORD satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a DWORD-based comparison condition.

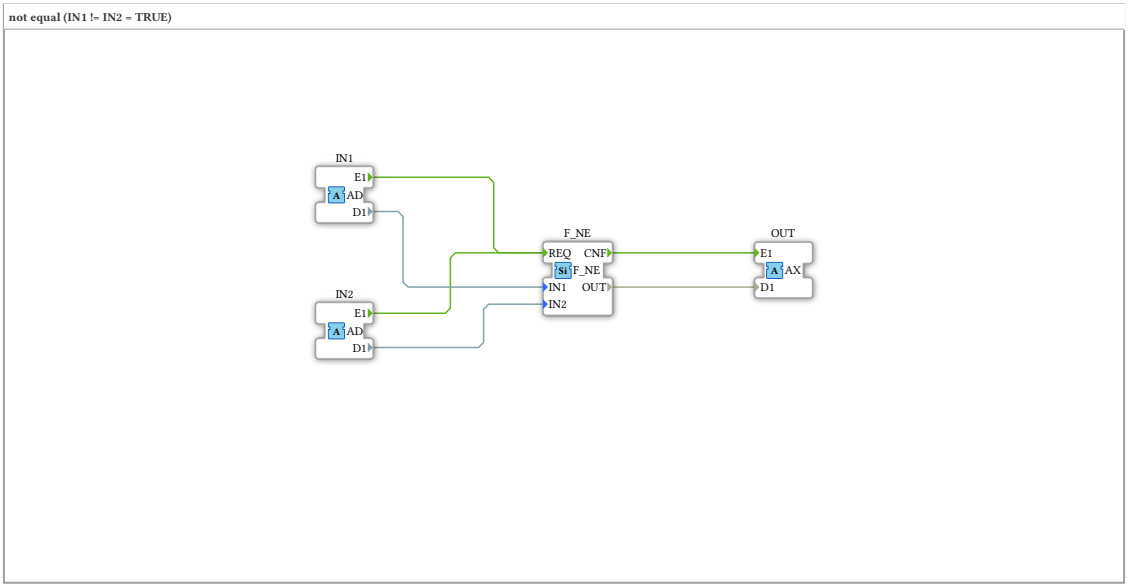
Comparison with Similar Function Blocks



- **AD_GT**: Checks for “greater than” – the inverse function of AD_LT.
- **AD_EQ**: Checks for equality of values.
- **AD_LE**: Performs the “less than or equal to” comparison – the extended version of AD_LT that includes the equality case.

AD_LT is the basic “less than” component without the equality case, complemented by AD_LE.

Conclusion



AD_LT is a simple yet important comparison block for IEC 61131-3 control applications using the DWORD data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AD_NE

Input value 1 -- left operand (IN1 != IN2) – *AD*
Input value 2 -- right operand (IN1 != IN2) – *AD*

AX – IN1 != IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AD_NE** compares two values of type `DWORD` (32-bit bit pattern (double word)) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `DWORD`, 32-bit bit pattern (double word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AD (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AD (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AD and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_NE (type iec61131::comparison::F_NE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AD/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the DWORD data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

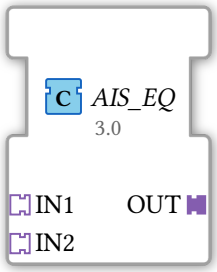
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking bit masks against a reference or threshold value of type DWORD.
- **Control Logic**: Triggering an action once two values of type DWORD satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a DWORD-based comparison condition.

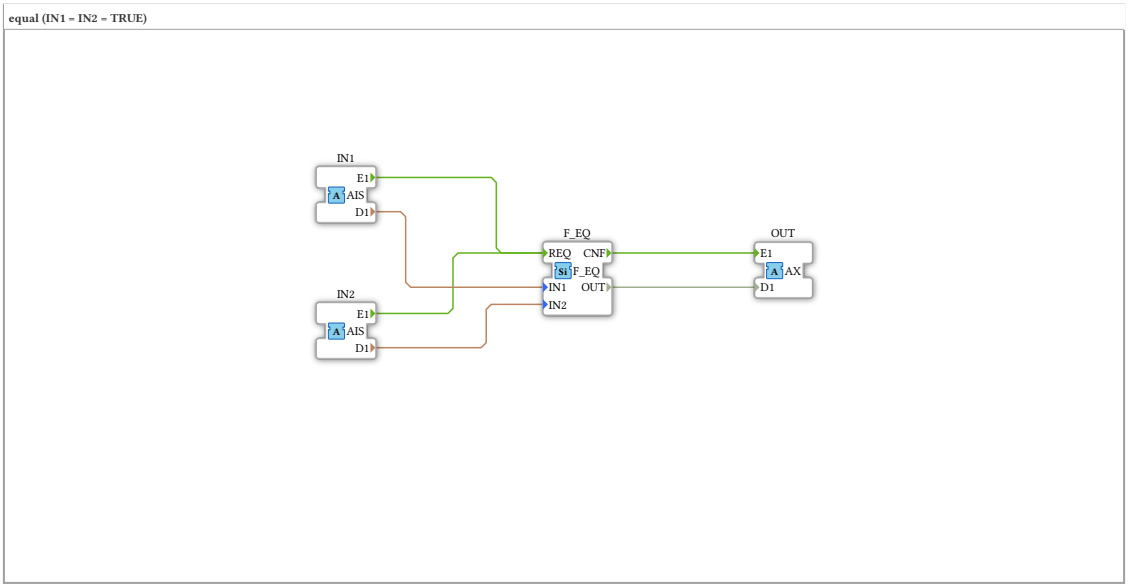
Comparison with Similar Function Blocks



- **AD_EQ**: Checks for “equal to” – the inverse function of AD_NE.
- **AD_EQ**: Checks for equality of values.

AD_NE is part of the complete AD comparison family (EQ/NE/GT/GE/LT/LE) for the DWORD data type.

Conclusion



AD_NE is a simple yet important comparison block for IEC 61131-3 control applications using the DWORD data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AIS_EQ

Input value 1 -- left operand (IN1 = IN2) – *AIS*
Input value 2 -- right operand (IN1 = IN2) – *AIS*

AX – IN1 = IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIS_EQ** compares two values of type `STRING` (character string) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison is performed lexicographically (character by character) according to the character encoding.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `STRING`, character string).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AIS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AIS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AIS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_EQ` (type `iec61131::comparison::F_EQ`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AIS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the `STRING` data type.
- **Comparison logic**: The comparison is performed lexicographically (character by character) according to the character encoding.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

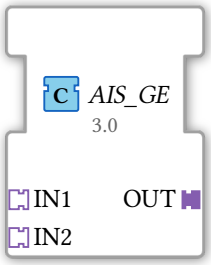
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking recipe and text identifiers against a reference or threshold value of type `STRING`.
- **Control Logic**: Triggering an action once two values of type `STRING` satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `STRING`-based comparison condition.

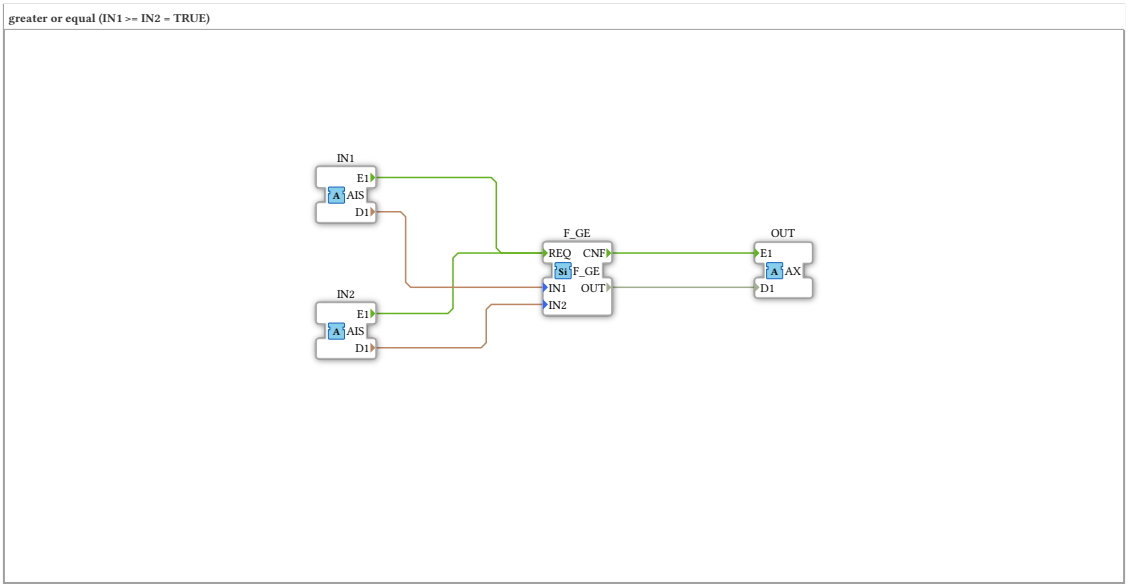
Comparison with Similar Function Blocks



- **AIS_NE**: Checks for “not equal to” – the inverse function of AIS_EQ.
- **AIS_NE**: Checks for inequality of values.

AIS_EQ is part of the complete AIS comparison family (EQ/NE/GT/GE/LT/LE) for the `STRING` data type.

Conclusion



AIS_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the `STRING` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AIS_GE

Input value 1 -- left operand (IN1 >= IN2) – *AIS*
Input value 2 -- right operand (IN1 >= IN2) – *AIS*

AX – IN1 >= IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AIS_GE** compares two values of type `STRING` (character string) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison is performed lexicographically (character by character) according to the character encoding.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `STRING`, character string).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AIS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AIS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AIS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GE` (type `iec61131::comparison::F_GE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AIS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the `STRING` data type.
- **Comparison logic**: The comparison is performed lexicographically (character by character) according to the character encoding.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

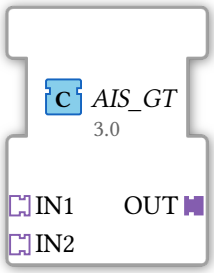
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking recipe and text identifiers against a reference or threshold value of type `STRING`.
- **Control Logic**: Triggering an action once two values of type `STRING` satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `STRING`-based comparison condition.

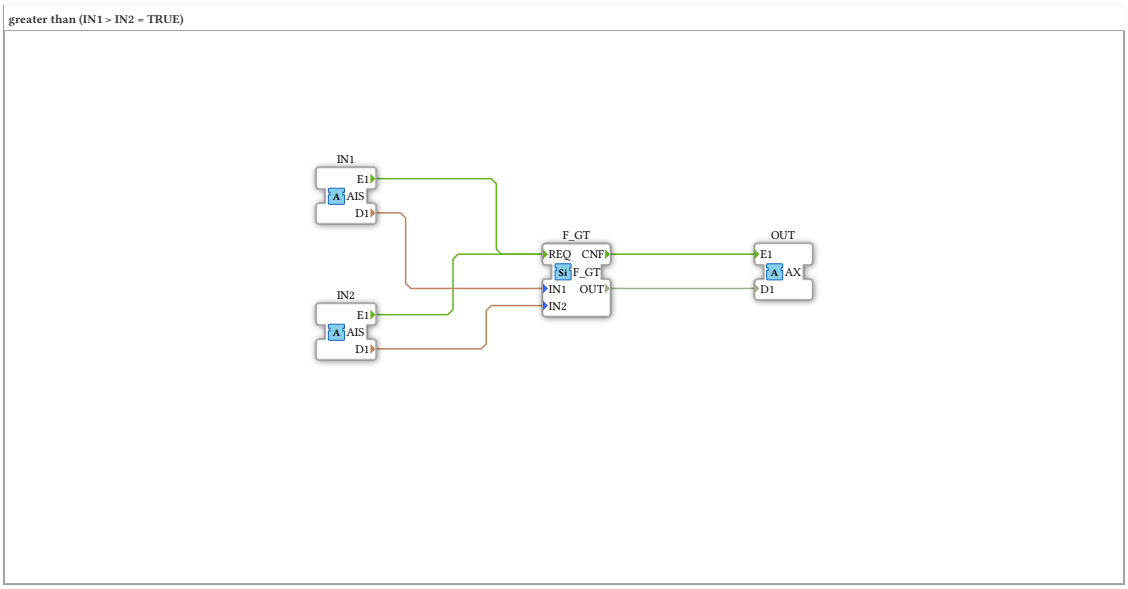
Comparison with Similar Function Blocks



- **AIS_LE**: Checks for “less than or equal to” – the inverse function of AIS_GE.
- **AIS_EQ**: Checks for equality of values.
- **AIS_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which AIS_GE is the extended version.

AIS_GE completes the AIS comparison family with the boundary case of equality.

Conclusion



AIS_GE is a simple yet important comparison block for IEC 61131-3 control applications using the `STRING` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AIS_GT

Input value 1 -- left operand (IN1 > IN2) – *AIS*
Input value 2 -- right operand (IN1 > IN2) – *AIS*

AX – IN1 > IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AIS_GT** compares two values of type `STRING` (character string) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison is performed lexicographically (character by character) according to the character encoding.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `STRING`, character string).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AIS (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AIS (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AIS and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GT (type iec61131::comparison::F_GT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AIS/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 ("greater than") for the STRING data type.
- **Comparison logic**: The comparison is performed lexicographically (character by character) according to the character encoding.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

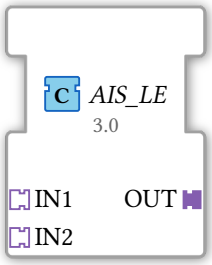
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking recipe and text identifiers against a reference or threshold value of type STRING.
- **Control Logic**: Triggering an action once two values of type STRING satisfy the "greater than" condition.
- **Data Filtering**: Selecting data records or signals that satisfy a STRING-based comparison condition.

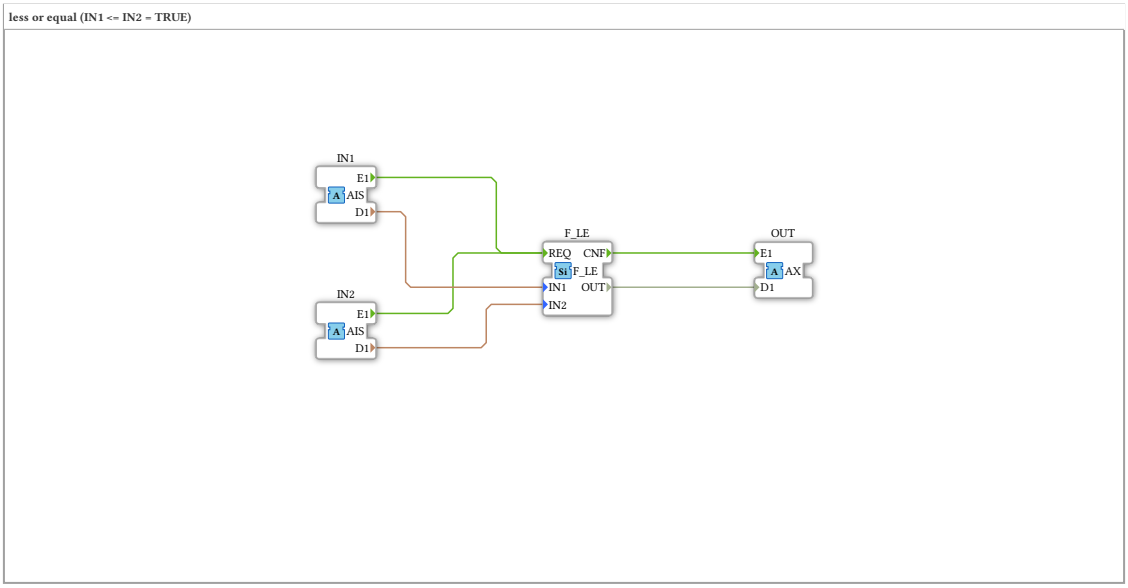
Comparison with Similar Function Blocks



- **AIS_LT**: Checks for "less than" – the inverse function of AIS_GT.
- **AIS_EQ**: Checks for equality of values.
- **AIS_GE**: Performs the "greater than or equal to" comparison – the extended version of AIS_GT that includes the equality case.

AIS_GT is the basic "greater than" component without the equality case, complemented by AIS_GE.

Conclusion



AIS_GT is a simple yet important comparison block for IEC 61131-3 control applications using the STRING data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AIS_LE

Input value 1 -- left operand (IN1 <= IN2) – *AIS*
Input value 2 -- right operand (IN1 <= IN2) – *AIS*

AX – IN1 <= IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AIS_LE** compares two values of type `STRING` (character string) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison is performed lexicographically (character by character) according to the character encoding.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `STRING`, character string).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AIS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AIS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AIS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LE` (type `iec61131::comparison::F_LE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AIS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the `STRING` data type.
- **Comparison logic**: The comparison is performed lexicographically (character by character) according to the character encoding.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

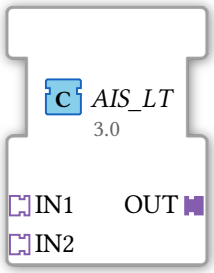
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking recipe and text identifiers against a reference or threshold value of type `STRING`.
- **Control Logic**: Triggering an action once two values of type `STRING` satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `STRING`-based comparison condition.

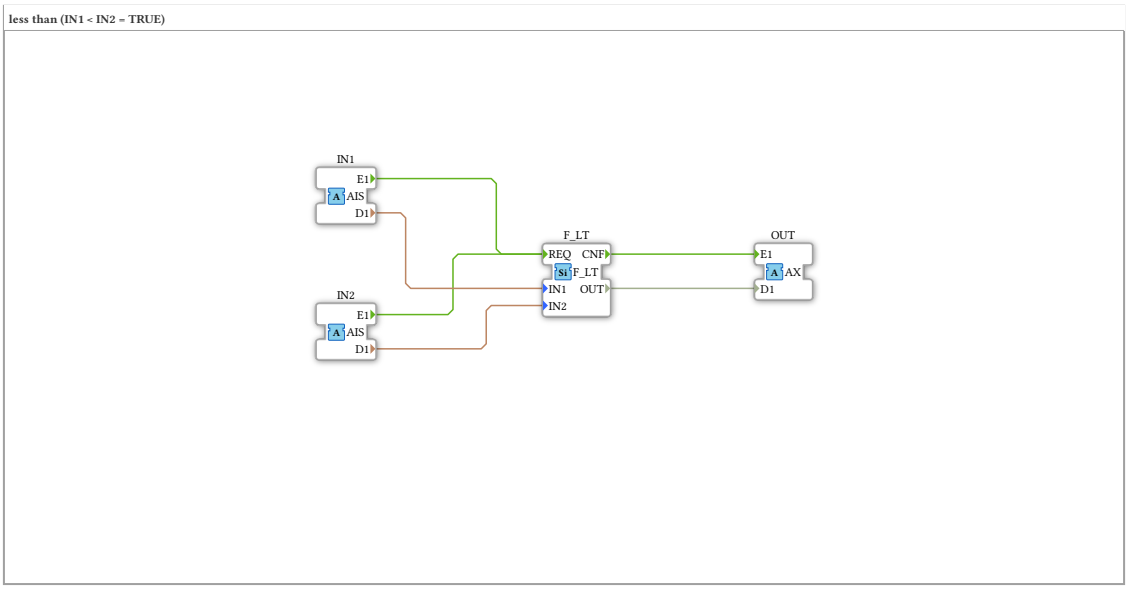
Comparison with Similar Function Blocks



- **AIS_GE**: Checks for “greater than or equal to” – the inverse function of AIS_LE.
- **AIS_EQ**: Checks for equality of values.
- **AIS_LT**: Performs the “less than” comparison – the base variant without the equality case, of which AIS_LE is the extended version.

AIS_LE completes the AIS comparison family with the boundary case of equality.

Conclusion



AIS_LE is a simple yet important comparison block for IEC 61131-3 control applications using the `STRING` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AIS_LT

Input value 1 -- left operand (IN1 < IN2) – *AIS*
Input value 2 -- right operand (IN1 < IN2) – *AIS*

AX – IN1 < IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AIS_LT** compares two values of type `STRING` (character string) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison is performed lexicographically (character by character) according to the character encoding.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `STRING`, character string).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AIS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AIS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AIS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LT` (type `iec61131::comparison::F_LT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AIS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the `STRING` data type.
- **Comparison logic**: The comparison is performed lexicographically (character by character) according to the character encoding.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

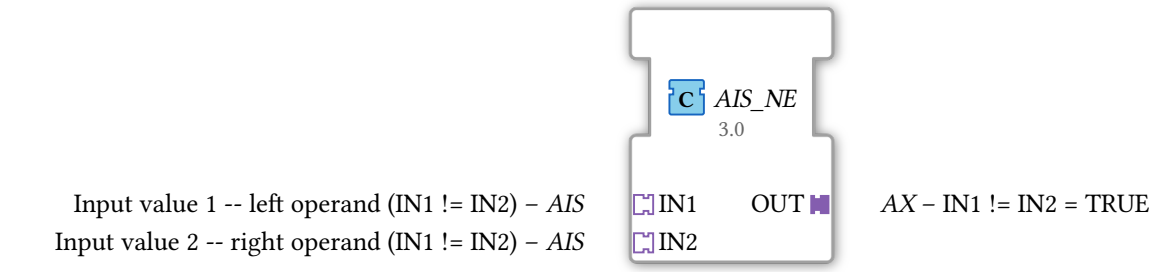
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

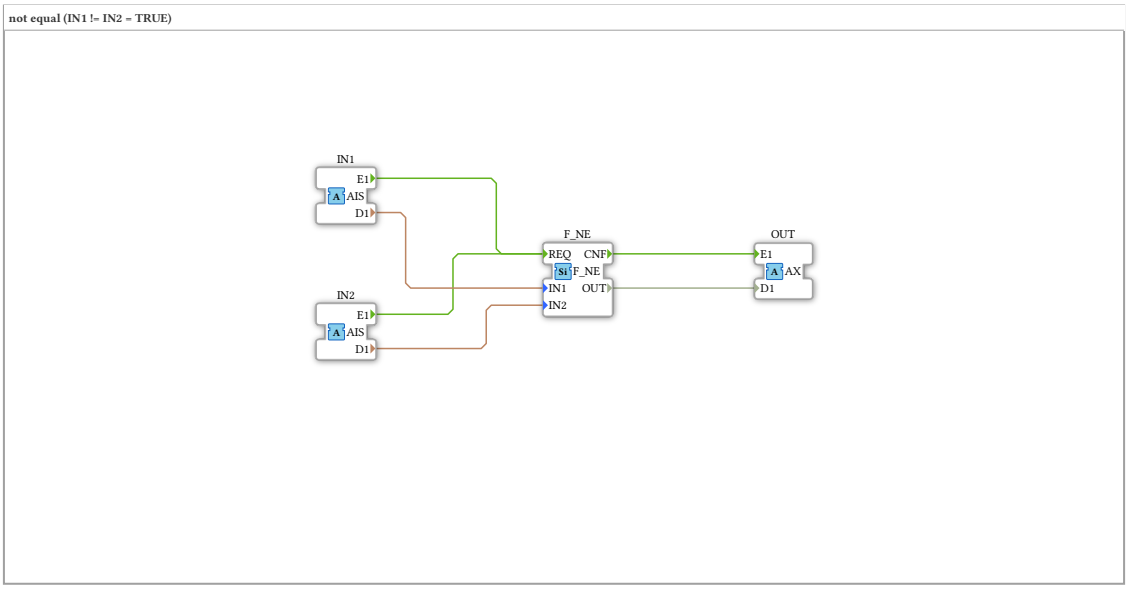
Application Scenarios

- **Limit Monitoring**: Checking recipe and text identifiers against a reference or threshold value of type `STRING`.
- **Control Logic**: Triggering an action once two values of type `STRING` satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `STRING`-based comparison condition.

Comparison with Similar Function Blocks



- **AIS_GT**: Checks for “greater than” – the inverse function of AIS_LT.
- **AIS_EQ**: Checks for equality of values.
- **AIS_LE**: Performs the “less than or equal to” comparison – the extended version of AIS_LT that includes the equality case.



AIS_LT is the basic “less than” component without the equality case, complemented by AIS_LE.

Conclusion

AIS_LT is a simple yet important comparison block for IEC 61131-3 control applications using the `STRING` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AIS_NE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIS_NE** compares two values of type `STRING` (character string) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison is performed lexicographically (character by character) according to the character encoding.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `STRING`, character string).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AIS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AIS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AIS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_NE` (type `iec61131::comparison::F_NE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AIS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the `STRING` data type.
- **Comparison logic**: The comparison is performed lexicographically (character by character) according to the character encoding.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

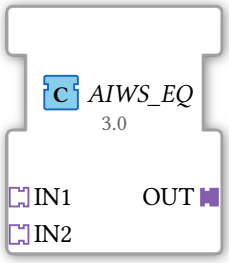
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking recipe and text identifiers against a reference or threshold value of type `STRING`.
- **Control Logic**: Triggering an action once two values of type `STRING` satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `STRING`-based comparison condition.

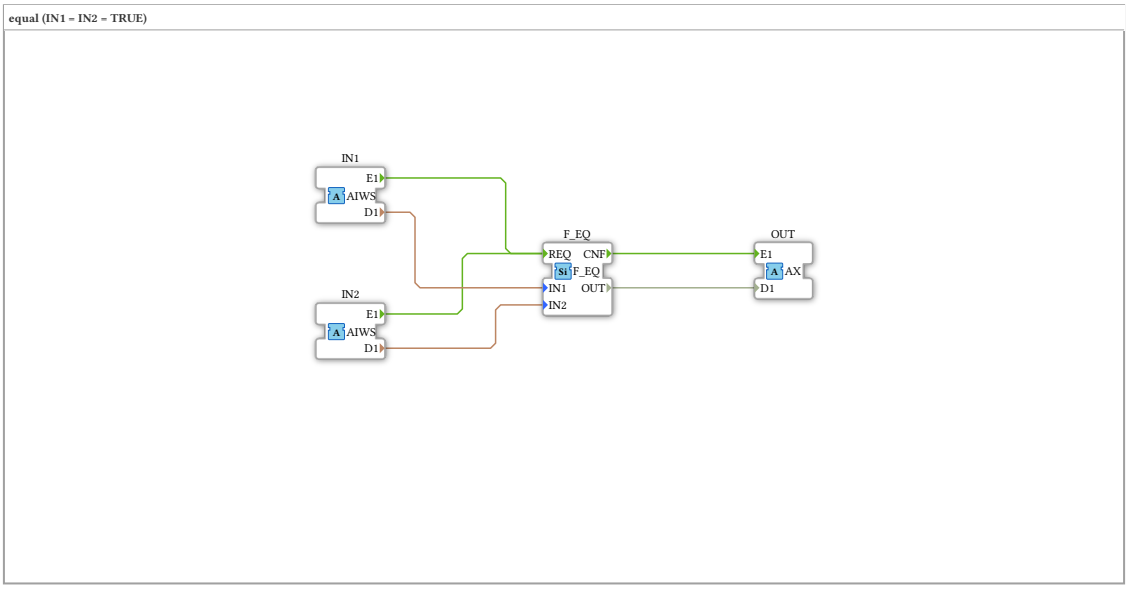
Comparison with Similar Function Blocks



- **AIS_EQ**: Checks for “equal to” – the inverse function of AIS_NE.
- **AIS_EQ**: Checks for equality of values.

AIS_NE is part of the complete AIS comparison family (EQ/NE/GT/GE/LT/LE) for the `STRING` data type.

Conclusion



AIS_NE is a simple yet important comparison block for IEC 61131-3 control applications using the `STRING` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AIWS_EQ

Input value 1 -- left operand (IN1 = IN2) – *AIWS*
Input value 2 -- right operand (IN1 = IN2) – *AIWS*

AX – IN1 = IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AIWS_EQ** compares two values of type `WSTRING` (wide (Unicode) character string) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison is performed lexicographically (character by character) according to the character encoding.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `WSTRING`, wide (Unicode) character string).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AIWS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AIWS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AIWS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_EQ` (type `iec61131::comparison::F_EQ`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AIWS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the `WSTRING` data type.
- **Comparison logic**: The comparison is performed lexicographically (character by character) according to the character encoding.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

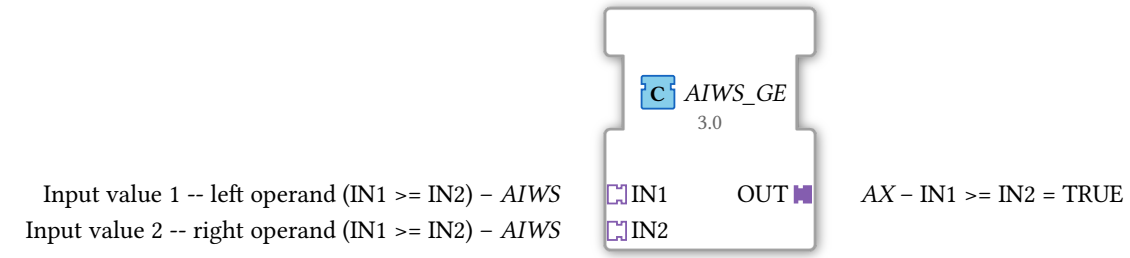
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

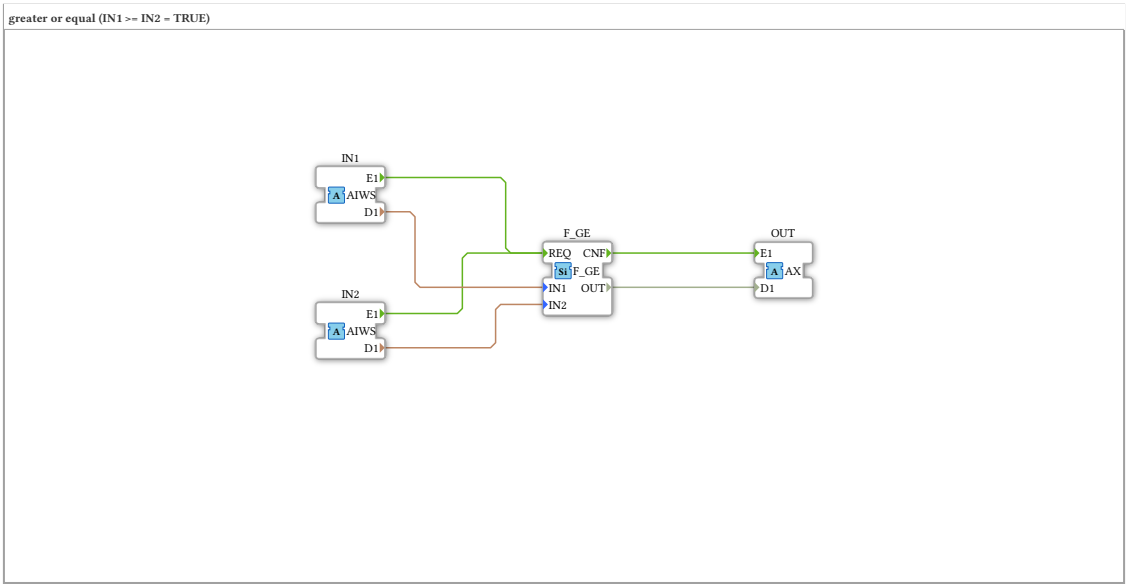
Application Scenarios

- **Limit Monitoring**: Checking multilingual text identifiers against a reference or threshold value of type `WSTRING`.
- **Control Logic**: Triggering an action once two values of type `WSTRING` satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `WSTRING`-based comparison condition.

Comparison with Similar Function Blocks



- **AIWS_NE**: Checks for “not equal to” – the inverse function of AIWS_EQ.
- **AIWS_NE**: Checks for inequality of values.



AIWS_EQ is part of the complete AIWS comparison family (EQ/NE/GT/GE/LT/LE) for the `WSTRING` data type.

Conclusion

AIWS_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the `WSTRING` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AIWS_GE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIWS_GE** compares two values of type `WSTRING` (wide (Unicode) character string) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison is performed lexicographically (character by character) according to the character encoding.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `WSTRING`, wide (Unicode) character string).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AIWS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AIWS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AIWS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GE` (type `iec61131::comparison::F_GE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AIWS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the `WSTRING` data type.
- **Comparison logic**: The comparison is performed lexicographically (character by character) according to the character encoding.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

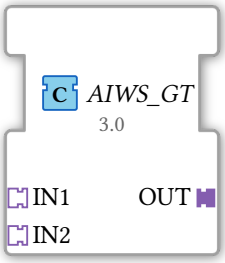
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking multilingual text identifiers against a reference or threshold value of type `WSTRING`.
- **Control Logic**: Triggering an action once two values of type `WSTRING` satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `WSTRING`-based comparison condition.

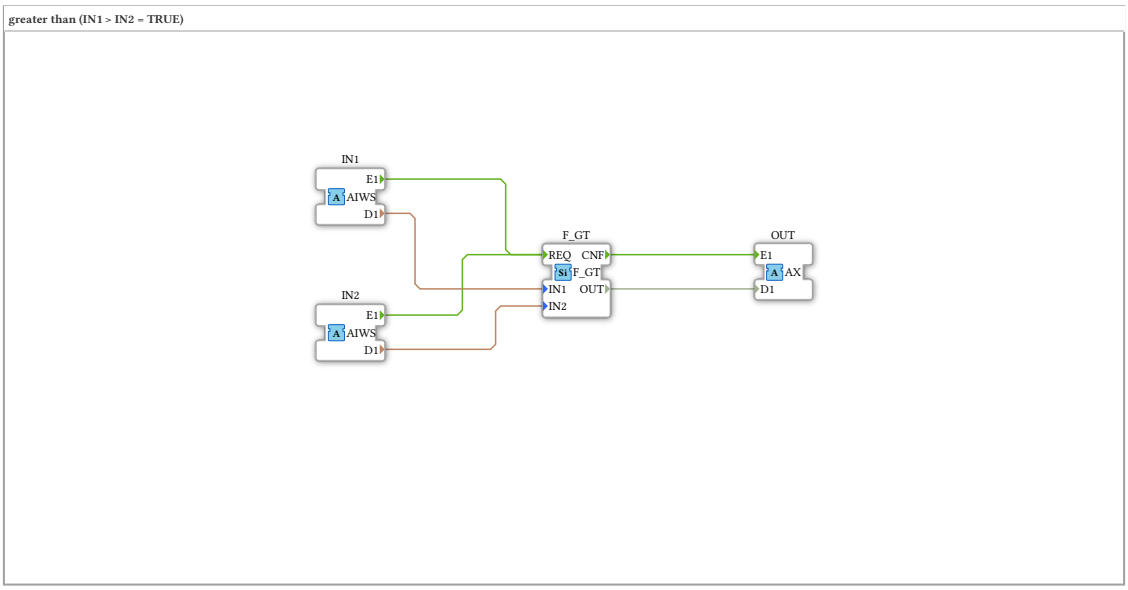
Comparison with Similar Function Blocks



- **AIWS_LE**: Checks for “less than or equal to” – the inverse function of AIWS_GE.
- **AIWS_EQ**: Checks for equality of values.
- **AIWS_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which AIWS_GE is the extended version.

AIWS_GE completes the AIWS comparison family with the boundary case of equality.

Conclusion



AIWS_GE is a simple yet important comparison block for IEC 61131-3 control applications using the `WSTRING` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AIWS_GT

Input value 1 -- left operand (IN1 > IN2) – *AIWS*
Input value 2 -- right operand (IN1 > IN2) – *AIWS*

AX – IN1 > IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AIWS_GT** compares two values of type `WSTRING` (wide (Unicode) character string) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison is performed lexicographically (character by character) according to the character encoding.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `WSTRING`, wide (Unicode) character string).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AIWS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AIWS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AIWS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GT` (type `iec61131::comparison::F_GT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AIWS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the `WSTRING` data type.
- **Comparison logic**: The comparison is performed lexicographically (character by character) according to the character encoding.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

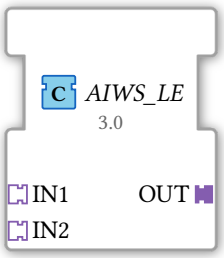
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking multilingual text identifiers against a reference or threshold value of type `WSTRING`.
- **Control Logic**: Triggering an action once two values of type `WSTRING` satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `WSTRING`-based comparison condition.

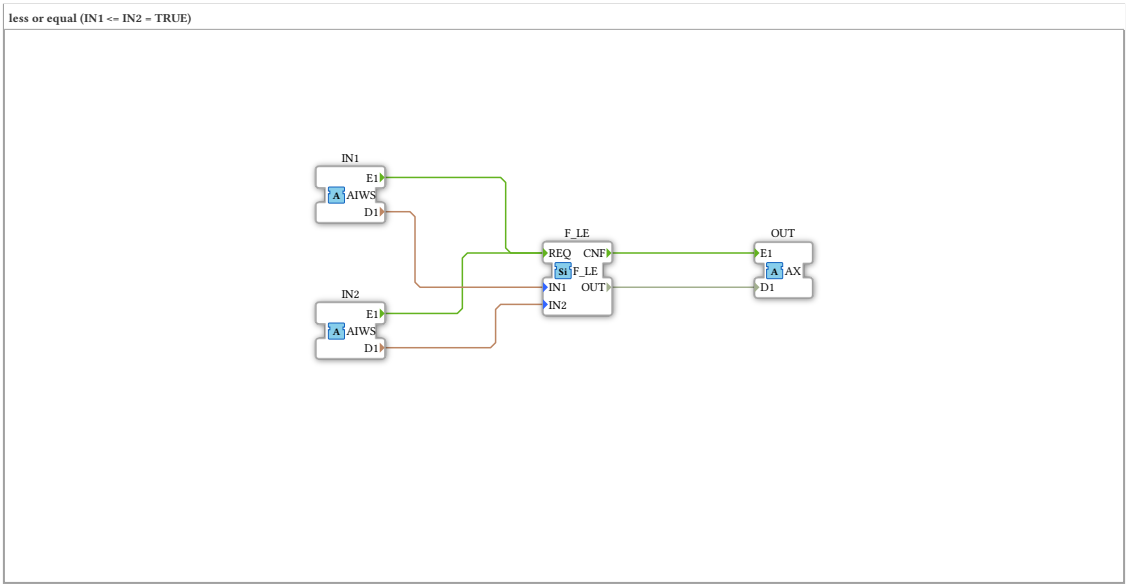
Comparison with Similar Function Blocks



- **AIWS_LT**: Checks for “less than” – the inverse function of AIWS_GT.
- **AIWS_EQ**: Checks for equality of values.
- **AIWS_GE**: Performs the “greater than or equal to” comparison – the extended version of AIWS_GT that includes the equality case.

AIWS_GT is the basic “greater than” component without the equality case, complemented by AIWS_GE.

Conclusion



AIWS_GT is a simple yet important comparison block for IEC 61131-3 control applications using the `WSTRING` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AIWS_LE

Input value 1 -- left operand (IN1 <= IN2) – *AIWS*
Input value 2 -- right operand (IN1 <= IN2) – *AIWS*

AX – IN1 <= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIWS_LE** compares two values of type `WSTRING` (wide (Unicode) character string) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison is performed lexicographically (character by character) according to the character encoding.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `WSTRING`, wide (Unicode) character string).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AIWS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AIWS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AIWS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LE` (type `iec61131::comparison::F_LE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AIWS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the `WSTRING` data type.
- **Comparison logic**: The comparison is performed lexicographically (character by character) according to the character encoding.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

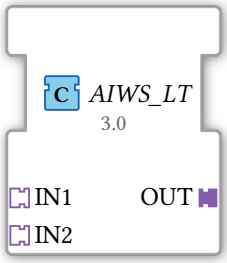
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking multilingual text identifiers against a reference or threshold value of type `WSTRING`.
- **Control Logic**: Triggering an action once two values of type `WSTRING` satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `WSTRING`-based comparison condition.

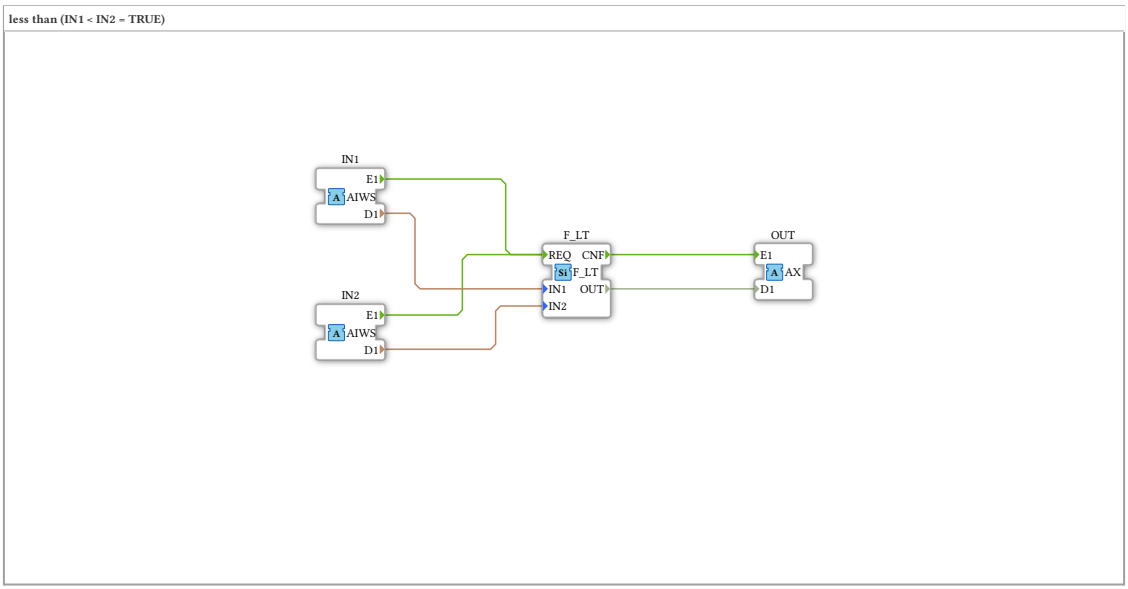
Comparison with Similar Function Blocks



- **AIWS_GE**: Checks for “greater than or equal to” – the inverse function of AIWS_LE.
- **AIWS_EQ**: Checks for equality of values.
- **AIWS_LT**: Performs the “less than” comparison – the base variant without the equality case, of which AIWS_LE is the extended version.

AIWS_LE completes the AIWS comparison family with the boundary case of equality.

Conclusion



AIWS_LE is a simple yet important comparison block for IEC 61131-3 control applications using the `WSTRING` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AIWS_LT

Input value 1 -- left operand (IN1 < IN2) – *AIWS*
Input value 2 -- right operand (IN1 < IN2) – *AIWS*

AX – IN1 < IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AIWS_LT** compares two values of type `WSTRING` (wide (Unicode) character string) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison is performed lexicographically (character by character) according to the character encoding.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `WSTRING`, wide (Unicode) character string).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AIWS (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AIWS (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AIWS and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LT (type iec61131::comparison::F_LT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AIWS/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the WSTRING data type.
- **Comparison logic**: The comparison is performed lexicographically (character by character) according to the character encoding.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

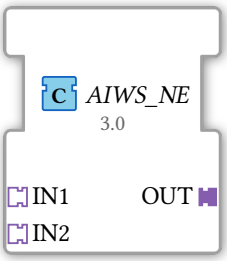
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking multilingual text identifiers against a reference or threshold value of type WSTRING.
- **Control Logic**: Triggering an action once two values of type WSTRING satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a WSTRING-based comparison condition.

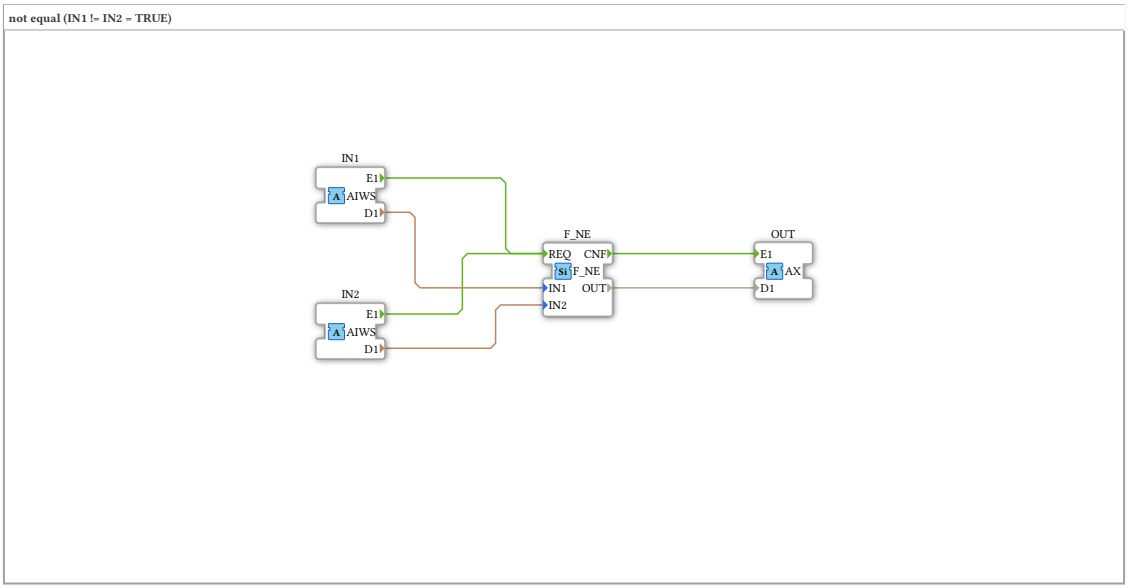
Comparison with Similar Function Blocks



- **AIWS_GT**: Checks for “greater than” – the inverse function of AIWS_LT.
- **AIWS_EQ**: Checks for equality of values.
- **AIWS_LE**: Performs the “less than or equal to” comparison – the extended version of AIWS_LT that includes the equality case.

AIWS_LT is the basic “less than” component without the equality case, complemented by AIWS_LE.

Conclusion



AIWS_LT is a simple yet important comparison block for IEC 61131-3 control applications using the WSTRING data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AIWS_NE

Input value 1 -- left operand (IN1 != IN2) – *AIWS*
Input value 2 -- right operand (IN1 != IN2) – *AIWS*

AX – IN1 != IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AIWS_NE** compares two values of type `WSTRING` (wide (Unicode) character string) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison is performed lexicographically (character by character) according to the character encoding.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `WSTRING`, wide (Unicode) character string).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AIWS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AIWS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AIWS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_NE` (type `iec61131::comparison::F_NE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AIWS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the `WSTRING` data type.
- **Comparison logic**: The comparison is performed lexicographically (character by character) according to the character encoding.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

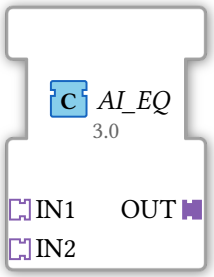
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking multilingual text identifiers against a reference or threshold value of type `WSTRING`.
- **Control Logic**: Triggering an action once two values of type `WSTRING` satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `WSTRING`-based comparison condition.

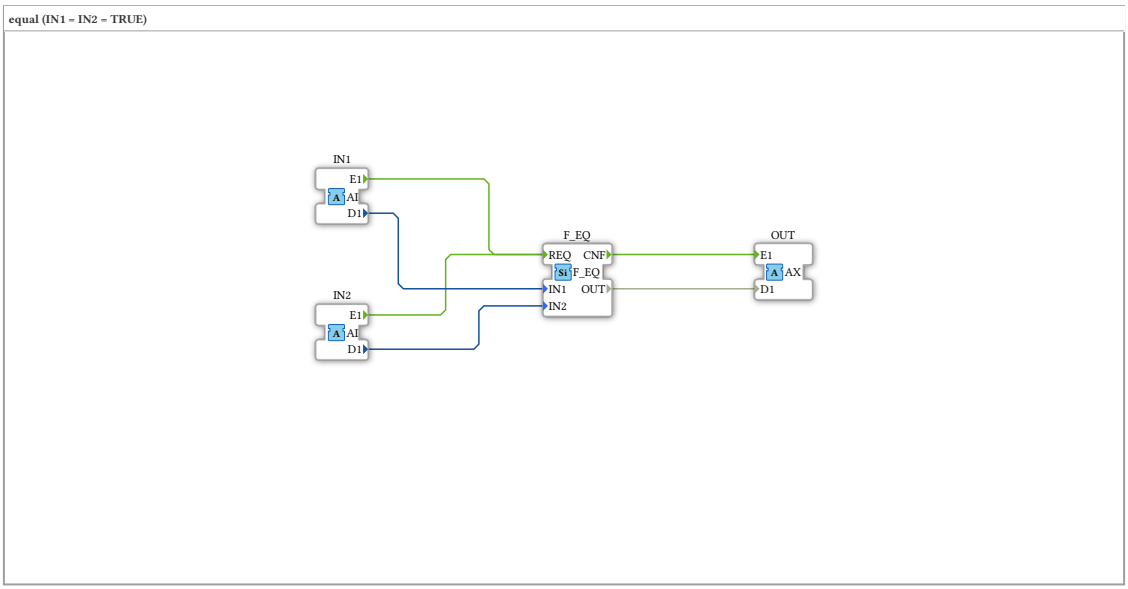
Comparison with Similar Function Blocks



- **AIWS_EQ**: Checks for “equal to” – the inverse function of AIWS_NE.
- **AIWS_EQ**: Checks for equality of values.

AIWS_NE is part of the complete AIWS comparison family (EQ/NE/GT/GE/LT/LE) for the `WSTRING` data type.

Conclusion



AIWS_NE is a simple yet important comparison block for IEC 61131-3 control applications using the `WSTRING` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AI_EQ

Input value 1 -- left operand (IN1 = IN2) – *AI*
Input value 2 -- right operand (IN1 = IN2) – *AI*

AX – IN1 = IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_EQ** compares two values of type `INT` (16-bit signed integer) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `INT`, 16-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_EQ` (type `iec61131::comparison::F_EQ`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the `INT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

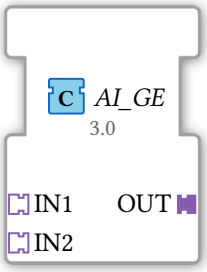
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking counter readings against a reference or threshold value of type `INT`.
- **Control Logic**: Triggering an action once two values of type `INT` satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `INT`-based comparison condition.

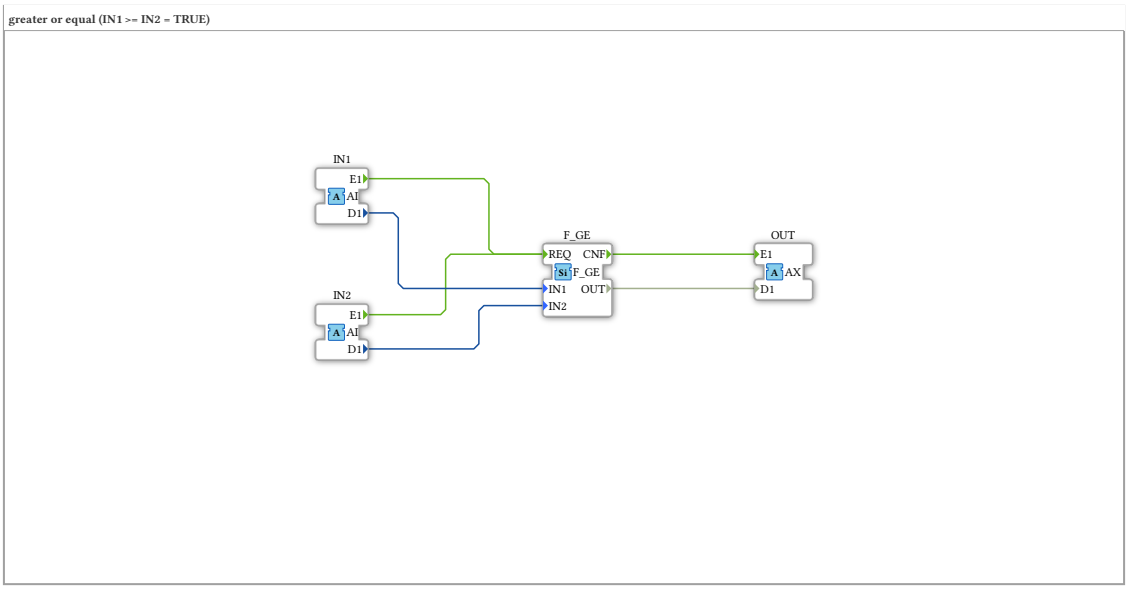
Comparison with Similar Function Blocks



- **AI_NE**: Checks for “not equal to” – the inverse function of AI_EQ.
- **AI_NE**: Checks for inequality of values.

AI_EQ is part of the complete AI comparison family (EQ/NE/GT/GE/LT/LE) for the `INT` data type.

Conclusion



AI_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the `INT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AI_GE

Input value 1 -- left operand (IN1 >= IN2) – *AI*
Input value 2 -- right operand (IN1 >= IN2) – *AI*

AX – IN1 >= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AI_GE** compares two values of type `INT` (16-bit signed integer) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `INT`, 16-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GE` (type `iec61131::comparison::F_GE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the `INT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

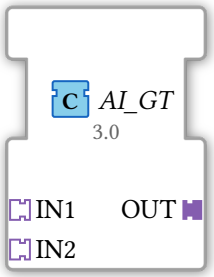
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking counter readings against a reference or threshold value of type `INT`.
- **Control Logic**: Triggering an action once two values of type `INT` satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `INT`-based comparison condition.

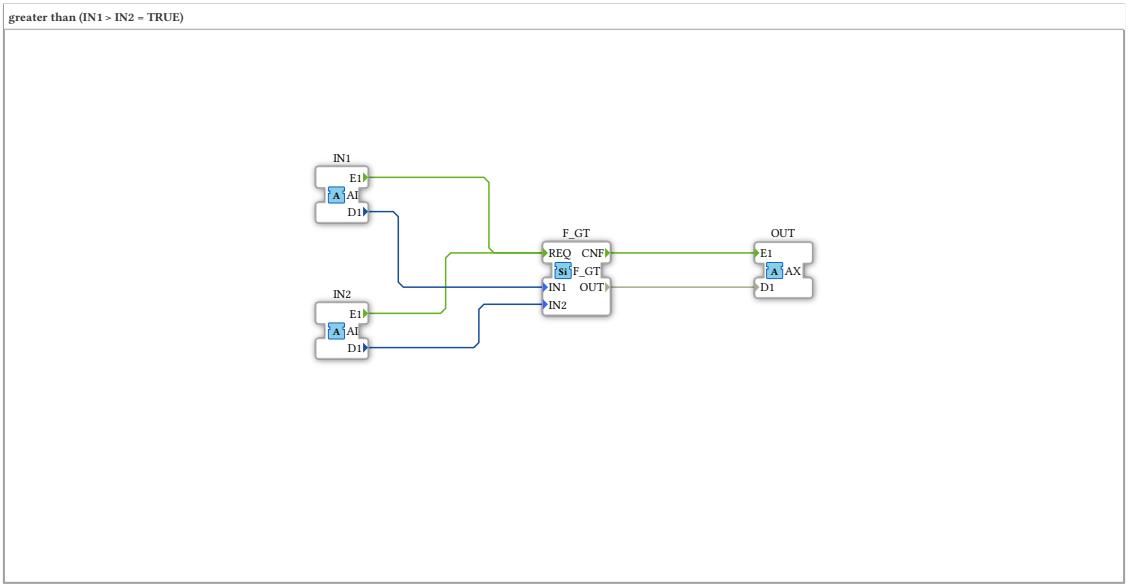
Comparison with Similar Function Blocks



- **AI_LE**: Checks for “less than or equal to” – the inverse function of AI_GE.
- **AI_EQ**: Checks for equality of values.
- **AI_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which AI_GE is the extended version.

AI_GE completes the AI comparison family with the boundary case of equality.

Conclusion



AI_GE is a simple yet important comparison block for IEC 61131-3 control applications using the `INT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AI_GT

Input value 1 -- left operand (IN1 > IN2) – *AI*
Input value 2 -- right operand (IN1 > IN2) – *AI*

AX – IN1 > IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_GT** compares two values of type `INT` (16-bit signed integer) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `INT`, 16-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GT` (type `iec61131::comparison::F_GT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the `INT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

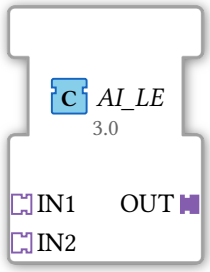
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking counter readings against a reference or threshold value of type `INT`.
- **Control Logic**: Triggering an action once two values of type `INT` satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `INT`-based comparison condition.

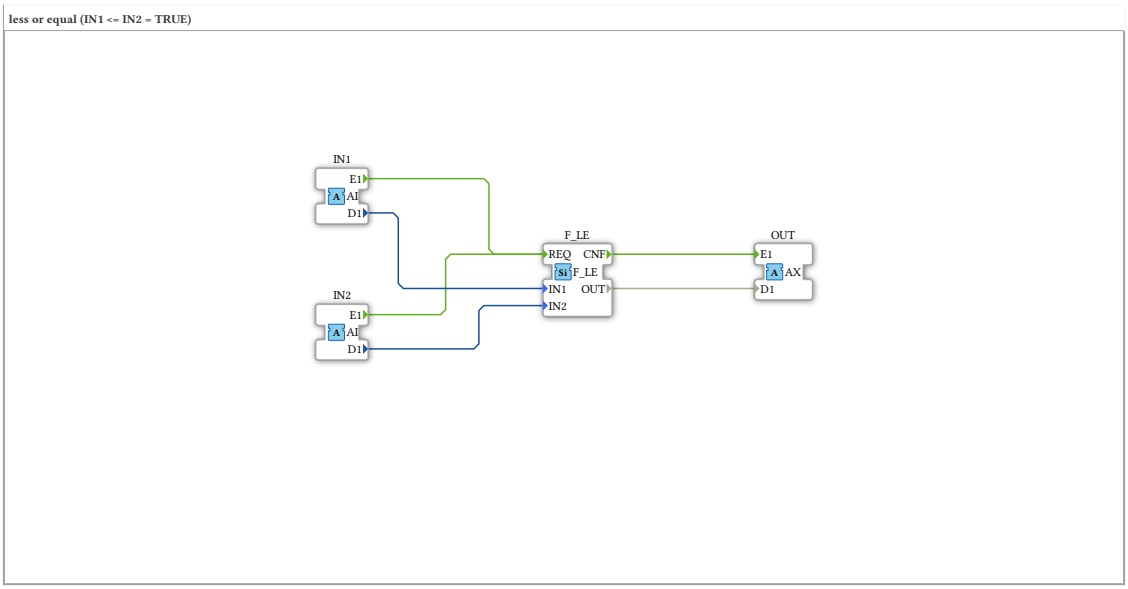
Comparison with Similar Function Blocks



- **AI_LT**: Checks for “less than” – the inverse function of AI_GT.
- **AI_EQ**: Checks for equality of values.
- **AI_GE**: Performs the “greater than or equal to” comparison – the extended version of AI_GT that includes the equality case.

AI_GT is the basic “greater than” component without the equality case, complemented by AI_GE.

Conclusion



AI_GT is a simple yet important comparison block for IEC 61131-3 control applications using the `INT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AI_LE

Input value 1 -- left operand (IN1 <= IN2) – *AI*
Input value 2 -- right operand (IN1 <= IN2) – *AI*

AX – IN1 <= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AI_LE** compares two values of type `INT` (16-bit signed integer) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `INT`, 16-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LE` (type `iec61131::comparison::F_LE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the `INT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

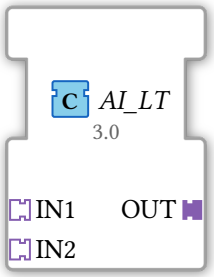
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking counter readings against a reference or threshold value of type `INT`.
- **Control Logic**: Triggering an action once two values of type `INT` satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `INT`-based comparison condition.

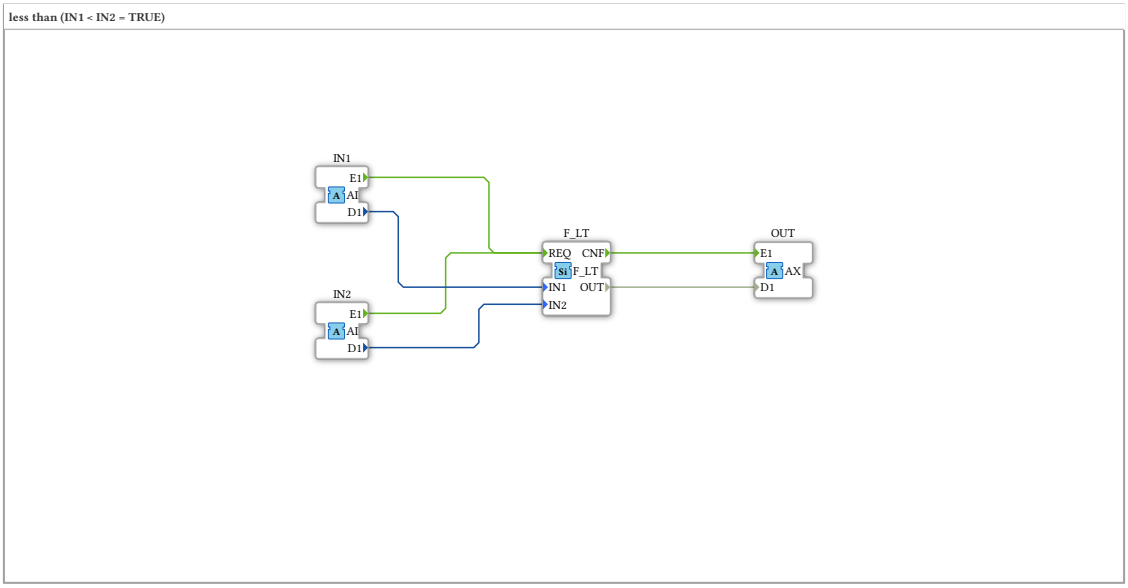
Comparison with Similar Function Blocks



- **AI_GE**: Checks for “greater than or equal to” – the inverse function of AI_LE.
- **AI_EQ**: Checks for equality of values.
- **AI_LT**: Performs the “less than” comparison – the base variant without the equality case, of which AI_LE is the extended version.

AI_LE completes the AI comparison family with the boundary case of equality.

Conclusion



AI_LE is a simple yet important comparison block for IEC 61131-3 control applications using the `INT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AI_LT

Input value 1 -- left operand (IN1 < IN2) – *AI*
Input value 2 -- right operand (IN1 < IN2) – *AI*

AX – IN1 < IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AI_LT** compares two values of type `INT` (16-bit signed integer) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `INT`, 16-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LT` (type `iec61131::comparison::F_LT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the `INT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

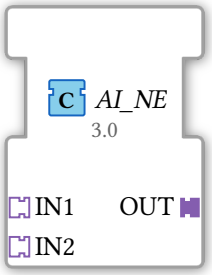
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking counter readings against a reference or threshold value of type `INT`.
- **Control Logic**: Triggering an action once two values of type `INT` satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `INT`-based comparison condition.

Comparison with Similar Function Blocks

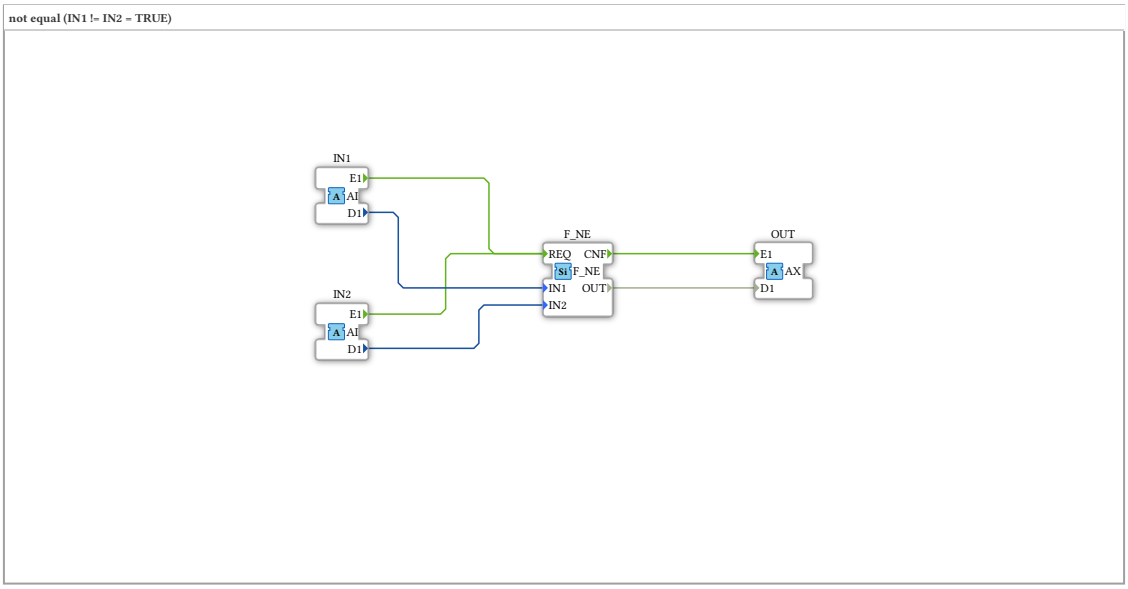


- **AI_GT**: Checks for “greater than” – the inverse function of AI_LT.
- **AI_EQ**: Checks for equality of values.
- **AI_LE**: Performs the “less than or equal to” comparison – the extended version of AI_LT that includes the equality case.

AI_LT is the basic “less than” component without the equality case, complemented by AI_LE.

Conclusion

AI_LT is a simple yet important comparison block for IEC 61131-3 control applications using the `INT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.



AI_NE

Input value 1 -- left operand (IN1 != IN2) – *AI*

Input value 2 -- right operand (IN1 != IN2) – *AI*

AX – IN1 != IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_NE** compares two values of type `INT` (16-bit signed integer) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `INT`, 16-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_NE` (type `iec61131::comparison::F_NE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the `INT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

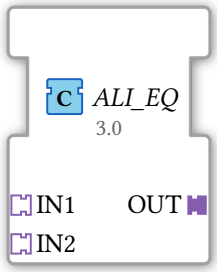
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

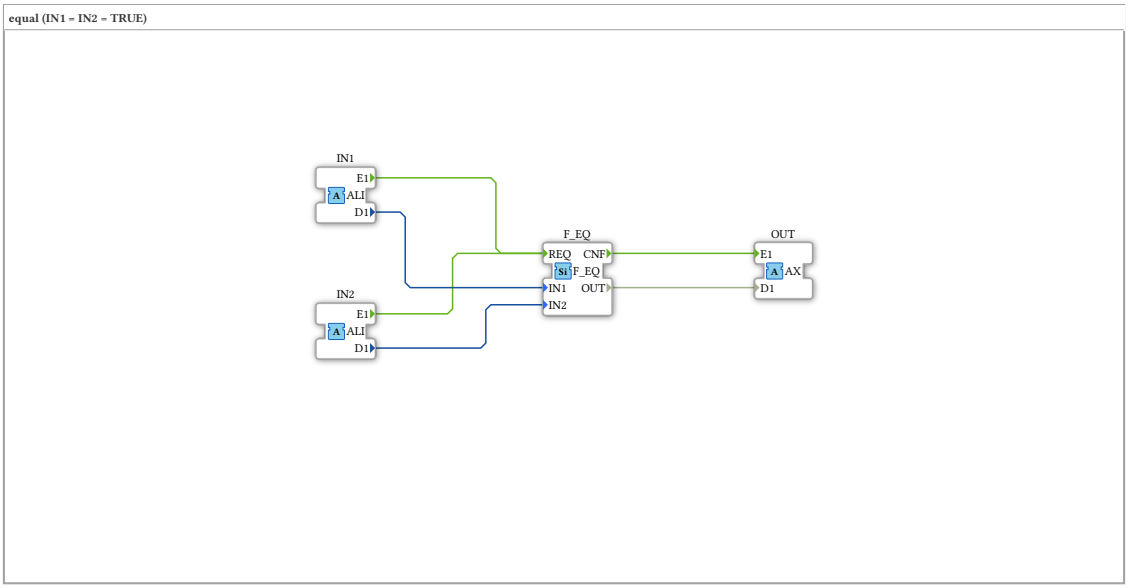
- **Limit Monitoring**: Checking counter readings against a reference or threshold value of type `INT`.
- **Control Logic**: Triggering an action once two values of type `INT` satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `INT`-based comparison condition.

Comparison with Similar Function Blocks



- **AI_EQ**: Checks for “equal to” – the inverse function of AI_NE.
- **AI_EQ**: Checks for equality of values.

AI_NE is part of the complete AI comparison family (EQ/NE/GT/GE/LT/LE) for the `INT` data type.



Conclusion

AI_NE is a simple yet important comparison block for IEC 61131-3 control applications using the `INT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ALI_EQ

Input value 1 -- left operand (IN1 = IN2) – *ALI*
Input value 2 -- right operand (IN1 = IN2) – *ALI*
AX – IN1 = IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ALI_EQ** compares two values of type `LINT` (64-bit signed integer) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LINT`, 64-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`ALI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`ALI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `ALI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_EQ` (type `iec61131::comparison::F_EQ`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`ALI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the `LINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

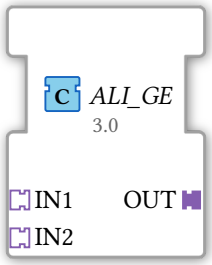
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

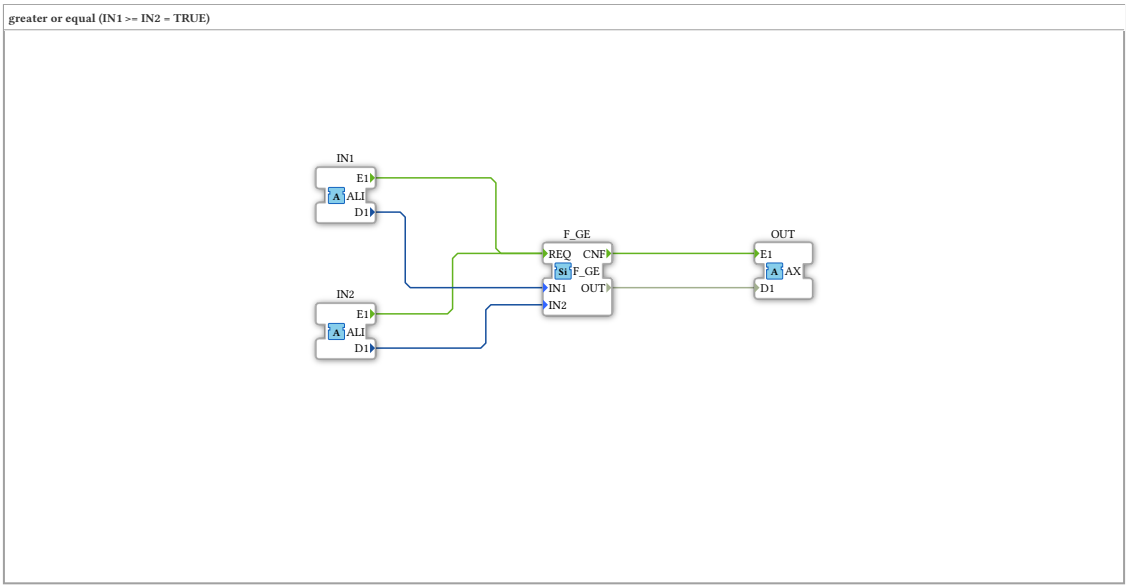
- **Limit Monitoring**: Checking large counter and total values against a reference or threshold value of type `LINT`.
- **Control Logic**: Triggering an action once two values of type `LINT` satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `LINT`-based comparison condition.

Comparison with Similar Function Blocks



- **ALI_NE**: Checks for “not equal to” – the inverse function of ALI_EQ.
- **ALI_NE**: Checks for inequality of values.

ALI_EQ is part of the complete ALI comparison family (EQ/NE/GT/GE/LT/LE) for the `LINT` data type.



Conclusion

ALI_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the `LINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ALI_GE

Input value 1 -- left operand (IN1 >= IN2) – *ALI*
Input value 2 -- right operand (IN1 >= IN2) – *ALI*
AX – IN1 >= IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ALI_GE** compares two values of type `LINT` (64-bit signed integer) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LINT`, 64-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`ALI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`ALI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `ALI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GE` (type `iec61131::comparison::F_GE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`ALI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the `LINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

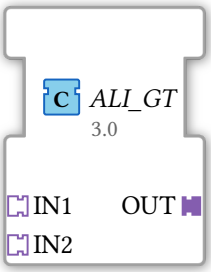
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

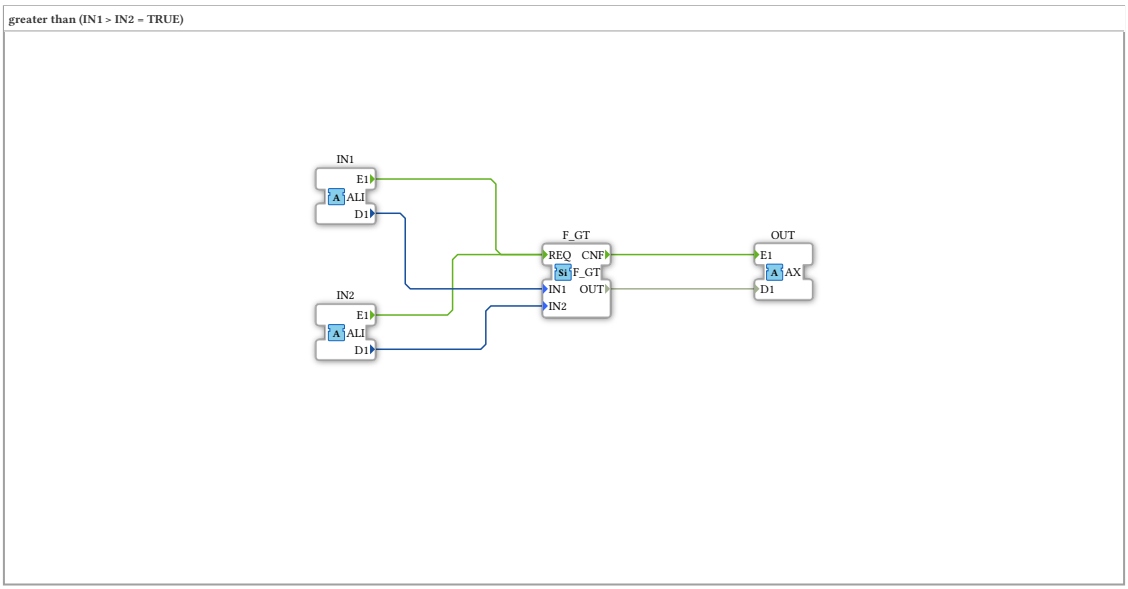
- **Limit Monitoring**: Checking large counter and total values against a reference or threshold value of type `LINT`.
- **Control Logic**: Triggering an action once two values of type `LINT` satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `LINT`-based comparison condition.

Comparison with Similar Function Blocks



- **ALI_LE**: Checks for “less than or equal to” – the inverse function of ALI_GE.
- **ALI_EQ**: Checks for equality of values.
- **ALI_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which ALI_GE is the extended version.

ALI_GE completes the ALI comparison family with the boundary case of equality.



Conclusion

ALI_GE is a simple yet important comparison block for IEC 61131-3 control applications using the `LINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ALI_GT

Input value 1 -- left operand (IN1 > IN2) – *ALI*
Input value 2 -- right operand (IN1 > IN2) – *ALI*
AX – IN1 > IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALI_GT** compares two values of type `LINT` (64-bit signed integer) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LINT`, 64-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`ALI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`ALI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `ALI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GT` (type `iec61131::comparison::F_GT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`ALI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the `LINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

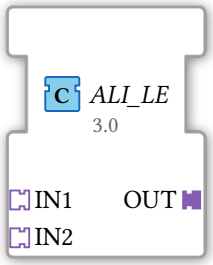
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

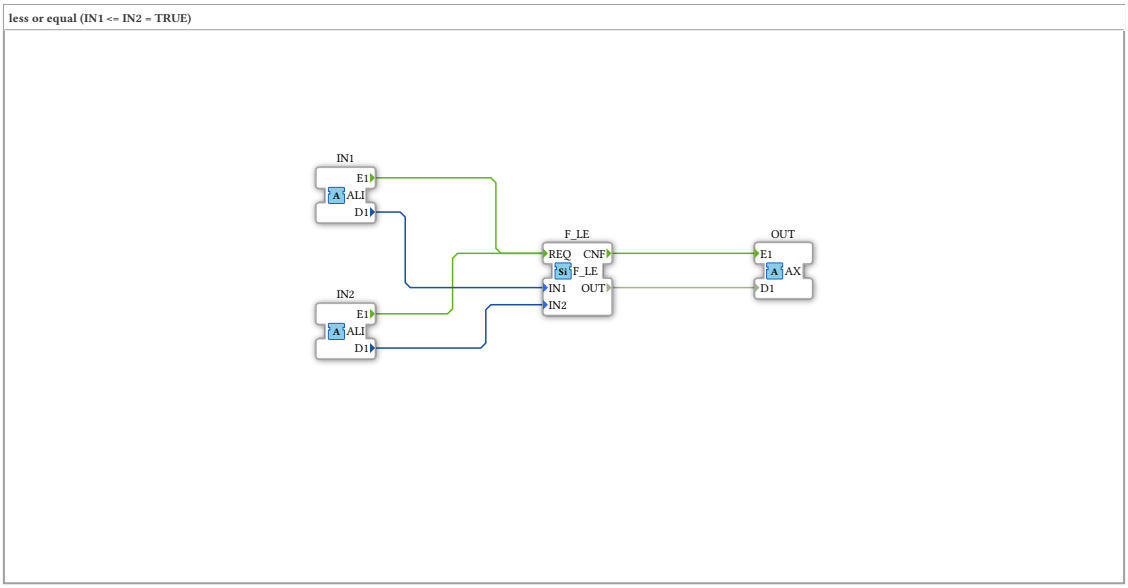
- **Limit Monitoring**: Checking large counter and total values against a reference or threshold value of type `LINT`.
- **Control Logic**: Triggering an action once two values of type `LINT` satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `LINT`-based comparison condition.

Comparison with Similar Function Blocks



- **ALI_LT**: Checks for “less than” – the inverse function of ALI_GT.
- **ALI_EQ**: Checks for equality of values.
- **ALI_GE**: Performs the “greater than or equal to” comparison – the extended version of ALI_GT that includes the equality case.

ALI_GT is the basic “greater than” component without the equality case, complemented by ALI_GE.



Conclusion

ALI_GT is a simple yet important comparison block for IEC 61131-3 control applications using the `LINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ALI_LE

Input value 1 -- left operand (IN1 <= IN2) – *ALI*
Input value 2 -- right operand (IN1 <= IN2) – *ALI*
AX – IN1 <= IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ALI_LE** compares two values of type `LINT` (64-bit signed integer) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LINT`, 64-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`ALI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`ALI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `ALI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LE` (type `iec61131::comparison::F_LE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`ALI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the `LINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

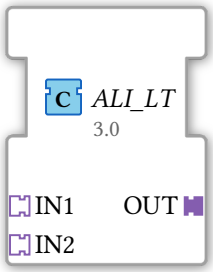
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking large counter and total values against a reference or threshold value of type `LINT`.
- **Control Logic**: Triggering an action once two values of type `LINT` satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `LINT`-based comparison condition.

Comparison with Similar Function Blocks

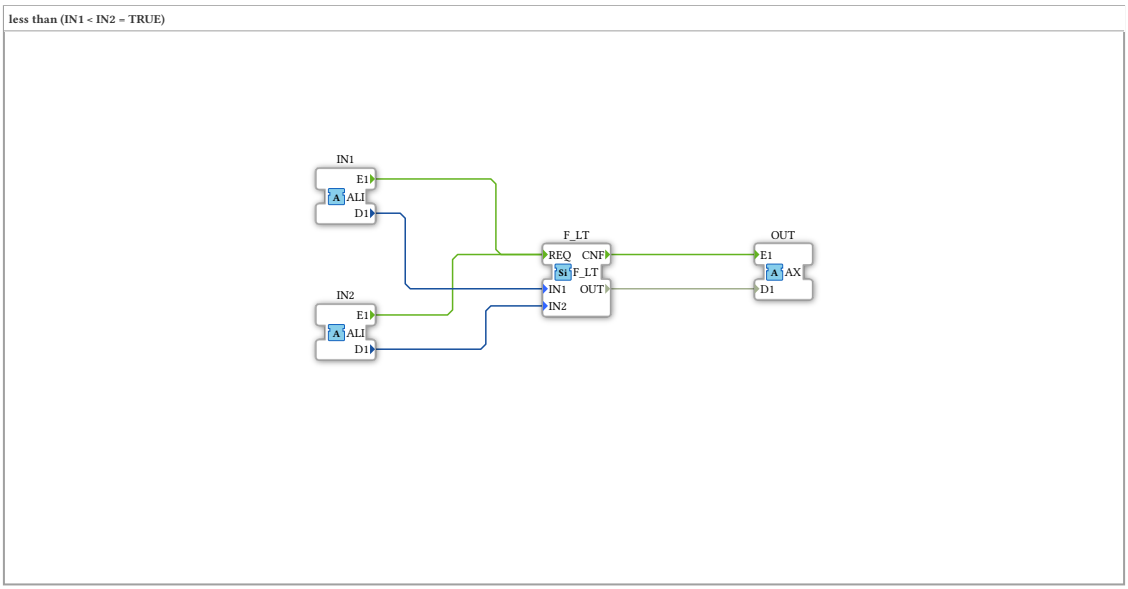


- **ALI_GE**: Checks for “greater than or equal to” – the inverse function of ALI_LE.
- **ALI_EQ**: Checks for equality of values.
- **ALI_LT**: Performs the “less than” comparison – the base variant without the equality case, of which ALI_LE is the extended version.

ALI_LE completes the ALI comparison family with the boundary case of equality.

Conclusion

ALI_LE is a simple yet important comparison block for IEC 61131-3 control applications using the `LINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.



ALI_LT

Input value 1 -- left operand (IN1 < IN2) – *ALI*

Input value 2 -- right operand (IN1 < IN2) – *ALI*

AX – IN1 < IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALI_LT** compares two values of type `LINT` (64-bit signed integer) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.

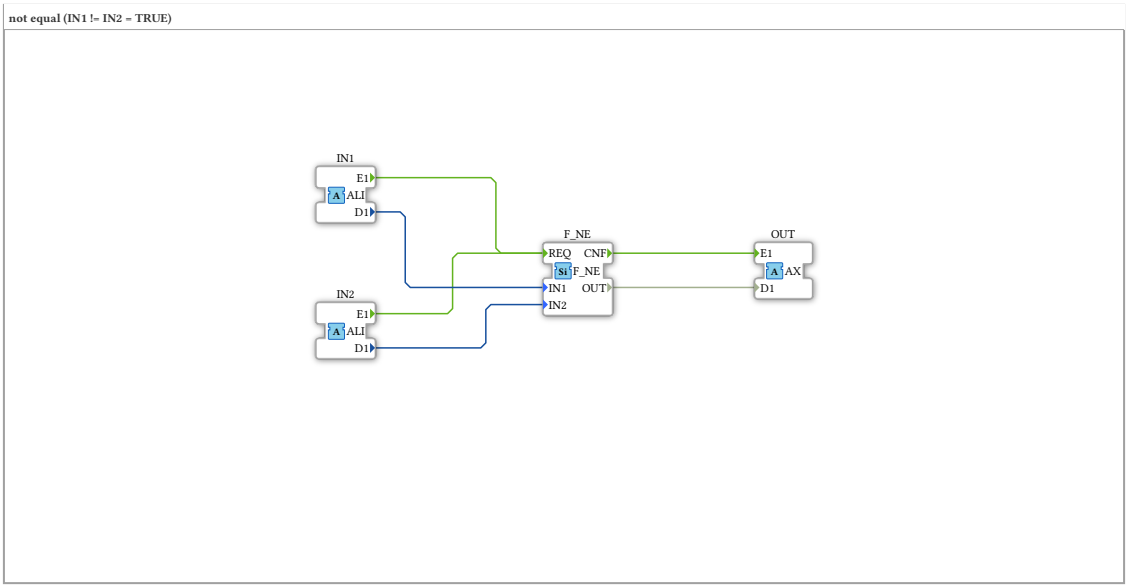
- **ALI_EQ**: Checks for equality of values.
- **ALI_LE**: Performs the “less than or equal to” comparison – the extended version of ALI_LT that includes the equality case.



ALI_LT is the basic “less than” component without the equality case, complemented by ALI_LE.

Conclusion

ALI_LT is a simple yet important comparison block for IEC 61131-3 control applications using the `LINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ALI_NE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALI_NE** compares two values of type `LINT` (64-bit signed integer) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LINT`, 64-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`ALI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`ALI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `ALI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_NE` (type `iec61131::comparison::F_NE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`ALI`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the `LINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

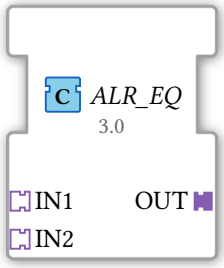
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking large counter and total values against a reference or threshold value of type `LINT`.
- **Control Logic**: Triggering an action once two values of type `LINT` satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `LINT`-based comparison condition.

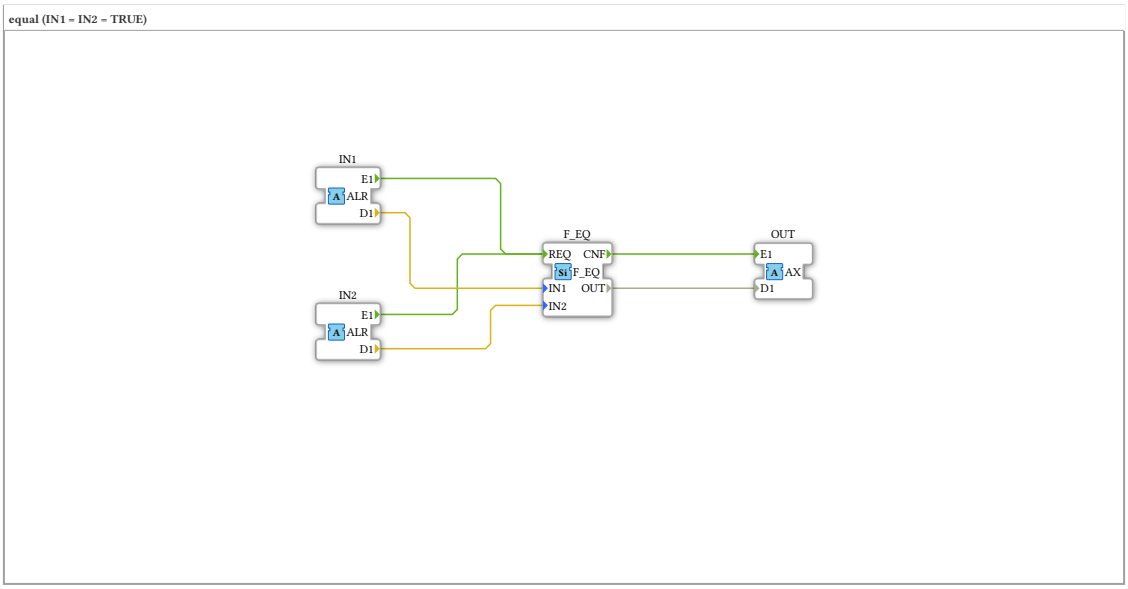
Comparison with Similar Function Blocks



- **ALI_EQ**: Checks for “equal to” – the inverse function of ALI_NE.
- **ALI_EQ**: Checks for equality of values.

ALI_NE is part of the complete ALI comparison family (EQ/NE/GT/GE/LT/LE) for the `LINT` data type.

Conclusion



ALI_NE is a simple yet important comparison block for IEC 61131-3 control applications using the `LINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ALR_EQ

Input value 1 -- left operand (IN1 = IN2) – *ALR*
Input value 2 -- right operand (IN1 = IN2) – *ALR*

AX – IN1 = IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ALR_EQ** compares two values of type `LREAL` (64-bit floating-point number (double precision)) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LREAL`, 64-bit floating-point number (double precision)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	ALR (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	ALR (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters ALR and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_EQ (type iec61131::comparison::F_EQ). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (ALR/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the LREAL data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

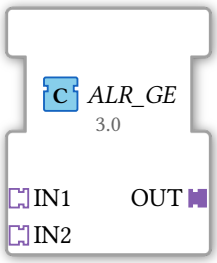
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking high-precision measurements against a reference or threshold value of type LREAL.
- **Control Logic**: Triggering an action once two values of type LREAL satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a LREAL-based comparison condition.

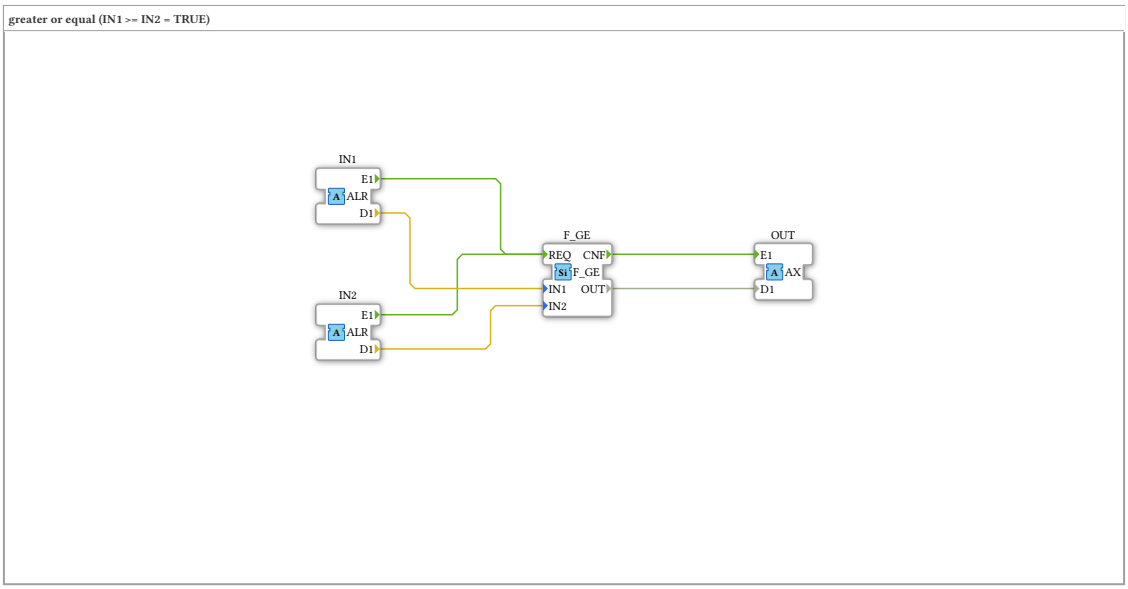
Comparison with Similar Function Blocks



- **ALR_NE**: Checks for “not equal to” – the inverse function of ALR_EQ.
- **ALR_NE**: Checks for inequality of values.

ALR_EQ is part of the complete ALR comparison family (EQ/NE/GT/GE/LT/LE) for the LREAL data type.

Conclusion



ALR_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the LREAL data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ALR_GE

Input value 1 -- left operand (IN1 >= IN2) – *ALR*
Input value 2 -- right operand (IN1 >= IN2) – *ALR*

AX – IN1 >= IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ALR_GE** compares two values of type `LREAL` (64-bit floating-point number (double precision)) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LREAL`, 64-bit floating-point number (double precision)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	ALR (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	ALR (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters ALR and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GE (type iec61131::comparison::F_GE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (ALR/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the LREAL data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

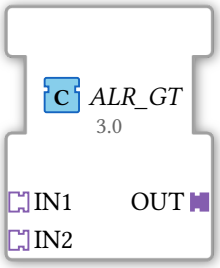
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking high-precision measurements against a reference or threshold value of type LREAL.
- **Control Logic**: Triggering an action once two values of type LREAL satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a LREAL-based comparison condition.

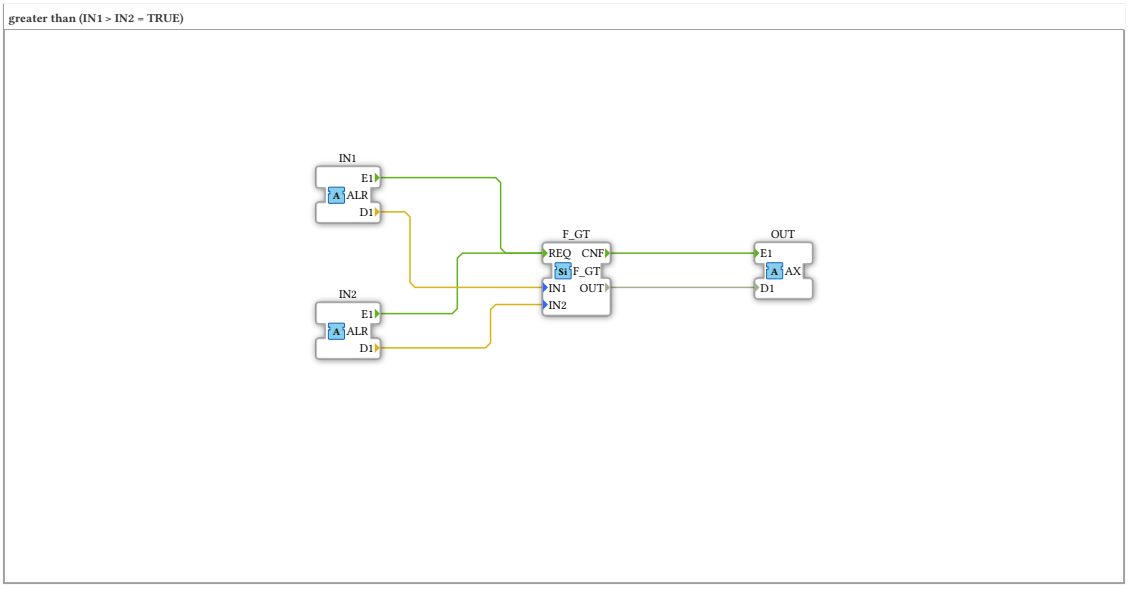
Comparison with Similar Function Blocks



- **ALR_LE**: Checks for “less than or equal to” – the inverse function of ALR_GE.
- **ALR_EQ**: Checks for equality of values.
- **ALR_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which ALR_GE is the extended version.

ALR_GE completes the ALR comparison family with the boundary case of equality.

Conclusion



ALR_GE is a simple yet important comparison block for IEC 61131-3 control applications using the LREAL data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ALR_GT

Input value 1 -- left operand (IN1 > IN2) – *ALR*
Input value 2 -- right operand (IN1 > IN2) – *ALR*

AX – IN1 > IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ALR_GT** compares two values of type `LREAL` (64-bit floating-point number (double precision)) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LREAL`, 64-bit floating-point number (double precision)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	ALR (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	ALR (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters ALR and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GT (type iec61131::comparison::F_GT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (ALR/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the LREAL data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

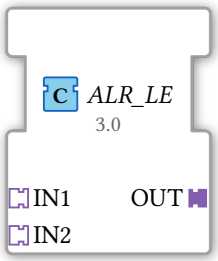
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking high-precision measurements against a reference or threshold value of type LREAL.
- **Control Logic**: Triggering an action once two values of type LREAL satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a LREAL-based comparison condition.

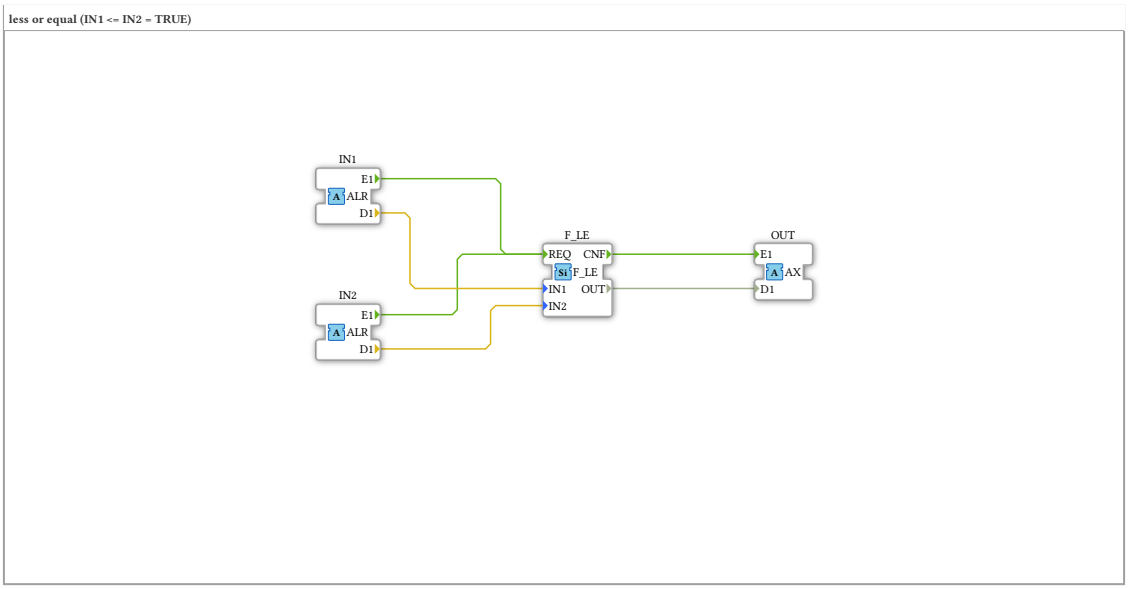
Comparison with Similar Function Blocks



- **ALR_LT**: Checks for “less than” – the inverse function of ALR_GT.
- **ALR_EQ**: Checks for equality of values.
- **ALR_GE**: Performs the “greater than or equal to” comparison – the extended version of ALR_GT that includes the equality case.

ALR_GT is the basic “greater than” component without the equality case, complemented by ALR_GE.

Conclusion



ALR_GT is a simple yet important comparison block for IEC 61131-3 control applications using the LREAL data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ALR_LE

Input value 1 -- left operand (IN1 <= IN2) – *ALR*
Input value 2 -- right operand (IN1 <= IN2) – *ALR*

AX – IN1 <= IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ALR_LE** compares two values of type `LREAL` (64-bit floating-point number (double precision)) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LREAL`, 64-bit floating-point number (double precision)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	ALR (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	ALR (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters ALR and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LE (type iec61131::comparison::F_LE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (ALR/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the LREAL data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

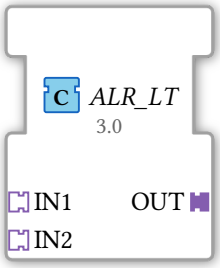
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking high-precision measurements against a reference or threshold value of type LREAL.
- **Control Logic**: Triggering an action once two values of type LREAL satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a LREAL-based comparison condition.

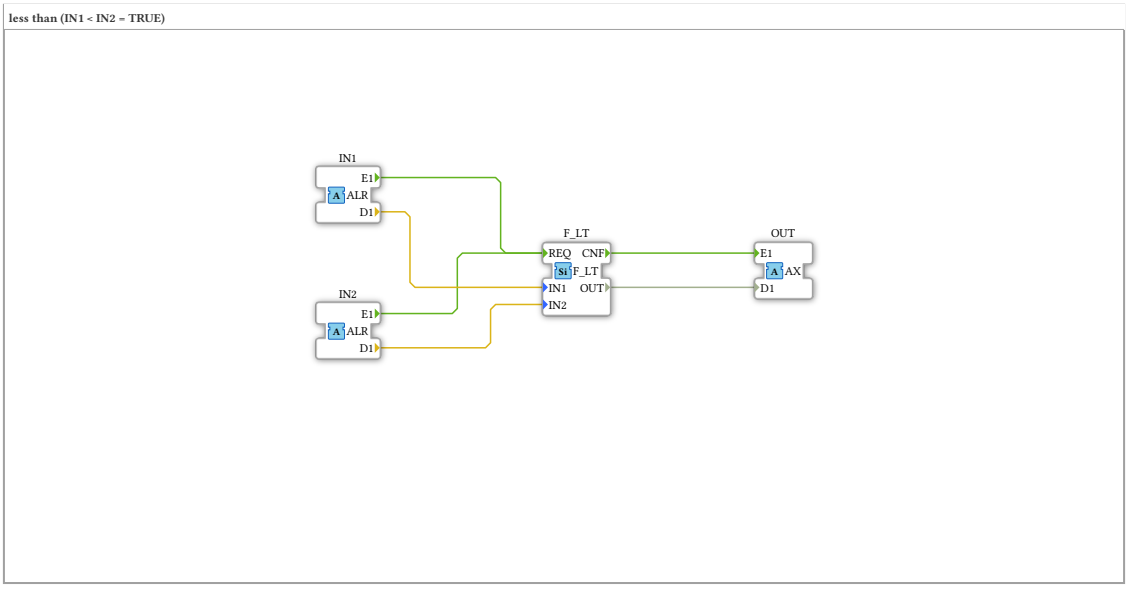
Comparison with Similar Function Blocks



- **ALR_GE**: Checks for “greater than or equal to” – the inverse function of ALR_LE.
- **ALR_EQ**: Checks for equality of values.
- **ALR_LT**: Performs the “less than” comparison – the base variant without the equality case, of which ALR_LE is the extended version.

ALR_LE completes the ALR comparison family with the boundary case of equality.

Conclusion



ALR_LE is a simple yet important comparison block for IEC 61131-3 control applications using the LREAL data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ALR_LT

The function block **ALR_LT** compares two values of type `LREAL` (64-bit floating-point number (double precision)) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LREAL`, 64-bit floating-point number (double precision)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	ALR (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	ALR (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters ALR and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LT (type iec61131::comparison::F_LT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (ALR/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the LREAL data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

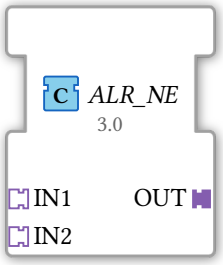
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking high-precision measurements against a reference or threshold value of type LREAL.
- **Control Logic**: Triggering an action once two values of type LREAL satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a LREAL-based comparison condition.

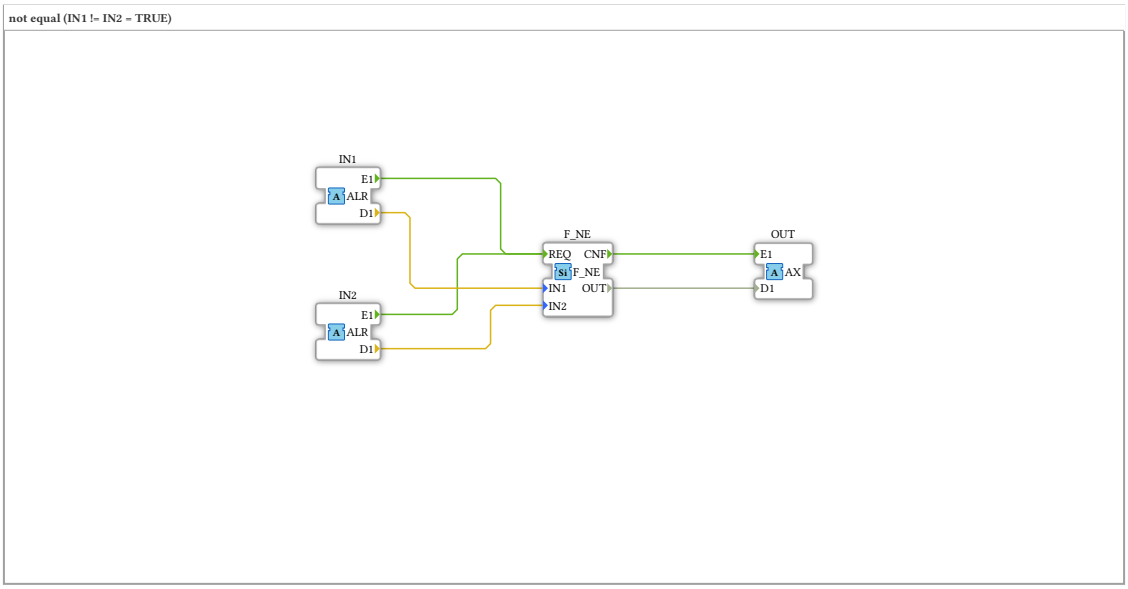
Comparison with Similar Function Blocks



- **ALR_GT**: Checks for “greater than” – the inverse function of ALR_LT.
- **ALR_EQ**: Checks for equality of values.
- **ALR_LE**: Performs the “less than or equal to” comparison – the extended version of ALR_LT that includes the equality case.

ALR_LT is the basic “less than” component without the equality case, complemented by ALR_LE.

Conclusion



ALR_LT is a simple yet important comparison block for IEC 61131-3 control applications using the LREAL data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ALR_NE

Input value 1 -- left operand (IN1 != IN2) – *ALR*
Input value 2 -- right operand (IN1 != IN2) – *ALR*

AX – IN1 != IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ALR_NE** compares two values of type `LREAL` (64-bit floating-point number (double precision)) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LREAL`, 64-bit floating-point number (double precision)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	ALR (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	ALR (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters ALR and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_NE (type iec61131::comparison::F_NE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (ALR/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the LREAL data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

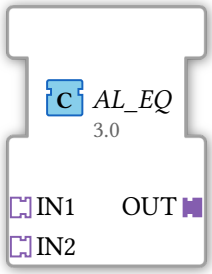
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking high-precision measurements against a reference or threshold value of type LREAL.
- **Control Logic**: Triggering an action once two values of type LREAL satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a LREAL-based comparison condition.

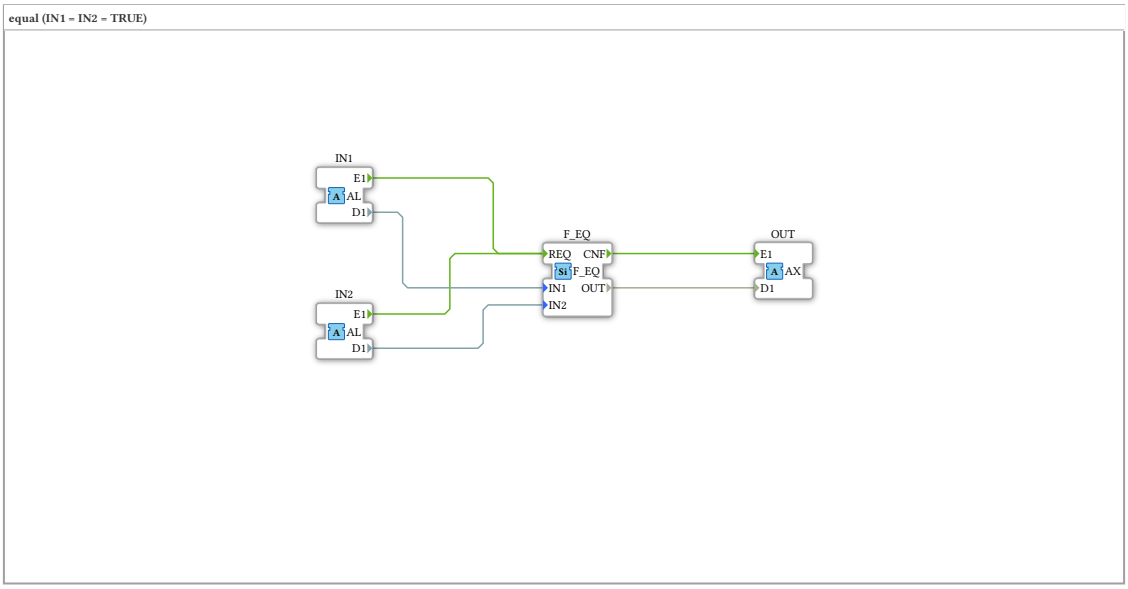
Comparison with Similar Function Blocks



- **ALR_EQ**: Checks for “equal to” – the inverse function of ALR_NE.
- **ALR_EQ**: Checks for equality of values.

ALR_NE is part of the complete ALR comparison family (EQ/NE/GT/GE/LT/LE) for the LREAL data type.

Conclusion



ALR_NE is a simple yet important comparison block for IEC 61131-3 control applications using the LREAL data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AL_EQ

Input value 1 -- left operand (IN1 = IN2) – *AL*
Input value 2 -- right operand (IN1 = IN2) – *AL*

AX – IN1 = IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AL_EQ** compares two values of type `LWORD` (64-bit bit pattern (long word)) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LWORD`, 64-bit bit pattern (long word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AL (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AL (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AL and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_EQ (type iec61131::comparison::F_EQ). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AL/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the LWORD data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

State Overview

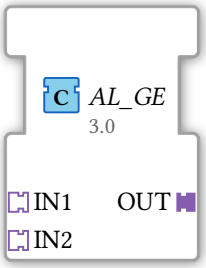
This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking extended bit masks against a reference or threshold value of type LWORD.
- **Control Logic**: Triggering an action once two values of type LWORD satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a LWORD-based comparison condition.

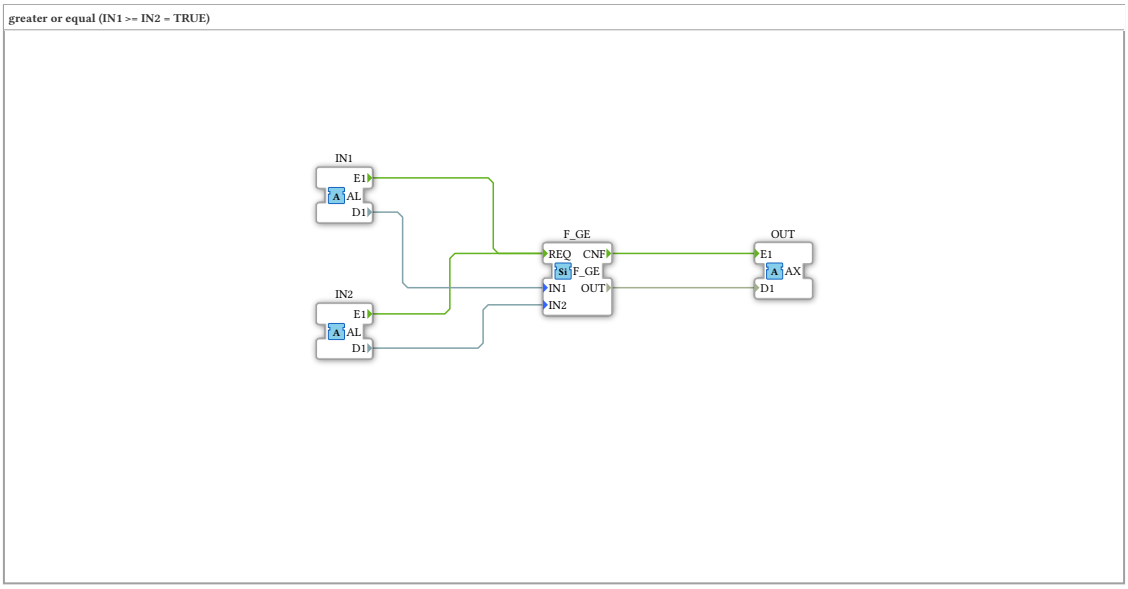
Comparison with Similar Function Blocks

- **AL_NE**: Checks for “not equal to” – the inverse function of AL_EQ.
- **AL_NE**: Checks for inequality of values.



AL_EQ is part of the complete AL comparison family (EQ/NE/GT/GE/LT/LE) for the LWORD data type.

Conclusion



AL_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the LWORD data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AL_GE

Input value 1 -- left operand (IN1 >= IN2) – *AL*
Input value 2 -- right operand (IN1 >= IN2) – *AL*

AX – IN1 >= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AL_GE** compares two values of type `LWORD` (64-bit bit pattern (long word)) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LWORD`, 64-bit bit pattern (long word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AL (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AL (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AL and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GE (type iec61131::comparison::F_GE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AL/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the LWORD data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

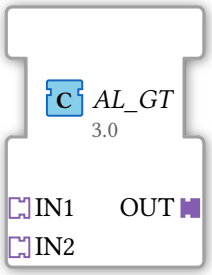
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking extended bit masks against a reference or threshold value of type LWORD.
- **Control Logic**: Triggering an action once two values of type LWORD satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a LWORD-based comparison condition.

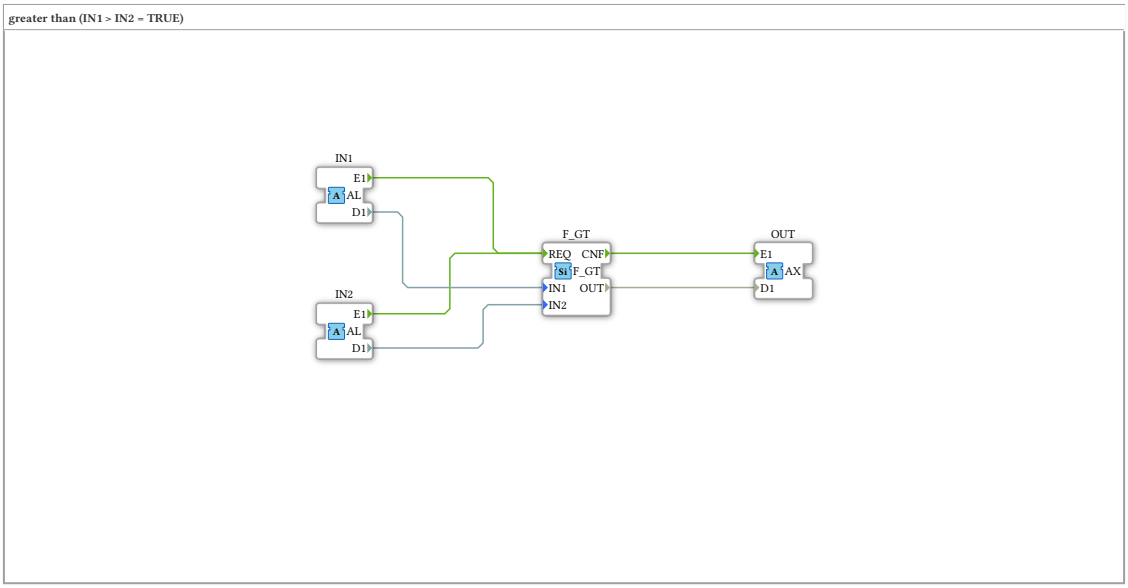
Comparison with Similar Function Blocks



- **AL_LE**: Checks for “less than or equal to” – the inverse function of AL_GE.
- **AL_EQ**: Checks for equality of values.
- **AL_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which AL_GE is the extended version.

AL_GE completes the AL comparison family with the boundary case of equality.

Conclusion



AL_GE is a simple yet important comparison block for IEC 61131-3 control applications using the LWORD data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AL_GT

Input value 1 -- left operand (IN1 > IN2) – *AL*
Input value 2 -- right operand (IN1 > IN2) – *AL*

AX – IN1 > IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AL_GT** compares two values of type `LWORD` (64-bit bit pattern (long word)) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LWORD`, 64-bit bit pattern (long word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AL (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AL (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AL and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GT (type iec61131::comparison::F_GT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AL/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the LWORD data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

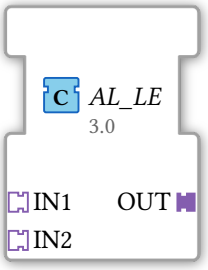
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking extended bit masks against a reference or threshold value of type LWORD.
- **Control Logic**: Triggering an action once two values of type LWORD satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a LWORD-based comparison condition.

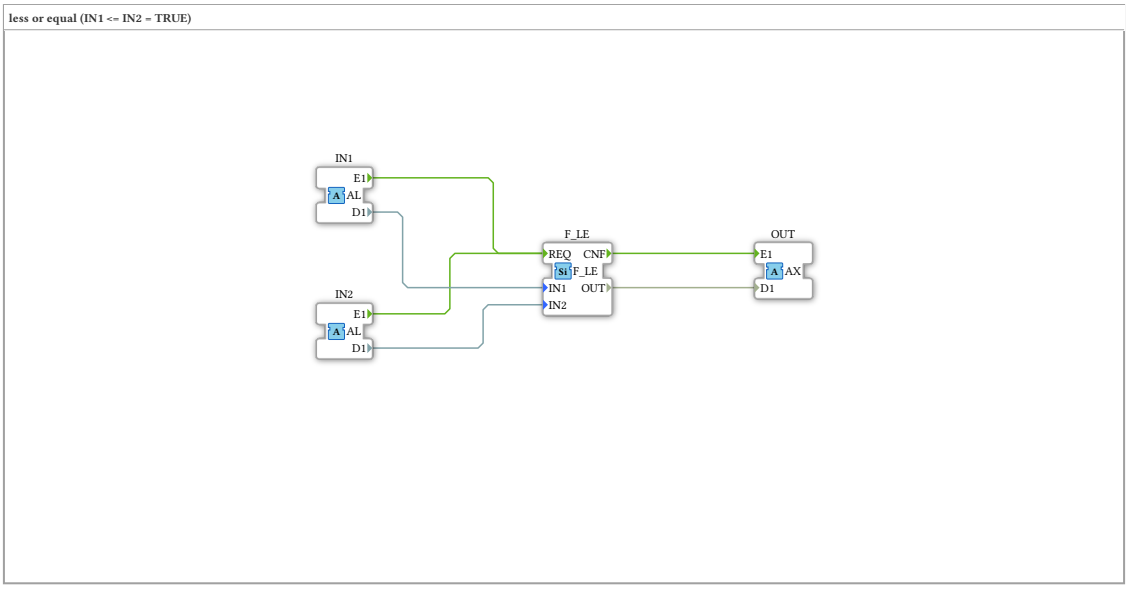
Comparison with Similar Function Blocks



- **AL_LT**: Checks for “less than” – the inverse function of AL_GT.
- **AL_EQ**: Checks for equality of values.
- **AL_GE**: Performs the “greater than or equal to” comparison – the extended version of AL_GT that includes the equality case.

AL_GT is the basic “greater than” component without the equality case, complemented by AL_GE.

Conclusion



AL_GT is a simple yet important comparison block for IEC 61131-3 control applications using the LWORD data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AL_LE

Input value 1 -- left operand (IN1 <= IN2) – *AL*
Input value 2 -- right operand (IN1 <= IN2) – *AL*

AX – IN1 <= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AL_LE** compares two values of type `LWORD` (64-bit bit pattern (long word)) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LWORD`, 64-bit bit pattern (long word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AL (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AL (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AL and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LE (type iec61131::comparison::F_LE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AL/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the LWORD data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

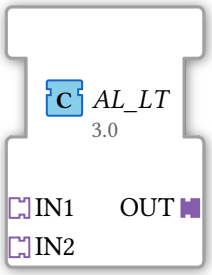
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking extended bit masks against a reference or threshold value of type LWORD.
- **Control Logic**: Triggering an action once two values of type LWORD satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a LWORD-based comparison condition.

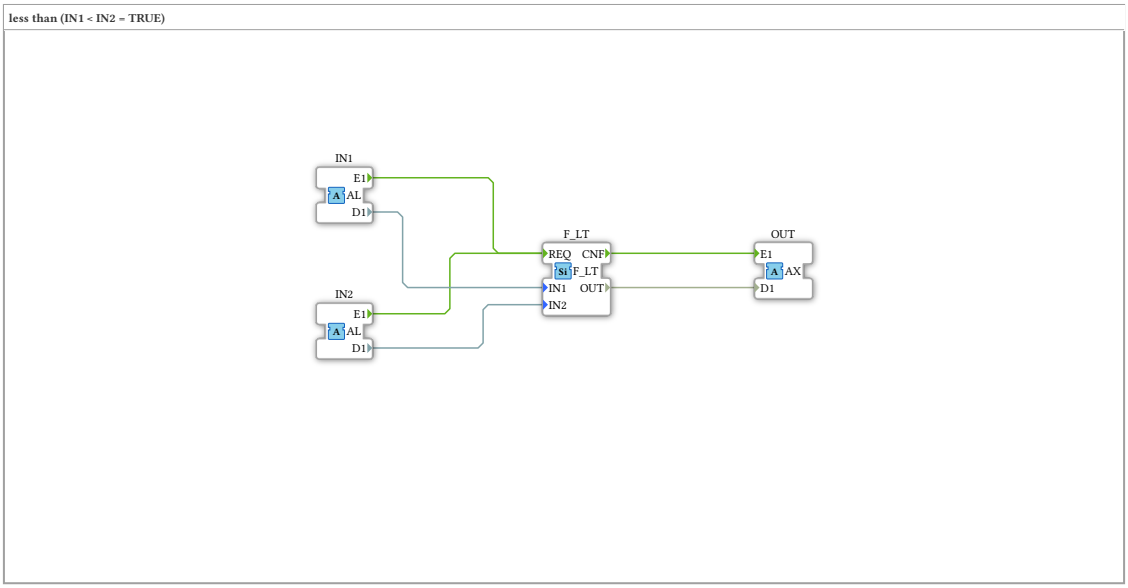
Comparison with Similar Function Blocks



- **AL_GE**: Checks for “greater than or equal to” – the inverse function of AL_LE.
- **AL_EQ**: Checks for equality of values.
- **AL_LT**: Performs the “less than” comparison – the base variant without the equality case, of which AL_LE is the extended version.

AL_LE completes the AL comparison family with the boundary case of equality.

Conclusion



AL_LE is a simple yet important comparison block for IEC 61131-3 control applications using the LWORD data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AL_LT

Input value 1 -- left operand (IN1 < IN2) – *AL*
Input value 2 -- right operand (IN1 < IN2) – *AL*

AX – IN1 < IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AL_LT** compares two values of type `LWORD` (64-bit bit pattern (long word)) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LWORD`, 64-bit bit pattern (long word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AL (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AL (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AL and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LT (type iec61131::comparison::F_LT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AL/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the LWORD data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

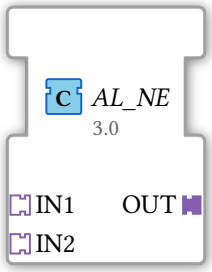
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking extended bit masks against a reference or threshold value of type LWORD.
- **Control Logic**: Triggering an action once two values of type LWORD satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a LWORD-based comparison condition.

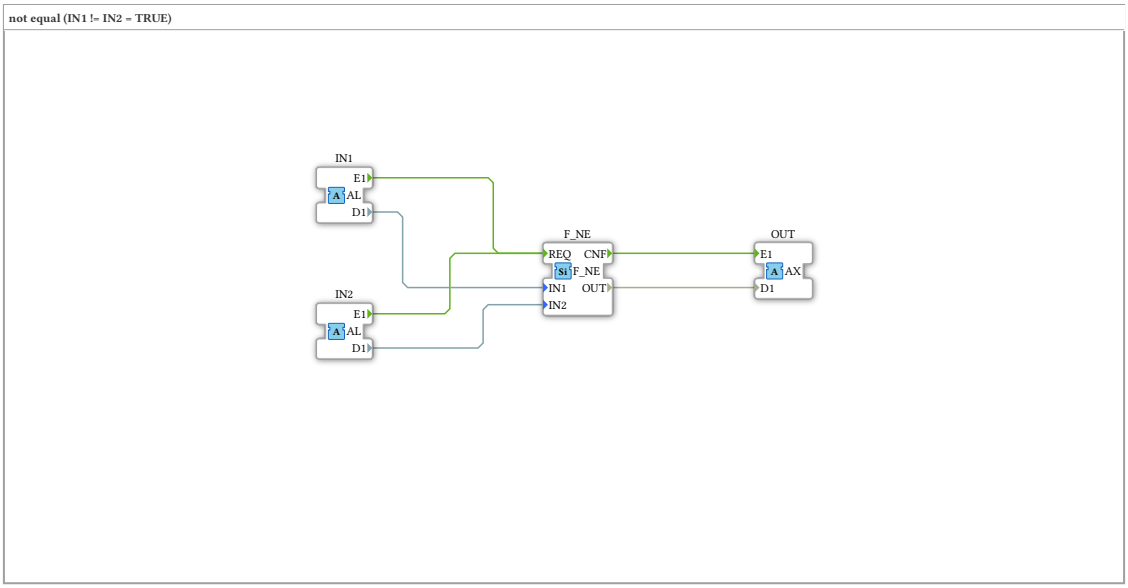
Comparison with Similar Function Blocks



- **AL_GT**: Checks for “greater than” – the inverse function of AL_LT.
- **AL_EQ**: Checks for equality of values.
- **AL_LE**: Performs the “less than or equal to” comparison – the extended version of AL_LT that includes the equality case.

AL_LT is the basic “less than” component without the equality case, complemented by AL_LE.

Conclusion



AL_LT is a simple yet important comparison block for IEC 61131-3 control applications using the LWORD data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AL_NE

Input value 1 -- left operand (IN1 != IN2) – *AL*
Input value 2 -- right operand (IN1 != IN2) – *AL*

AX – IN1 != IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AL_NE** compares two values of type `LWORD` (64-bit bit pattern (long word)) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `LWORD`, 64-bit bit pattern (long word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AL (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AL (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AL and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_NE (type iec61131::comparison::F_NE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AL/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the LWORD data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

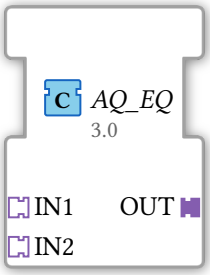
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking extended bit masks against a reference or threshold value of type LWORD.
- **Control Logic**: Triggering an action once two values of type LWORD satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a LWORD-based comparison condition.

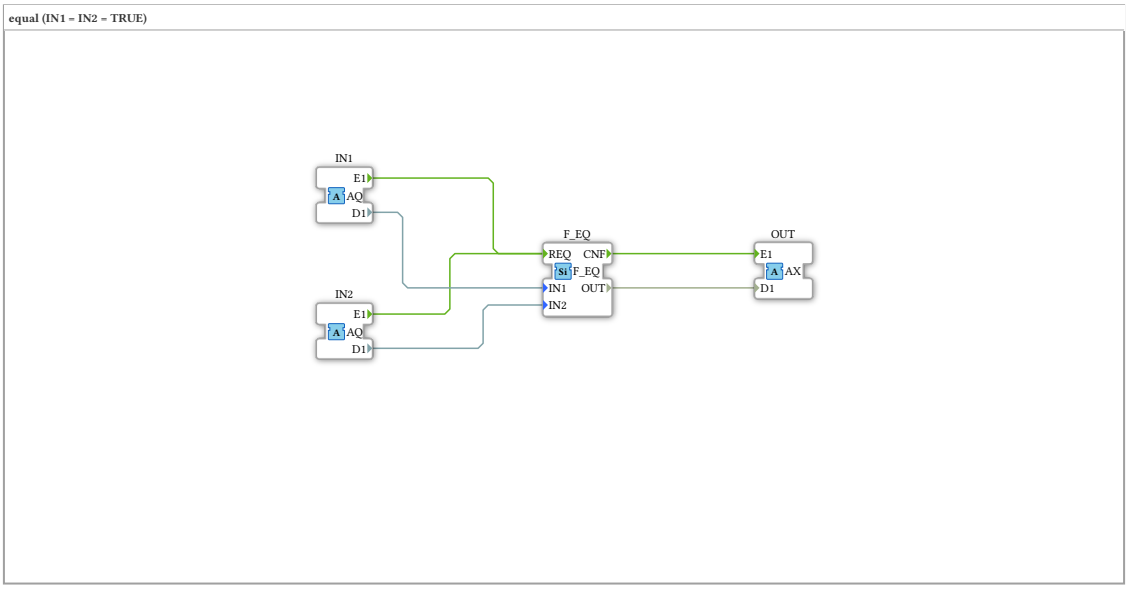
Comparison with Similar Function Blocks



- **AL_EQ**: Checks for “equal to” – the inverse function of AL_NE.
- **AL_EQ**: Checks for equality of values.

AL_NE is part of the complete AL comparison family (EQ/NE/GT/GE/LT/LE) for the LWORD data type.

Conclusion



AL_NE is a simple yet important comparison block for IEC 61131-3 control applications using the LWORD data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AQ_EQ

Input value 1 -- left operand (IN1 = IN2) – *AQ*
Input value 2 -- right operand (IN1 = IN2) – *AQ*

AX – IN1 = IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AQ_EQ** compares two values of type `QUARTER` (2-bit value (quarter byte)) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `QUARTER`, 2-bit value (quarter byte)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AQ (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AQ (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AQ and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_EQ (type iec61131::comparison::F_EQ). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AQ/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the QUARTER data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

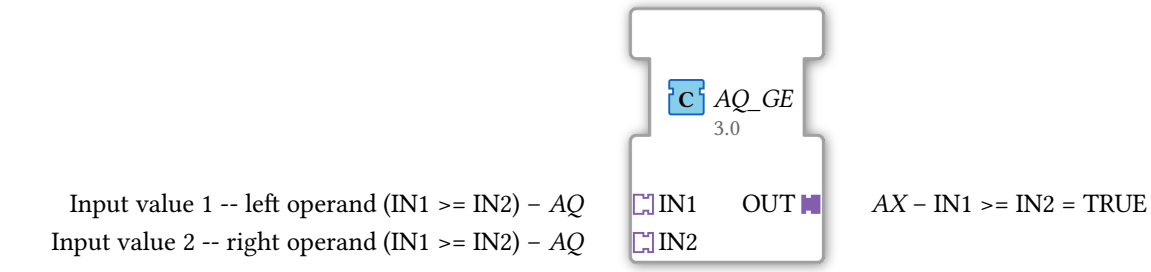
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

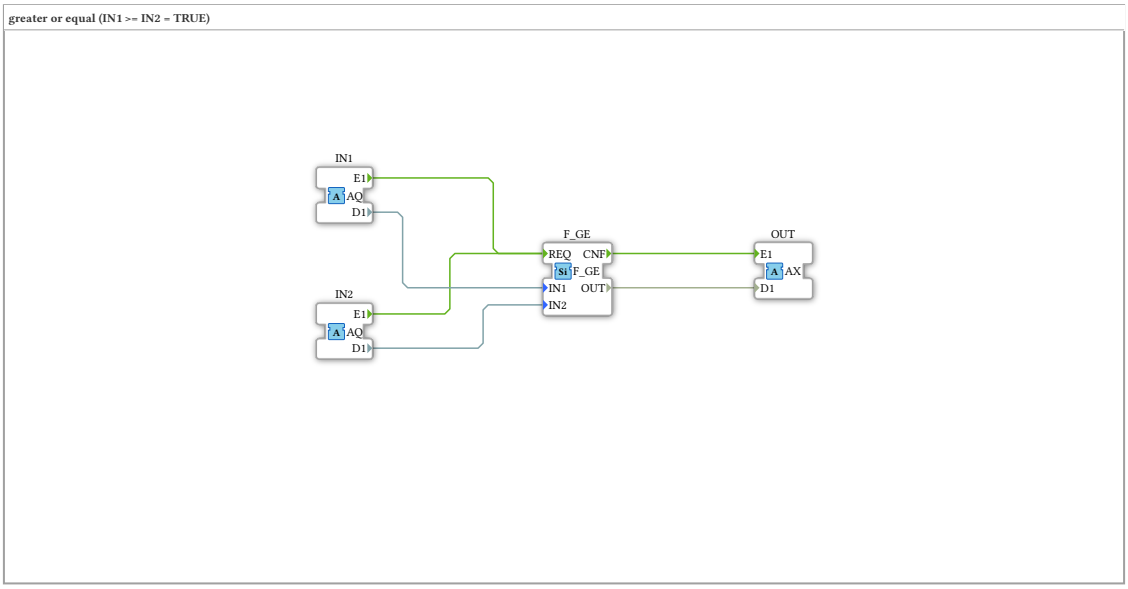
Application Scenarios

- **Limit Monitoring**: Checking compact status fields against a reference or threshold value of type QUARTER.
- **Control Logic**: Triggering an action once two values of type QUARTER satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a QUARTER-based comparison condition.

Comparison with Similar Function Blocks



- **AQ_NE**: Checks for “not equal to” – the inverse function of AQ_EQ.
- **AQ_NE**: Checks for inequality of values.



AQ_EQ is part of the complete AQ comparison family (EQ/NE/GT/GE/LT/LE) for the QUARTER data type.

Conclusion

AQ_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the QUARTER data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AQ_GE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AQ_GE** compares two values of type `QUARTER` (2-bit value (quarter byte)) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `QUARTER`, 2-bit value (quarter byte)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AQ (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AQ (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AQ and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GE (type iec61131::comparison::F_GE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AQ/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 ("greater than or equal to") for the QUARTER data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

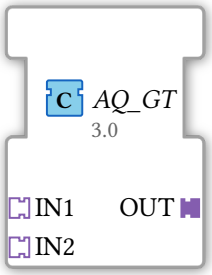
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking compact status fields against a reference or threshold value of type QUARTER.
- **Control Logic**: Triggering an action once two values of type QUARTER satisfy the "greater than or equal to" condition.
- **Data Filtering**: Selecting data records or signals that satisfy a QUARTER-based comparison condition.

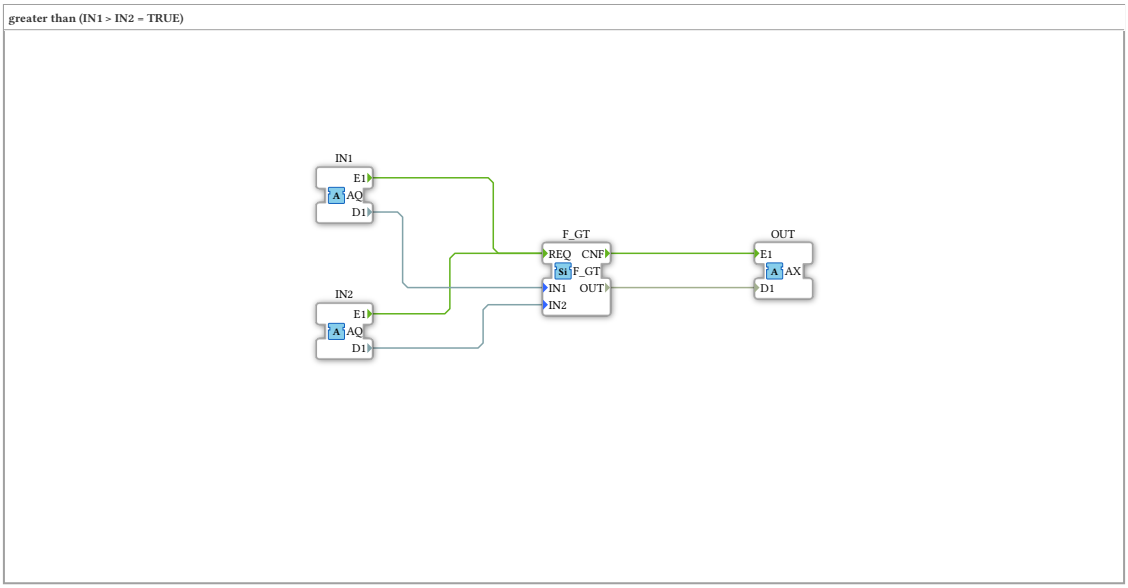
Comparison with Similar Function Blocks



- **AQ_LE**: Checks for "less than or equal to" – the inverse function of AQ_GE.
- **AQ_EQ**: Checks for equality of values.
- **AQ_GT**: Performs the "greater than" comparison – the base variant without the equality case, of which AQ_GE is the extended version.

AQ_GE completes the AQ comparison family with the boundary case of equality.

Conclusion



AQ_GE is a simple yet important comparison block for IEC 61131-3 control applications using the QUARTER data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AQ_GT

Input value 1 -- left operand (IN1 > IN2) – *AQ*
Input value 2 -- right operand (IN1 > IN2) – *AQ*

AX – IN1 > IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AQ_GT** compares two values of type `QUARTER` (2-bit value (quarter byte)) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `QUARTER`, 2-bit value (quarter byte)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AQ (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AQ (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AQ and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GT (type iec61131::comparison::F_GT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AQ/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 ("greater than") for the QUARTER data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

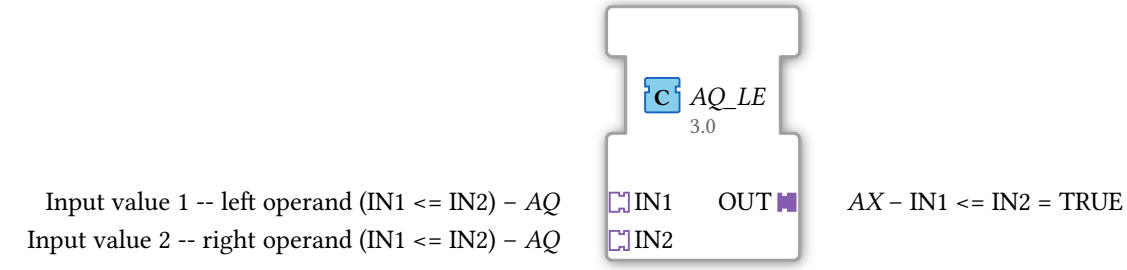
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

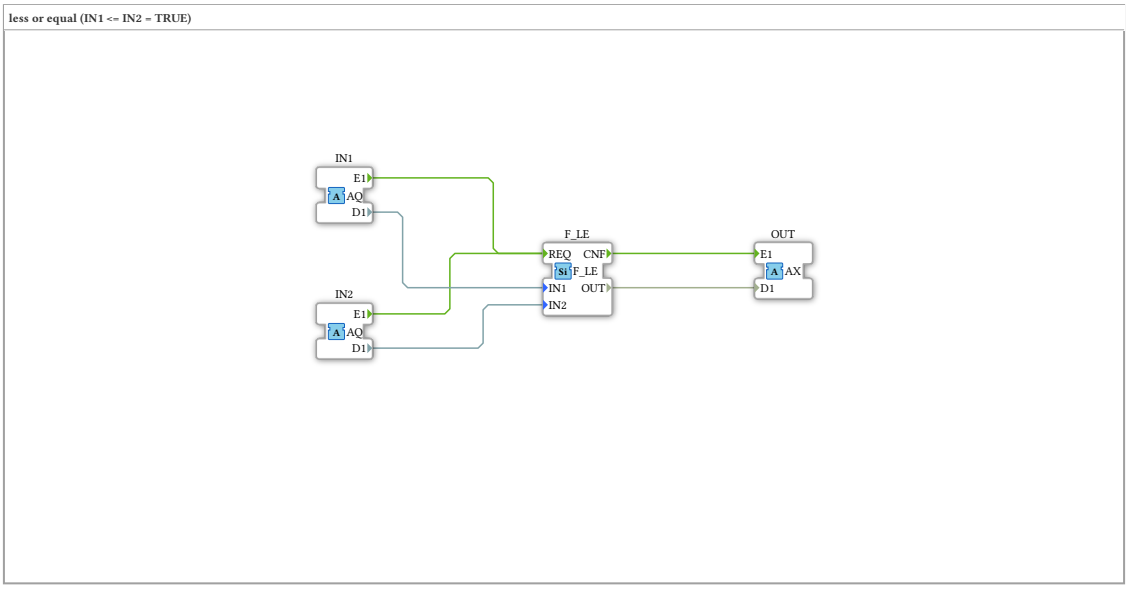
Application Scenarios

- **Limit Monitoring**: Checking compact status fields against a reference or threshold value of type QUARTER.
- **Control Logic**: Triggering an action once two values of type QUARTER satisfy the "greater than" condition.
- **Data Filtering**: Selecting data records or signals that satisfy a QUARTER-based comparison condition.

Comparison with Similar Function Blocks



- **AQ_LT**: Checks for "less than" – the inverse function of AQ_GT.
- **AQ_EQ**: Checks for equality of values.
- **AQ_GE**: Performs the "greater than or equal to" comparison – the extended version of AQ_GT that includes the equality case.



AQ_GT is the basic "greater than" component without the equality case, complemented by AQ_GE.

Conclusion

AQ_GT is a simple yet important comparison block for IEC 61131-3 control applications using the QUARTER data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AQ_LE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AQ_LE** compares two values of type `QUARTER` (2-bit value (quarter byte)) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `QUARTER`, 2-bit value (quarter byte)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AQ (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AQ (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AQ and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LE (type iec61131::comparison::F_LE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AQ/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 ("less than or equal to") for the QUARTER data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

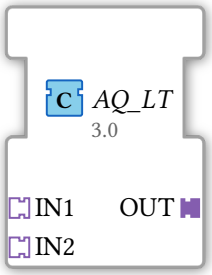
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking compact status fields against a reference or threshold value of type QUARTER.
- **Control Logic**: Triggering an action once two values of type QUARTER satisfy the "less than or equal to" condition.
- **Data Filtering**: Selecting data records or signals that satisfy a QUARTER-based comparison condition.

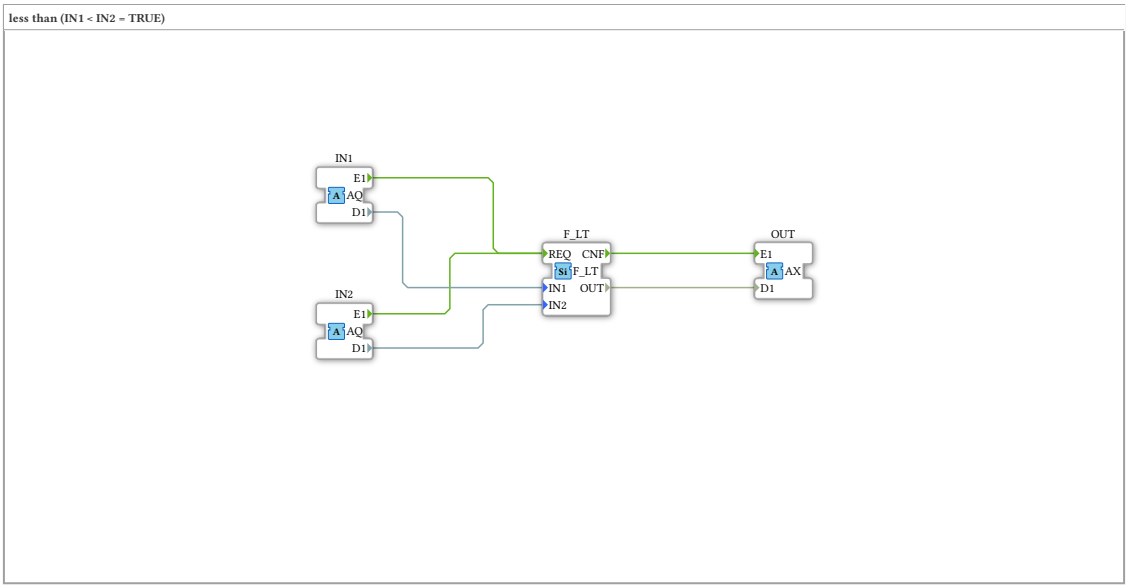
Comparison with Similar Function Blocks



- **AQ_GE**: Checks for "greater than or equal to" – the inverse function of AQ_LE.
- **AQ_EQ**: Checks for equality of values.
- **AQ_LT**: Performs the "less than" comparison – the base variant without the equality case, of which AQ_LE is the extended version.

AQ_LE completes the AQ comparison family with the boundary case of equality.

Conclusion



AQ_LE is a simple yet important comparison block for IEC 61131-3 control applications using the QUARTER data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AQ_LT

Input value 1 -- left operand (IN1 < IN2) – *AQ*
Input value 2 -- right operand (IN1 < IN2) – *AQ*

AX – IN1 < IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AQ_LT** compares two values of type `QUARTER` (2-bit value (quarter byte)) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `QUARTER`, 2-bit value (quarter byte)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AQ (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AQ (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AQ and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LT (type iec61131::comparison::F_LT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AQ/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the QUARTER data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

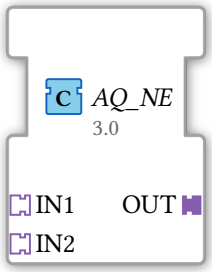
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking compact status fields against a reference or threshold value of type QUARTER.
- **Control Logic**: Triggering an action once two values of type QUARTER satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a QUARTER-based comparison condition.

Comparison with Similar Function Blocks

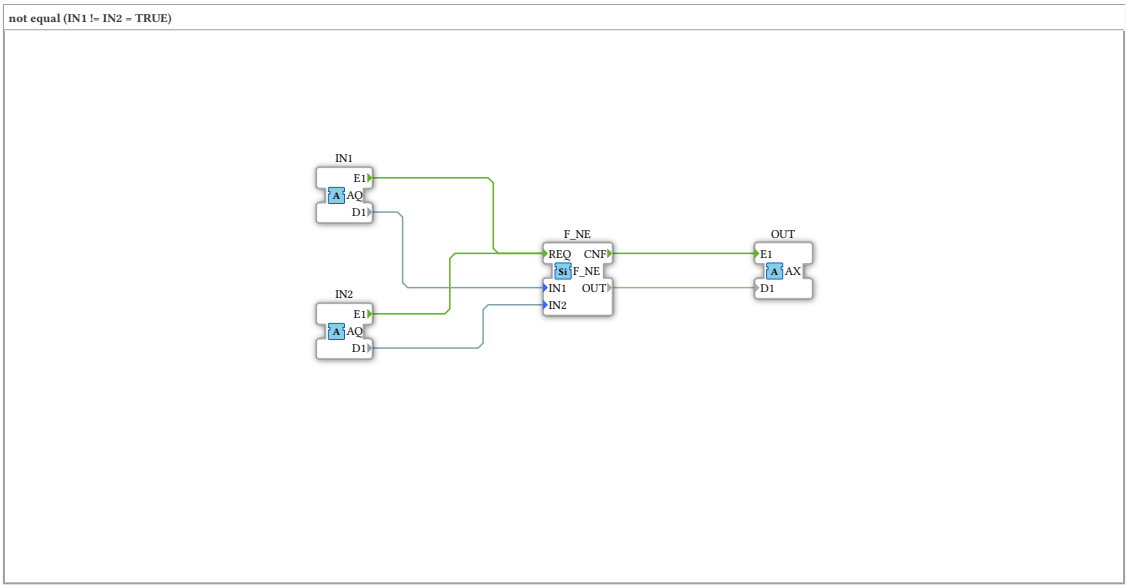


- **AQ_GT**: Checks for “greater than” – the inverse function of AQ_LT.
- **AQ_EQ**: Checks for equality of values.
- **AQ_LE**: Performs the “less than or equal to” comparison – the extended version of AQ_LT that includes the equality case.

AQ_LT is the basic “less than” component without the equality case, complemented by AQ_LE.

Conclusion

AQ_LT is a simple yet important comparison block for IEC 61131-3 control applications using the QUARTER data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.



AQ_NE

Input value 1 -- left operand (IN1 != IN2) – *AQ*

Input value 2 -- right operand (IN1 != IN2) – *AQ*

AX – IN1 != IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AQ_NE** compares two values of type `QUARTER` (2-bit value (quarter byte)) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `QUARTER`, 2-bit value (quarter byte)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AQ (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AQ (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AQ and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_NE (type iec61131::comparison::F_NE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AQ/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the QUARTER data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

State Overview

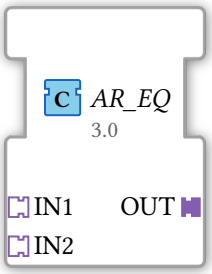
This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking compact status fields against a reference or threshold value of type QUARTER.
- **Control Logic**: Triggering an action once two values of type QUARTER satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a QUARTER-based comparison condition.

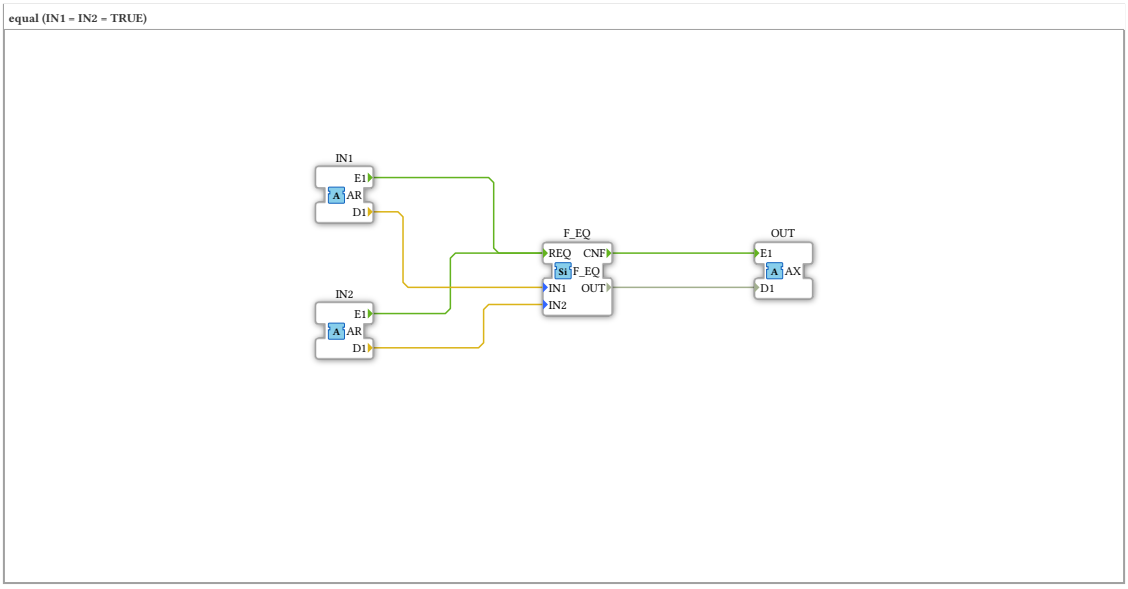
Comparison with Similar Function Blocks

- **AQ_EQ**: Checks for “equal to” – the inverse function of AQ_NE.
- **AQ_EQ**: Checks for equality of values.



AQ_NE is part of the complete AQ comparison family (EQ/NE/GT/GE/LT/LE) for the QUARTER data type.

Conclusion



AQ_NE is a simple yet important comparison block for IEC 61131-3 control applications using the QUARTER data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AR_EQ

Input value 1 -- left operand (IN1 = IN2) – *AR*
Input value 2 -- right operand (IN1 = IN2) – *AR*

AX – IN1 = IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AR_EQ** compares two values of type `REAL` (32-bit floating-point number (single precision)) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `REAL`, 32-bit floating-point number (single precision)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AR (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AR (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AR and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_EQ (type iec61131::comparison::F_EQ). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AR/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the REAL data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

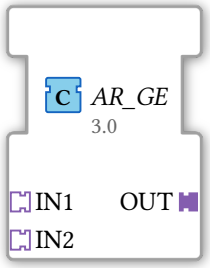
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking measured values against a reference or threshold value of type REAL.
- **Control Logic**: Triggering an action once two values of type REAL satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a REAL-based comparison condition.

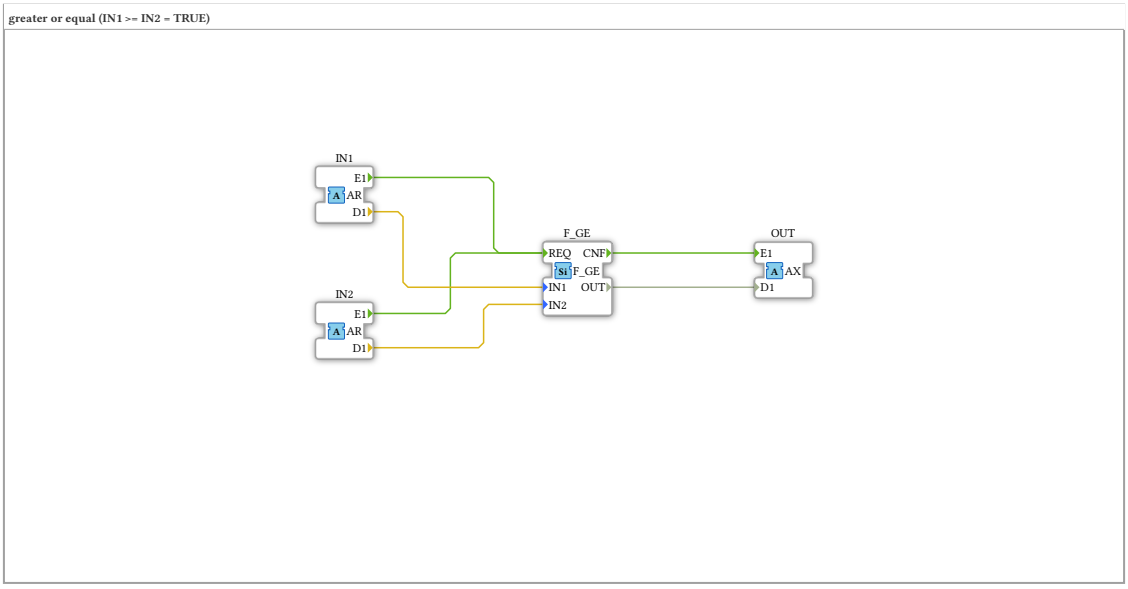
Comparison with Similar Function Blocks



- **AR_NE**: Checks for “not equal to” – the inverse function of AR_EQ.
- **AR_NE**: Checks for inequality of values.

AR_EQ is part of the complete AR comparison family (EQ/NE/GT/GE/LT/LE) for the REAL data type.

Conclusion



AR_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the REAL data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AR_GE

Input value 1 -- left operand (IN1 >= IN2) – *AR*
Input value 2 -- right operand (IN1 >= IN2) – *AR*

AX – IN1 >= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AR_GE** compares two values of type `REAL` (32-bit floating-point number (single precision)) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `REAL`, 32-bit floating-point number (single precision)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AR (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AR (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AR and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GE (type iec61131::comparison::F_GE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AR/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the REAL data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

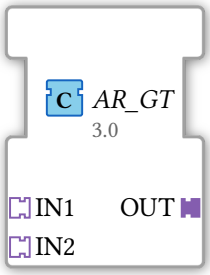
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking measured values against a reference or threshold value of type REAL.
- **Control Logic**: Triggering an action once two values of type REAL satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a REAL-based comparison condition.

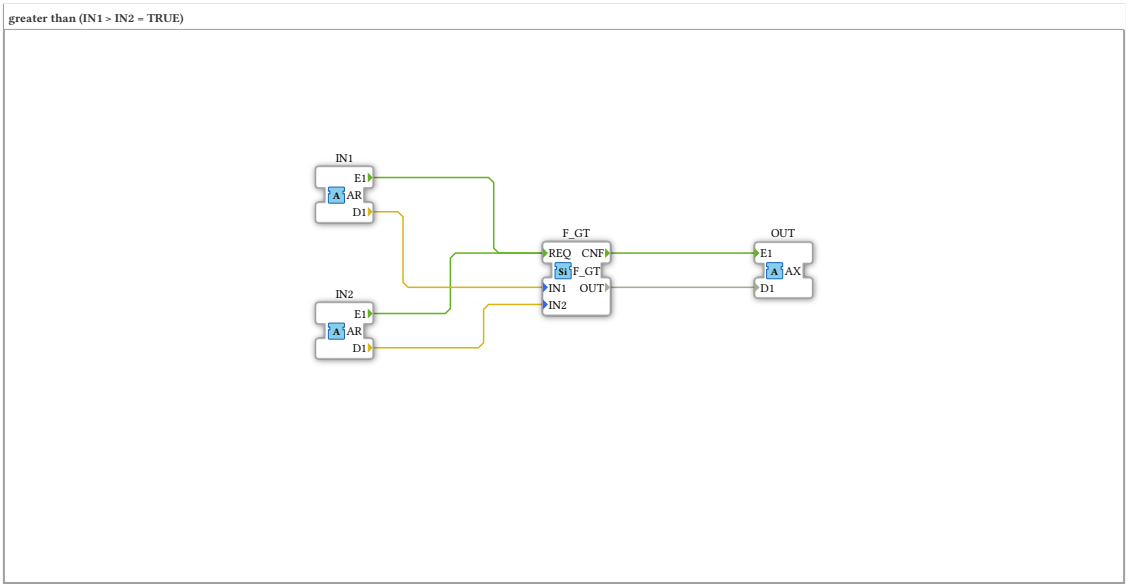
Comparison with Similar Function Blocks



- **AR_LE**: Checks for “less than or equal to” – the inverse function of AR_GE.
- **AR_EQ**: Checks for equality of values.
- **AR_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which AR_GE is the extended version.

AR_GE completes the AR comparison family with the boundary case of equality.

Conclusion



AR_GE is a simple yet important comparison block for IEC 61131-3 control applications using the REAL data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AR_GT

Input value 1 -- left operand (IN1 > IN2) – *AR*
Input value 2 -- right operand (IN1 > IN2) – *AR*

AX – IN1 > IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AR_GT** compares two values of type `REAL` (32-bit floating-point number (single precision)) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `REAL`, 32-bit floating-point number (single precision)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AR (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AR (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AR and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GT (type iec61131::comparison::F_GT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AR/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the REAL data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

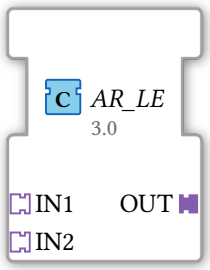
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking measured values against a reference or threshold value of type REAL.
- **Control Logic**: Triggering an action once two values of type REAL satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a REAL-based comparison condition.

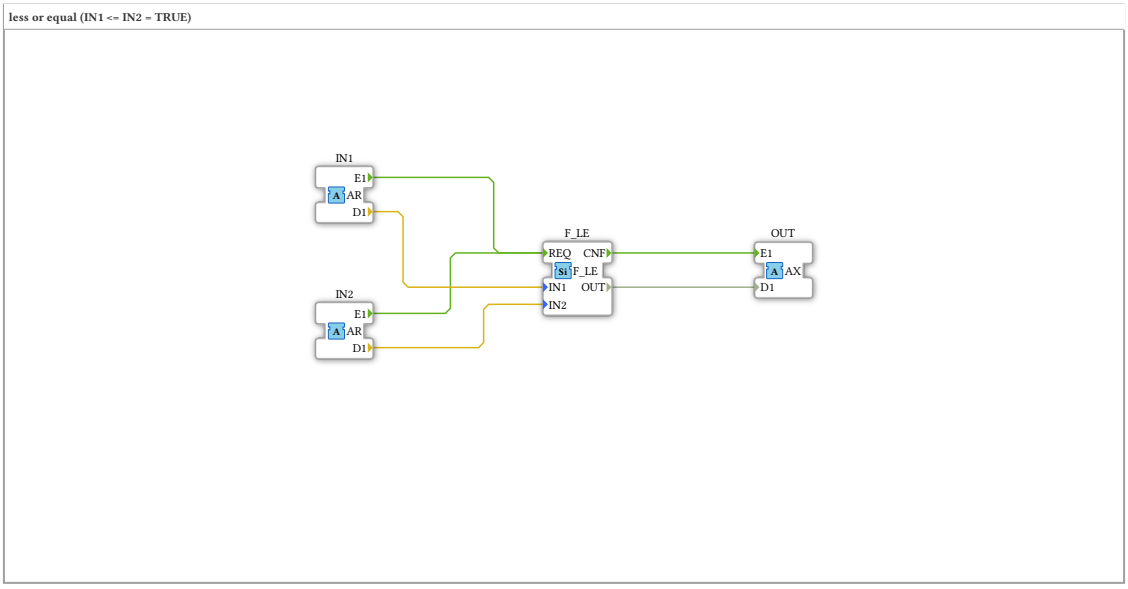
Comparison with Similar Function Blocks



- **AR_LT**: Checks for “less than” – the inverse function of AR_GT.
- **AR_EQ**: Checks for equality of values.
- **AR_GE**: Performs the “greater than or equal to” comparison – the extended version of AR_GT that includes the equality case.

AR_GT is the basic “greater than” component without the equality case, complemented by AR_GE.

Conclusion



AR_GT is a simple yet important comparison block for IEC 61131-3 control applications using the REAL data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AR_LE

Input value 1 -- left operand (IN1 <= IN2) – *AR*
Input value 2 -- right operand (IN1 <= IN2) – *AR*

AX – IN1 <= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AR_LE** compares two values of type `REAL` (32-bit floating-point number (single precision)) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `REAL`, 32-bit floating-point number (single precision)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AR (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AR (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AR and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LE (type iec61131::comparison::F_LE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AR/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the REAL data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

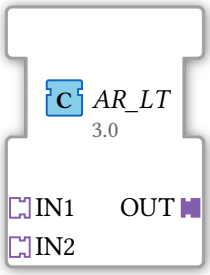
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking measured values against a reference or threshold value of type REAL.
- **Control Logic**: Triggering an action once two values of type REAL satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a REAL-based comparison condition.

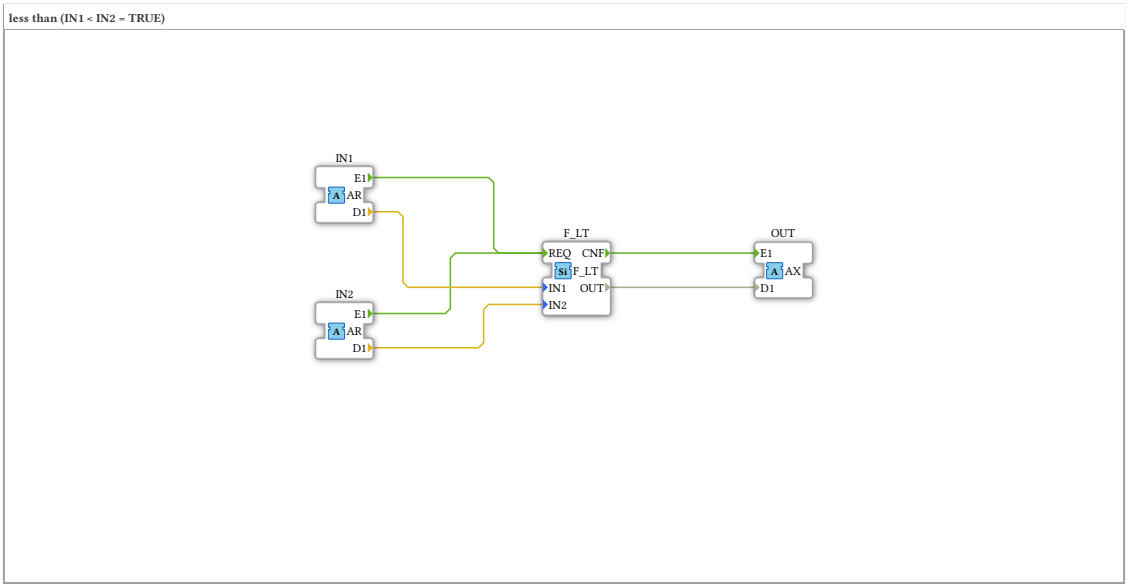
Comparison with Similar Function Blocks



- **AR_GE**: Checks for “greater than or equal to” – the inverse function of AR_LE.
- **AR_EQ**: Checks for equality of values.
- **AR_LT**: Performs the “less than” comparison – the base variant without the equality case, of which AR_LE is the extended version.

AR_LE completes the AR comparison family with the boundary case of equality.

Conclusion



AR_LE is a simple yet important comparison block for IEC 61131-3 control applications using the REAL data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AR_LT

Input value 1 -- left operand (IN1 < IN2) – *AR*
Input value 2 -- right operand (IN1 < IN2) – *AR*

AX – IN1 < IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AR_LT** compares two values of type `REAL` (32-bit floating-point number (single precision)) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `REAL`, 32-bit floating-point number (single precision)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AR (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AR (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AR and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LT (type iec61131::comparison::F_LT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AR/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the REAL data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

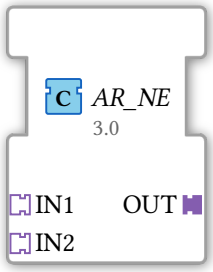
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking measured values against a reference or threshold value of type REAL.
- **Control Logic**: Triggering an action once two values of type REAL satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a REAL-based comparison condition.

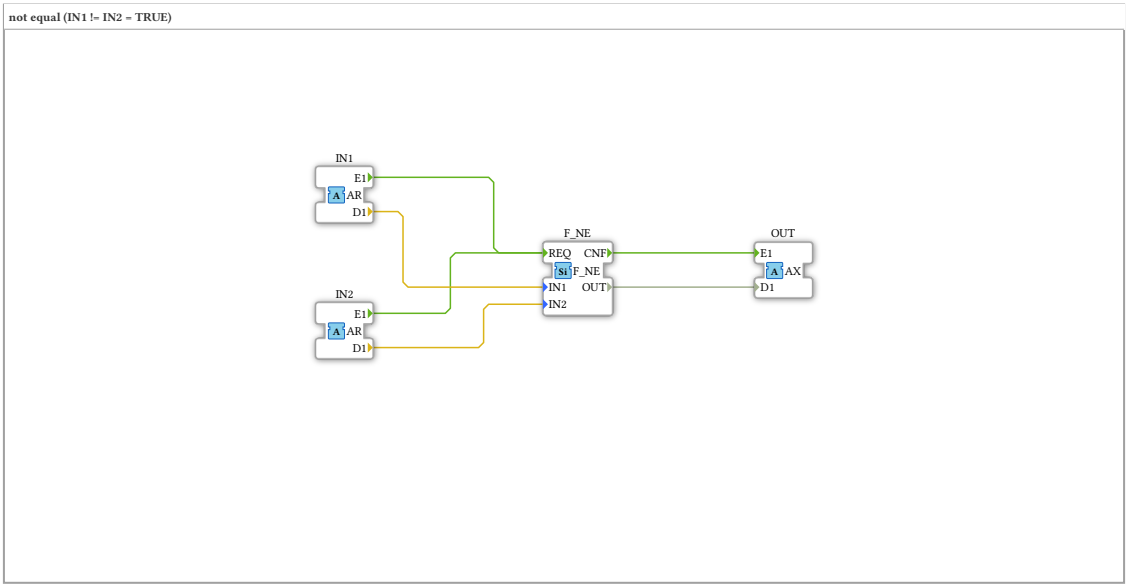
Comparison with Similar Function Blocks



- **AR_GT**: Checks for “greater than” – the inverse function of AR_LT.
- **AR_EQ**: Checks for equality of values.
- **AR_LE**: Performs the “less than or equal to” comparison – the extended version of AR_LT that includes the equality case.

AR_LT is the basic “less than” component without the equality case, complemented by AR_LE.

Conclusion



AR_LT is a simple yet important comparison block for IEC 61131-3 control applications using the REAL data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AR_NE

Input value 1 -- left operand (IN1 != IN2) – *AR*
Input value 2 -- right operand (IN1 != IN2) – *AR*

AX – IN1 != IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AR_NE** compares two values of type `REAL` (32-bit floating-point number (single precision)) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `REAL`, 32-bit floating-point number (single precision)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AR (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AR (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AR and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_NE (type iec61131::comparison::F_NE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AR/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the REAL data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

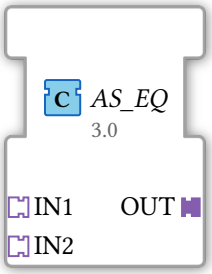
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking measured values against a reference or threshold value of type REAL.
- **Control Logic**: Triggering an action once two values of type REAL satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a REAL-based comparison condition.

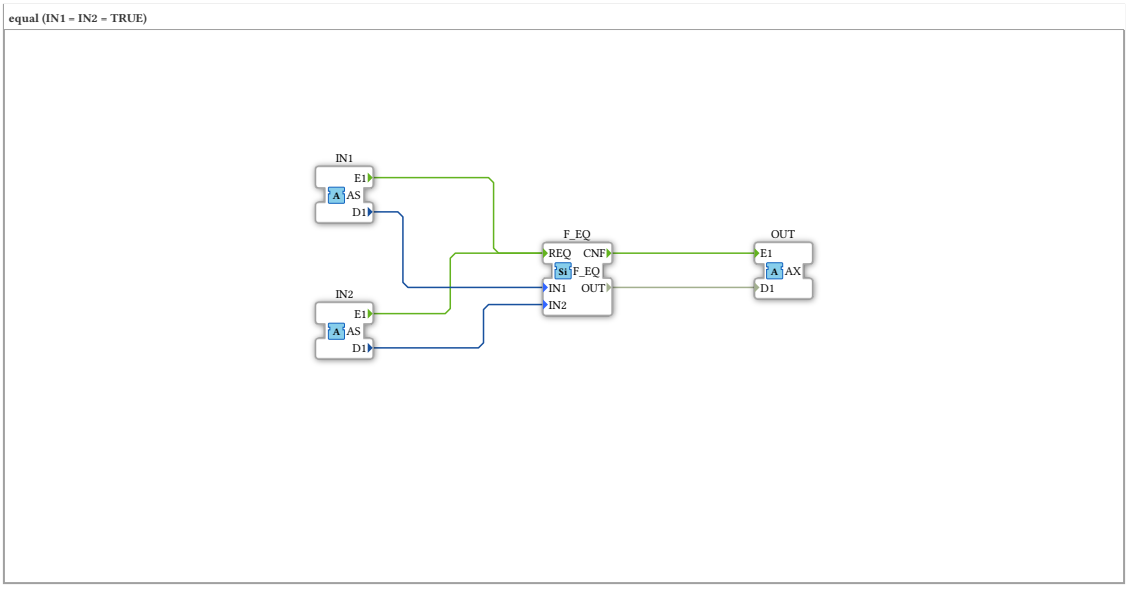
Comparison with Similar Function Blocks



- **AR_EQ**: Checks for “equal to” – the inverse function of AR_NE.
- **AR_EQ**: Checks for equality of values.

AR_NE is part of the complete AR comparison family (EQ/NE/GT/GE/LT/LE) for the REAL data type.

Conclusion



AR_NE is a simple yet important comparison block for IEC 61131-3 control applications using the REAL data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AS_EQ

Input value 1 -- left operand (IN1 = IN2) – *AS*
Input value 2 -- right operand (IN1 = IN2) – *AS*

AX – IN1 = IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AS_EQ** compares two values of type `SINT` (8-bit signed integer) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `SINT`, 8-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AS (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AS (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AS and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_EQ (type iec61131::comparison::F_EQ). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AS/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the SINT data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

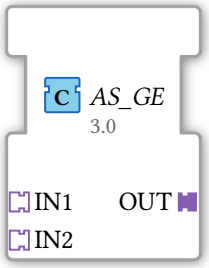
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking small counter and index values against a reference or threshold value of type SINT.
- **Control Logic**: Triggering an action once two values of type SINT satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a SINT-based comparison condition.

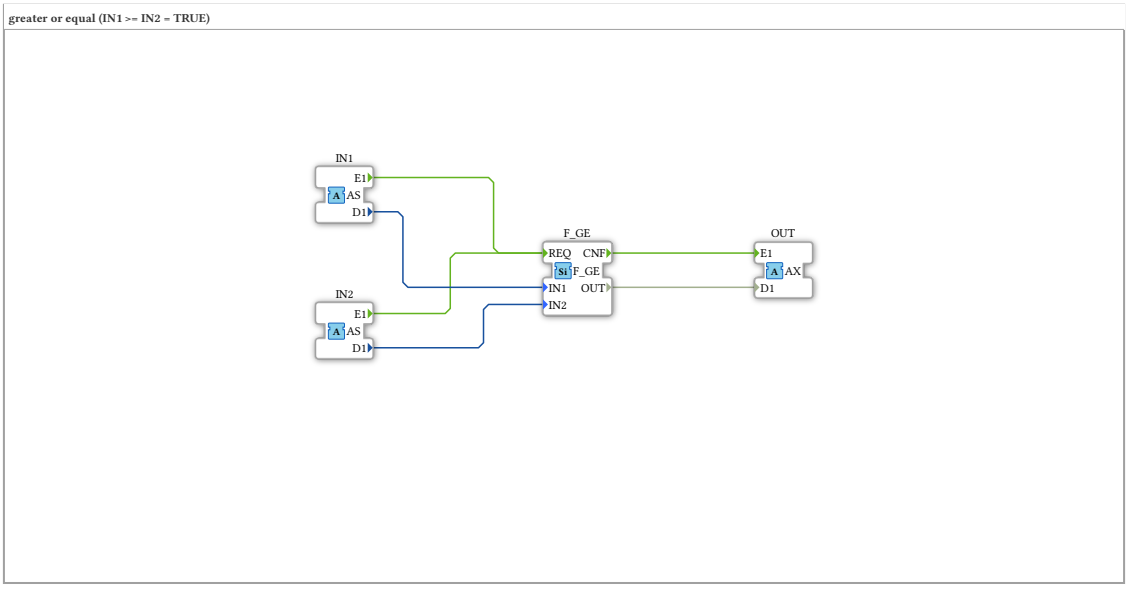
Comparison with Similar Function Blocks



- **AS_NE**: Checks for “not equal to” – the inverse function of AS_EQ.
- **AS_NE**: Checks for inequality of values.

AS_EQ is part of the complete AS comparison family (EQ/NE/GT/GE/LT/LE) for the SINT data type.

Conclusion



AS_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the SINT data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AS_GE

Input value 1 -- left operand (IN1 >= IN2) – *AS*
Input value 2 -- right operand (IN1 >= IN2) – *AS*

AX – IN1 >= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AS_GE** compares two values of type `SINT` (8-bit signed integer) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `SINT`, 8-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AS (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AS (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AS and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GE (type iec61131::comparison::F_GE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AS/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 ("greater than or equal to") for the SINT data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

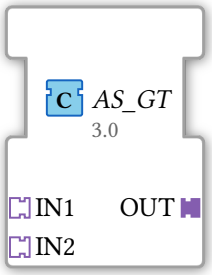
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking small counter and index values against a reference or threshold value of type SINT.
- **Control Logic**: Triggering an action once two values of type SINT satisfy the "greater than or equal to" condition.
- **Data Filtering**: Selecting data records or signals that satisfy a SINT-based comparison condition.

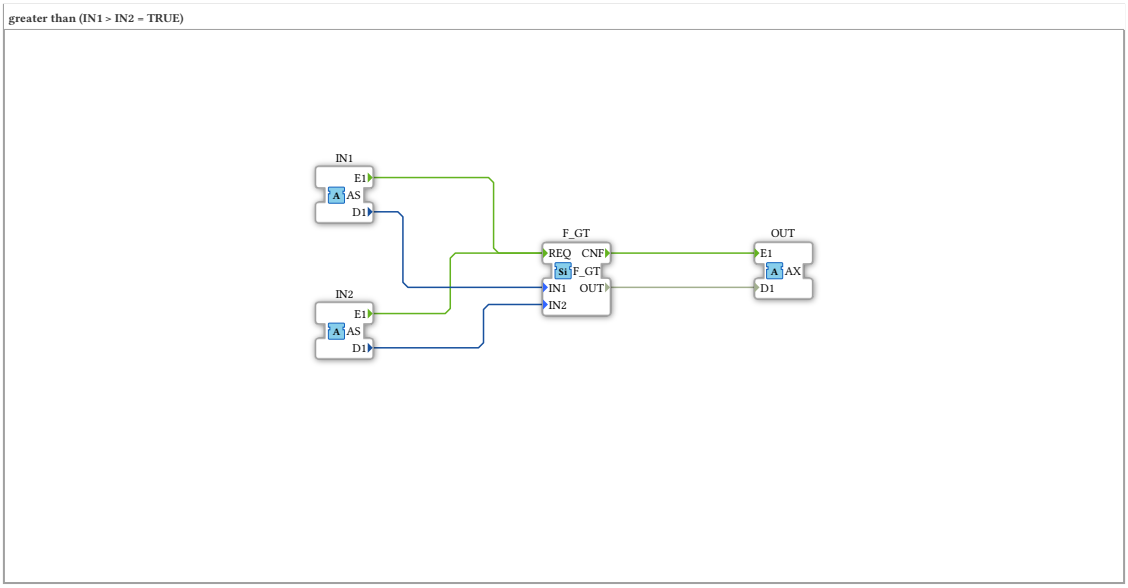
Comparison with Similar Function Blocks



- **AS_LE**: Checks for "less than or equal to" – the inverse function of AS_GE.
- **AS_EQ**: Checks for equality of values.
- **AS_GT**: Performs the "greater than" comparison – the base variant without the equality case, of which AS_GE is the extended version.

AS_GE completes the AS comparison family with the boundary case of equality.

Conclusion



AS_GE is a simple yet important comparison block for IEC 61131-3 control applications using the SINT data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AS_GT

Input value 1 -- left operand (IN1 > IN2) – *AS*
Input value 2 -- right operand (IN1 > IN2) – *AS*

AX – IN1 > IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AS_GT** compares two values of type `SINT` (8-bit signed integer) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `SINT`, 8-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AS (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AS (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AS and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GT (type iec61131::comparison::F_GT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AS/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the SINT data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

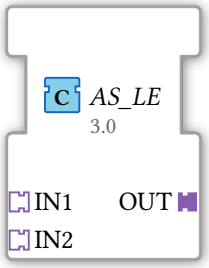
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking small counter and index values against a reference or threshold value of type SINT.
- **Control Logic**: Triggering an action once two values of type SINT satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a SINT-based comparison condition.

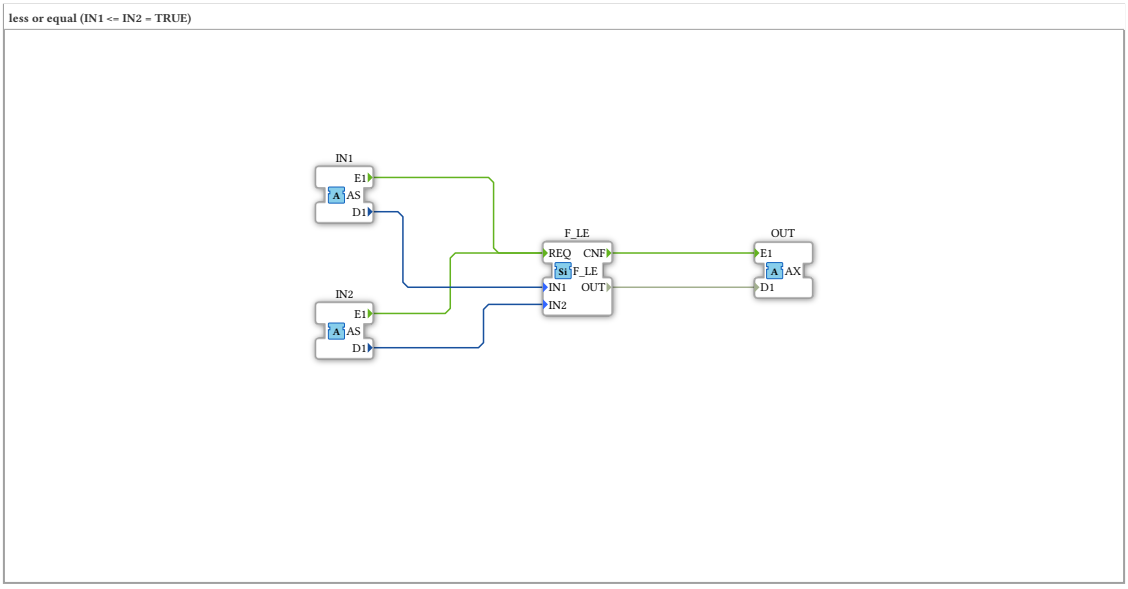
Comparison with Similar Function Blocks



- **AS_LT**: Checks for “less than” – the inverse function of AS_GT.
- **AS_EQ**: Checks for equality of values.
- **AS_GE**: Performs the “greater than or equal to” comparison – the extended version of AS_GT that includes the equality case.

AS_GT is the basic “greater than” component without the equality case, complemented by AS_GE.

Conclusion



AS_GT is a simple yet important comparison block for IEC 61131-3 control applications using the SINT data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AS_LE

Input value 1 -- left operand (IN1 <= IN2) – *AS*
Input value 2 -- right operand (IN1 <= IN2) – *AS*

AX – IN1 <= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AS_LE** compares two values of type `SINT` (8-bit signed integer) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `SINT`, 8-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AS (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AS (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AS and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LE (type iec61131::comparison::F_LE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AS/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 ("less than or equal to") for the SINT data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

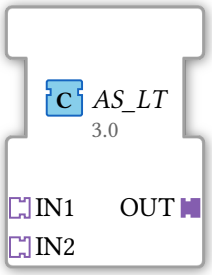
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking small counter and index values against a reference or threshold value of type SINT.
- **Control Logic**: Triggering an action once two values of type SINT satisfy the "less than or equal to" condition.
- **Data Filtering**: Selecting data records or signals that satisfy a SINT-based comparison condition.

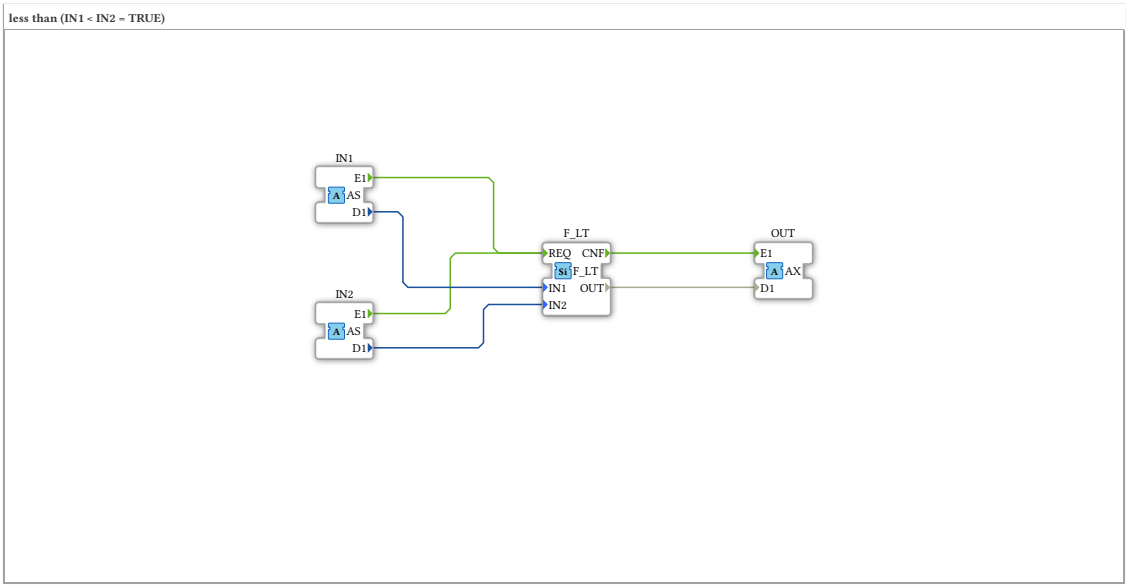
Comparison with Similar Function Blocks



- **AS_GE**: Checks for "greater than or equal to" – the inverse function of AS_LE.
- **AS_EQ**: Checks for equality of values.
- **AS_LT**: Performs the "less than" comparison – the base variant without the equality case, of which AS_LE is the extended version.

AS_LE completes the AS comparison family with the boundary case of equality.

Conclusion



AS_LE is a simple yet important comparison block for IEC 61131-3 control applications using the SINT data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AS_LT

Input value 1 -- left operand (IN1 < IN2) – *AS*
Input value 2 -- right operand (IN1 < IN2) – *AS*

AX – IN1 < IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AS_LT** compares two values of type `SINT` (8-bit signed integer) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `SINT`, 8-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AS (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AS (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AS and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LT (type iec61131::comparison::F_LT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AS/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the SINT data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

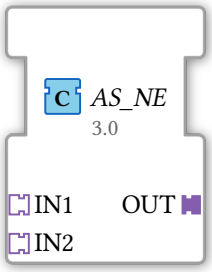
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking small counter and index values against a reference or threshold value of type SINT.
- **Control Logic**: Triggering an action once two values of type SINT satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a SINT-based comparison condition.

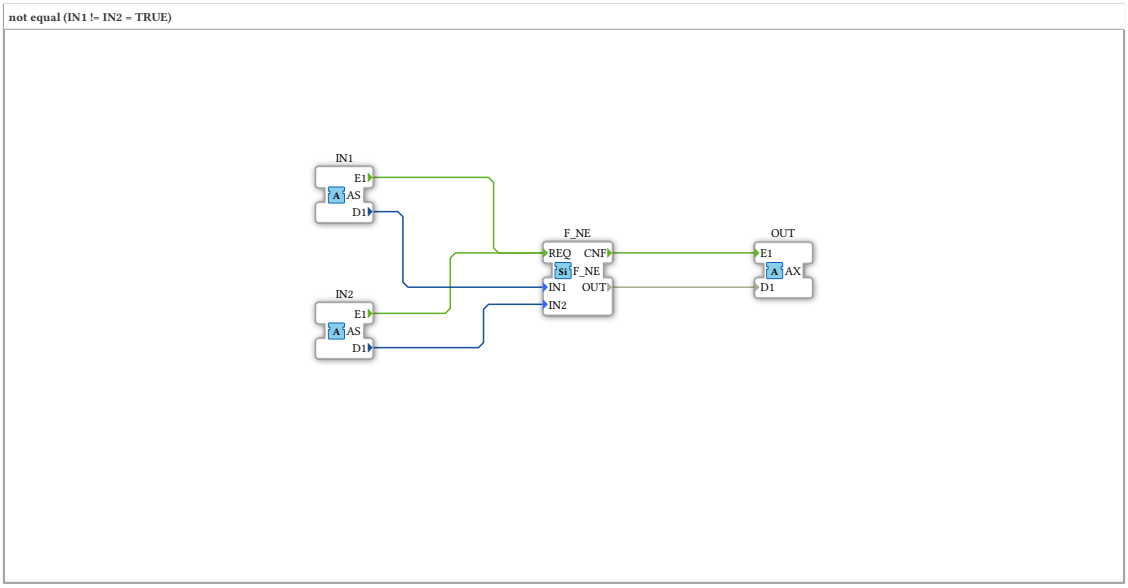
Comparison with Similar Function Blocks



- **AS_GT**: Checks for “greater than” – the inverse function of AS_LT.
- **AS_EQ**: Checks for equality of values.
- **AS_LE**: Performs the “less than or equal to” comparison – the extended version of AS_LT that includes the equality case.

AS_LT is the basic “less than” component without the equality case, complemented by AS_LE.

Conclusion



AS_LT is a simple yet important comparison block for IEC 61131-3 control applications using the SINT data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AS_NE

Input value 1 -- left operand (IN1 != IN2) – *AS*
Input value 2 -- right operand (IN1 != IN2) – *AS*

AX – IN1 != IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AS_NE** compares two values of type `SINT` (8-bit signed integer) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `SINT`, 8-bit signed integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	AS (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	AS (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters AS and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_NE (type iec61131::comparison::F_NE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (AS/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the SINT data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

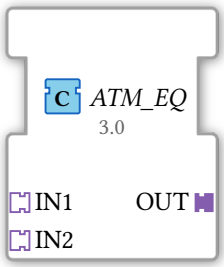
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking small counter and index values against a reference or threshold value of type SINT.
- **Control Logic**: Triggering an action once two values of type SINT satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a SINT-based comparison condition.

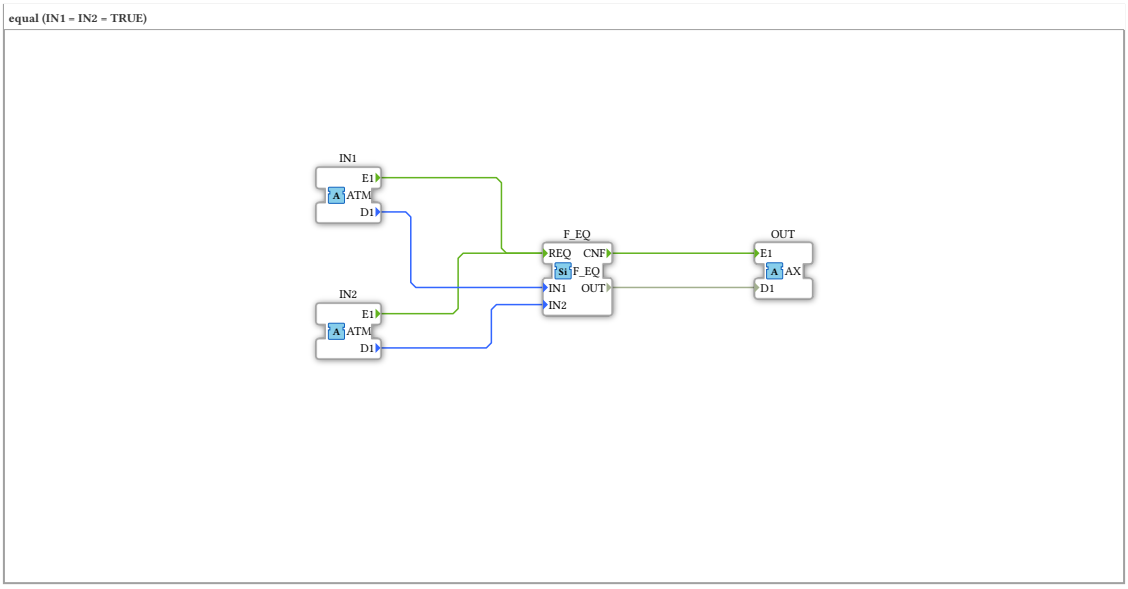
Comparison with Similar Function Blocks



- **AS_EQ**: Checks for “equal to” – the inverse function of AS_NE.
- **AS_EQ**: Checks for equality of values.

AS_NE is part of the complete AS comparison family (EQ/NE/GT/GE/LT/LE) for the SINT data type.

Conclusion



AS_NE is a simple yet important comparison block for IEC 61131-3 control applications using the SINT data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ATM_EQ

Input value 1 -- left operand (IN1 = IN2) – *ATM*
Input value 2 -- right operand (IN1 = IN2) – *ATM*

AX – IN1 = IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_EQ** compares two values of type `TIME` (duration) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The duration of the two time values is compared.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `TIME`, duration).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	ATM (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	ATM (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters ATM and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_EQ (type iec61131::comparison::F_EQ). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (ATM/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the TIME data type.
- **Comparison logic**: The duration of the two time values is compared.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

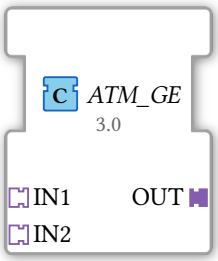
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking timing and delay values against a reference or threshold value of type TIME.
- **Control Logic**: Triggering an action once two values of type TIME satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a TIME-based comparison condition.

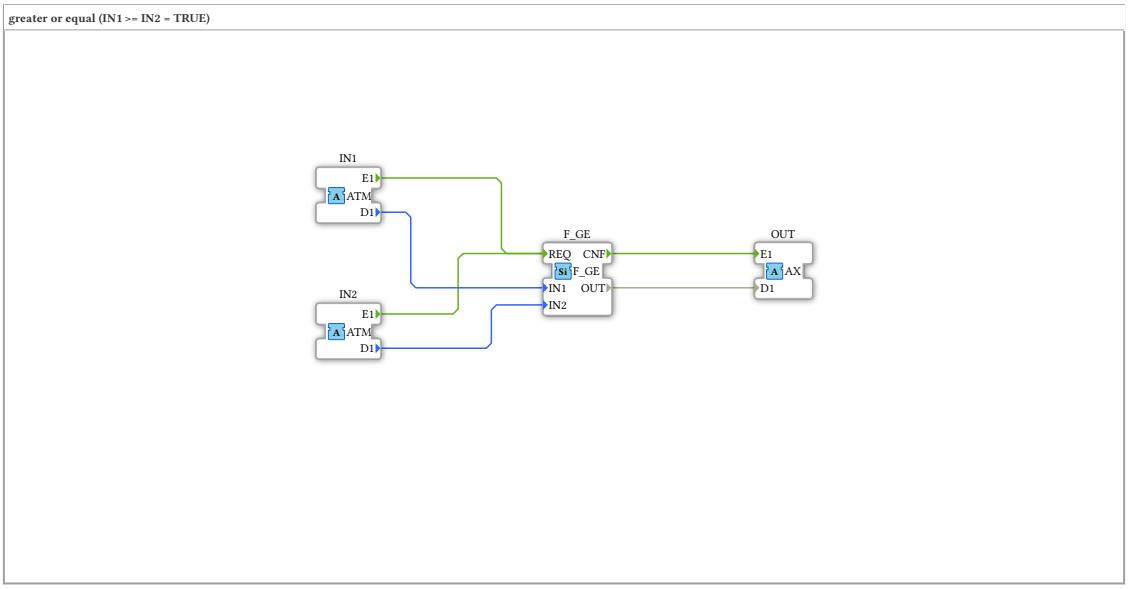
Comparison with Similar Function Blocks



- **ATM_NE**: Checks for “not equal to” – the inverse function of ATM_EQ.
- **ATM_NE**: Checks for inequality of values.

ATM_EQ is part of the complete ATM comparison family (EQ/NE/GT/GE/LT/LE) for the TIME data type.

Conclusion



ATM_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the TIME data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ATM_GE

Input value 1 -- left operand (IN1 >= IN2) – *ATM*
Input value 2 -- right operand (IN1 >= IN2) – *ATM*

AX – IN1 >= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ATM_GE** compares two values of type `TIME` (duration) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The duration of the two time values is compared.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `TIME`, duration).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	ATM (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	ATM (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters ATM and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GE (type iec61131::comparison::F_GE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (ATM/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the TIME data type.
- **Comparison logic**: The duration of the two time values is compared.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

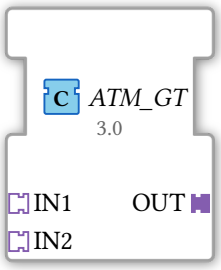
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking timing and delay values against a reference or threshold value of type TIME.
- **Control Logic**: Triggering an action once two values of type TIME satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a TIME-based comparison condition.

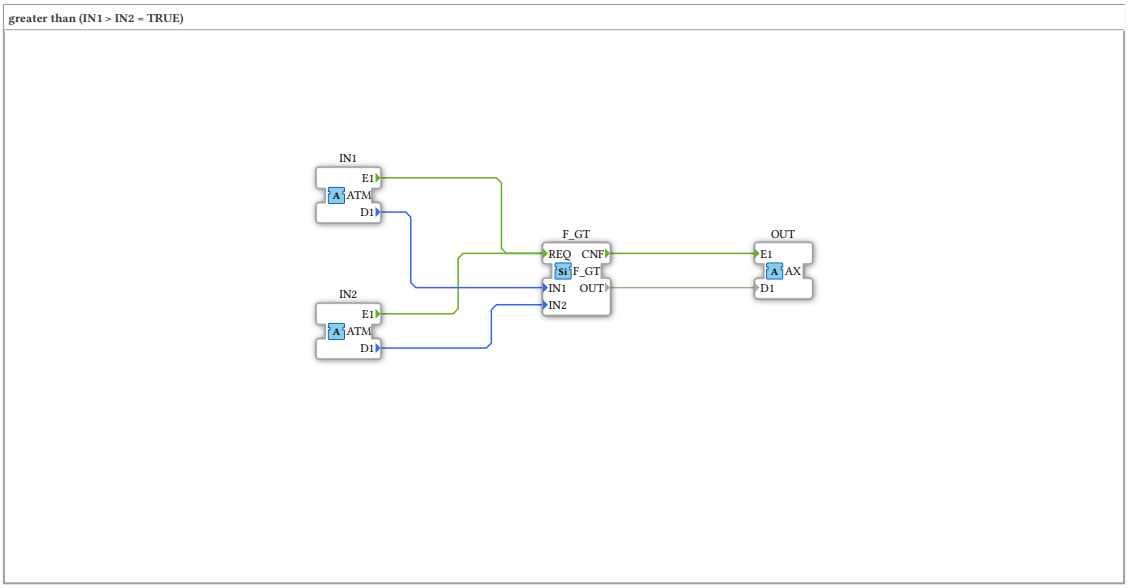
Comparison with Similar Function Blocks



- **ATM_LE**: Checks for “less than or equal to” – the inverse function of ATM_GE.
- **ATM_EQ**: Checks for equality of values.
- **ATM_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which ATM_GE is the extended version.

ATM_GE completes the ATM comparison family with the boundary case of equality.

Conclusion



ATM_GE is a simple yet important comparison block for IEC 61131-3 control applications using the TIME data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ATM_GT

Input value 1 -- left operand (IN1 > IN2) – *ATM*
Input value 2 -- right operand (IN1 > IN2) – *ATM*

AX – IN1 > IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_GT** compares two values of type `TIME` (duration) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The duration of the two time values is compared.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `TIME`, duration).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	ATM (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	ATM (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters ATM and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_GT (type iec61131::comparison::F_GT). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (ATM/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the TIME data type.
- **Comparison logic**: The duration of the two time values is compared.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

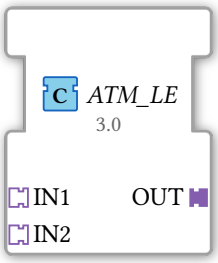
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking timing and delay values against a reference or threshold value of type TIME.
- **Control Logic**: Triggering an action once two values of type TIME satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a TIME-based comparison condition.

Comparison with Similar Function Blocks

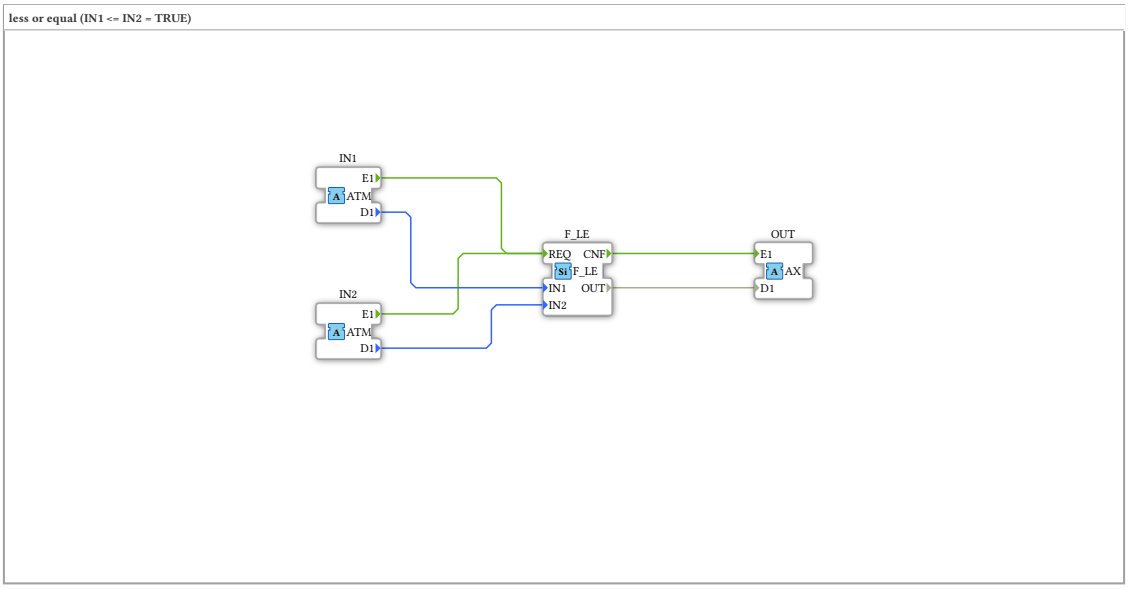


- **ATM_LT**: Checks for “less than” – the inverse function of ATM_GT.
- **ATM_EQ**: Checks for equality of values.
- **ATM_GE**: Performs the “greater than or equal to” comparison – the extended version of ATM_GT that includes the equality case.

ATM_GT is the basic “greater than” component without the equality case, complemented by ATM_GE.

Conclusion

ATM_GT is a simple yet important comparison block for IEC 61131-3 control applications using the TIME data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.



ATM_LE

Input value 1 -- left operand (IN1 <= IN2) – *ATM*

Input value 2 -- right operand (IN1 <= IN2) – *ATM*

AX – IN1 <= IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_LE** compares two values of type `TIME` (duration) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The duration of the two time values is compared.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `TIME`, duration).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	ATM (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	ATM (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters ATM and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_LE (type iec61131::comparison::F_LE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (ATM/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the TIME data type.
- **Comparison logic**: The duration of the two time values is compared.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

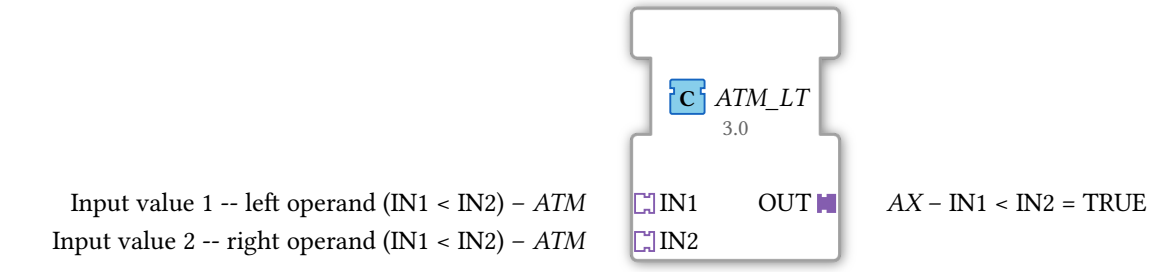
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

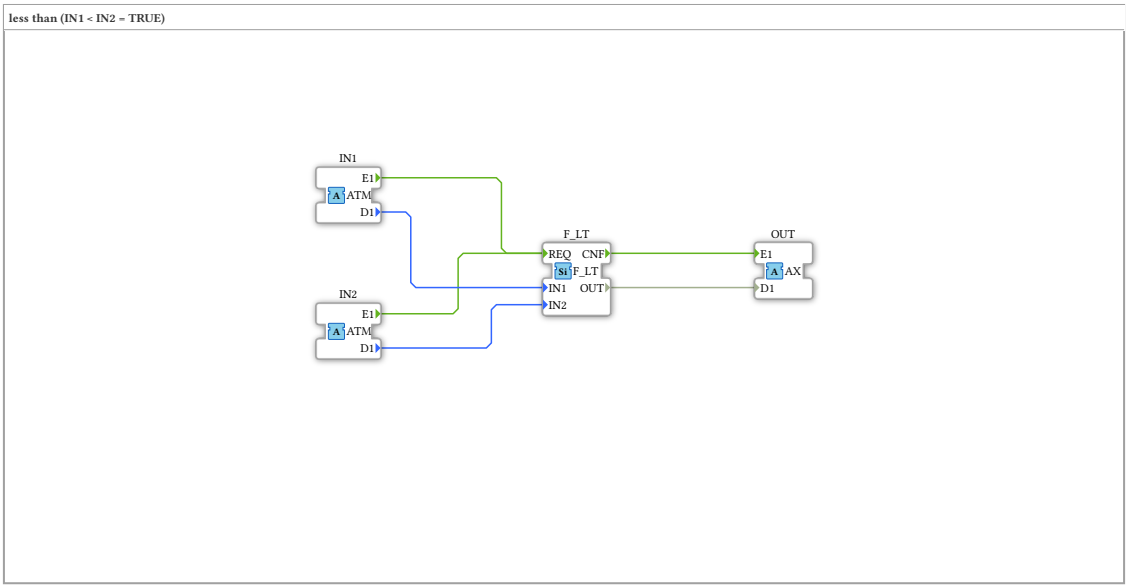
Application Scenarios

- **Limit Monitoring**: Checking timing and delay values against a reference or threshold value of type TIME.
- **Control Logic**: Triggering an action once two values of type TIME satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a TIME-based comparison condition.

Comparison with Similar Function Blocks



- **ATM_GE**: Checks for “greater than or equal to” – the inverse function of ATM_LE.
- **ATM_EQ**: Checks for equality of values.
- **ATM_LT**: Performs the “less than” comparison – the base variant without the equality case, of which ATM_LE is the extended version.



ATM_LE completes the ATM comparison family with the boundary case of equality.

Conclusion

ATM_LE is a simple yet important comparison block for IEC 61131-3 control applications using the TIME data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ATM_LT

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_LT** compares two values of type `TIME` (duration) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The duration of the two time values is compared.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `TIME`, duration).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`ATM` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`ATM` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `ATM` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LT` (type `iec61131::comparison::F_LT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`ATM`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the `TIME` data type.
- **Comparison logic**: The duration of the two time values is compared.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

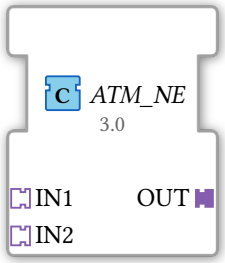
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking timing and delay values against a reference or threshold value of type `TIME`.
- **Control Logic**: Triggering an action once two values of type `TIME` satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `TIME`-based comparison condition.

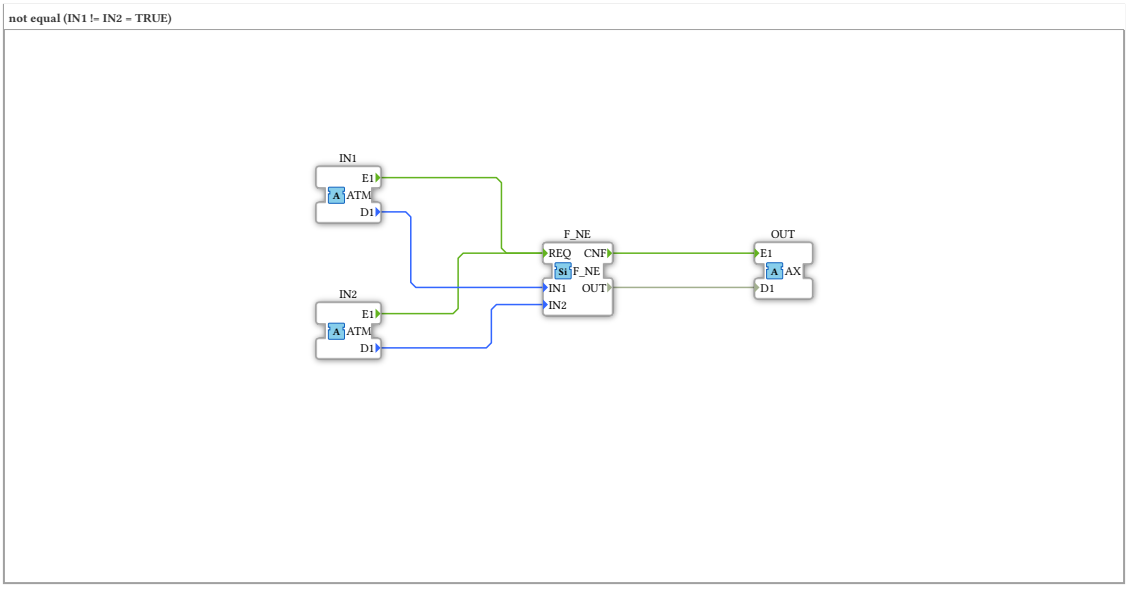
Comparison with Similar Function Blocks



- **ATM_GT**: Checks for “greater than” – the inverse function of ATM_LT.
- **ATM_EQ**: Checks for equality of values.
- **ATM_LE**: Performs the “less than or equal to” comparison – the extended version of ATM_LT that includes the equality case.

ATM_LT is the basic “less than” component without the equality case, complemented by ATM_LE.

Conclusion



ATM_LT is a simple yet important comparison block for IEC 61131-3 control applications using the `TIME` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ATM_NE

Input value 1 -- left operand (IN1 != IN2) – *ATM*
Input value 2 -- right operand (IN1 != IN2) – *ATM*

AX – IN1 != IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_NE** compares two values of type `TIME` (duration) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The duration of the two time values is compared.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `TIME`, duration).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	ATM (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	ATM (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	AX (Plug)	Output	Adapter for the comparison result and the output event

The adapters ATM and AX are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block F_NE (type iec61131::comparison::F_NE). There, the current values of IN1.D1 and IN2.D1 are compared.
3. The internal function block generates an output event (CNF) and outputs the Boolean result (OUT).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value OUT.D1 is set to TRUE or FALSE.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (ATM/AX), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the TIME data type.
- **Comparison logic**: The duration of the two time values is compared.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

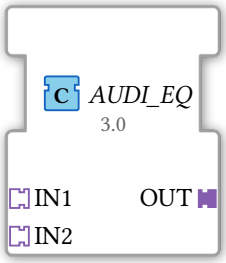
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checking timing and delay values against a reference or threshold value of type TIME.
- **Control Logic**: Triggering an action once two values of type TIME satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a TIME-based comparison condition.

Comparison with Similar Function Blocks

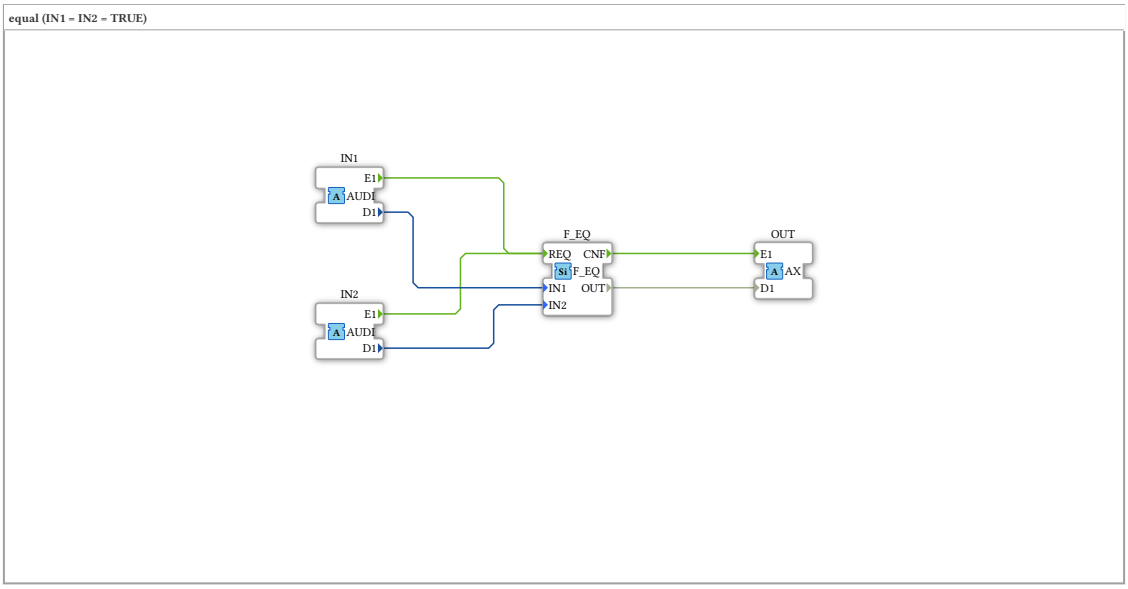


- **ATM_EQ**: Checks for “equal to” – the inverse function of ATM_NE.
- **ATM_EQ**: Checks for equality of values.

ATM_NE is part of the complete ATM comparison family (EQ/NE/GT/GE/LT/LE) for the TIME data type.

Conclusion

ATM_NE is a simple yet important comparison block for IEC 61131-3 control applications using the TIME data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.



AUDI_EQ

Input value 1 -- left operand (IN1 = IN2) – *AUDI*

Input value 2 -- right operand (IN1 = IN2) – *AUDI*

AX – IN1 = IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AUDI_EQ** compares two analog values for equality. It is implemented as a composite function block (FB) and uses adapters to communicate with the environment. The result is a Boolean value, which is output via another adapter. The function block complies with the IEC 61131-3 classification “Standard comparison function”.

Interface Structure

The FB has only adapter interfaces. No direct event or data inputs/outputs are defined. The actual inputs/outputs are implemented via the adapter types.

Event Inputs

- **IN1.E1** (via adapter `IN1`): Event input of the first value to be compared.
- **IN2.E1** (via adapter `IN2`): Event input of the second value to be compared.

Event Outputs

- **OUT.E1** (via adapter `OUT`): Event output – activated once the comparison is complete and the result is valid.

Data Inputs

- **IN1.D1** (via adapter `IN1`): First comparison value (analog).
- **IN2.D1** (via adapter `IN2`): Second comparison value (analog).

Data Outputs

- **OUT.D1** (via adapter `OUT`): Boolean result of the comparison (`TRUE` if both values are equal, otherwise `FALSE`).

Adapters

Adapter	Direction	Type	Short Description
`IN1`	Socket	`adapter::types::unidirectional::AUDI`	Returns the first analog value including event.
`IN2`	Socket	`adapter::types::unidirectional::AUDI`	Returns the second analog value including event.
`OUT`	Plug	`adapter::types::unidirectional::AX`	Outputs the comparison result (Boolean) with an event.

Functionality

The function block **AUDI_EQ** internally contains a pre-existing function block `iec61131::comparison::F_EQ` for simple equality checking.

- As soon as an event arrives at one of the two input adapters (`IN1` or `IN2`), the internal function block `F_EQ` is called.
- The current data values from `IN1.D1` and `IN2.D1` are passed to `F_EQ`.
- The internal function block compares both values and returns a Boolean result.
- After processing is complete, the internal function block (FB) outputs an event that is forwarded via the output adapter `OUT`.
- Simultaneously, the comparison result is made available at the data output `OUT.D1`.

The function block operates purely **combinatorially** – it does not store any states and executes the comparison logic anew with each activation.

Technical Features

- **Composite FB**: The function block is implemented as a network of sub-FBs, enabling a modular and reusable structure.
- **Adapter-Based Interface**: The use of the unidirectional adapters `AUDI` and `AX` allows for flexible encapsulation of event and data channels. The adapters define the actual inputs and outputs.
- **Standard Component**: The internal FB `F_EQ` is part of the IEC 61131-3 library and guarantees platform-independent comparison logic.
- **No State Machine**: The function block does not have an internal state diagram but delegates the logic entirely to the embedded FB.

State Overview

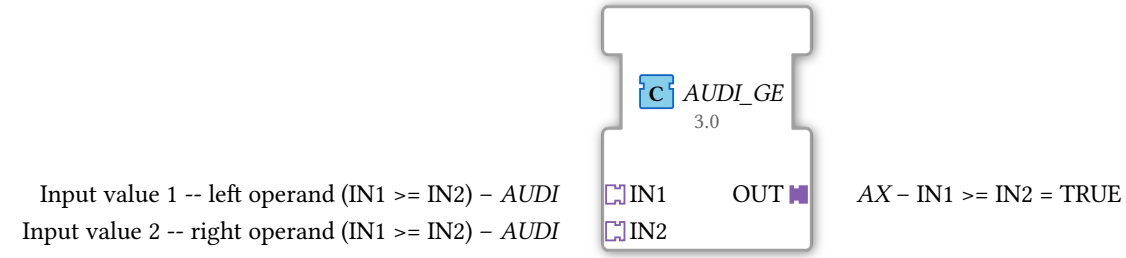
The FB **AUDI_EQ** has **no independent states**. The internal logic is purely event-driven and results directly in the output. Therefore, a state overview is not available.

Application Scenarios

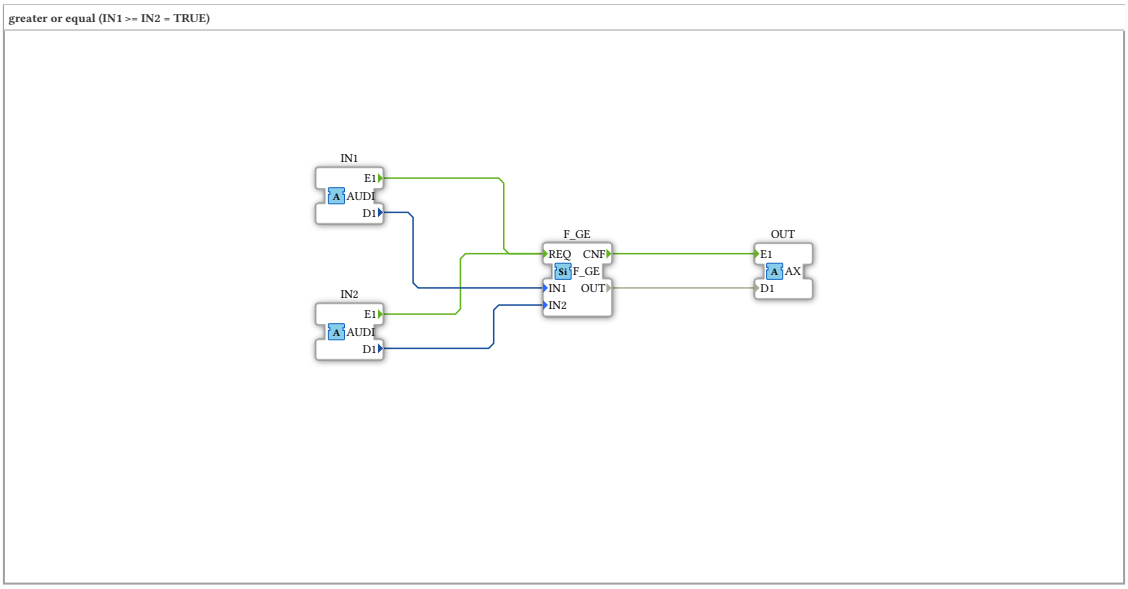
- **Monitoring Process Variables**: Checking two analog values (e.g., pressure sensors, temperature sensors) for equality.
- **Redundancy Check**: Comparing two independently measured values to detect sensor failures.
- **Signal Matching**: In control systems where it must be ensured that two input signals have the same value before an action is triggered.

Comparison with Similar Function Blocks

- **`F_EQ` (directly used)** – The internal function block `F_EQ` offers the same comparison logic, but without adapters. It requires explicit event and data inputs.
- **`F_NE` (inequality)** – Performs an inequality comparison; structurally similar, but the result is inverted.
- **`AUDI_GT` (greater than)** – Analogous structure with adapters, but a different comparison operator.



The **AUDI_EQ** differs in its pre-built adapter interface, which enables easy integration into existing adapter networks. It is specifically designed for applications that require standardized input/output via unidirectional adapters.



Conclusion

The **AUDI_EQ** is an easy-to-use, composite function block for equality comparisons with two analog values. Its adapter-based interface allows for seamless integration into modular control systems. The

internal use of standardized IEC function blocks ensures reliable functionality defined according to IEC 61131-3. This function block is particularly suitable for applications requiring a clear separation of event and data flows via adapters.

AUDI_GE

• – ○ • – ○ • – ○ •

Introduction

The function block `AUDI_GE` performs a “greater than or equal to” comparison of two values. It provides the result as a Boolean value. The block is implemented as a composition and internally uses the standard comparison block `F_GE` from the IEC 61131-3 library. Input and output are exclusively via unidirectional adapters.

Interface Structure

Event Inputs

- **No direct event inputs**

The comparison is triggered via the **socket adapters** `IN1` and `IN2`. Each of these adapters sends an event to the internal module as soon as valid data is available.

Event Outputs

- **No direct event outputs**

The result of the comparison is passed on as an event via the **Plug Adapter** `OUT` as soon as the evaluation is complete.

Data Inputs

The data values to be compared are obtained via the following adapters:

- **Adapter `IN1`** – provides the first comparison value (type corresponding to adapter `AUDI`).

- **Adapter `IN2`** – provides the second comparison value (type corresponding to adapter `AUDI`).

Data Outputs

- **Adapter `OUT`** – outputs the Boolean value `TRUE` if `IN1 ≥ IN2` is present, otherwise `FALSE` (type corresponds to adapter `AX`).

Adapters

Adapter	Direction	Type	Description
`IN1`	Socket	`adapter::types::unidirectional::AUDI`	First Input Value
`IN2`	Socket	`adapter::types::unidirectional::AUDI`	Second Input Value
`OUT`	Plug	`adapter::types::unidirectional::AX`	Output: `IN1 >= IN2` (boolean)

Functionality

1. The events from `IN1.E1` and `IN2.E1` are routed to the internal `F_GE` module (via an OR operator – both events trigger the same `REQ` input).
2. Simultaneously, the data `IN1.D1` and `IN2.D1` are transferred to the corresponding inputs `F_GE.IN1` and `F_GE.IN2`.
3. The internal function block `F_GE` calculates `IN1 ≥ IN2`.
4. The result appears at output `F_GE.OUT` and is passed on to adapter `OUT.D1`.
5. The event `F_GE.CNF` triggers `OUT.E1` to signal to the environment that a new result is available.

Technical Features

- The function block is entirely adapter-based – it has no traditional event or data inputs at the top level.
- The adapters `AUDI` and `AX` are unidirectional and must be defined in the corresponding project.
- Execution is asynchronous: As soon as one of the two input adapters provides an event, the comparison is recalculated. Synchronization of the values is not required, as both data must be available simultaneously for the result to be meaningful.
- The function block configuration complies with the IEC 61131-3 standard and the Eclipse 4diac environment.

State Overview

The function block itself does not have an explicit state machine – all control logic resides in the internal `F_GE`. Its behavior is deterministic:

- **Waiting for Trigger**: As long as no event arrives at `IN1` or `IN2`, the output `OUT` remains unchanged.
- **Calculation**: When an event arrives, the comparison is performed.
- **Result Output**: The result is provided at the output, and an event is sent to the `OUT` adapter.

Application Scenarios

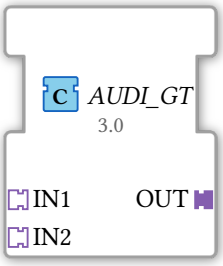
- **Status Monitoring**: Checking whether a measured value reaches or exceeds a threshold.
- **Actuator Control**: Activating an output as soon as a condition `Wert1 ≥ Wert2` is met.
- **Value Comparison in Production Plants**: Comparing target/actual values in continuous processes.
- **Simple Logical Interconnections**: As part of more complex safety or control logic.

Comparison with Similar Function Blocks

- **AUDI_GT** (greater than) – compares against `>`, returns `TRUE` only if the first value is strictly greater.
- **AUDI_EQ** (equal) – compares for equality.
- **AUDI_LE** (less or equal) – the counterpart to ≤.
- **AUDI_GE** is the direct counterpart to `AUDI_LE` and covers the case of "at least equal". Compared to a single function block like `F_GE`, `AUDI_GE` offers adapter-based encapsulation, which facilitates reuse in different projects.

Conclusion

AUDI_GEis a specialized comparison block that enables flexible and clean interface definition through the use of adapters. It is particularly suitable for modular automation



`projects where values are exchanged via standardized interfaces. Internal use of the provenF_GE` block guarantees correct and efficient comparison operations.

AUDI_GT

Input value 1 -- left operand (IN1 > IN2) – *AUDI*
Input value 2 -- right operand (IN1 > IN2) – *AUDI*

AX – IN1 > IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The AUDI_GT function block performs a “greater than” comparison of two values. It is designed as an IEC 61131-3 compliant comparison block and uses an adapter-based interface to transmit values and events. The block is part of the iec61131::comparison library.

Interface Structure

Event Inputs

- **IN1.E1** – Event input for the first value (via adapter IN1)
- **IN2.E1** – Event input for the second value (via adapter IN2) Both events are connected to the internal REQ input of the F_GT block.

Event Outputs

- **OUT.E1** – Event output that is activated after the comparison is complete (via adapter OUT). The result is then available at the data output.

Data Inputs

- **IN1.D1** – First input value (via adapter IN1, type depends on adapter AUDI)
- **IN2.D1** – Second input value (via adapter IN2, type depends on adapter AUDI)

Data Outputs

- **OUT.D1** – Comparison result: TRUE if IN1 > IN2, otherwise FALSE (via adapter OUT, type depends on adapter AX)

Adapters

- **Socket IN1** (Type: `adapter::types::unidirectional::AUDI`) – Connection for the first value to be compared.
- **Socket IN2** (Type: `adapter::types::unidirectional::AUDI`) – Connection for the second value to be compared.
- **Plug OUT** (Type: `adapter::types::unidirectional::AX`) – Output of the comparison result.

The adapters used are unidirectional and each provides one event port and one data port.

Functionality

The AUDI_GT function block encapsulates the basic comparison function block F_GT from the IEC 61131-3 library. The input adapters IN1 and IN2 each provide a value (D1) and a start signal (E1). Both events are connected to the REQ input of F_GT, so that the comparison is triggered as soon as at least one of the events occurs. Internally, F_GT performs the comparison of the two values. The result (BOOL) is provided via the output adapter OUT, simultaneously generating an event (E1).

Technical Features

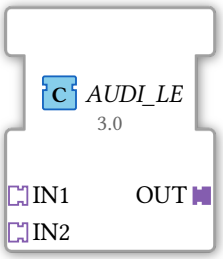
- The function block uses adapters instead of direct input/output ports, which allows for flexible encapsulation and reuse of the interfaces.
- The events from both inputs are combined on the same REQ input of the internal F_GT. This means that the function block re-performs the comparison with each event received at IN1 or IN2.
- The function block outputs the result as a BOOL value (TRUE/FALSE). The exact data types of the adapters (AUDI, AX) are application-specific and may vary depending on the context.
- The function block is identified as part of the `iec61131::comparison` library and complies with the IEC 61131-3 standard.

State Overview

The AUDI_GT function block does not have its own state machine. All logic is implemented by the internal F_GT, which performs a simple combinational comparison. There are no internal states or memory behaviors; the result is recalculated with each activation.

Application Scenarios

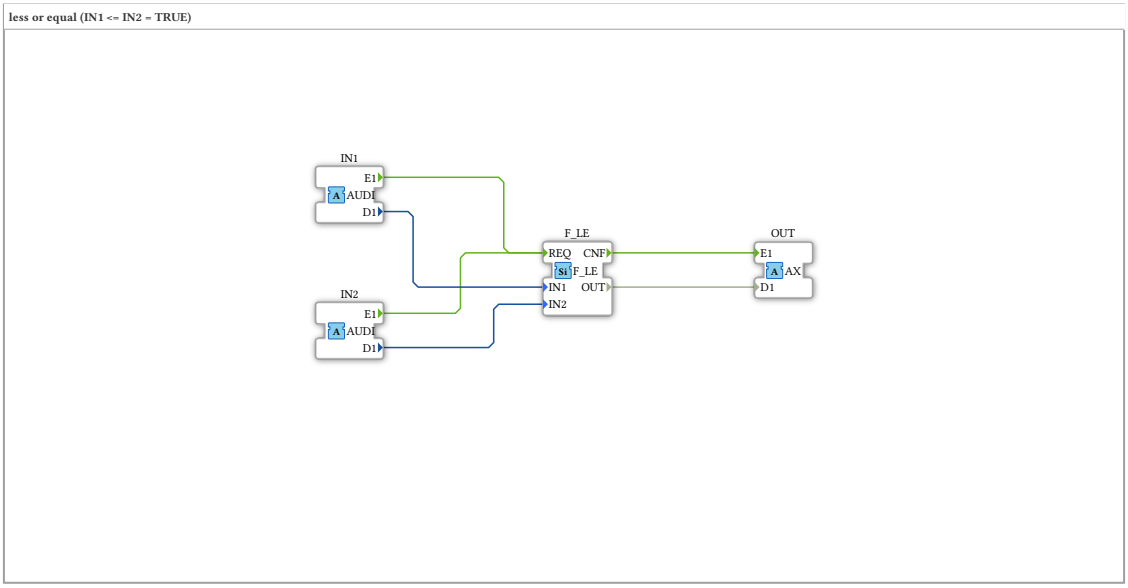
- **Process Monitoring**: Comparison of measured values (e.g., temperature, pressure) with a threshold value. If Value1 > Value2, an alarm is triggered.
- **Logical Decisions**: In automation processes, e.g., sorting logic or priority controls.
- **Safety Functions**: Checking whether a current value exceeds a limit.
- **Adapter-Based Systems**: Wherever modular, reusable interfaces via adapters are desired.



Comparison with Similar Function Blocks

- **GT (Greater Than)**: Simple comparators like `F_GT` (IEC 61131-3) have direct inputs. `AUDI_GT` extends this to an adapter-based interface, which facilitates integration into heterogeneous systems.
- **GE (Greater or Equal)**, **LT (Less Than)**, **EQ (Equal)**: Analogous function blocks for other comparison operations. This function block only supports "Greater Than".
- **Comparison Cascades**: Multiple AUDI_GTs can be linked to create more complex expressions by connecting their outputs to the inputs of other function blocks.

Conclusion



The AUDI_GT is a dedicated comparison function block for the "greater than" function with adapter-based inputs and outputs. It offers a standardized, modular interface according to IEC 61131-3 and is particularly suitable for use in distributed automation systems that require loose coupling of components. Thanks to its adapter technology, the function block can be flexibly embedded in various contexts.

AUDI_LE

Input value 1 -- left operand (IN1 <= IN2) – *AUDI*
Input value 2 -- right operand (IN1 <= IN2) – *AUDI*

AX – IN1 <= IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUDI_LE** performs a less-than-equal-to comparison of two values. It is built as a composite function block based on the standardized comparison block `F_LE` from the IEC 61131 classification. Communication with the environment occurs exclusively via adapter interfaces, allowing the block to be integrated modularly into event-driven processes.

Interface Structure

Event Inputs

Name	Data Type	Description
`IN1.E1`	EVENT	Event input of adapter IN1 – triggers processing of the first value.
`IN2.E1`	EVENT	Event input of adapter IN2 – triggers processing of the second value.

Note: Both events must be received for a comparison to take place (logical AND operation in the internal network).

Event Outputs

Label	Data Type	Description
`OUT.E1`	EVENT	Event output of adapter OUT – is activated as soon as the comparison result is available.

Data Inputs

Label	Data Type	Description

IN1.D1	ANY	First value to be compared (via adapter IN1).
IN2.D1	ANY	Second value to be compared (via adapter IN2).

Data Outputs

Label	Data Type	Description
OUT.D1	BOOL	Comparison result: TRUE if IN1 ≤ IN2; otherwise FALSE.

Adapter

Name	Type	Direction	Description
IN1	adapter::types::unidirectional::AUDI	Socket (Input)	Capture the first value (event + data).
IN2	adapter::types::unidirectional::AUDI	Socket (Input)	Capture the second value (event + data).
OUT	adapter::types::unidirectional::AX	Plug (Output)	Output the comparison result (event + data).

Functionality

1. The function block (FB) expects one event and one data value at each of its two input adapters (IN1 and IN2).
2. Internally, the two events are combined (via an implicit AND condition in the network), and the embedded function block F_LE is started with the data values.
3. F_LE performs the comparison IN1 ≤ IN2 and places the result (Boolean value) at its data output.
4. As soon as the result is available, the event at the output adapter OUT is triggered, and the result value is made available via OUT.D1.

Technical Features

- **Adapter-Based Interfaces:** The function block (FB) does not have traditional individual ports but uses standardized unidirectional adapters. This facilitates reuse and integration into complex communication structures.
- **Composite Structure:** All logic is implemented via an internal FB (F_LE). This makes the function block easy to understand and extend.
- **Event Synchronization:** Both input events must arrive before processing starts. This ensures that current value pairs are always compared.

State Overview

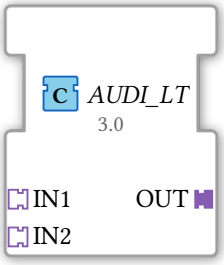
The FB does not have its own directed state machine, as it operates purely combinatorially. The internal F_LE is also stateless. The only relevant logic is the AND operation of the events – after receiving both events, the result is output once.

Application Scenarios

- **Limit Monitoring:** Check whether a measured value exceeds a threshold.
- **Enabling Logic:** Activate an action only if the current requirement is less than or equal to a maximum allowable value.
- **Comparison Chains:** Combine multiple AUDI_LE function blocks to implement complex conditions (e.g., x ≤ y ≤ z).

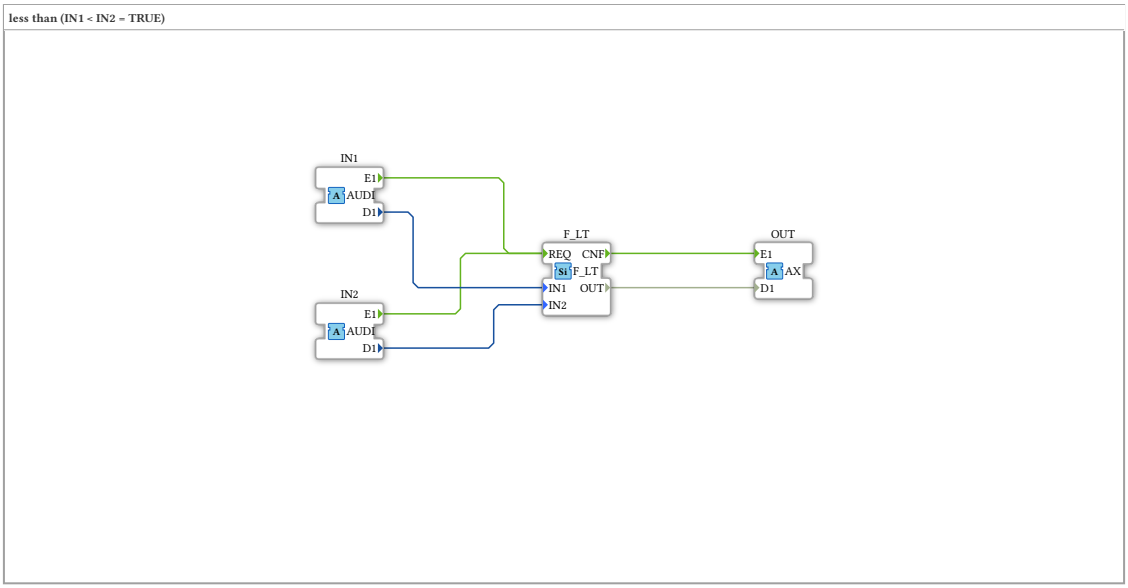
Comparison with Similar Function Blocks

FB	Function	Difference to AUDI_LE
AUDI_LT	Less than (<)	Not including equality.
AUDI_EQ	Equality (=)	Checks for exact matches only.
AUDI_GE	Greater Than or Equal To (≥)	Reverse comparison direction.



AUDI_AND	Logical AND	Works with Boolean values, not numerical comparisons.

Conclusion



AUDI_LE` is a specialized comparison block that, thanks to its adapter interfaces, is particularly well-suited for modular, event-driven automation solutions. It offers clear, standardized logic for the “less than or equal to” condition and, due to its composite structure, can be easily integrated into custom applications.

AUDI_LT

Input value 1 -- left operand (IN1 < IN2) – *AUDI*
Input value 2 -- right operand (IN1 < IN2) – *AUDI*

AX – IN1 < IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block `AUDI_LT` performs a “less than” comparison between two input values. It is frequently used in automation technology to monitor thresholds or make logical decisions. The block is classified as a “standard comparison function” according to IEC 61131-3 and uses adapters for flexible connection of different data types.

Interface Structure

Event Inputs

Events are forwarded to the function block from external sources via the adapter sockets:

- `IN1.E1` – Event that triggers the comparison operation as soon as a new value is present at `IN1`.
- `IN2.E1` – Event that also triggers the comparison operation as soon as a new value is present at `IN2`.

Event Outputs

- `OUT.E1` – Event that is output after the comparison is complete and signals that the result at data output `OUT.D1` is valid.

Data Inputs

- `IN1.D1` – First value to be compared (data of the adapter type `AUDI`).
- `IN2.D1` – Second value to be compared (data of the adapter type `AUDI`).

Data Outputs

- `OUT.D1` – Comparison result: `TRUE` if `IN1 < IN2`, otherwise `FALSE` (data of the adapter type `AX`).

Adapters

- `IN1` – Socket (input) of type `adapter::types::unidirectional::AUDI`. Sends an event (`E1`) and a data value (`D1`) to the FB.
- `IN2` – Socket (input) of the same type as `AUDI`. Provides the second input value.
- `OUT` – Plug (output) of type `adapter::types::unidirectional::AX`. Receives the result event (`E1`) and the result data value (`D1`) for passing to subsequent function blocks.

Functionality

This function block performs a numerical comparison of the two data points at `IN1` and `IN2`. As soon as one of the two events (`IN1.E1` or `IN2.E1`) occurs, the internal function block `F_LT` (Less Than) is called. This function reads the current values of `IN1` and `IN2` and calculates their relative size. The result (`TRUE` / `FALSE`) is provided at the data output `OUT.D1`, and the event `OUT.E1` is triggered simultaneously. Since both event inputs are connected to the same `REQ` input of the internal function block, the comparison is performed again whenever either value changes.

Technical Features

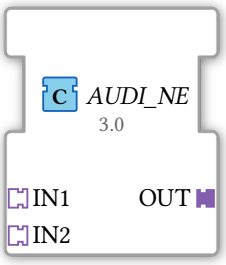
- **Adapter-Based Interfaces** – The use of the adapters `AUDI` and `AX` enables universal coupling to various data types without requiring the function block itself to be typed. The actual type adaptation takes place in the adapter definitions.
- **Asynchronous Triggering** – The comparison is always started when an event arrives at `IN1` or `IN2`. This allows the function block to react immediately to changes in either of the two inputs.
- **Stateless** – The function block has no internal state; the output signal depends solely on the current input values.

State Overview

The function block is purely functional and does not require its own state machine. It performs a one-time comparison operation after each event and then returns to an empty wait state.

Application Scenarios

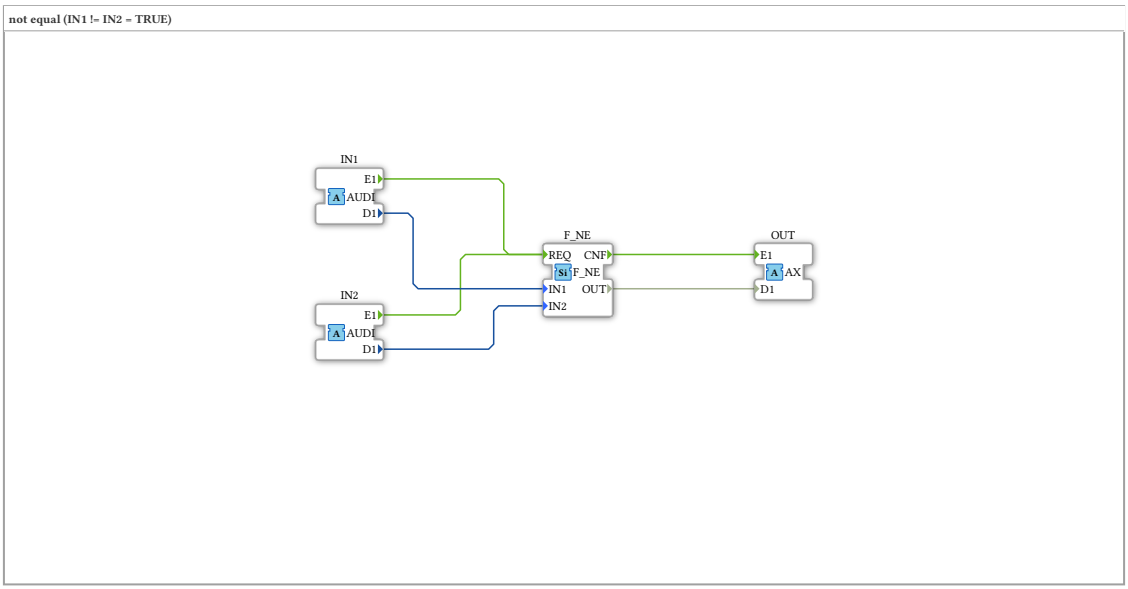
- **Limit Monitoring** – e.g., checking whether a temperature falls below a threshold.
- **Range Check** – Combination with other comparison blocks (e.g., `AUDI_GT`) to implement “inside” or “outside” logic.
- **Control Logic** – Boolean decisions depending on two analog or digital variables.



Comparison with Similar Blocks

- **`AUDI_EQ`** – Checks for equality (`IN1 = IN2`).
- **`AUDI_GT`** – Checks for greater than (`IN1 > IN2`).
- **`AUDI_LT`** – Checks for less than (`IN1 < IN2`). All three blocks have identical interfaces and differ only in their comparison operation. They can be easily interchanged to adapt the logic.

Conclusion



The `AUDI_LT` is a simple yet robust comparison module that can be flexibly integrated into a wide variety of automation environments thanks to its adapter interfaces. Its asynchronous operation and the clear separation of events and data make it a fundamental tool for value comparison tasks in control engineering.

AUDI_NE

Input value 1 -- left operand (IN1 != IN2) – *AUDI*
Input value 2 -- right operand (IN1 != IN2) – *AUDI*

AX – IN1 != IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AUDI_NE** performs a not equal check. It compares two input values provided via adapters and outputs the comparison result as a Boolean value via an output adapter. This block is primarily used in automation systems that support adapter-based, event-driven communication.

Interface Structure

Event Inputs

The function block does not have separate event inputs on the interface itself. Events are transmitted via the adapter sockets **IN1** and **IN2**. Each of these sockets contains an event input (E1), the arrival of which triggers the internal comparison.

Event Outputs

The output adapter **OUT** provides an event output (E1). This signals the completion of the comparison and indicates that the result at the data output is valid.

Data Inputs

- **IN1.D1** – First value to be compared (data type depends on the adapter definition `adapter::types::unidirectional::AUDI`).
- **IN2.D1** – Second value to be compared (same data type as IN1).

Data Outputs

- **OUT.D1** – Boolean result of the inequality check: `TRUE` if IN1 != IN2, otherwise `FALSE`.

Adapter

Adapter	Type	Direction	Description
IN1	`adapter::types::unidirectional::AUDI`	Socket	Captures the first input value
IN2	`adapter::types::unidirectional::AUDI`	Socket	Receives the second input value
OUT	`adapter::types::unidirectional::AX`	Plug	Outputs the comparison result

Functionality

The **AUDI_NE** is a composite function block. Internally, it uses the standardized comparison block **F_NE (Not Equal)** from the IEC 61131 library.

- If an event occurs at **IN1.E1** or **IN2.E1**, the signal is forwarded to the internal block **F_NE.REQ**.
- Simultaneously, the current data values from **IN1.D1** and **IN2.D1** are transferred to **F_NE.IN1** and **F_NE.IN2**.
- **F_NE** performs the inequality comparison and outputs the result via **F_NE.OUT** and an acknowledgment event via **F_NE.CNF**.
- The acknowledgment event is passed to **OUT.E1**, and the result to **OUT.D1**.

The function block (FB) thus operates in an event-driven manner: Each event at either of the two inputs triggers a new comparison, and the output is updated immediately.

Technical Features

- **Adapter-based interface**: Adapters are used instead of discrete inputs/outputs. This enables a type-safe and modular connection with other function blocks that use the same adapter protocol.
- **Two independent event sources**: Both IN1 and IN2 can provide an event. The internal behavior is designed so that a new comparison is started after each event – regardless of the source.
- **Reuse of Standardized Logic**: The actual comparison function is implemented by the embedded FB **F_NE**, ensuring high reliability and compliance with IEC 61131.

State Overview

The FB has no explicit states (no ECC). It is a combinational block without memory. The output is determined solely by the current input values and the triggering event.

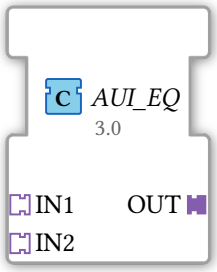
Application Scenarios

- **Deviation Monitoring**: Checks whether two measured values (e.g., setpoint and actual values) differ. The result can be used for alarming or control.
- **Redundancy Check**: In safety-critical systems, the discrepancy between two redundant sensors can indicate a fault.
- **State Comparisons**: Compares binary states or count values to detect changes or inconsistencies.

Comparison with Similar Function Blocks

- **AUDI_EQ (Equal)**: The counterpart for equality checking. Same interface, but inverted logic: Output `TRUE` on equality.
- **Direct Use of F_NE**: Without the adapter wrapper, F_NE could be used directly. However, **AUDI_NE** offers a standardized adapter interface that improves integration and type safety in frameworks like 4diac.

Conclusion



The **AUDI_NE** is a practical function block for non-equal comparison in adapter-based IEC 61131 systems. By using adapters and embedding the proven **F_NE** function block, it combines type safety with established functionality. It is particularly suitable for event-driven automation solutions where modular and reusable components are required.

AUDI_NE —

AUI_EQ

Input value 1 -- left operand (IN1 = IN2) – *AUI*
Input value 2 -- right operand (IN1 = IN2) – *AUI*

AX – IN1 = IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The AUI_EQ function block performs an equality comparison between two analog values. It is classified as a standard comparison function according to IEC 61131-3 and uses adapters for type-safe communication with the environment. The result is output as a Boolean value, which is `true` if and only if both input values are equal.

Interface Structure

Event Inputs

- **IN1.E1** – Trigger for the comparison (sent when the first value is updated).
- **IN2.E1** – Alternative trigger for the comparison (sent when the second value is updated).

Both events are associated with the same internal processing event; the comparison is triggered when either event occurs.

Event Outputs

- **OUT.E1** – Confirmation that the comparison is complete and the result is available at the data output.

Data Inputs

- **IN1.D1** – First analog value to be compared.
- **IN2.D1** – Second analog value to be compared.

Data Outputs

- **OUT.D1** – Comparison result: `true` if `IN1.D1 == IN2.D1`, otherwise `false`.

Adapters

- **IN1** (Socket) – Adapter type `adapter::types::unidirectional::AUI`, encapsulates the first input value and the associated event.
- **IN2** (Socket) – Adapter of type `adapter::types::unidirectional::AUI`, encapsulates the second input value and the associated event.
- **OUT** (Plug) – Adapter of type `adapter::types::unidirectional::AX`, encapsulates the result and the output event.

The adapters enable loose coupling between the function block and its environment, simplifying reuse in different applications.

Functionality

AUI_EQ delegates the actual comparison logic to the internal function block `F_EQ` (type `iec61131::comparison::F_EQ`). As soon as an event arrives at one of the input adapters (IN1 or IN2), the calculation is started. The internal `F_EQ` compares the two passed values and returns the Boolean result. After the calculation is complete, the result is output via the output adapter OUT, and a corresponding event is sent.

The function block is event-driven – it reacts to input events and does not require its own cyclic call.

Technical Features

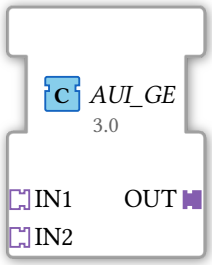
- The function block uses only adapters for communication, which offers high flexibility when connecting to various data sources and sinks.
- Internally, it is based on the standard function block `F_EQ` from the IEC 61131 library, which provides a robust and tested comparison function.
- The input events are logically ORed: Each of the two events triggers a recalculation. This simplifies control, as only the currently updated signal needs to be sent.
- The function block has been further developed in several versions and was last updated in 2025.

State Overview

AUI_EQ does not have an explicit state machine. Its behavior is entirely determined by the event processing of the internal `F_EQ`. Upon the arrival of an event, the function block performs a calculation and sends the result – there are no waiting or blocking states.

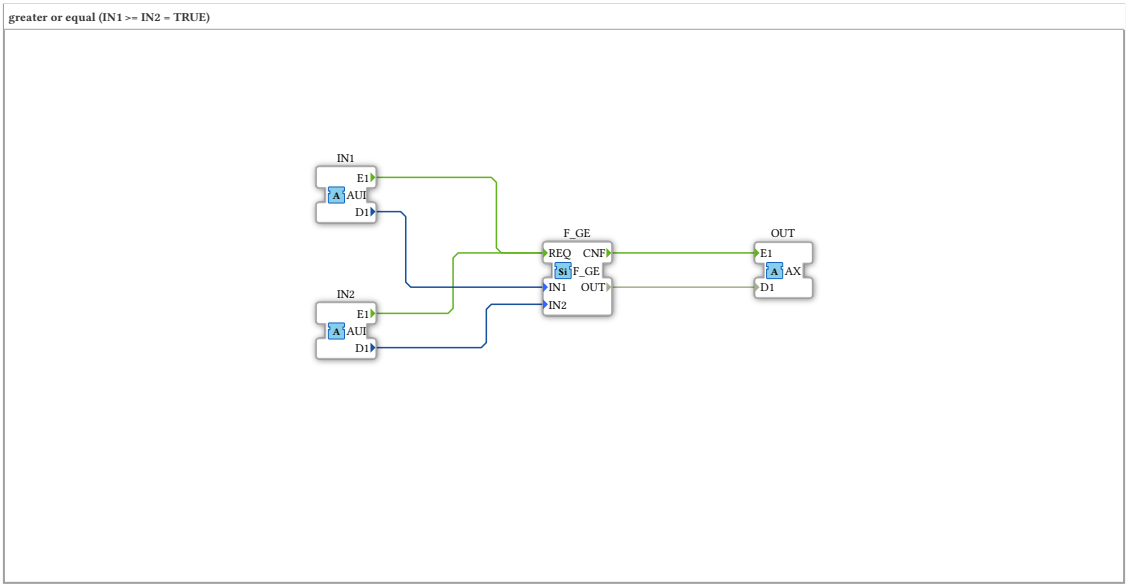
Application Scenarios

- **Equality Monitoring**: Checking whether two sensor readings (e.g., temperature, pressure) have the same value.
- **Alarming**: Triggering an alarm if two redundant measurements differ (logical negation of the output).
- **Control**: Switching actuators when a setpoint matches an actual value.
- **Plausibility Check**: Comparing analog values from different sources for error detection.



Comparison with Similar Function Blocks

In addition to `AUI_EQ`, the IEC 61131 library contains other comparison blocks such as `AUI_GT` (greater than), `AUI_LT` (less than), and `AUI_NE` (not equal to). These share the same adapter interface but differ in their comparison operation. `AUI_EQ` is specifically optimized for equality testing and does not offer any other comparison logic. For more comprehensive comparisons (e.g., greater than or equal to), combinations with logic blocks are required.



Conclusion

The AUI_EQ function block implements a simple and reliable equality check for analog values. The use of adapters makes it highly adaptable to various automation environments. Its event-driven operation and the internal use of a standardized comparison module ensure consistent and high-performance execution. AUI_EQ is therefore a fundamental building block for monitoring and control tasks where value equality must be determined.

AUI_GE

Input value 1 -- left operand (IN1 >= IN2) – *AUI*
Input value 2 -- right operand (IN1 >= IN2) – *AUI*
AX – IN1 >= IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AUI_GE** compares two values and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type depends on the adapter type `AUI`, usually a numeric value).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AUI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AUI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AUI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GE` (type `iec61131::comparison::F_GE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters, allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”).
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

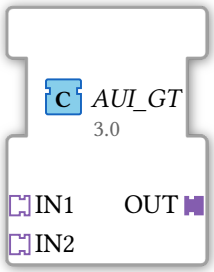
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checks whether a measured value (e.g., fill level, rotational speed) has reached or exceeded a predefined threshold.
- **Control Logic**: Activates an action (e.g., stop a pump) when an actual value reaches or exceeds a setpoint.
- **Data Filtering**: Selects data records or signals that meet a minimum condition.

Comparison with Similar Function Blocks

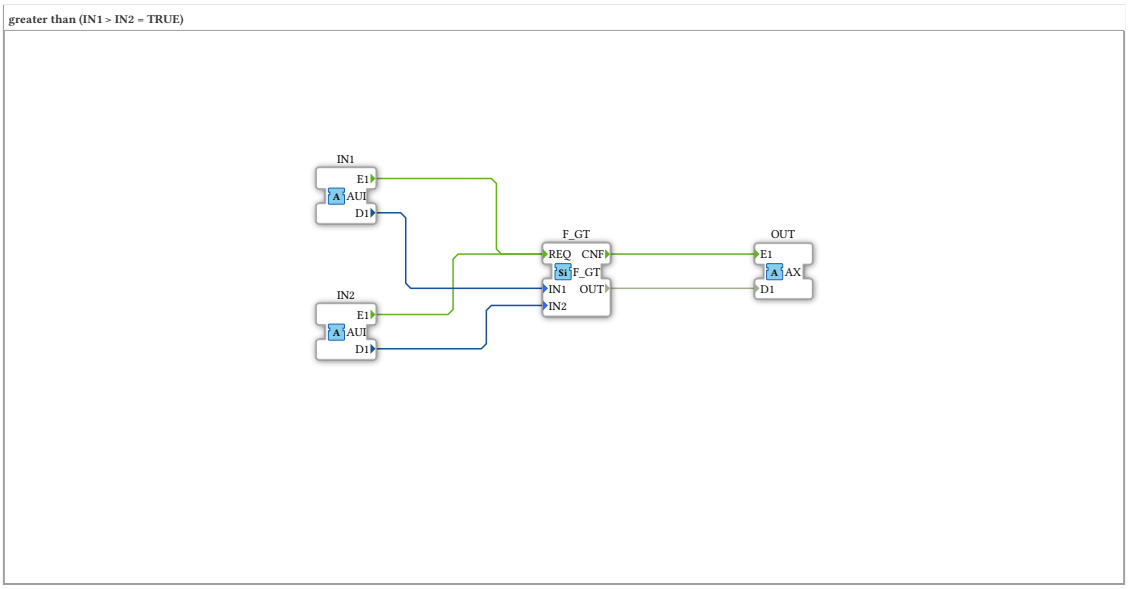


- **AUI_LE**: Checks for “less than or equal to” – the inverse function of AUI_GE.
- **AUI_EQ**: Checks for equality of values.
- **AUI_GT**: Checks for “greater than” – the base variant without the equality case, of which AUI_GE is the extended version.

AUI_GE completes the AUI comparison family with the boundary case of equality, making it the right choice when a threshold should be inclusive.

Conclusion

AUI_GE is a simple yet important comparison block for IEC 61131-3 control applications. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.



AUI_GT

Input value 1 -- left operand (IN1 > IN2) – *AUI*

Input value 2 -- right operand (IN1 > IN2) – *AUI*

AX – IN1 > IN2 = TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUI_GT** compares two values and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type depends on the adapter type `AUI`, usually a numeric value).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AUI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AUI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AUI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GT` (type `iec61131::comparison::F_GT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters, allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”).
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

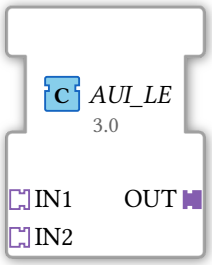
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

Application Scenarios

- **Limit Monitoring**: Checks whether a measured value (e.g., temperature, pressure) exceeds a predefined threshold.
- **Control Logic**: Activates an action (e.g., open a valve) when a setpoint is greater than the actual value.
- **Data Filtering**: Selects data records or signals that meet a specific condition.

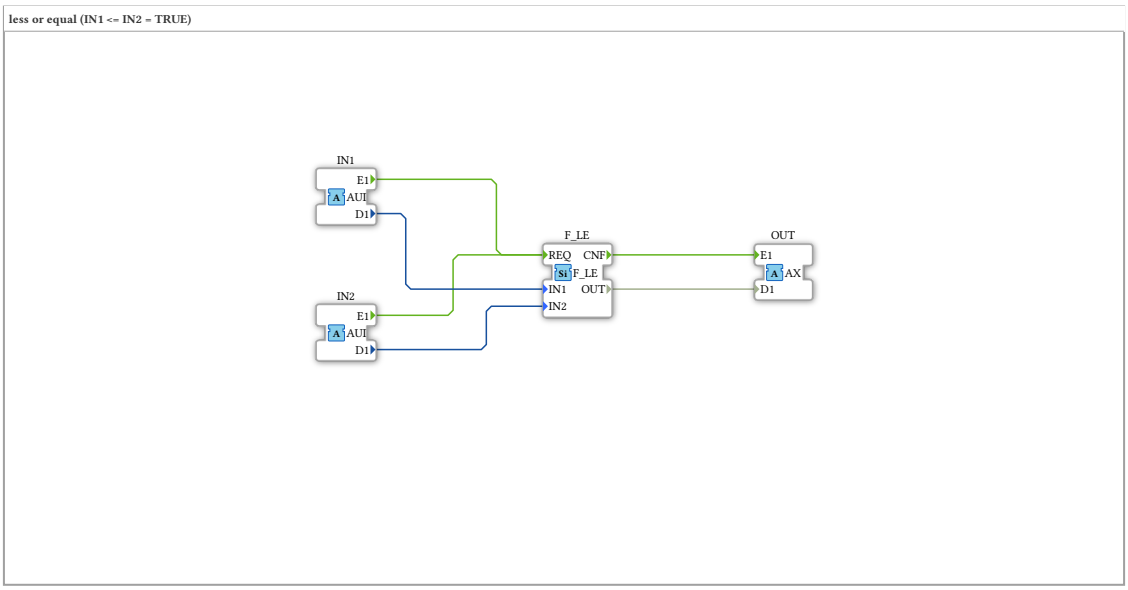
Comparison with Similar Function Blocks



- **AUI_LT**: Checks for “less than” values – the inverse function of AUI_GT.
- **AUI_EQ**: Checks for equality of values.
- **AUI_GE** / **AUI_LE**: Perform “greater than or equal to” and “less than or equal to” comparisons, respectively – they are extended versions of AUI_GT and AUI_LT.

AUI_GT is the basic “greater than” component, enabling easy integration into adapter-based networks via the two socket adapters.

Conclusion



AUI_GT is a simple yet important comparison block for IEC 61131-3 control applications. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AUI_LE

Input value 1 -- left operand (IN1 <= IN2) – *AUI*
Input value 2 -- right operand (IN1 <= IN2) – *AUI*

AX – IN1 <= IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AUI_LE** performs a less-than-equal-to comparison of two analog input values. It is implemented as a composite block that internally uses the IEC 61131-3 block `F_LE`. The result (a BOOL value) is provided via an output adapter. The function block is suitable for event-driven limit monitoring in automation systems.

Interface Structure

Event Inputs

- **IN1.E1** (via adapter IN1) – Event that triggers the comparison as soon as the first input value is available.
- **IN2.E1** (via adapter IN2) – Event that triggers the comparison as soon as the second input value is available.

Event Outputs

- **OUT.E1** (via adapter OUT) – Event output after a successful comparison, indicating that the result is valid.

Data Inputs

- **IN1.D1** (via adapter IN1) – First input value (analog, type according to adapter `AUI`).
- **IN2.D1** (via adapter IN2) – Second input value (analog, type according to adapter `AUI`).

Data Outputs

- **OUT.D1** (via adapter OUT) – Comparison result (BOOL): `TRUE` if IN1 ≤ IN2, otherwise `FALSE`.

Adapters

- **IN1** – Socket (Type: `adapter::types::unidirectional::AUI`) for the first analog value.

- **IN2** – Socket (Type: `adapter::types::unidirectional::AUI`) for the second analog value.
- **OUT** – Plug (Type: `adapter::types::unidirectional::AX`) for the comparison result.

Functionality

The module contains an internal network with a `F_LE` module. The events of the two input adapters (`IN1.E1` and `IN2.E1`) are connected to the `REQ` input of the `F_LE` module. Each incoming event (regardless of the input) triggers a comparison of the current data values `IN1.D1` and `IN2.D1`. The internal `F_LE` calculates `(IN1 ≤ IN2)` and stores the result on its output `OUT`. This result is output via the adapter `OUT.D1`, and simultaneously, an event is sent via `OUT.E1`.

Technical Features

- **Adapter-based interface**: The inputs and outputs are implemented as unidirectional adapters, enabling flexible integration with other components.
- **Event triggering**: The comparison is triggered by any event present at either input – simultaneous events at both inputs are not required.
- **Internal Standard Block**: The comparison logic uses the tested IEC 61131-3 block `F_LE`.
- **License**: This block is licensed under the Eclipse Public License 2.0 (EPL-2.0), Copyright (c) 2013 TU Wien ACIN.

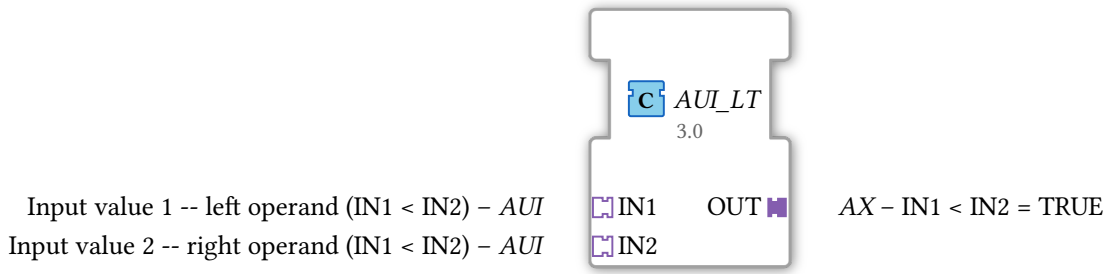
State Overview

The block does not have an explicit state machine. It operates in an event-driven manner, and its output is the direct result of the internal combinatorial comparison. After event processing, the result remains stable until the next event.

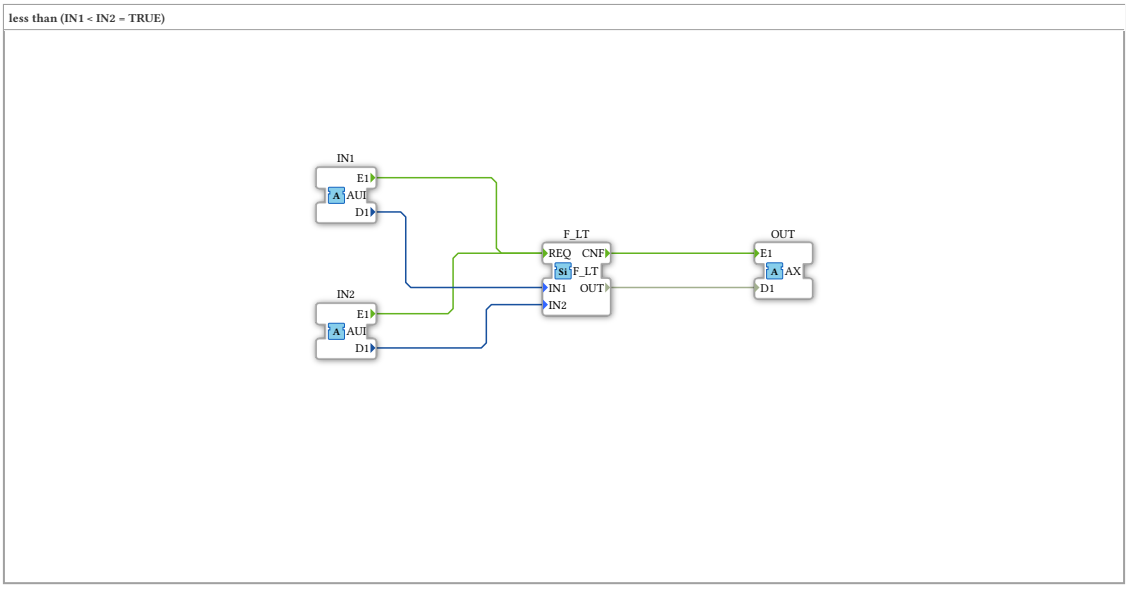
Application Scenarios

- **Limit Monitoring**: Checking whether a measured value (e.g., temperature, pressure) exceeds a set threshold.
- **Control Logic**: Triggering an action when two analog signals are in a defined relationship (e.g., fill level ≤ maximum fill level).
- **Safety Functions**: Compares redundant sensor values for "less than or equal to" for fault detection.

Comparison with Similar Function Blocks



- **AUI_LT**: Performs a "less than" (strict less) comparison.
- **AUI_EQ**: Checks for equality between the two values.
- **AUI_GT**: Checks for "greater than".
- **AUI_GE**: Checks for "greater than or equal to".



All these function blocks have the same adapter interface (AUI for inputs, AX for outputs) and differ only in their comparison operation.

Conclusion

The `AUI_LE` function block offers a simple and reliable way to check analog signals for "less than or equal to". Thanks to its adapter-based interface and event-driven execution, it can be seamlessly integrated into automation projects that require standardized comparison functions.

AUI_LT

• – ○ • – ○ • – ○ •

Introduction

The function block `AUI_LT` performs a less-than comparison (<) between two input values. It is accessed via adapter interfaces and is suitable for use in component-based automation systems according to IEC 61131-3. The block performs the comparison asynchronously and outputs the result as a Boolean value via an output adapter.

Interface Structure

Event Inputs

Name	Description
IN1.E1	Event at socket adapter IN1; triggers the comparison as soon as a new value is present at IN1.
IN2.E1	Event at socket adapter IN2; triggers the comparison as soon as a new value is present at IN2.

Event Outputs

Name	Description
OUT.E1	Event at plug adapter OUT; signals that a valid result is present at OUT.D1 after a comparison.

Data Inputs

Name	Description
IN1.D1	First value of the comparison (ANY_BIT compatible).
IN2.D1	Second value of the comparison (ANY_BIT compatible).

Data Outputs

Name	Description
OUT.D1	Comparison result: `true`, if IN1.D1 < IN2.D1; sonst `false`.

Adapter

Bezeichnung	Typ	Richtung	Beschreibung
IN1	AUI (unidirectional)	Socket	Eingangsadapter für den ersten Wert und dessen Ereignis.
IN2	AUI (unidirectional)	Socket	Eingangsadapter für den zweiten Wert und dessen Ereignis.
OUT	AX (unidirectional)	Plug	Ausgangsadapter für das Vergleichsergebnis und das zugehörige Ereignis.

Funktionsweise

Der `AUI_LT`-Baustein ist als Composite-FB realisiert. Intern wird ein einzelner `F_LT`-Funktionsblock (aus der IEC 61131-3 Vergleichsbibliothek) verwendet.

- Die **Ereignis-Eingänge** `IN1.E1` und `IN2.E1` sind beide mit dem `REQ`-Eingang des internen `F_LT` verbunden. Sobald an einem der beiden Adapter ein Ereignis eintrifft, wird der Vergleich angestoßen.
- Die **Datenwerte** `IN1.D1` und `IN2.D1` werden direkt an die entsprechenden Eingänge `IN1` und `IN2` des `F_LT` weitergeleitet.
- Nach Abschluss der Berechnung signalisiert der `F_LT` über seinen Ausgang `CNF` das Ereignis `OUT.E1` und stellt das Vergleichsergebnis am Datenausgang `OUT.D1` bereit.

Der Vergleich erfolgt nach der Logik: **IN1.D1 < IN2.D1 ⟹ OUT.D1 = true**, andernfalls `false`.

Technische Besonderheiten

- **Adapterbasierte Kommunikation**: Alle Ein- und Ausgänge erfolgen über unidirektionale Adapter (Typen `AUI` und `AX`). Dies ermöglicht eine lose Kopplung und Wiederverwendung in verschiedenen Umgebungen.
- **Asynchrone Auslösung**: Da beide Ereigniseingänge auf den gleichen `REQ` des internen `F_LT` führen, kann der Vergleich durch ein Ereignis an **einem** der beiden Eingänge gestartet werden. Es ist nicht erforderlich, dass beide Ereignisse gleichzeitig eintreffen.
- **Typkompatibilität**: Der Baustein arbeitet mit beliebigen `ANY_BIT`-Datentypen (z. B. `BOOL`, `BYTE`, `WORD`, `DWORD`, `LWORD`), sofern die angeschlossenen Adapter dies unterstützen.
- **Keine Zustandsspeicherung**: Der FB ist rein kombinatorisch; er speichert keine historischen Werte.

Zustandsübersicht

Da der `AUI_LT` keine explizite Zustandsmaschine besitzt, existiert lediglich ein **impliziter Zustand**:

Zustand	Beschreibung
Bereit	Wartet auf ein Ereignis an IN1.E1 oder IN2.E1. Nach Auslösung wird der Vergleich durchgeführt und das Ergebnis über OUT ausgegeben. Der FB kehrt sofort in den Bereit-Zustand zurück.

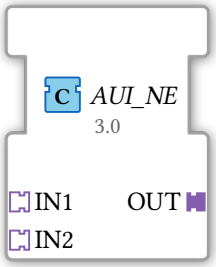
Anwendungsszenarien

- **Grenzwertüberwachung**: Prüfen, ob ein Messwert unter einem Schwellwert liegt, z. B. `Temperatur < Grenzwert`.
- **Steuerungslogik**: Bedingte Aktivierung von Ausgängen, z. B. Ventil öffnen, wenn `Druck < Sollwert`.
- **Interlock-Bedingungen**: Sicherheitsabfragen, bei denen ein Betrieb nur erlaubt ist, wenn eine Größe kleiner als eine andere ist.
- **Vergleichsketten**: Kombination mit anderen Vergleichsbausteinen (z. B. `AUI_EQ`, `AUI_GT`) zur Realisierung komplexer logischer Bedingungen.

Vergleich mit ähnlichen Bausteinen

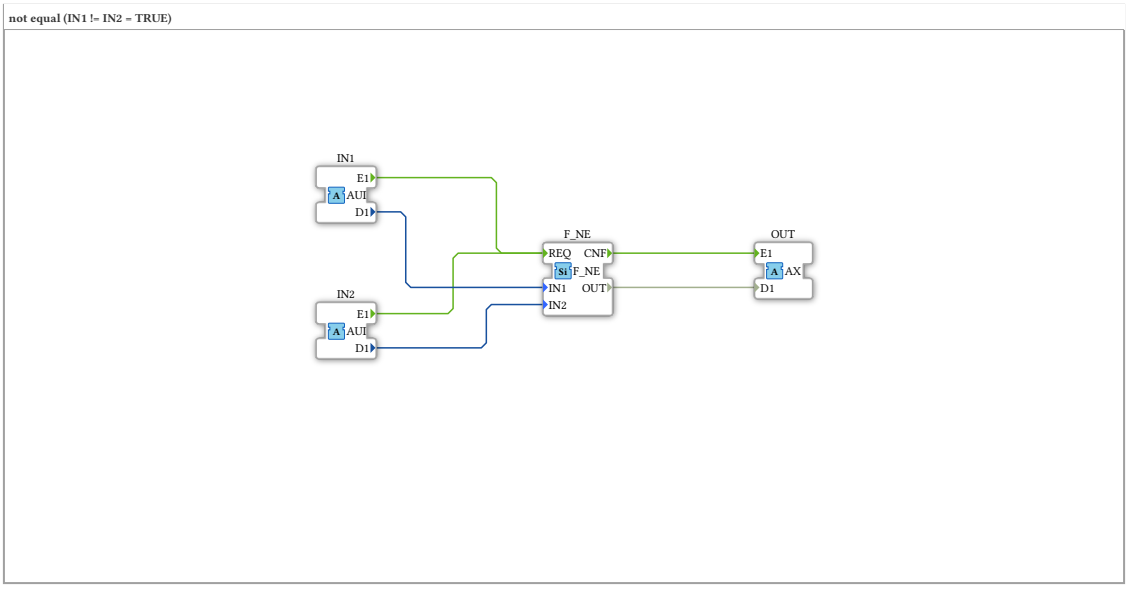
Baustein	Funktion	Schnittstelle	Besonderheit
AUI_LT	Kleiner als (<)	Adapter (AUI, AX)	Asynchron, zwei separate Ereigniseingänge

F_LT	Kleiner als (<)	Standard-Ports (REQ/CNF, ANY_BIT)	Direkte Ereignis-/Datenports, kein Adapter
AUI_EQ	Gleich (=)	Adapter (AUI, AX)	Gleiche Struktur, anderer Vergleichsoperator
AUI_GT	Größer als (>)	Adapter (AUI, AX)	Same structure, different comparison operator



The `AUI_LT` offers particularly flexible integration into IEC 61131-3 compliant systems via its adapter interfaces, while the internal `F_LT` provides the standardized comparison logic.

Conclusion



The `AUI_LT` is a compact and reliable function block for less-than comparisons in adapter-based automation environments. Its asynchronous event processing and loose coupling via adapters make it ideal for modular control applications where simple conditions need to be evaluated decentrally and in a resource-efficient manner.

AUI_NE

Input value 1 -- left operand (IN1 != IN2) – *AUI*
Input value 2 -- right operand (IN1 != IN2) – *AUI*

AX – IN1 != IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block `AUI_NE` performs a not equal comparison for two input values. It is built as a composite function block (FB) from the IEC 61131-3 comparison block `F_NE`. Communication with the environment is via standardized adapter interfaces (`AUI` for the inputs, `AX` for the output). This allows it to be seamlessly integrated into adapter-based architectures of the 4diac IDE.

Interface Structure

Event Inputs

The FB does not have direct event inputs. Events are received via the **socket adapters** `IN1` and `IN2`:

Adapter	Event	Description
`IN1`	Event via adapter input E1	Starts the comparison when the value is available at `IN1`.
`IN2`	Event via adapter input E1	Starts the comparison when the value is available at `IN2`.

Both events trigger the activation of the internal `F_NE` module.

Event Outputs

The FB has no direct event outputs. The result is output via the **Plug Adapter** `OUT`:

Adapter	Event	Description
`OUT`	Event via Adapter Output E1	Indicates that the comparison is complete and the result value is valid.

Data Inputs

Data is also provided via the socket adapters:

Adapter	Data Point	Type	Description
`IN1`	D1	ANY (via AUI)	First comparison value
`IN2`	D2	ANY (via AUI)	Second comparison value

The exact data types are determined by the adapter instance used (`adapter::types::unidirectional::AUI`).

Data Outputs

The result value is output via the plug adapter:

Adapter	Data Point	Type	Description
`OUT`	D1	BOOL (via AX)	`TRUE`, if IN1 ≠ IN2; `FALSE` other

Adapter

Adapter	Direction	Type	Description
`IN1`	Socket	`adapter::types::unidirectional::AUI`	Receiver adapter for the first input value.
`IN2`	Socket	`adapter::types::unidirectional::AUI`	Receiver adapter for the second input value.
`OUT`	Plug	`adapter::types::unidirectional::AX`	Output adapter for the comparison result.

Functionality

Each incoming event via `IN1.E1` or `IN2.E1` triggers the internal function block `F_NE` (IEC 61131-3: `NOT EQUAL`). `F_NE` compares the values at data points `IN1.D1` and `IN2.D2`. The result (BOOL) is forwarded to the output adapter `OUT.D1`, and simultaneously an event is sent to `OUT.E1` to signal the result retrieval.

The function block operates **event-driven** – a comparison is only recalculated if at least one of the two input adapters receives an event. This avoids unnecessary processing load.

Technical Features

- **Adapter Encapsulation**: All input/output is handled via standardized adapters, allowing the function block to be integrated into complex adapter networks.

- **Reuse**: Internally, the proven IEC 61131-3 block `F_NE` is used, which implements an efficient, type-independent non-equal comparison.
- **Unidirectional Adapters**: The adapters used (`AUI`, `AX`) are unidirectional – they each support only one data and event direction, which increases the clarity of data flows.
- **No State Storage**: The function block is stateless; each event triggers a recalculation.

State Overview

The FB `AUI_NE` itself does not have its own state machine. Its behavior is entirely determined by the internal `F_NE` block, which implements a simple functional sequence without states. The event-driven control (input ⟶ calculation ⟶ output) is strictly causal.

Application Scenarios

- **Deviation Monitoring**: Check whether two measured values (e.g., temperature, pressure) differ from each other.
- **Threshold Violation**: Combine with other blocks to use inequality as part of a plausibility check.
- **Data Validation**: Detect whether two redundant signals provide different values (comparison of copies).
- **Event-Driven Comparisons**: Embedding in applications that only require a comparison when one of the inputs changes.

Comparison with Similar Blocks

Block	Comparison Function	Special Feature
`AUI_EQ`	Equal	Result `TRUE` for equal values
`AUI_NE`	Not equal	Result `TRUE` for different values
`AUI_GT`	Greater than	Result `TRUE` if IN1 > IN2
`AUI_LT`	Less than	Result `TRUE` if IN1 < IN2

All the aforementioned components share the same adapter interface and can therefore be easily exchanged or combined.

Conclusion

The `AUI_NE` is a simple yet reliable function block for comparing the difference between two values within an adapter-based 4diac environment. Its strengths lie in its clean encapsulation via adapters, event-driven execution, and high reusability thanks to the underlying IEC 61131-3 component. It is particularly well-suited for modular, expandable automation solutions.

AULI_EQ

Input value 1 -- left operand (IN1 = IN2) – *AULI*

Input value 2 -- right operand (IN1 = IN2) – *AULI*

AX – IN1 = IN2 = TRUE

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_EQ** compares two values of type `ULINT` (64-bit unsigned integer) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `ULINT`, 64-bit unsigned integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AULI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AULI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AULI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_EQ` (type `iec61131::comparison::F_EQ`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AULI/AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the `ULINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

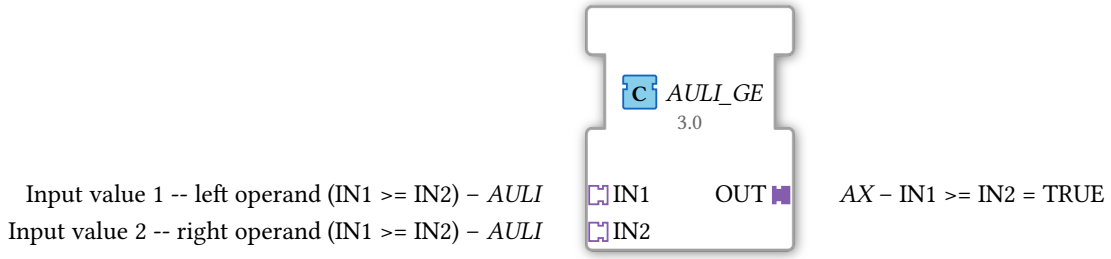
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

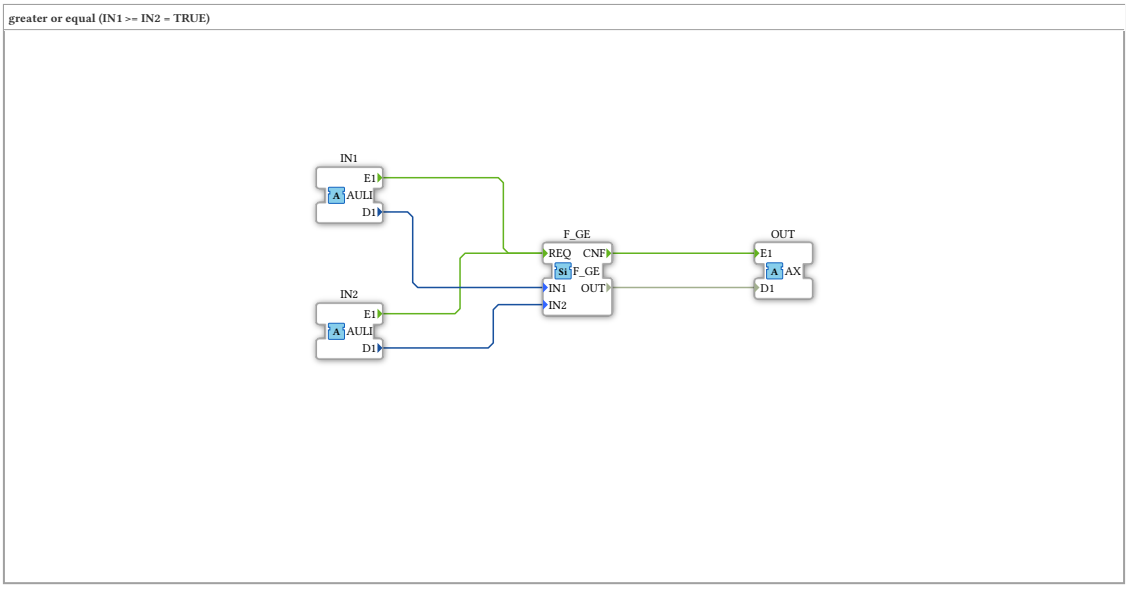
Application Scenarios

- **Limit Monitoring**: Checking large counter and quantity values against a reference or threshold value of type `ULINT`.
- **Control Logic**: Triggering an action once two values of type `ULINT` satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `ULINT`-based comparison condition.

Comparison with Similar Function Blocks



- **AULI_NE**: Checks for “not equal to” – the inverse function of AULI_EQ.
- **AULI_NE**: Checks for inequality of values.



AULI_EQ is part of the complete AULI comparison family (EQ/NE/GT/GE/LT/LE) for the `ULINT` data type.

Conclusion

AULI_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the `ULINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AULI_GE

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_GE** compares two values of type `ULINT` (64-bit unsigned integer) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `ULINT`, 64-bit unsigned integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AULI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AULI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AULI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GE` (type `iec61131::comparison::F_GE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AULI/AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the `ULINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

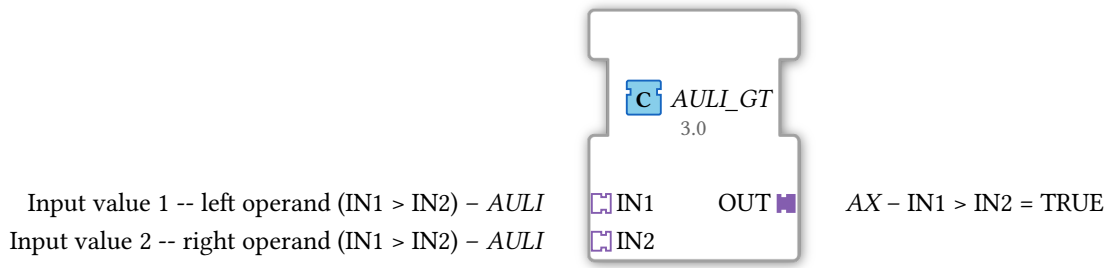
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

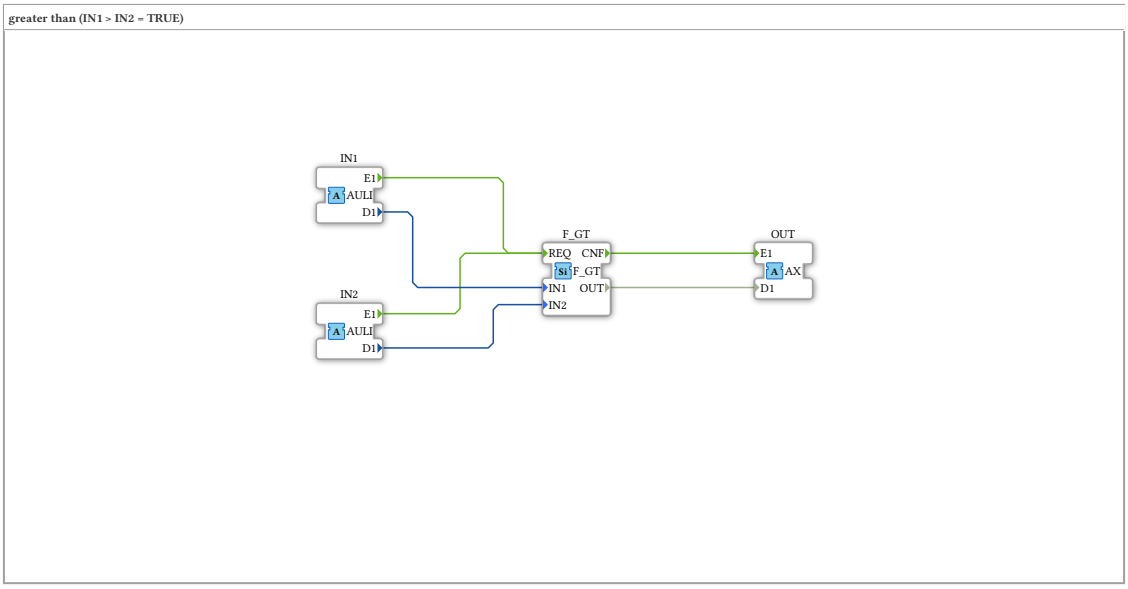
Application Scenarios

- **Limit Monitoring**: Checking large counter and quantity values against a reference or threshold value of type `ULINT`.
- **Control Logic**: Triggering an action once two values of type `ULINT` satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `ULINT`-based comparison condition.

Comparison with Similar Function Blocks



- **AULI_LE**: Checks for “less than or equal to” – the inverse function of AULI_GE.
- **AULI_EQ**: Checks for equality of values.
- **AULI_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which AULI_GE is the extended version.



AULI_GE completes the AULI comparison family with the boundary case of equality.

Conclusion

AULI_GE is a simple yet important comparison block for IEC 61131-3 control applications using the `ULINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AULI_GT

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_GT** compares two values of type `ULINT` (64-bit unsigned integer) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `ULINT`, 64-bit unsigned integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AULI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AULI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AULI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GT` (type `iec61131::comparison::F_GT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AULI/AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the `ULINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

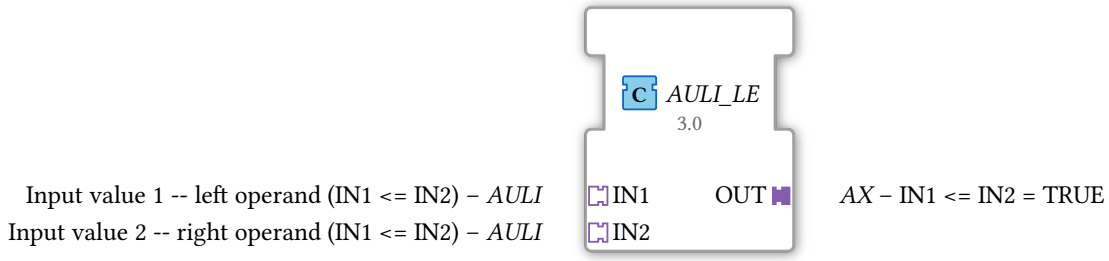
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

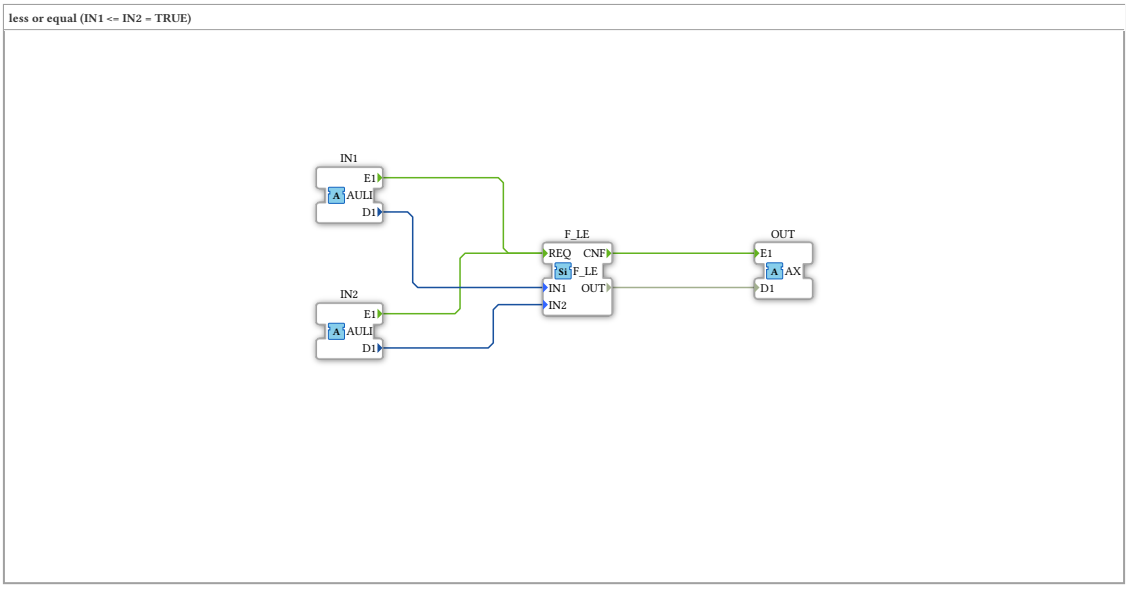
Application Scenarios

- **Limit Monitoring**: Checking large counter and quantity values against a reference or threshold value of type `ULINT`.
- **Control Logic**: Triggering an action once two values of type `ULINT` satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `ULINT`-based comparison condition.

Comparison with Similar Function Blocks



- **AULI_LT**: Checks for “less than” – the inverse function of AULI_GT.
- **AULI_EQ**: Checks for equality of values.
- **AULI_GE**: Performs the “greater than or equal to” comparison – the extended version of AULI_GT that includes the equality case.



AULI_GT is the basic “greater than” component without the equality case, complemented by AULI_GE.

Conclusion

AULI_GT is a simple yet important comparison block for IEC 61131-3 control applications using the `ULINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AULI_LE

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_LE** compares two values of type `ULINT` (64-bit unsigned integer) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `ULINT`, 64-bit unsigned integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AULI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AULI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AULI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LE` (type `iec61131::comparison::F_LE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AULI/AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the `ULINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

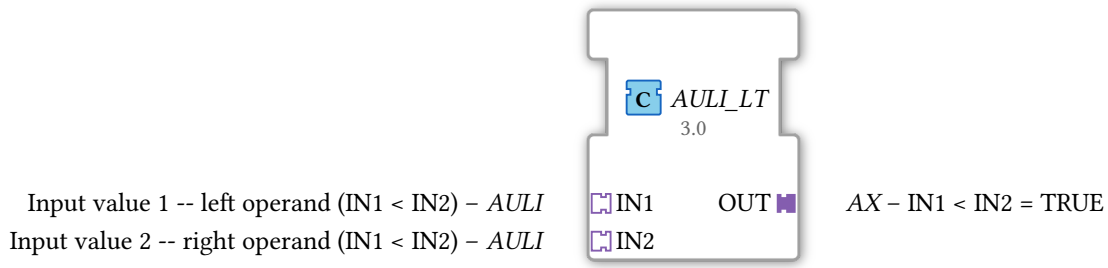
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

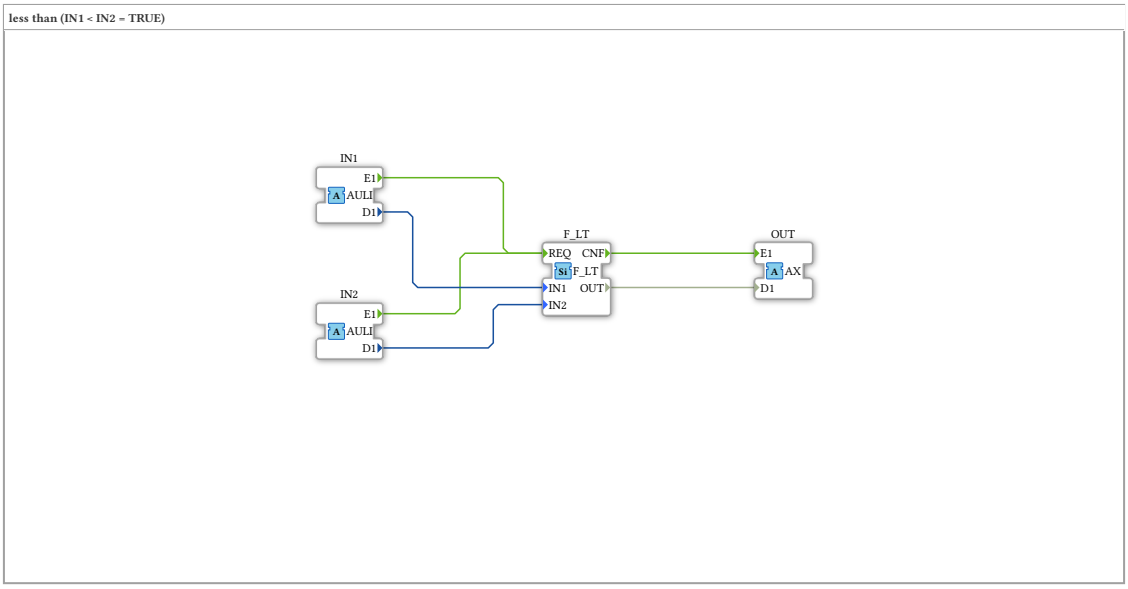
Application Scenarios

- **Limit Monitoring**: Checking large counter and quantity values against a reference or threshold value of type `ULINT`.
- **Control Logic**: Triggering an action once two values of type `ULINT` satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `ULINT`-based comparison condition.

Comparison with Similar Function Blocks



- **AULI_GE**: Checks for “greater than or equal to” – the inverse function of AULI_LE.
- **AULI_EQ**: Checks for equality of values.
- **AULI_LT**: Performs the “less than” comparison – the base variant without the equality case, of which AULI_LE is the extended version.



AULI_LE completes the AULI comparison family with the boundary case of equality.

Conclusion

AULI_LE is a simple yet important comparison block for IEC 61131-3 control applications using the `ULINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AULI_LT

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_LT** compares two values of type `ULINT` (64-bit unsigned integer) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `ULINT`, 64-bit unsigned integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AULI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AULI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AULI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LT` (type `iec61131::comparison::F_LT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AULI/AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the `ULINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

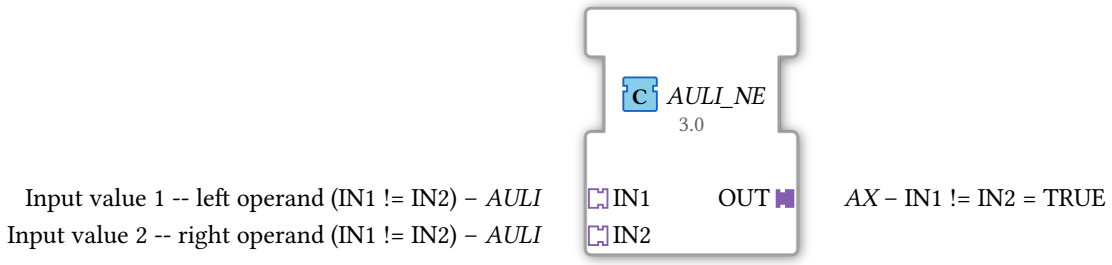
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

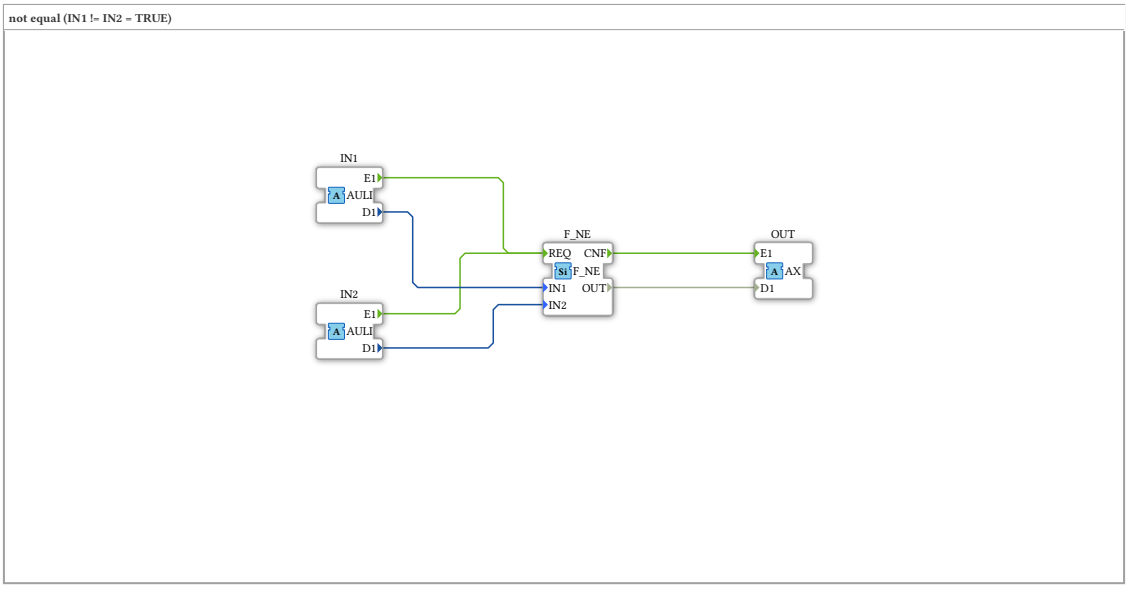
Application Scenarios

- **Limit Monitoring**: Checking large counter and quantity values against a reference or threshold value of type `ULINT`.
- **Control Logic**: Triggering an action once two values of type `ULINT` satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `ULINT`-based comparison condition.

Comparison with Similar Function Blocks



- **AULI_GT**: Checks for “greater than” – the inverse function of AULI_LT.
- **AULI_EQ**: Checks for equality of values.
- **AULI_LE**: Performs the “less than or equal to” comparison – the extended version of AULI_LT that includes the equality case.



AULI_LT is the basic “less than” component without the equality case, complemented by AULI_LE.

Conclusion

AULI_LT is a simple yet important comparison block for IEC 61131-3 control applications using the `ULINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AULI_NE

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_NE** compares two values of type `ULINT` (64-bit unsigned integer) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `ULINT`, 64-bit unsigned integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AULI` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AULI` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AULI` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_NE` (type `iec61131::comparison::F_NE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AULI/AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the `ULINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

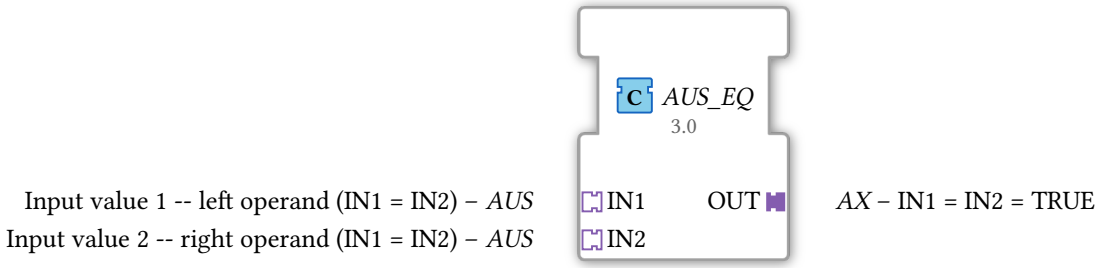
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

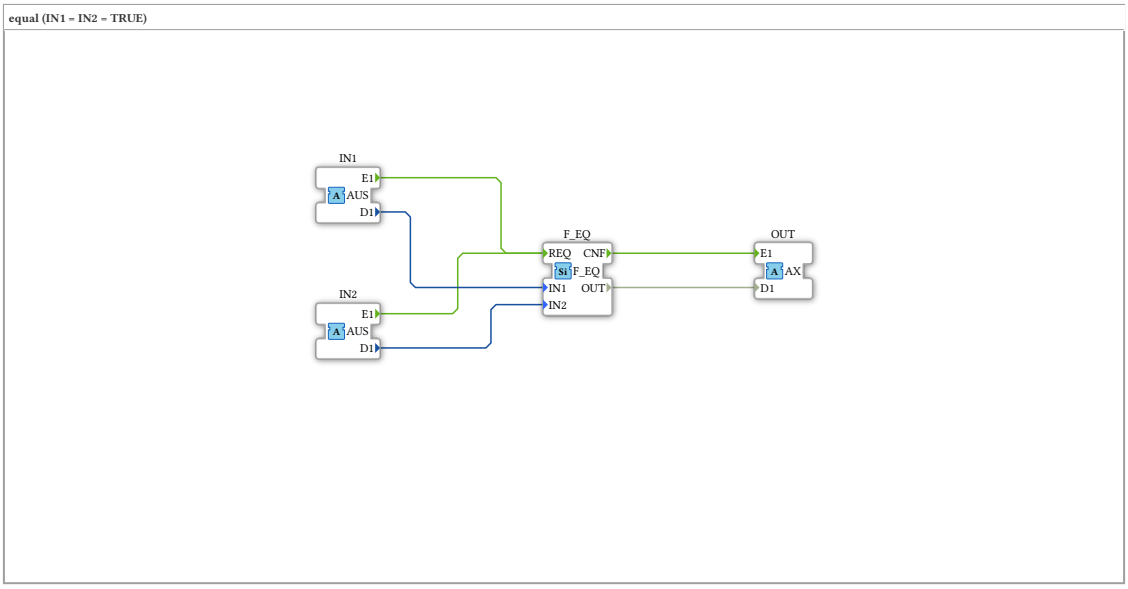
Application Scenarios

- **Limit Monitoring**: Checking large counter and quantity values against a reference or threshold value of type `ULINT`.
- **Control Logic**: Triggering an action once two values of type `ULINT` satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `ULINT`-based comparison condition.

Comparison with Similar Function Blocks



- **AULI_EQ**: Checks for “equal to” – the inverse function of AULI_NE.
- **AULI_EQ**: Checks for equality of values.



AULI_NE is part of the complete AULI comparison family (EQ/NE/GT/GE/LT/LE) for the `ULINT` data type.

Conclusion

AULI_NE is a simple yet important comparison block for IEC 61131-3 control applications using the `ULINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AUS_EQ

• – ○ • – ○ • – ○ •

Introduction

The function block **AUS_EQ** compares two values of type `USINT` (8-bit unsigned integer) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `USINT`, 8-bit unsigned integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AUS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AUS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AUS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_EQ` (type `iec61131::comparison::F_EQ`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AUS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the `USINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

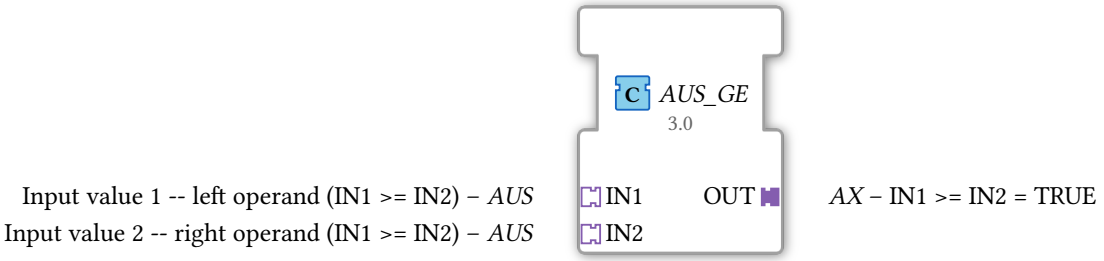
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

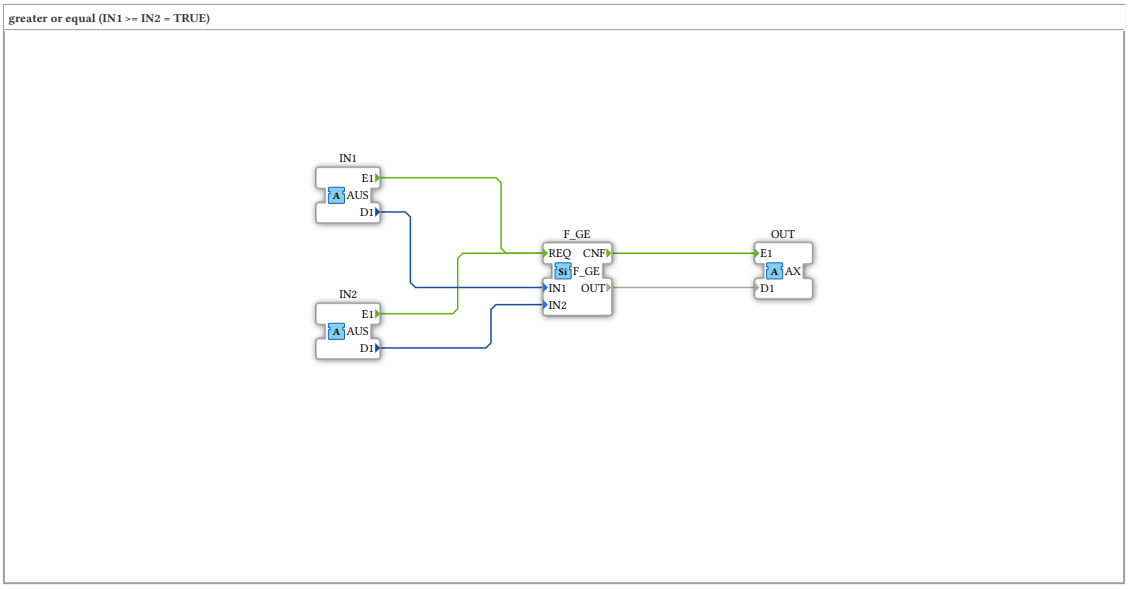
Application Scenarios

- **Limit Monitoring**: Checking small counter and index values against a reference or threshold value of type `USINT`.
- **Control Logic**: Triggering an action once two values of type `USINT` satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `USINT`-based comparison condition.

Comparison with Similar Function Blocks



- **AUS_NE**: Checks for “not equal to” – the inverse function of AUS_EQ.
- **AUS_NE**: Checks for inequality of values.



AUS_EQ is part of the complete AUS comparison family (EQ/NE/GT/GE/LT/LE) for the `USINT` data type.

Conclusion

AUS_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the `USINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AUS_GE

• – ○ • – ○ • – ○ •

Introduction

The function block **AUS_GE** compares two values of type `USINT` (8-bit unsigned integer) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `USINT`, 8-bit unsigned integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AUS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AUS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AUS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GE` (type `iec61131::comparison::F_GE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AUS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the `USINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

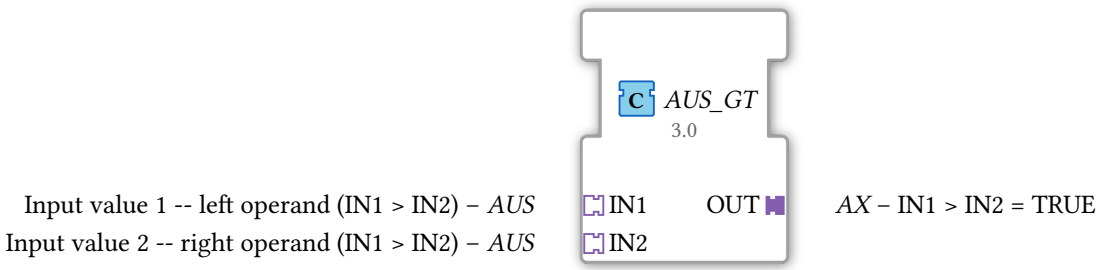
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

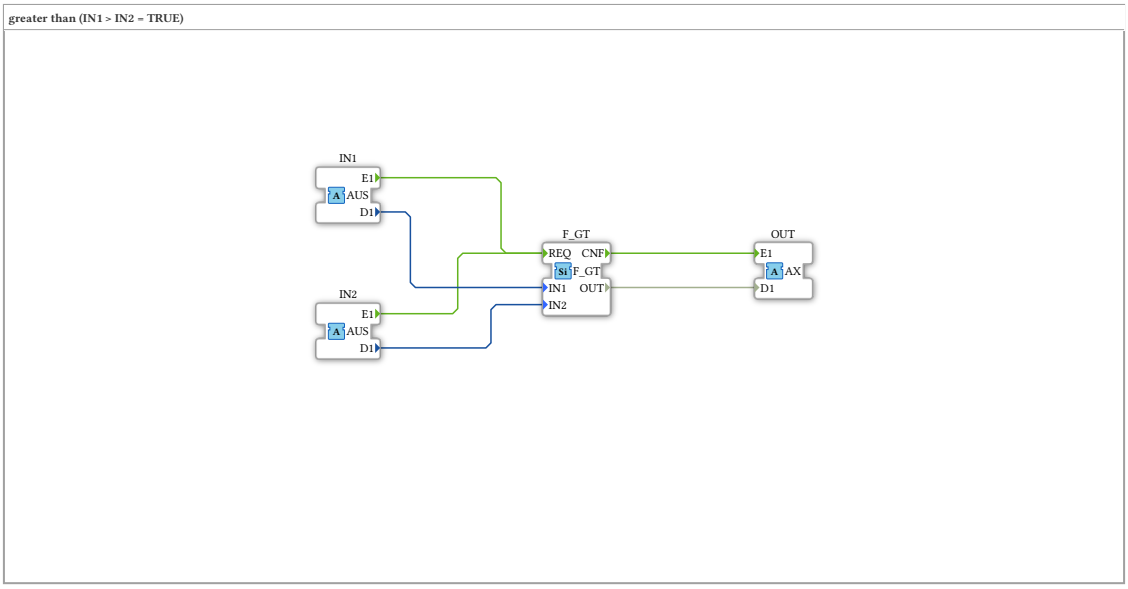
Application Scenarios

- **Limit Monitoring**: Checking small counter and index values against a reference or threshold value of type `USINT`.
- **Control Logic**: Triggering an action once two values of type `USINT` satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `USINT`-based comparison condition.

Comparison with Similar Function Blocks



- **AUS_LE**: Checks for “less than or equal to” – the inverse function of AUS_GE.
- **AUS_EQ**: Checks for equality of values.
- **AUS_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which AUS_GE is the extended version.



AUS_GE completes the AUS comparison family with the boundary case of equality.

Conclusion

AUS_GE is a simple yet important comparison block for IEC 61131-3 control applications using the `USINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AUS_GT

• – ○ • – ○ • – ○ •

Introduction

The function block **AUS_GT** compares two values of type `USINT` (8-bit unsigned integer) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `USINT`, 8-bit unsigned integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AUS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AUS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AUS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GT` (type `iec61131::comparison::F_GT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AUS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the `USINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

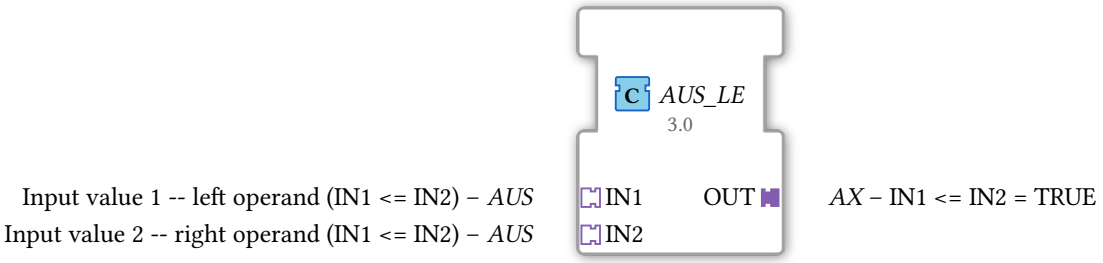
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

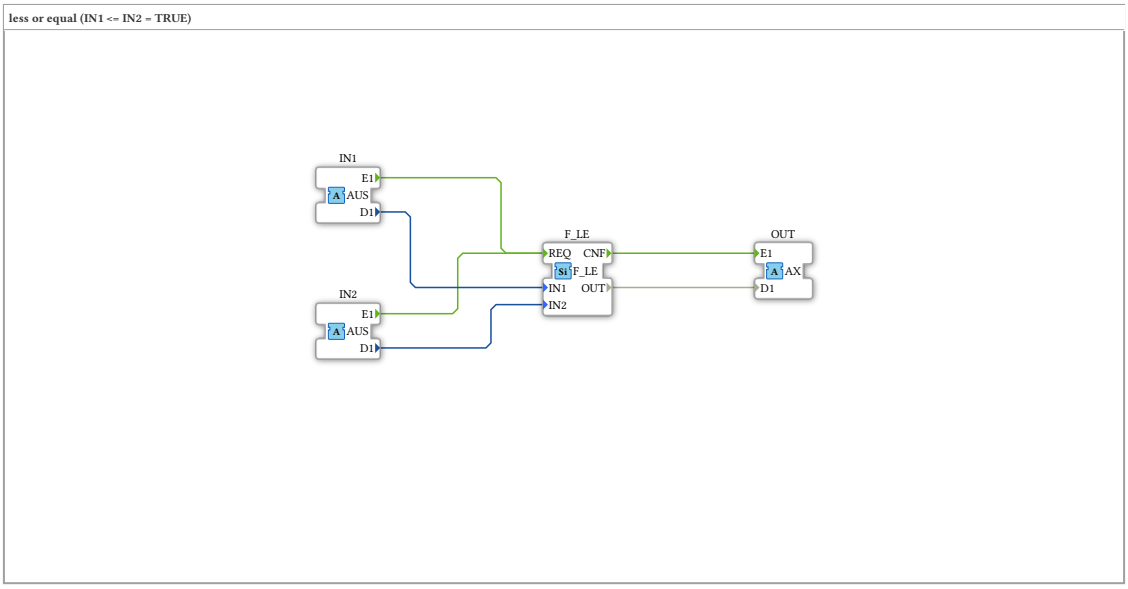
Application Scenarios

- **Limit Monitoring**: Checking small counter and index values against a reference or threshold value of type `USINT`.
- **Control Logic**: Triggering an action once two values of type `USINT` satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `USINT`-based comparison condition.

Comparison with Similar Function Blocks



- **AUS_LT**: Checks for “less than” – the inverse function of AUS_GT.
- **AUS_EQ**: Checks for equality of values.
- **AUS_GE**: Performs the “greater than or equal to” comparison – the extended version of AUS_GT that includes the equality case.



AUS_GT is the basic “greater than” component without the equality case, complemented by AUS_GE.

Conclusion

AUS_GT is a simple yet important comparison block for IEC 61131-3 control applications using the `USINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AUS_LE

• – ○ • – ○ • – ○ •

Introduction

The function block **AUS_LE** compares two values of type `USINT` (8-bit unsigned integer) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `USINT`, 8-bit unsigned integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AUS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AUS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AUS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LE` (type `iec61131::comparison::F_LE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AUS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the `USINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

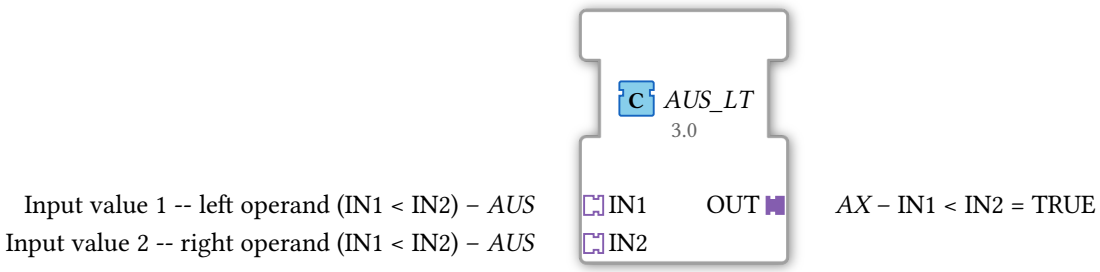
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

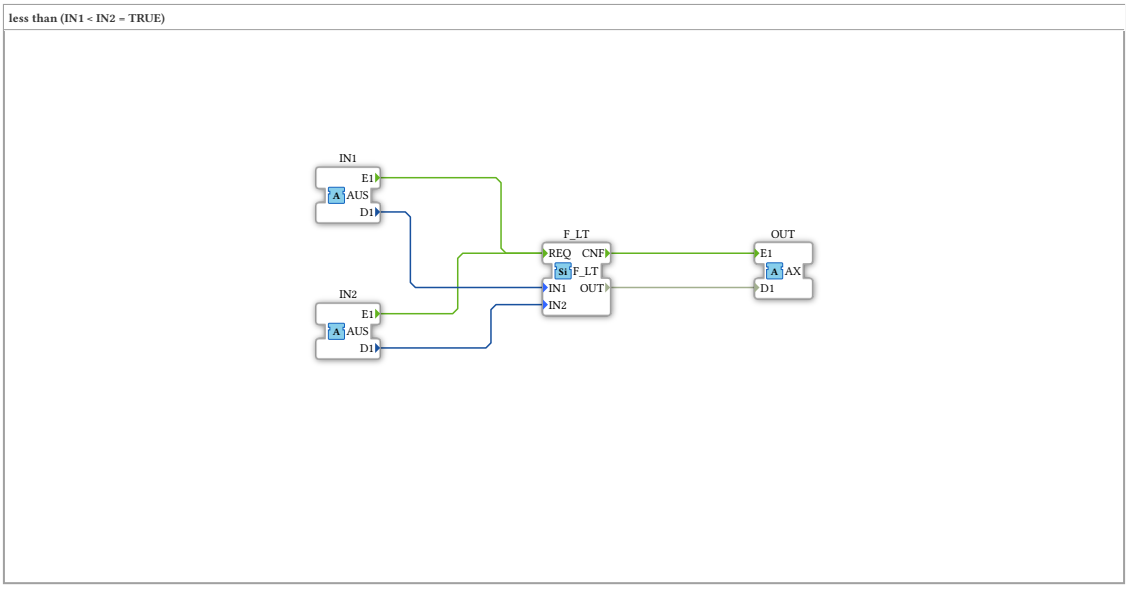
Application Scenarios

- **Limit Monitoring**: Checking small counter and index values against a reference or threshold value of type `USINT`.
- **Control Logic**: Triggering an action once two values of type `USINT` satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `USINT`-based comparison condition.

Comparison with Similar Function Blocks



- **AUS_GE**: Checks for “greater than or equal to” – the inverse function of AUS_LE.
- **AUS_EQ**: Checks for equality of values.
- **AUS_LT**: Performs the “less than” comparison – the base variant without the equality case, of which AUS_LE is the extended version.



AUS_LE completes the AUS comparison family with the boundary case of equality.

Conclusion

AUS_LE is a simple yet important comparison block for IEC 61131-3 control applications using the `USINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AUS_LT

• – ○ • – ○ • – ○ •

Introduction

The function block **AUS_LT** compares two values of type `USINT` (8-bit unsigned integer) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `USINT`, 8-bit unsigned integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AUS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AUS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AUS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LT` (type `iec61131::comparison::F_LT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AUS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the `USINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

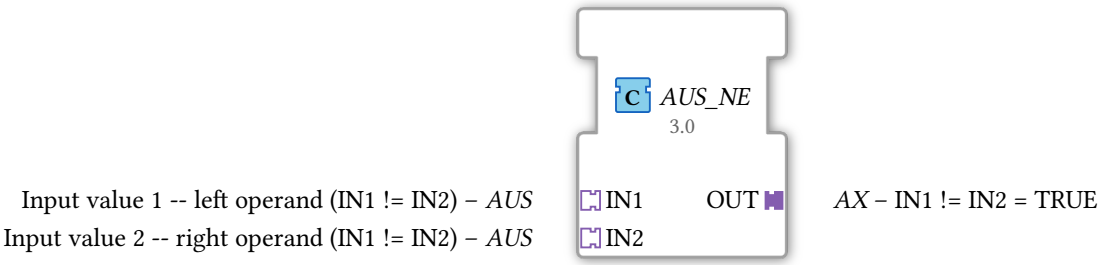
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

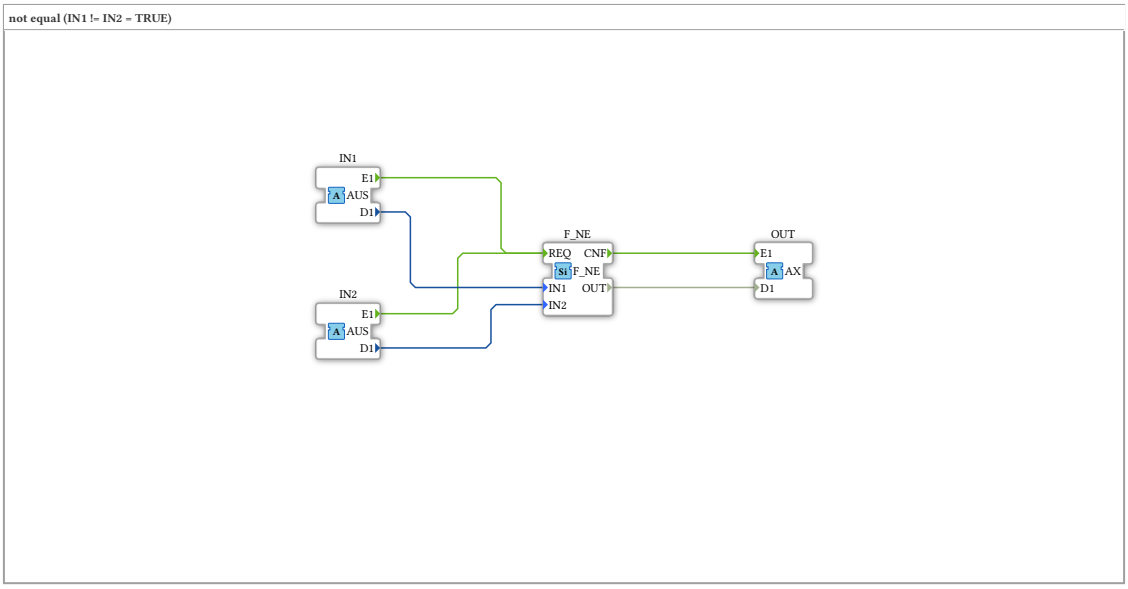
Application Scenarios

- **Limit Monitoring**: Checking small counter and index values against a reference or threshold value of type `USINT`.
- **Control Logic**: Triggering an action once two values of type `USINT` satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `USINT`-based comparison condition.

Comparison with Similar Function Blocks



- **AUS_GT**: Checks for “greater than” – the inverse function of AUS_LT.
- **AUS_EQ**: Checks for equality of values.
- **AUS_LE**: Performs the “less than or equal to” comparison – the extended version of AUS_LT that includes the equality case.



AUS_LT is the basic “less than” component without the equality case, complemented by AUS_LE.

Conclusion

AUS_LT is a simple yet important comparison block for IEC 61131-3 control applications using the `USINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AUS_NE

• – ○ • – ○ • – ○ •

Introduction

The function block **AUS_NE** compares two values of type `USINT` (8-bit unsigned integer) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The comparison follows the usual numeric ordering.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `USINT`, 8-bit unsigned integer).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AUS` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AUS` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AUS` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_NE` (type `iec61131::comparison::F_NE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AUS`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the `USINT` data type.
- **Comparison logic**: The comparison follows the usual numeric ordering.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

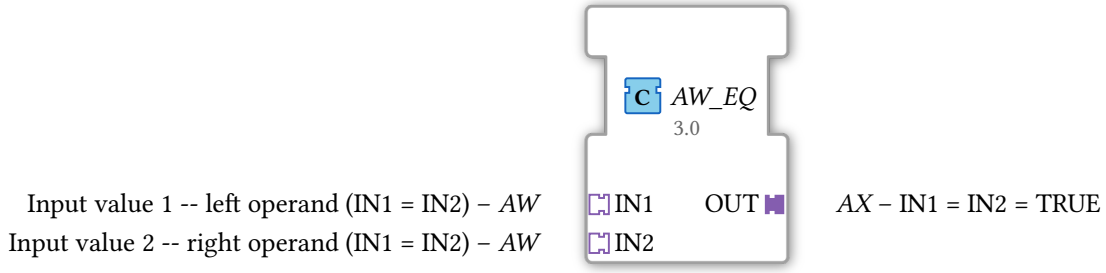
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

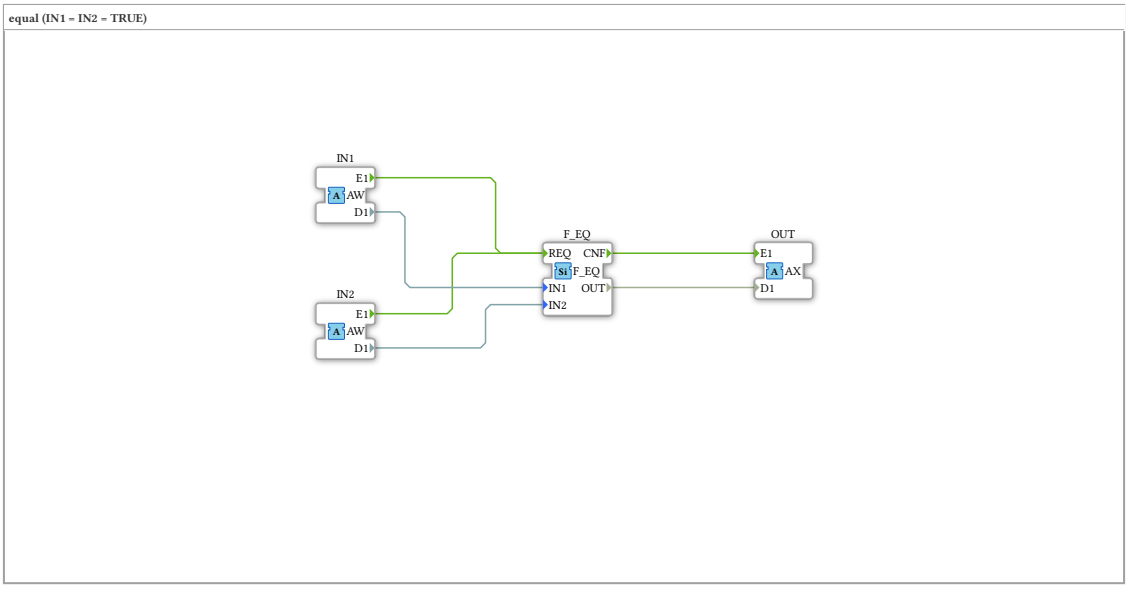
Application Scenarios

- **Limit Monitoring**: Checking small counter and index values against a reference or threshold value of type `USINT`.
- **Control Logic**: Triggering an action once two values of type `USINT` satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `USINT`-based comparison condition.

Comparison with Similar Function Blocks



- **AUS_EQ**: Checks for “equal to” – the inverse function of AUS_NE.
- **AUS_EQ**: Checks for equality of values.



AUS_NE is part of the complete AUS comparison family (EQ/NE/GT/GE/LT/LE) for the `USINT` data type.

Conclusion

AUS_NE is a simple yet important comparison block for IEC 61131-3 control applications using the `USINT` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AW_EQ

• – ○ • – ○ • – ○ •

Introduction

The function block **AW_EQ** compares two values of type `WORD` (16-bit bit pattern (word)) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `WORD`, 16-bit bit pattern (word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AW` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AW` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AW` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_EQ` (type `iec61131::comparison::F_EQ`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AW`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“equal to”) for the `WORD` data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

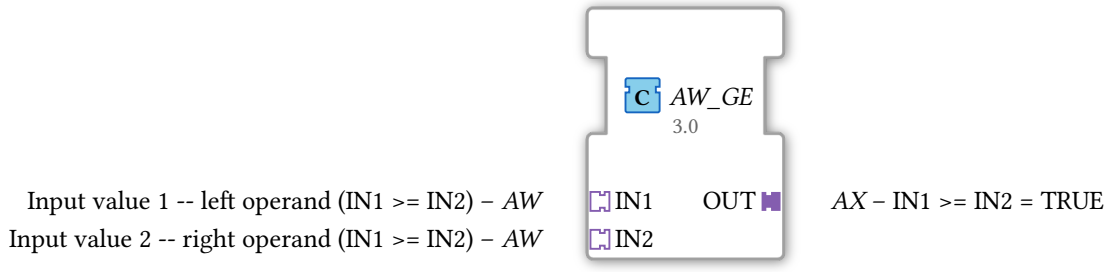
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

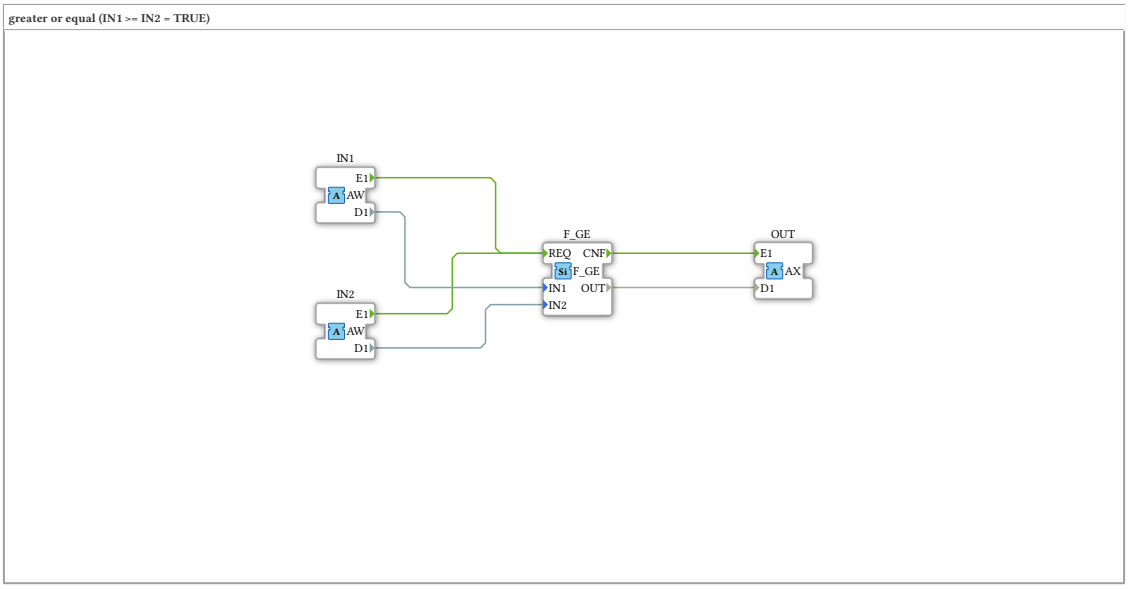
Application Scenarios

- **Limit Monitoring**: Checking status words against a reference or threshold value of type `WORD`.
- **Control Logic**: Triggering an action once two values of type `WORD` satisfy the “equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `WORD`-based comparison condition.

Comparison with Similar Function Blocks



- **AW_NE**: Checks for “not equal to” – the inverse function of AW_EQ.
- **AW_NE**: Checks for inequality of values.



AW_EQ is part of the complete AW comparison family (EQ/NE/GT/GE/LT/LE) for the `WORD` data type.

Conclusion

AW_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the `WORD` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AW_GE

• – ○ • – ○ • – ○ •

Introduction

The function block **AW_GE** compares two values of type `WORD` (16-bit bit pattern (word)) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `WORD`, 16-bit bit pattern (word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AW` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AW` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AW` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GE` (type `iec61131::comparison::F_GE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AW`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the `WORD` data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

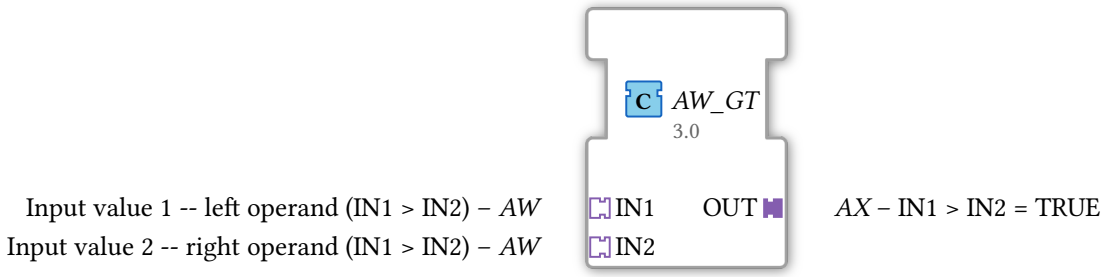
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

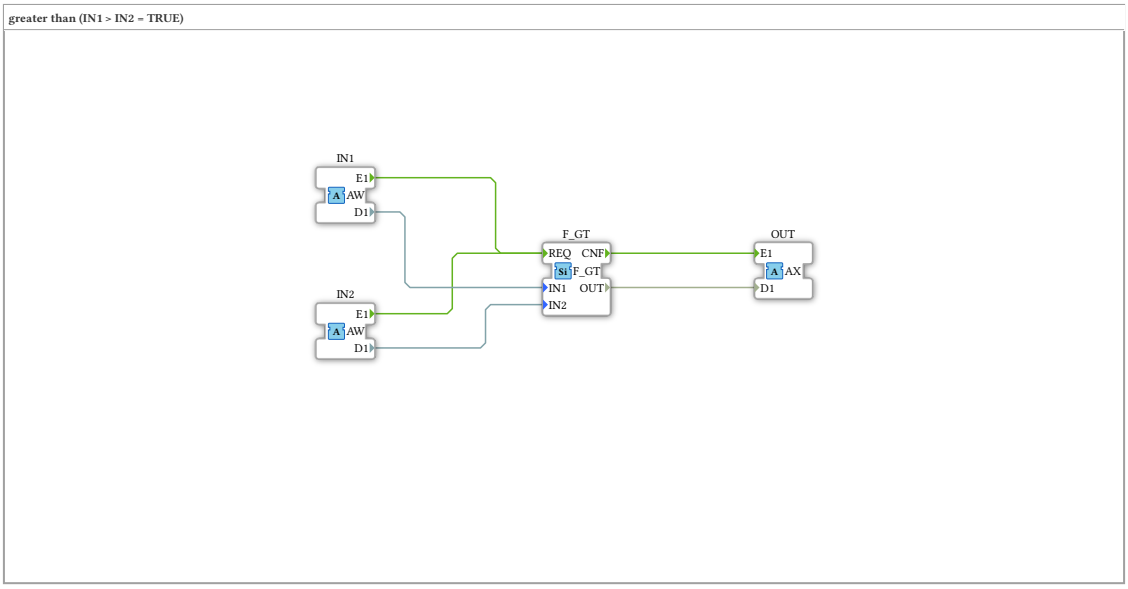
Application Scenarios

- **Limit Monitoring**: Checking status words against a reference or threshold value of type `WORD`.
- **Control Logic**: Triggering an action once two values of type `WORD` satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `WORD`-based comparison condition.

Comparison with Similar Function Blocks



- **AW_LE**: Checks for “less than or equal to” – the inverse function of AW_GE.
- **AW_EQ**: Checks for equality of values.
- **AW_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which AW_GE is the extended version.



AW_GE completes the AW comparison family with the boundary case of equality.

Conclusion

AW_GE is a simple yet important comparison block for IEC 61131-3 control applications using the `WORD` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AW_GT

• – ○ • – ○ • – ○ •

Introduction

The function block **AW_GT** compares two values of type `WORD` (16-bit bit pattern (word)) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `WORD`, 16-bit bit pattern (word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AW` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AW` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AW` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GT` (type `iec61131::comparison::F_GT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AW`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the `WORD` data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

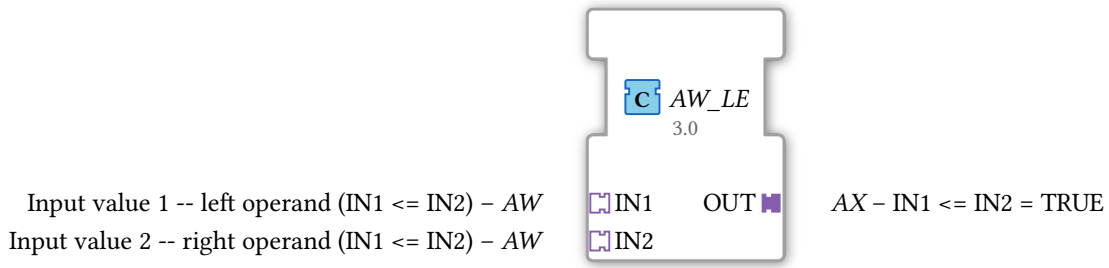
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

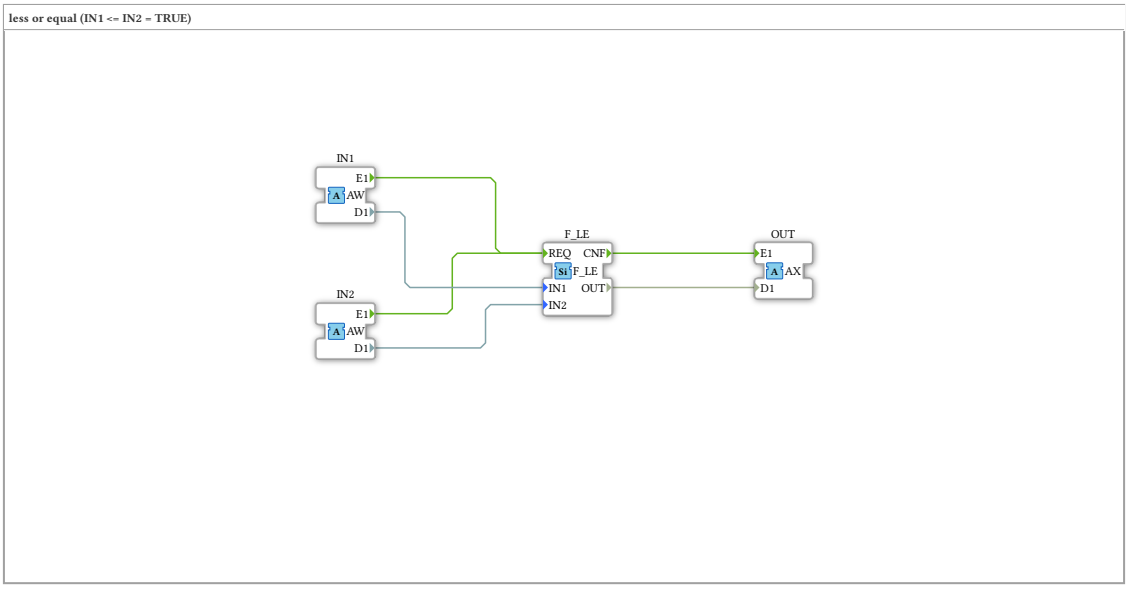
Application Scenarios

- **Limit Monitoring**: Checking status words against a reference or threshold value of type `WORD`.
- **Control Logic**: Triggering an action once two values of type `WORD` satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `WORD`-based comparison condition.

Comparison with Similar Function Blocks



- **AW_LT**: Checks for “less than” – the inverse function of AW_GT.
- **AW_EQ**: Checks for equality of values.
- **AW_GE**: Performs the “greater than or equal to” comparison – the extended version of AW_GT that includes the equality case.



AW_GT is the basic “greater than” component without the equality case, complemented by AW_GE.

Conclusion

AW_GT is a simple yet important comparison block for IEC 61131-3 control applications using the `WORD` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AW_LE

• – ○ • – ○ • – ○ •

Introduction

The function block **AW_LE** compares two values of type `WORD` (16-bit bit pattern (word)) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `WORD`, 16-bit bit pattern (word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AW` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AW` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AW` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LE` (type `iec61131::comparison::F_LE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AW`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the `WORD` data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

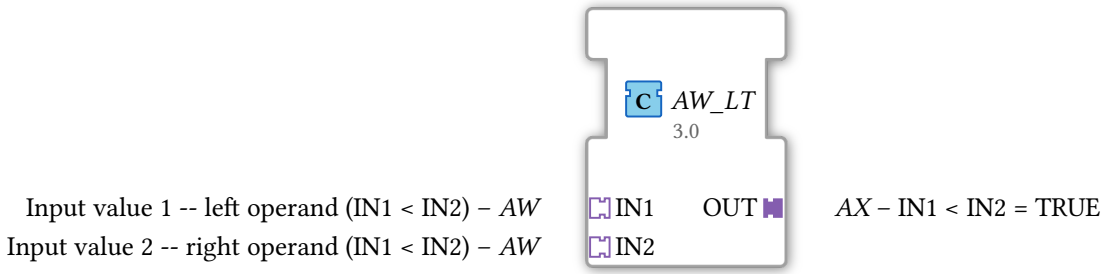
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

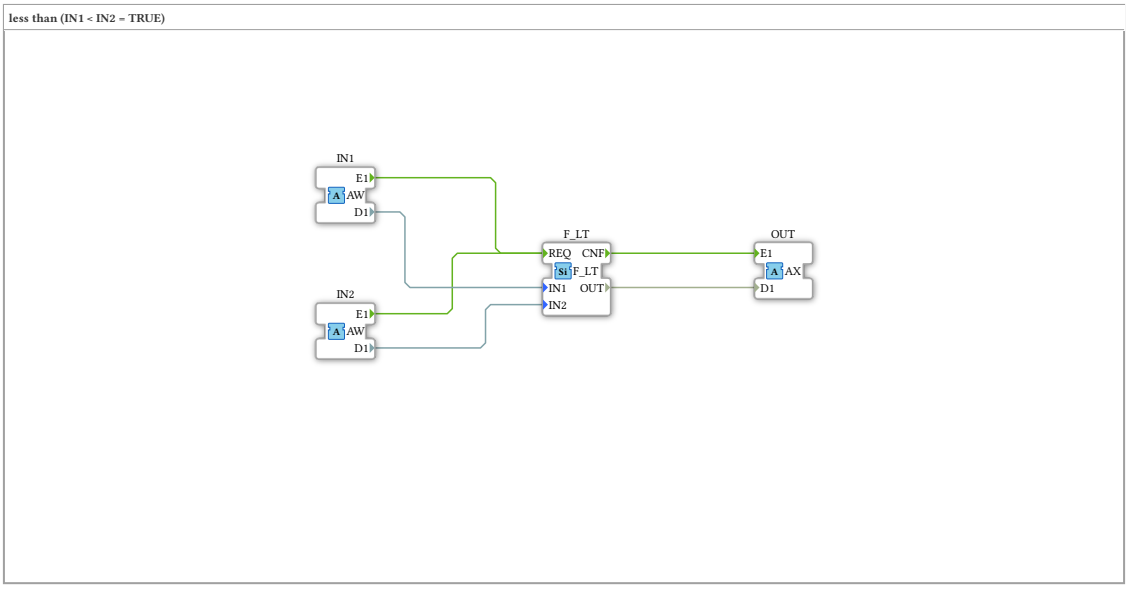
Application Scenarios

- **Limit Monitoring**: Checking status words against a reference or threshold value of type `WORD`.
- **Control Logic**: Triggering an action once two values of type `WORD` satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `WORD`-based comparison condition.

Comparison with Similar Function Blocks



- **AW_GE**: Checks for “greater than or equal to” – the inverse function of AW_LE.
- **AW_EQ**: Checks for equality of values.
- **AW_LT**: Performs the “less than” comparison – the base variant without the equality case, of which AW_LE is the extended version.



AW_LE completes the AW comparison family with the boundary case of equality.

Conclusion

AW_LE is a simple yet important comparison block for IEC 61131-3 control applications using the `WORD` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AW_LT

• – ○ • – ○ • – ○ •

Introduction

The function block **AW_LT** compares two values of type `WORD` (16-bit bit pattern (word)) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `WORD`, 16-bit bit pattern (word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AW` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AW` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AW` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LT` (type `iec61131::comparison::F_LT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AW`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the `WORD` data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

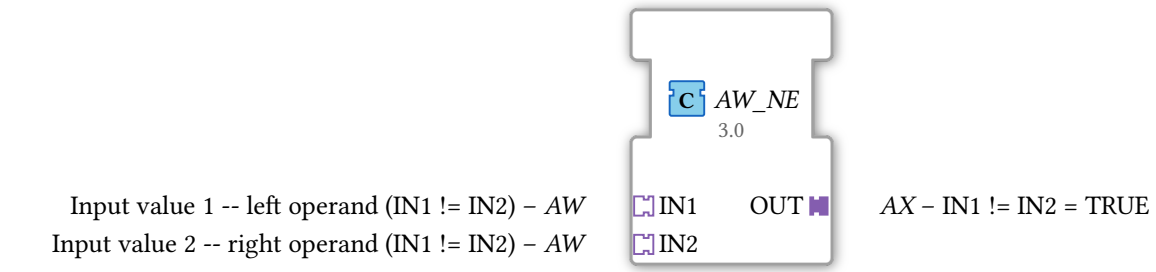
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

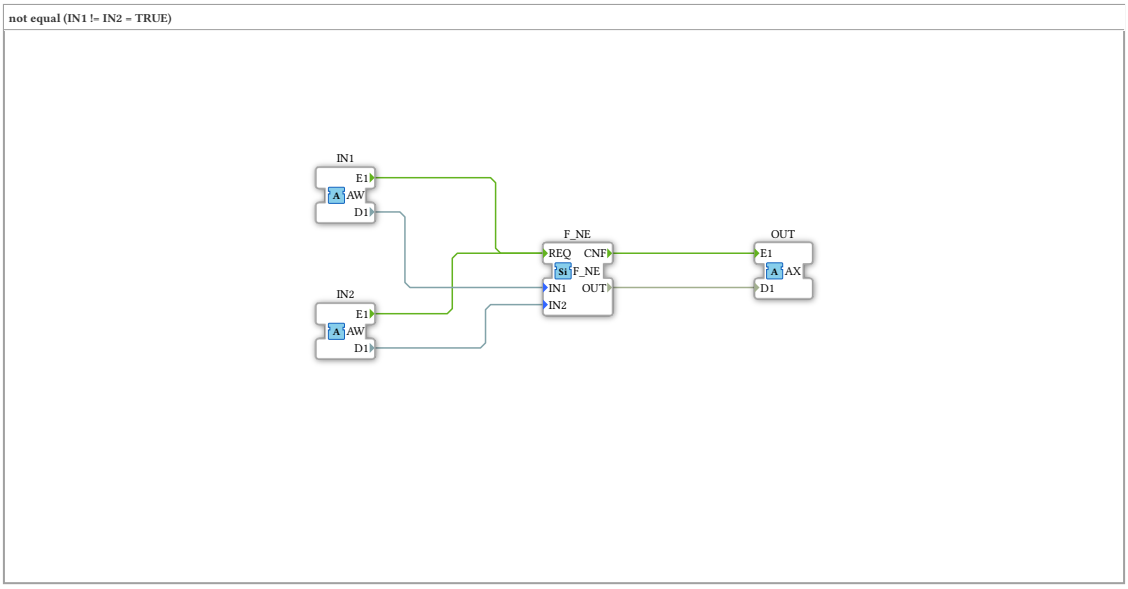
Application Scenarios

- **Limit Monitoring**: Checking status words against a reference or threshold value of type `WORD`.
- **Control Logic**: Triggering an action once two values of type `WORD` satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `WORD`-based comparison condition.

Comparison with Similar Function Blocks



- **AW_GT**: Checks for “greater than” – the inverse function of AW_LT.
- **AW_EQ**: Checks for equality of values.
- **AW_LE**: Performs the “less than or equal to” comparison – the extended version of AW_LT that includes the equality case.



AW_LT is the basic “less than” component without the equality case, complemented by AW_LE.

Conclusion

AW_LT is a simple yet important comparison block for IEC 61131-3 control applications using the `WORD` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AW_NE

• – ○ • – ○ • – ○ •

Introduction

The function block **AW_NE** compares two values of type `WORD` (16-bit bit pattern (word)) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. The bit patterns are interpreted as unsigned integers and compared numerically.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `WORD`, 16-bit bit pattern (word)).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AW` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AW` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AW` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_NE` (type `iec61131::comparison::F_NE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AW`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the `WORD` data type.
- **Comparison logic**: The bit patterns are interpreted as unsigned integers and compared numerically.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

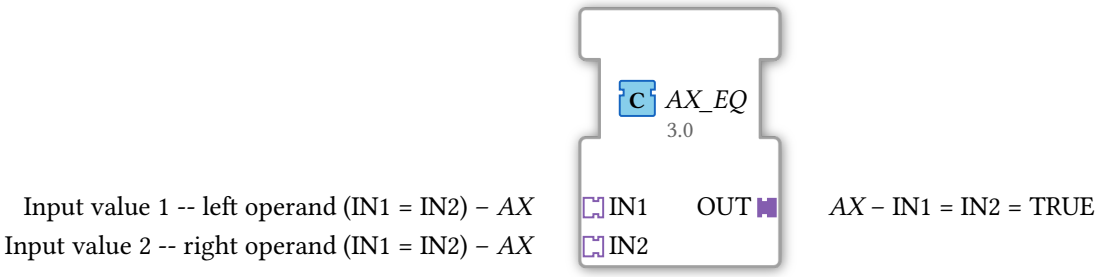
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

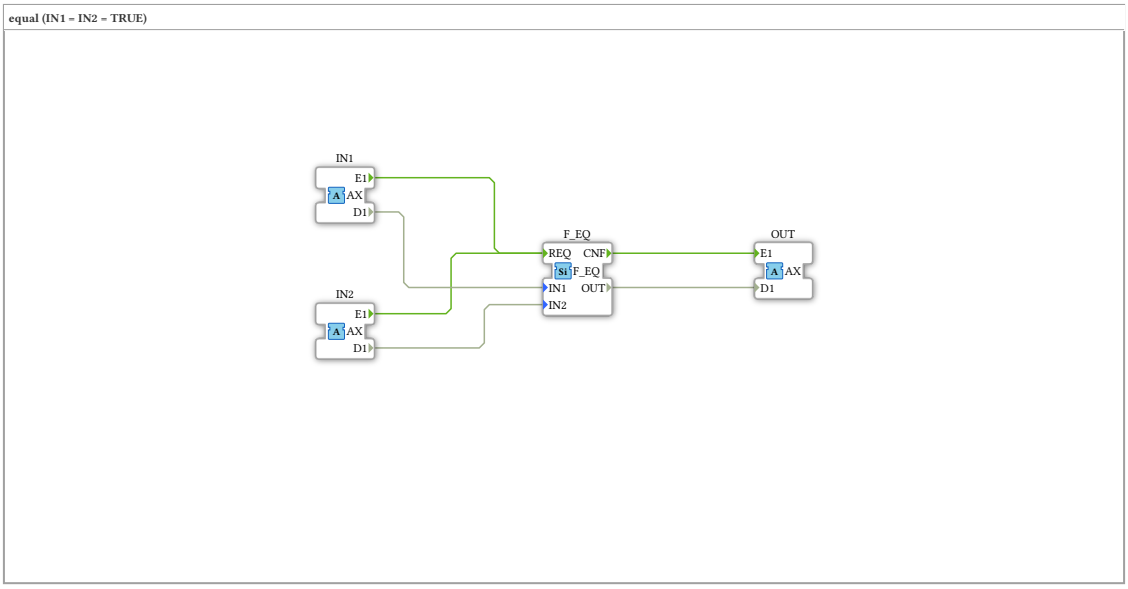
Application Scenarios

- **Limit Monitoring**: Checking status words against a reference or threshold value of type `WORD`.
- **Control Logic**: Triggering an action once two values of type `WORD` satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `WORD`-based comparison condition.

Comparison with Similar Function Blocks



- **AW_EQ**: Checks for “equal to” – the inverse function of AW_NE.
- **AW_EQ**: Checks for equality of values.



AW_NE is part of the complete AW comparison family (EQ/NE/GT/GE/LT/LE) for the `WORD` data type.

Conclusion

AW_NE is a simple yet important comparison block for IEC 61131-3 control applications using the `WORD` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AX_EQ

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_EQ** compares two values of type `BOOL` (Boolean value) and checks whether the first value (IN1) is equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. `FALSE` is considered the smaller and `TRUE` the greater value.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `BOOL`, Boolean value).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 = IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AX` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AX` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AX` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_EQ` (type `iec61131::comparison::F_EQ`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AX`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 ("equal to") for the `BOOL` data type.
- **Comparison logic**: `FALSE` is considered the smaller and `TRUE` the greater value.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

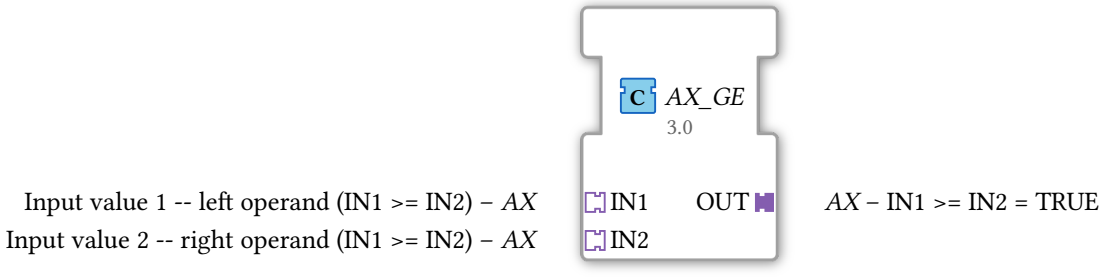
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

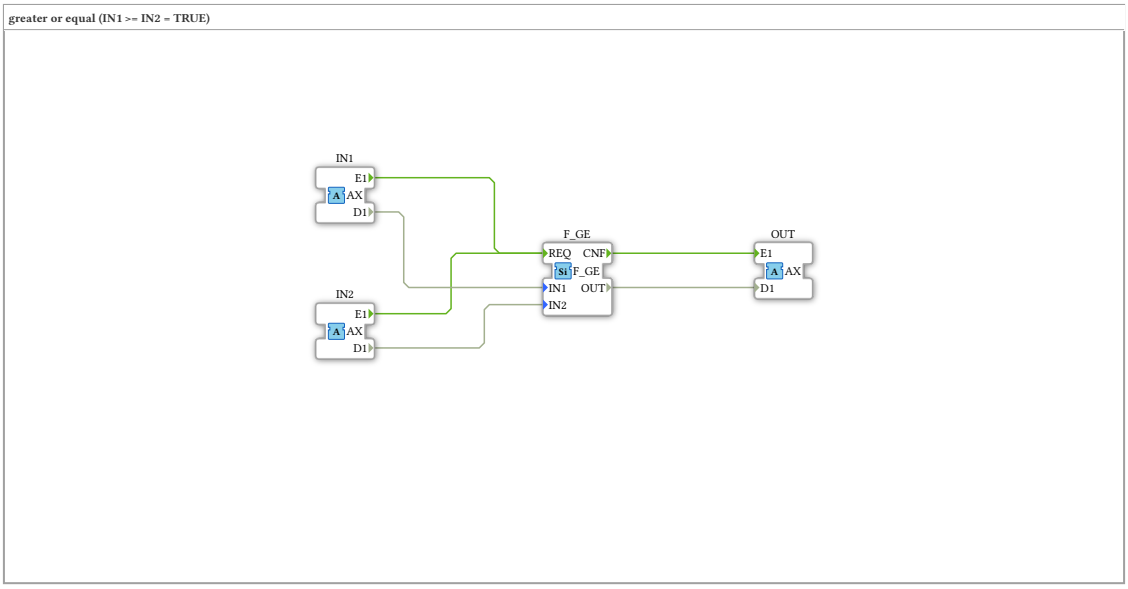
Application Scenarios

- **Limit Monitoring**: Checking enable and state bits against a reference or threshold value of type `BOOL`.
- **Control Logic**: Triggering an action once two values of type `BOOL` satisfy the "equal to" condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `BOOL`-based comparison condition.

Comparison with Similar Function Blocks



- **AX_NE**: Checks for "not equal to" – the inverse function of AX_EQ.
- **AX_NE**: Checks for inequality of values.



AX_EQ is part of the complete AX comparison family (EQ/NE/GT/GE/LT/LE) for the `BOOL` data type.

Conclusion

AX_EQ is a simple yet important comparison block for IEC 61131-3 control applications using the `BOOL` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AX_GE

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_GE** compares two values of type `BOOL` (Boolean value) and checks whether the first value (IN1) is greater than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. `FALSE` is considered the smaller and `TRUE` the greater value.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `BOOL`, Boolean value).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 >= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AX` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AX` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AX` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GE` (type `iec61131::comparison::F_GE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AX`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than or equal to”) for the `BOOL` data type.
- **Comparison logic**: `FALSE` is considered the smaller and `TRUE` the greater value.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

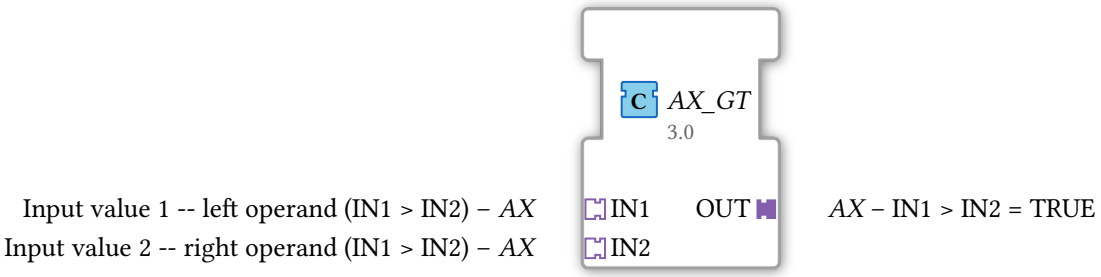
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

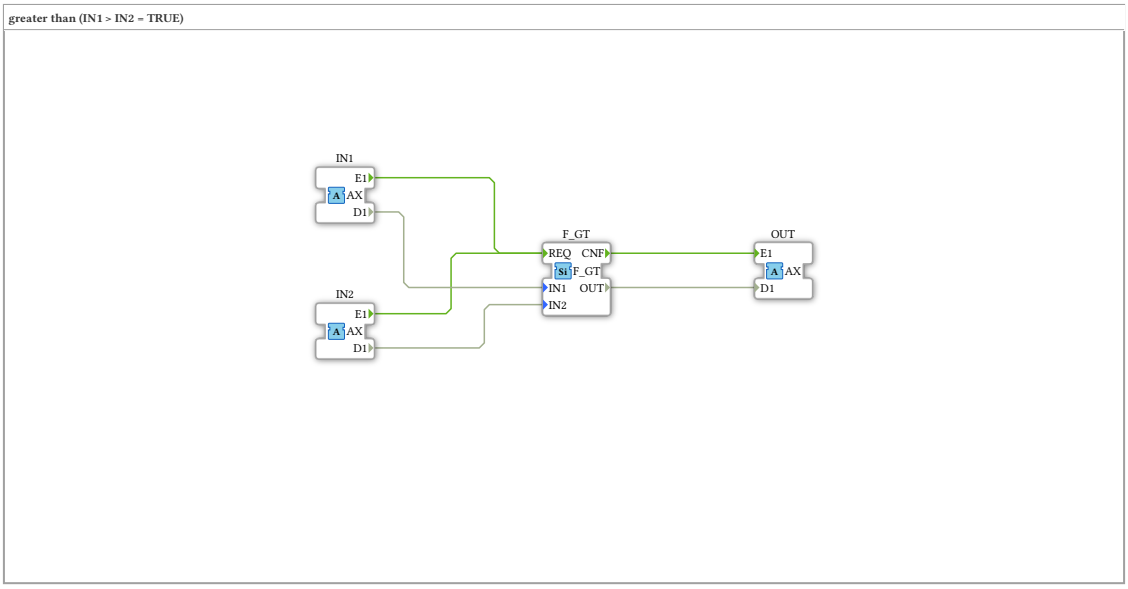
Application Scenarios

- **Limit Monitoring**: Checking enable and state bits against a reference or threshold value of type `BOOL`.
- **Control Logic**: Triggering an action once two values of type `BOOL` satisfy the “greater than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `BOOL`-based comparison condition.

Comparison with Similar Function Blocks



- **AX_LE**: Checks for “less than or equal to” – the inverse function of AX_GE.
- **AX_EQ**: Checks for equality of values.
- **AX_GT**: Performs the “greater than” comparison – the base variant without the equality case, of which AX_GE is the extended version.



AX_GE completes the AX comparison family with the boundary case of equality.

Conclusion

AX_GE is a simple yet important comparison block for IEC 61131-3 control applications using the `BOOL` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AX_GT

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_GT** compares two values of type `BOOL` (Boolean value) and checks whether the first value (IN1) is greater than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. `FALSE` is considered the smaller and `TRUE` the greater value.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `BOOL`, Boolean value).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 > IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AX` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AX` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AX` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_GT` (type `iec61131::comparison::F_GT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AX`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“greater than”) for the `BOOL` data type.
- **Comparison logic**: `FALSE` is considered the smaller and `TRUE` the greater value.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

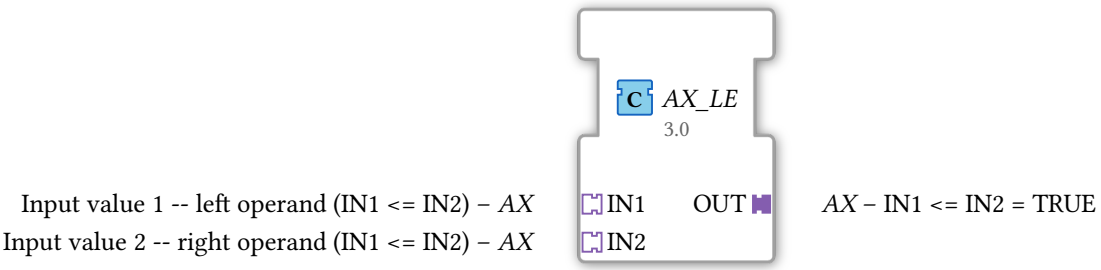
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

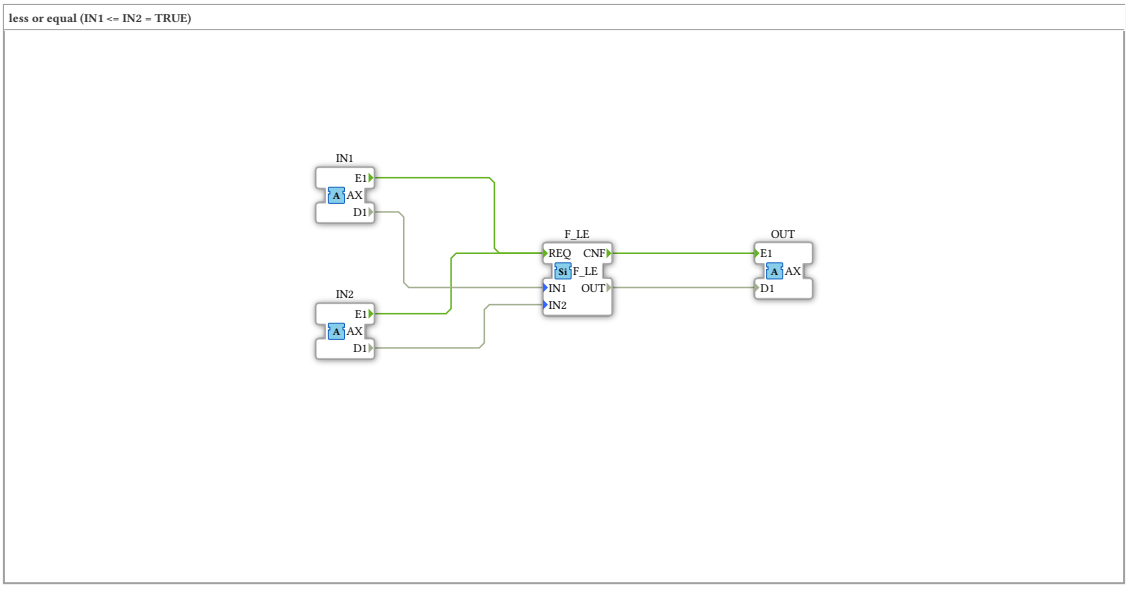
Application Scenarios

- **Limit Monitoring**: Checking enable and state bits against a reference or threshold value of type `BOOL`.
- **Control Logic**: Triggering an action once two values of type `BOOL` satisfy the “greater than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `BOOL`-based comparison condition.

Comparison with Similar Function Blocks



- **AX_LT**: Checks for “less than” – the inverse function of AX_GT.
- **AX_EQ**: Checks for equality of values.
- **AX_GE**: Performs the “greater than or equal to” comparison – the extended version of AX_GT that includes the equality case.



AX_GT is the basic “greater than” component without the equality case, complemented by AX_GE.

Conclusion

AX_GT is a simple yet important comparison block for IEC 61131-3 control applications using the `BOOL` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AX_LE

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_LE** compares two values of type `BOOL` (Boolean value) and checks whether the first value (IN1) is less than or equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. `FALSE` is considered the smaller and `TRUE` the greater value.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `BOOL`, Boolean value).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 <= IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AX` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AX` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AX` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LE` (type `iec61131::comparison::F_LE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AX`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than or equal to”) for the `BOOL` data type.
- **Comparison logic**: `FALSE` is considered the smaller and `TRUE` the greater value.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

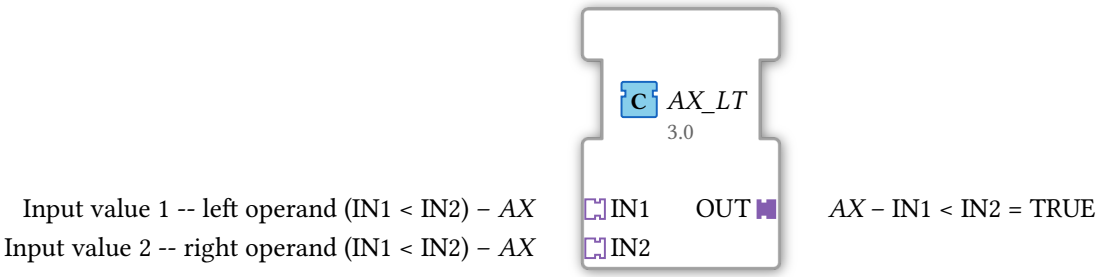
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

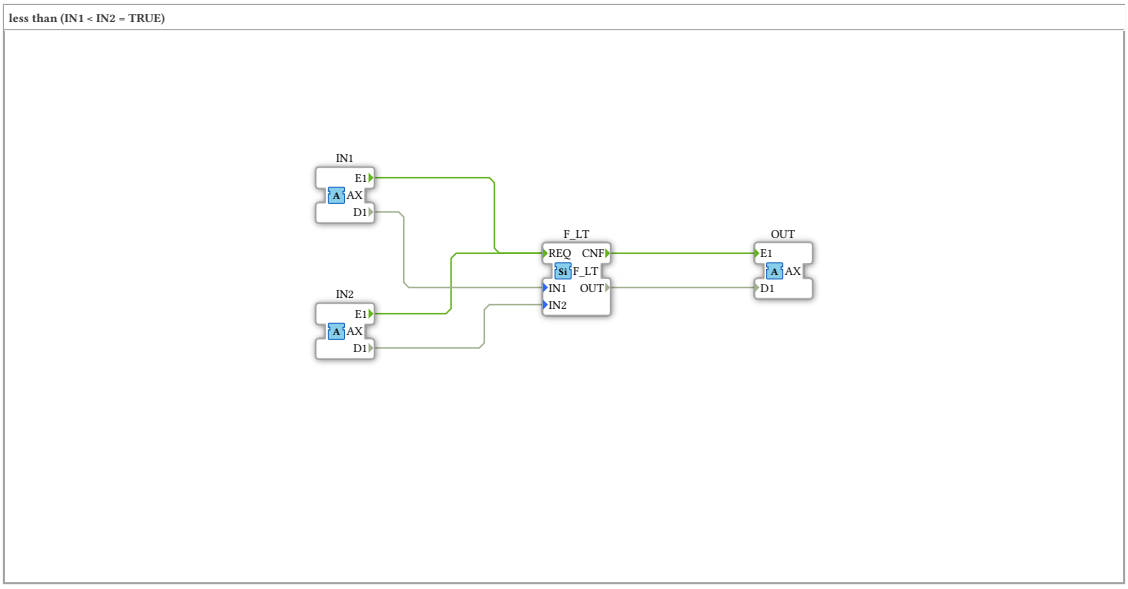
Application Scenarios

- **Limit Monitoring**: Checking enable and state bits against a reference or threshold value of type `BOOL`.
- **Control Logic**: Triggering an action once two values of type `BOOL` satisfy the “less than or equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `BOOL`-based comparison condition.

Comparison with Similar Function Blocks



- **AX_GE**: Checks for “greater than or equal to” – the inverse function of AX_LE.
- **AX_EQ**: Checks for equality of values.
- **AX_LT**: Performs the “less than” comparison – the base variant without the equality case, of which AX_LE is the extended version.



AX_LE completes the AX comparison family with the boundary case of equality.

Conclusion

AX_LE is a simple yet important comparison block for IEC 61131-3 control applications using the `BOOL` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AX_LT

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_LT** compares two values of type `BOOL` (Boolean value) and checks whether the first value (IN1) is less than the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. `FALSE` is considered the smaller and `TRUE` the greater value.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `BOOL`, Boolean value).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 < IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AX` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AX` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AX` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_LT` (type `iec61131::comparison::F_LT`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AX`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“less than”) for the `BOOL` data type.
- **Comparison logic**: `FALSE` is considered the smaller and `TRUE` the greater value.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

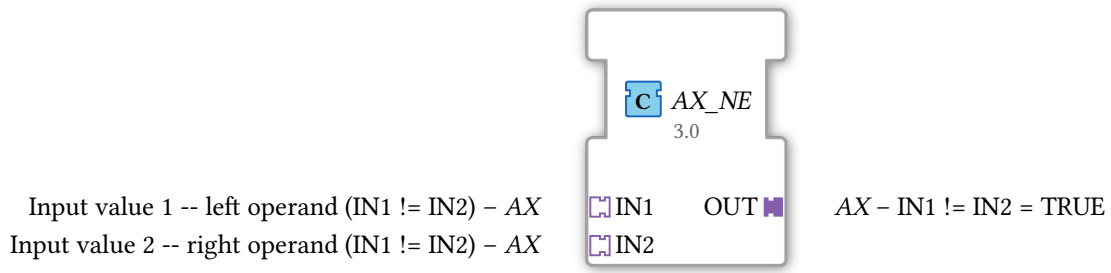
State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

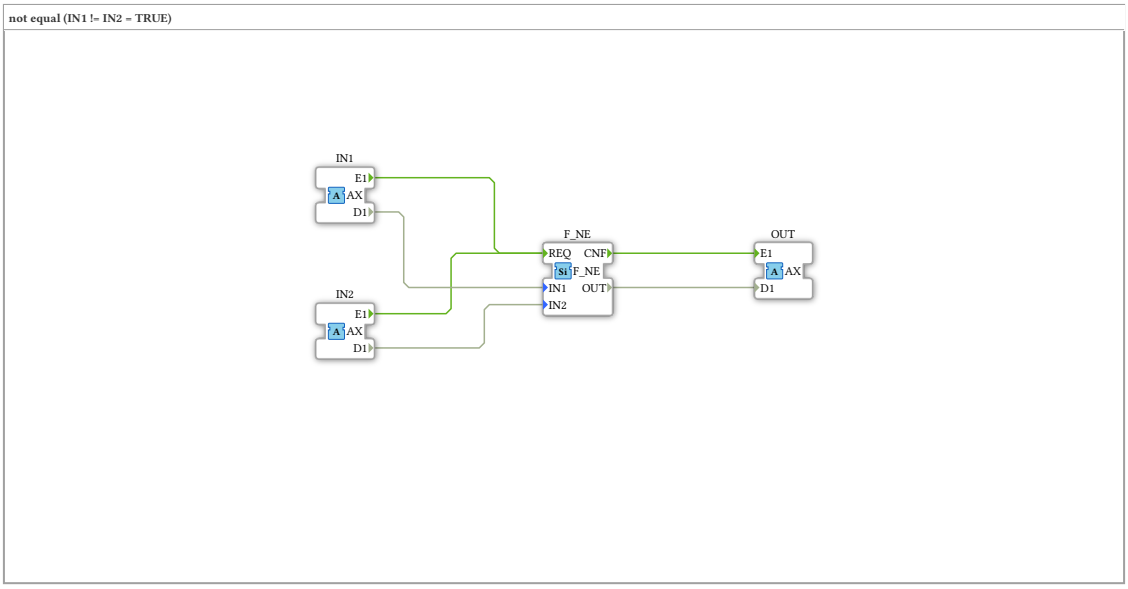
Application Scenarios

- **Limit Monitoring**: Checking enable and state bits against a reference or threshold value of type `BOOL`.
- **Control Logic**: Triggering an action once two values of type `BOOL` satisfy the “less than” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `BOOL`-based comparison condition.

Comparison with Similar Function Blocks



- **AX_GT**: Checks for “greater than” – the inverse function of AX_LT.
- **AX_EQ**: Checks for equality of values.
- **AX_LE**: Performs the “less than or equal to” comparison – the extended version of AX_LT that includes the equality case.



AX_LT is the basic “less than” component without the equality case, complemented by AX_LE.

Conclusion

AX_LT is a simple yet important comparison block for IEC 61131-3 control applications using the `BOOL` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

AX_NE

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_NE** compares two values of type `BOOL` (Boolean value) and checks whether the first value (IN1) is not equal to the second value (IN2). The result is provided as a Boolean value via the output adapter. The function block is event-driven and operates asynchronously. `FALSE` is considered the smaller and `TRUE` the greater value.

Interface Structure

The function block has no direct event or data inputs and outputs, but communicates exclusively via adapters.

Event Inputs

- **IN1.E1**: Event input of socket adapter IN1 – triggers the comparison.
- **IN2.E1**: Event input of socket adapter IN2 – also triggers the comparison.

Event Outputs

- **OUT.E1**: Event output of the plug adapter OUT – indicates that the comparison result is available at the data output.

Data Inputs

- **IN1.D1**: First value to be compared (data type `BOOL`, Boolean value).
- **IN2.D1**: Second value to be compared (data type same as IN1).

Data Outputs

- **OUT.D1**: Boolean result of the comparison – `TRUE` if `IN1 != IN2`, otherwise `FALSE`.

Adapters

Adapter	Type	Direction	Description
IN1	`AX` (Socket)	Input	Adapter for the first comparison value and its associated event
IN2	`AX` (Socket)	Input	Adapter for the second comparison value and its associated event
OUT	`AX` (Plug)	Output	Adapter for the comparison result and the output event

The adapters `AX` and `AX` are unidirectional interfaces, each providing one event channel and one data channel.

Functionality

1. The function block waits for an event at one of the socket adapters **IN1.E1** or **IN2.E1**.
2. As soon as such an event arrives, it is forwarded to the internal function block `F_NE` (type `iec61131::comparison::F_NE`). There, the current values of `IN1.D1` and `IN2.D1` are compared.
3. The internal function block generates an output event (`CNF`) and outputs the Boolean result (`OUT`).
4. This event is propagated to the plug adapter **OUT.E1**, and the data value `OUT.D1` is set to `TRUE` or `FALSE`.
5. Output occurs only when the input values change or when another event occurs.

Technical Features

- **Adapter-based interface**: The function block uses only adapters (`AX`/`AX`), allowing for flexible integration into various communication contexts.
- **Asynchronous processing**: The comparison operation is triggered by an event at one of the input adapters; the output signal is delivered in response to the event.
- **Standard compliance**: The function block implements the comparison function from IEC 61131-3 (“not equal to”) for the `BOOL` data type.
- **Comparison logic**: `FALSE` is considered the smaller and `TRUE` the greater value.
- **No state machines**: The function block is purely combinational – the result is generated immediately after the event; there is no internal state.

State Overview

This function block does not have an explicit state machine (ECC). Its internal logic consists of a direct connection between the adapters and a standardized comparison function block. Output occurs immediately upon event input.

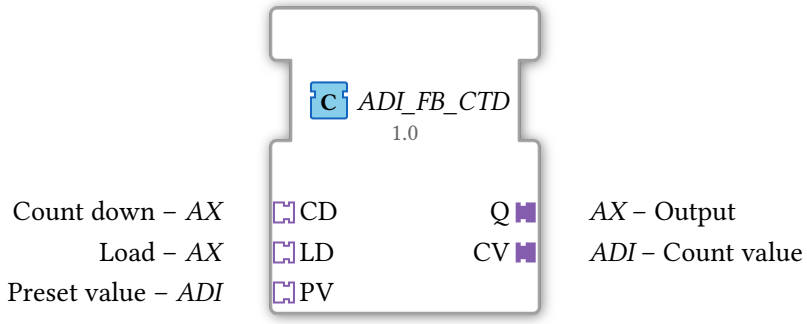
Application Scenarios

- **Limit Monitoring**: Checking enable and state bits against a reference or threshold value of type `BOOL`.
- **Control Logic**: Triggering an action once two values of type `BOOL` satisfy the “not equal to” condition.
- **Data Filtering**: Selecting data records or signals that satisfy a `BOOL`-based comparison condition.

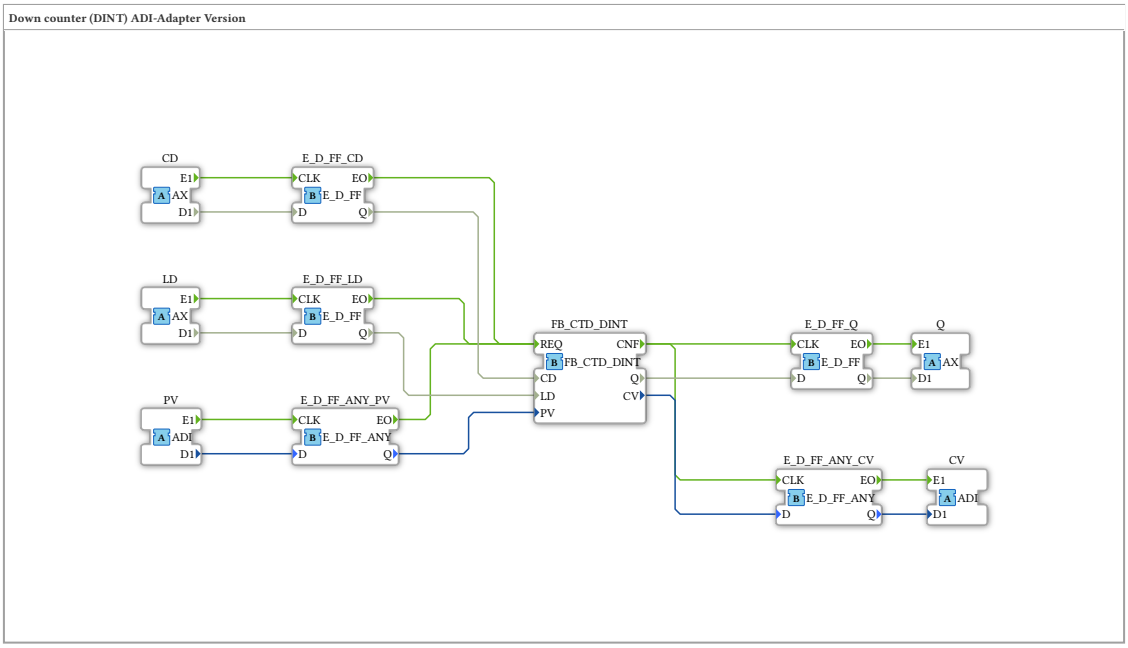
Comparison with Similar Function Blocks

- **AX_EQ**: Checks for “equal to” – the inverse function of AX_NE.
- **AX_EQ**: Checks for equality of values.

AX_NE is part of the complete AX comparison family (EQ/NE/GT/GE/LT/LE) for the `BOOL` data type.



Conclusion



AX_NE is a simple yet important comparison block for IEC 61131-3 control applications using the `BOOL` data type. Its adapter-oriented interface makes it versatile and allows for a clear separation of event and data paths. Due to its event-driven operation, it is particularly suitable for real-time systems where conditions must react immediately to changes in values.

ADI_FB_CTD

• – ○ • – ○ • – ○ •

Introduction

The **ADI_FB_CTD** is a down counter for values of type `DINT` that communicates exclusively via ADI adapters. It encapsulates an internal standard counter and enables counting down, loading a default value, and outputting the current counter value – all via standardized adapter interfaces.

Interface Structure

Event Inputs

The FB does not have direct event inputs. Events are provided via the adapter sockets **CD**, **LD**, and **PV**.

Event Outputs

Name	Type	Description
CNF	Event	Acknowledgement signal output after each processing of an incoming event.

Data Inputs

No direct data inputs; data is provided via the adapter sockets.

Data Outputs

No direct data outputs; data is provided via the adapter plugs.

Adapter

Name	Type	Direction	Description
CD	`adapter::types::unidirectional::AX`	Socket (Input)	Countdown event; the data value (D1) is passed to the internal counter as a CD pulse.
LD	`adapter::types::unidirectional::AX`	Socket (Input)	Load the counter with the current value of **PV** The data value (D1) signals the charging process.
PV	`adapter::types::unidirectional::ADI`	Socket (Input)	Preset value as `DINT`; the event (E1) triggers an update of the internal PV register.

Q	adapter::types::unidirectional::AX	Plug (Output)	Output signal indicating whether the meter reading has reached zero (e.g., TRUE for zero).
CV	adapter::types::unidirectional::ADI	Plug (Output)	Current meter reading as DINT; output with each update.

Functionality

The ADI_FB_CTD uses an internal IEC 61131 counter (FB_CTD_DINT). All communication takes place via ADI adapters that combine an event (E1) and a data value (D1):

- An event at the **CD** socket causes the internal counter to decrement its current value by **1**.
- An event at the **LD** socket loads the counter to the value last provided via **PV**.
- An event at the **PV** socket updates the default value in the internal register; the counter itself is not changed. Only a subsequent LD event takes over the new value.

All incoming events (CD, LD, and PV) are routed to the common REQ input of the internal counter. The internal function block distinguishes between counting and loading based on the data values. Upon completion of the action, the event CNF is triggered, simultaneously operating the output adapters **Q** and **CV** and setting the event output CNF.

Technical Features

- **Always Active Output:** The function block outputs an event on the **Q** adapter with **every** update (via CD, LD, or PV) – even if the corresponding data value does not change. If a triggering output is only desired upon an actual state change, a filter block such as AX_D_FF must be placed upstream.
- **Adapter-Based Interface:** All inputs and outputs are implemented as ADI adapters. This enables loose coupling and easy reusability in modular control architectures.
- **Internal Standard Counter:** The counting logic is based on an established IEC 61131 component and is therefore robust and reliable.

State Overview

The FB does not have its own state machine. Its behavior is determined by the internal FB_CTD_DINT, which can operate in the following modes:

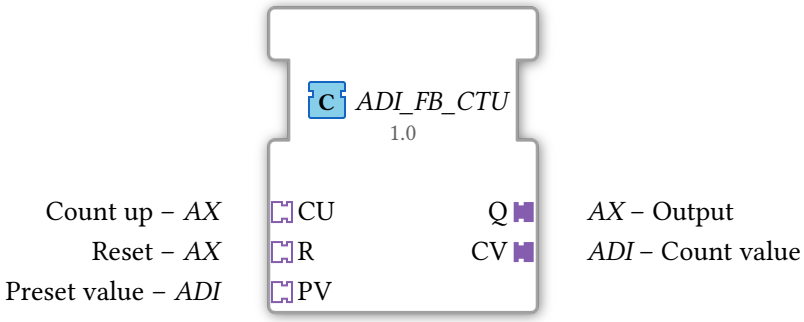
- **Loading:** When an event occurs at the **LD** adapter, the counter is set to the current PV value.
- **Counting:** When an event occurs at the **CD** adapter, the counter is decremented.
- **Waiting:** No event is present; the counter retains its current value.

After each processing step, the FB is immediately ready for the next event (no blocking).

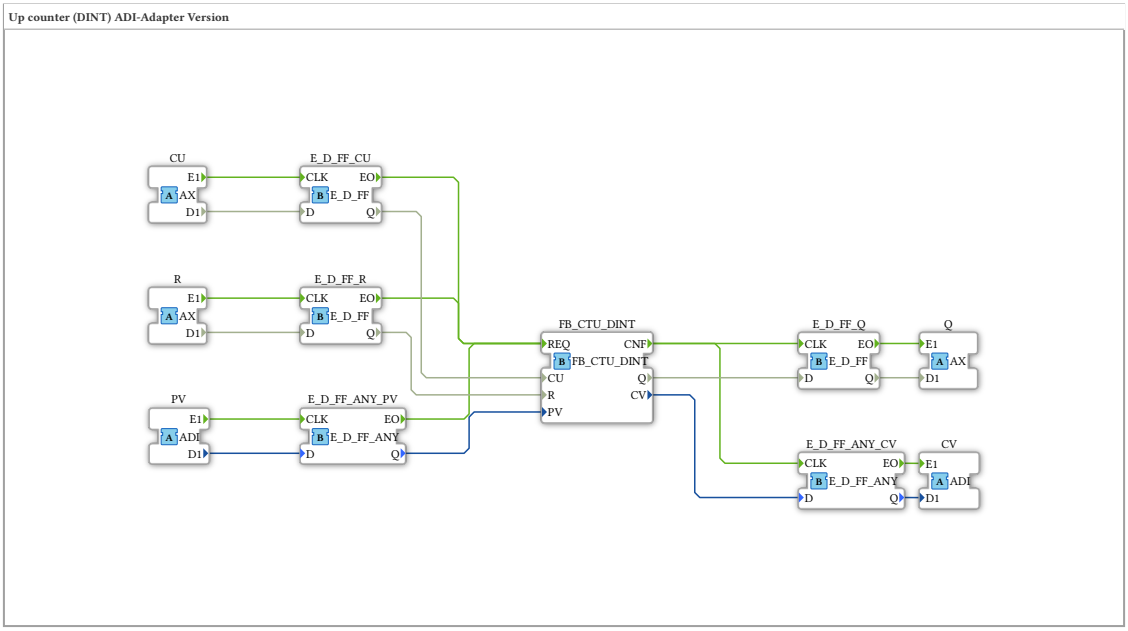
Application Scenarios

- **Workpiece Counting:** A sensor reports each passing workpiece as an event on **CD**. The counter decrements from a predefined starting value (**PV**) to zero. When the counter reaches zero, a signal (e.g., "Container full") can be output via **Q**.
- **Time Delay:** In combination with a clock, the counter functions as a down timer, the remaining time of which is read via **CV**.
- **Control of Processes:** The current counter value (**CV**) serves as a parameter for subsequent steps (e.g., positioning, quantity control).

Comparison with Similar Function Blocks



- **CTU (Up Counter)** – counts only upwards; ADI_FB_CTD only downwards.
- **CTUD (Up/Down Counter)** – can count in both directions; ADI_FB_CTD is specialized for one direction.
- **Standard IEC 61499 Counters** – use separate event and data ports, while ADI_FB_CTD unifies the interfaces via adapters.
- **ADI_FB_CTU** – structurally identical, but with upcount logic (also available as an adapter version).



The advantage of the adapter version lies in its more modular, reusable interface; the disadvantage is the higher level of abstraction and the need for filtering when required.

Conclusion

The ADI_FB_CTD is a reliable downcounter for `DINT` values, which, thanks to its consistently adapter-based interface, integrates ideally into loosely coupled control architectures. The fact that the **Q** output triggers with every update must be considered during system design. Thanks to the internal standard counter, the counting logic is robust and proven – a reliable component for downcounting scenarios.

ADI_FB_CTU

• – ◦ • – ◦ • – ◦ •

Introduction

The ADI_FB_CTU is an up-counter for DINT integers, whose inputs and outputs are provided via standardized adapters (AX and ADI). It encapsulates the standard function block `FB_CTU_DINT` and enables its integration into modular, adapter-based systems. This function block is suitable for general counting tasks in automation technology.

Interface Structure

The function block does not have direct event or data interfaces, but only adapters for connection. The following table explains the available adapters, their type, and their function.

Direction	Name	Adapter Type	Description
Input (Socket)	`CU`	`AX`	Count pulse input (event + data)
Input (Socket)	`R`	`AX`	Reset input (event + data)
Input (Socket)	`PV`	`ADI`	Preset value for comparison

Output (Plug)	Q	AX	Output signal – active when meter reading ≥ PV
Output (Plug)	CV	ADI	Current meter reading

The adapters AX (event adapter) and ADI (data adapter) are unidirectional. Both events and their associated data values are transmitted via these adapters.

Event Inputs

No direct event inputs. Events are supplied via the adapters CU and R (of type AX).

Event Outputs

A direct event output, CNF, signals confirmation of processing. Additionally, an output event is sent via the adapter Q (type AX) with each update.

Data Inputs

No direct data inputs. The default value is provided via the adapter PV (type ADI).

Data Outputs

No direct data outputs. The current counter reading is output via the adapter CV (type ADI).

Adapters

The function block uses three sockets (input adapters) and two plugs (output adapters):

- **CU (socket, AX)**: Count pulse – the internal counter is incremented with each event.
- **R (socket, AX)**: Reset – resets the counter to zero.
- **PV (Socket, ADI)**: Preset Value – sets the threshold at which output Q becomes active.
- **Q (Plug, AX)**: Output – becomes active as soon as the counter value reaches or exceeds the value of PV.
- **CV (Plug, ADI)**: Current counter value – can be read by downstream function blocks.

Functionality

The ADI_FB_CTU implements a simple increment counter with preset value comparison.

- Each event at input CU increments the internal counter by 1.

An event at input R resets the counter to 0.

The default value PV is updated when an event arrives at input PV.

After each processing operation (regardless of whether it was triggered by CU, R, or PV), the acknowledgment event CNF is output. Simultaneously, output adapter Q is also updated with an event, and the current counter value is provided via adapter CV.

Internally, a standard function block FB_CTU_DINT is used, with its inputs and outputs wired via the adapters. The counter value is of type DINT (32-bit integer).

Technical Features

- **Adapter-based interface** – enables loose coupling and easy integration into adapter-based architectures (e.g., according to IEC 61499).
- **Unidirectional Adapters** – the adapters AX and ADI each transmit in only one direction.
- **Acknowledgement Event CNF** – any event at an input triggers an immediate acknowledgement.
- **No Edge Detection** – the function block reacts to any event, not to the rising or falling edges of a digital signal.
- **Note in Source Code** – the frequent output of the Q.E1 event can lead to unnecessary load in time-critical applications; filtering may be necessary.

State Overview

The function block has only one internal state: the current counter value (initial value = 0). Depending on the incoming events, the following state transitions occur:

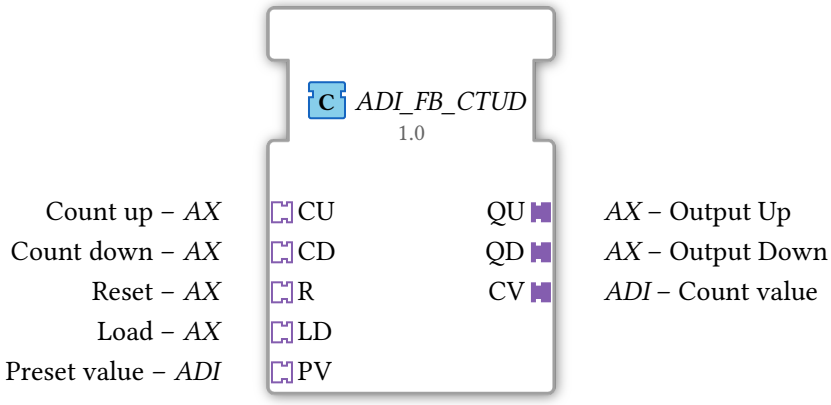
| Event | Condition | New State (Counter) | Output |
** ... |-----|----|---------|---|
CU	–	Counter + 1	CNF, Q.E1, CV
R	–	0	CNF, Q.E1, CV
PV	–	unchanged	CNF, Q.E1, CV (PV value is stored internally)

Output `Q` (via the adapter) is set as soon as `Zähler ≥ PV` is reached. The current value of `Q` is included with every output.

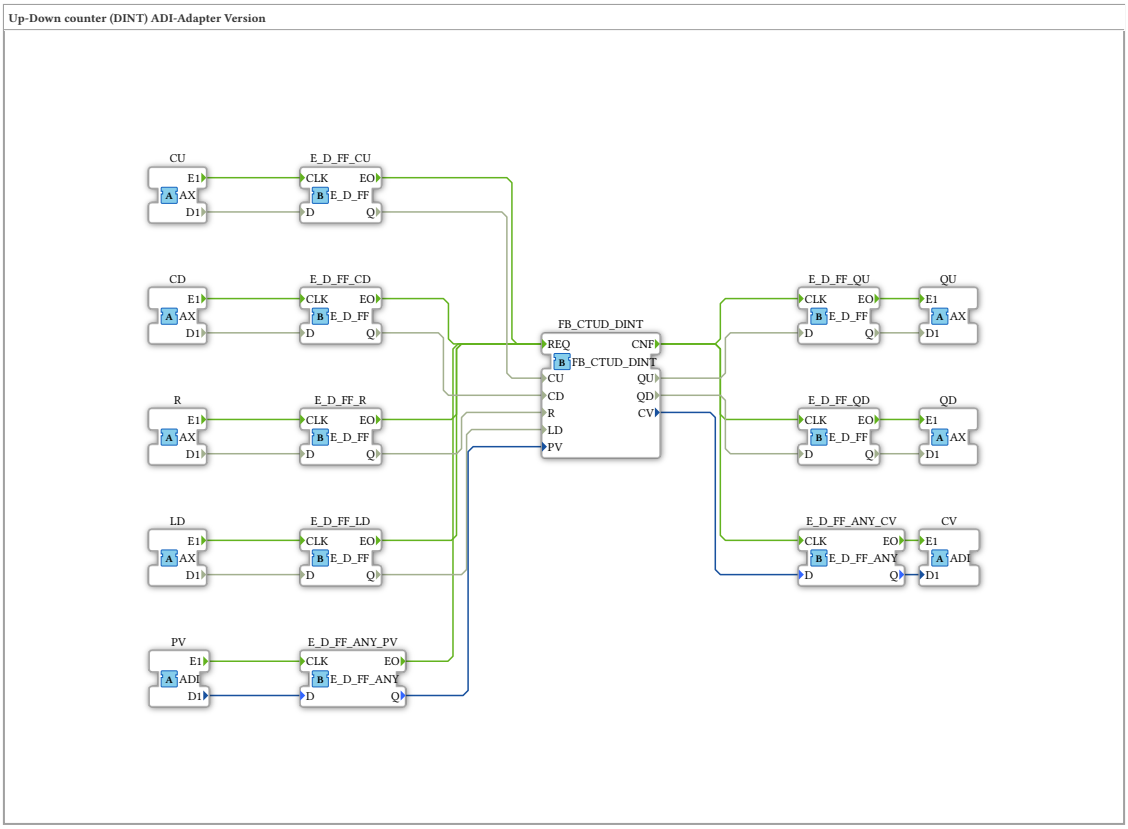
Application Scenarios

- **Event Counting** – Counting pulses, e.g., part passage, machine cycles.
- **Fill Level Monitoring** – Recording the number of containers or batches.
- **Production Control** – Triggering an action when a specific quantity is reached.
- **Time Measurement** – In combination with a pulse generator, the number of pulses can be used as a measure of time.
- **Adapter-based automation systems** – wherever a standardized adapter interface is required.

Comparison with similar components



Component	Properties
`CTU` (Standard, without adapter)	Same counting function, but with direct event and data inputs/outputs. Easier to use in classic IEC 61499 networks.
`ADI_FB_CTUD`	Up/down counter, also adapter-based. Additionally offers a down count input.
`FB_CTU_DINT`(Internal)	Same counting logic, but without adapter encapsulation. The adapter version offers a uniform, modular interface.
`CTU` with AX filter	If edge detection is required, pure change detection can be achieved by preceding it with an AX_D_FF.



The ADI_FB_CTU is designed as a wrapper for the standard counter and facilitates reuse in adapter-based frameworks.

Conclusion

The ADI_FB_CTU is a flexible, adapter-based increment counter for DINT values. It encapsulates the proven counting logic of `FB_CTU_DINT` and makes it available via standardized adapters (AX and ADI). The fact that output events are generated with each update should be considered during system design. The function block is ideally suited for modular, expandable automation solutions that require a uniform adapter interface.

ADI_FB_CTUD

• – ○ • – ○ • – ○ •

Introduction

The **ADI_FB_CTUD** is an up/down counting function block for integer values (DINT). It implements a forward/backward counter that is controlled via standardized **adapter interfaces**. The block encapsulates the IEC 61131-3 component `FB_CTUD_DINT` and provides its functionality via event-driven adapters.

Interface Structure

Event Inputs

The block does not have direct event inputs. Control is exclusively via the **sockets**:

- **CU (Count Up)** – Event to increment the counter value
- **CD (Count Down)** – Event to decrement the counter value
- **R (Reset)** – Event to reset the counter value to zero
- **LD (Load)** – Event to load the preset value
- **PV (Preset Value)** – Event to set the preset value (data value)

These adapters provide both an event and a data value (for AX adapters, via the data output `D1`).

Event Outputs

- **CNF** – Acknowledge event, which is output after each processing of one of the input events.

Data Inputs

The data values of the input adapters are processed via the connections of the internal function block `FB_CTUD_DINT`. The adapters provide the following data:

- **CU.D1** – Counting direction (Bool, 1 = Count up)
- **CD.D1** – Counting direction (Bool, 1 = Count down)

(Note: In standard CTUD-DINT, only one counting event with direction selection is typically used; here, CU/CD are treated as separate events.)

- **R.D1** – Reset signal (Bool)

- **LD.D1** – Load signal (Bool)
- **PV.D1** – Preset value (DINT)

Data Outputs

The output data is provided via the plug adapters:

- **QU.D1** – Counter has incremented (Bool, after CU event)
- **QD.D1** – Counter has decremented (Bool, after CD event)
- **CV.D1** – Current count value (DINT)

Adapters

The function block uses three different adapter types:

- **unidirectional::AX** – for event and Boolean data (CU, CD, R, LD as sockets; QU, QD as plugs)
- **unidirectional::ADI** – for value transfer (PV as a socket, CV as a plug)

The adapters are designed to transfer both the event and the associated data value in one operation.

Functionality

The internal function block `FB_CTUD_DINT` implements the classic up/down counter logic:

- When an event occurs on **CU**, the counter value is incremented by 1, provided `CU.D1` = TRUE (or the event alone is considered an up pulse).
- When an event occurs on **CD**, the counter value is decremented by 1, provided `CD.D1` = TRUE.
- An event on **R** resets the counter value to 0.
- An event on **LD** loads the current counter value with the value passed via **PV**.
- After each processing step, **CNF** is output, as well as the events **QU.E1** and **QD.E1** via the corresponding adapters if the counter value has changed.

Important: The function block fires the output events (QU.E1, QD.E1) on *every* update (CU, CD, R, LD, PV) – not just on an actual value change. If only edge detection (on-change) is required, the use of an **AX_D_FF** as a filter is recommended.

Technical Features

- **Adapter-based interface:** All inputs and outputs are via standardized unidirectional adapters, which increases reusability and encapsulation.
- **IEC 61131-3 Compatibility:** The internal counter complies with the standard and allows for easy migration between different control systems.
- **Always Active Events:** As described above, output events are generated with every input event – this can lead to high bus load in time-critical applications.
- **No Top-Level State Machine:** The function block (FB) does not have its own ECC; all logic is executed by the internal FB.

State Overview

The function block does not have an explicit state machine. Processing is strictly event-driven:

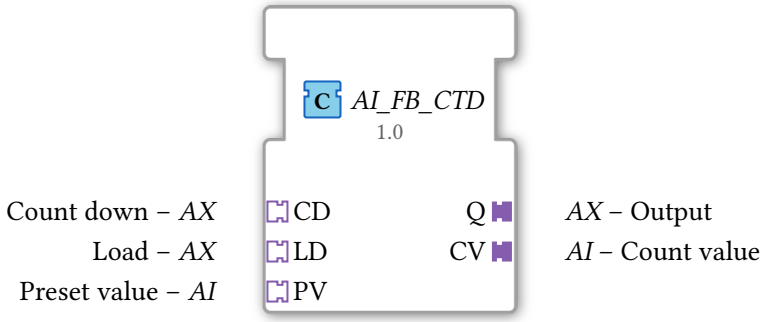
1. Wait for an event at one of the sockets.
2. Process the associated data value (if available) and the internal counter state.
3. Output **CNF** and, if applicable, **QU.E1** and **QD.E1**.
4. Return to step 1.

Application Scenarios

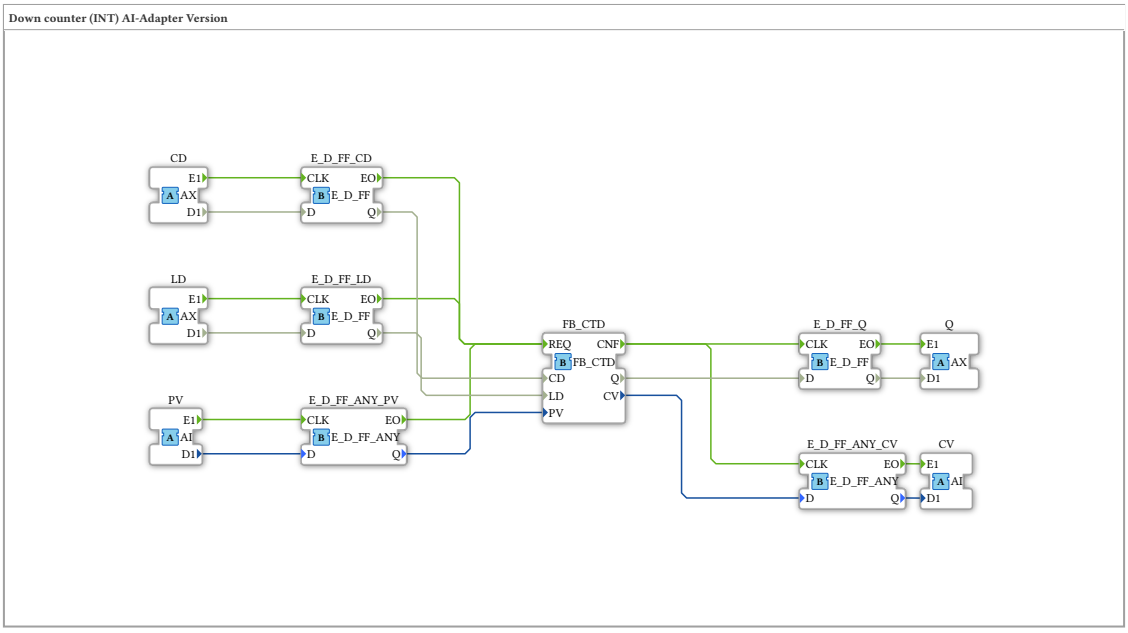
- **Counting pulses** in manufacturing systems (e.g., workpiece counters).
- **Position detection** with incremental encoders (counting up/down).
- **Bill of materials and inventory counting** with reset capability.
- **Event-driven controllers** in automation technology, where counter readings are exchanged via adapters.

Comparison with similar function blocks

Property	ADI_FB_CTUD	Standard CTUD (IEC 61131-3)
Interface	Adapter-based (AX/ADI)	Direct inputs/outputs (events, data)



Event behavior	Output on every update	Mostly edge- or value-dependent
Reusability	Easy due to adapter encapsulation	Dependent on the specific controller
Compatibility	IEC 61131-3 compliant (internal)	Direct standard implementation
Filtering	Recommendation: AX_D_FF	Partially integrated



The ADI_FB_CTUD offers clean, adapter-based encapsulation, but requires additional measures for on-change triggering if needed.

Conclusion

The **ADI_FB_CTUD** is a flexible and standards-compliant up/down counter with a DINT value range, distinguished by its modern adapter interface. It is particularly suitable for modular control architectures where components communicate via standardized adapters. The always-active event output should be considered when integrating it into real-time systems.

AI_FB_CTD

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_FB_CTD** is a down counter for integer values, standardized according to IEC 61499-2. It consistently uses adapter interfaces (AX, AI) to transport events and data. The block is implemented as a wrapper around the classic IEC 61131 function block `FB_CTD` and enables a modular, adapter-based connection in 4diac IDE networks. Every incoming event via the counter controllers (CD, LD, PV) updates the internal counter and triggers an output event.

Interface Structure

Event Inputs

The function block does not have direct, separate event inputs. The necessary events are provided via the **Socket Adapters** (CD, LD, PV) – each of these modules carries an event (E1) that triggers the counter logic.

Socket	Event (in the adapter)	Description
CD	E1	Counting event (down counter)
LD	E1	Load event (set to PV)
PV	E1	Default update

Event Outputs

Name	Type	Description
CNF	Event	Acknowledge event after each counter update (CD, LD, PV)

Additionally, the output events are also transmitted via the **Plug Adapters** Q and CV (E1 each).

Data Inputs

There are no direct data inputs. All data values are transmitted via the socket adapters:

- **CD** provides the down count pulse (D1) – a logical value that decrements the counter.
- **LD** provides the charge signal (D1) – a logical value that sets the counter to the current PV value.
- **PV** provides the setpoint value (D1) – an integer that is loaded as the new meter reading.

Data Outputs

There are no direct data outputs. The output data is provided via the plug adapters:

- **Q** provides the meter status (D1) – BOOL, TRUE if the meter reading is ≤ 0.
- **CV** provides the current meter reading (D1) – INT.

Adapters

Label	Direction	Type	Description
CD	Socket	`adapter::types::unidirectional::AX`	Counter input (event + data) for counting down
LD	Socket	`adapter::types::unidirectional::AX`	Load input (event + data) for setting to PV
PV	Socket	`adapter::types::unidirectional::AI`	Default input (event + data) for the preset value
Q	Plug	`adapter::types::unidirectional::AX`	Output signal (event + data) – counter ≤ 0
CV	Plug	`adapter::types::unidirectional::AI`	Output counter value (event + current counter reading)

Functionality

The function block internally contains a function block `iec61131::counters::FB_CTD`, which implements the actual counting logic. The function is as follows:

1. An event at **CD** (via `CD.E1`), **LD** (`LD.E1`), or **PV** (`PV.E1`) triggers the internal function block via its event input `REQ`.
2. The internal function block evaluates the associated data:

- On a **CD** event, the counter is decremented by 1 (if the associated date is TRUE).
- On a **LD** event, the counter is set to the current value of **PV** (if the load date is TRUE).
- In the event of a **PV** event, the default value is updated internally (the counter remains unchanged).

1. After processing, the internal FB generates its `CNF` event. This is distributed to the external outputs:

- `CNF` (direct event output)
- `Q.E1` (event of plug adapter Q)
- `CV.E1` (event of plug adapter CV)

1. Simultaneously, the following data is transferred:

- `FB_CTD.Q` (BOOL) ⟶ `Q.D1`
- `FB_CTD.CV` (INT) ⟶ `CV.D1`

` Note: The output event is triggered **with every update** (i.e., on CD, LD, or PV). A simple value change without an event (On-Change) is not implemented.

Technical Features

- **License and Origin**: This function block is licensed under the **Eclipse Public License 2.0** (EPL 2.0). It was developed as teaching material for the master craftsman schools at Ostbahnhof.
- **Adapter-Based Communication**: Unlike classic FB interfaces, all inputs and outputs are implemented via adapters (AX, AI). This enables flexible, hierarchical wiring and reuse in complex control architectures.
- **On-Change Filter**: The function block fires the output event on **every** input event, regardless of an actual value change. If change detection is required, the use of an **AX_D_FF** (Differentiator Flip-Flop) as a pre-filter is recommended (see also the copyright notice in the XML).
- **Internal FB**: The counting logic is based on the standard module `FB_CTD`From IEC 61131 (adapted for 4diac). This ensures deterministic behavior and compatibility with PLC programs.

State Overview

The function block does not have an explicit state machine. The only internal variable is the **current counter value** (integer). This value is modified by the following events:

- Initial value: 0 (or set to PV via LD)
- CD event: Counter = Counter - 1 (if the associated date is TRUE, otherwise no change)
- LD event: Counter = PV (if the loading date is TRUE)
- PV event: PV value is stored internally; the counter remains unchanged.

Therefore, a graphical state machine is not required.

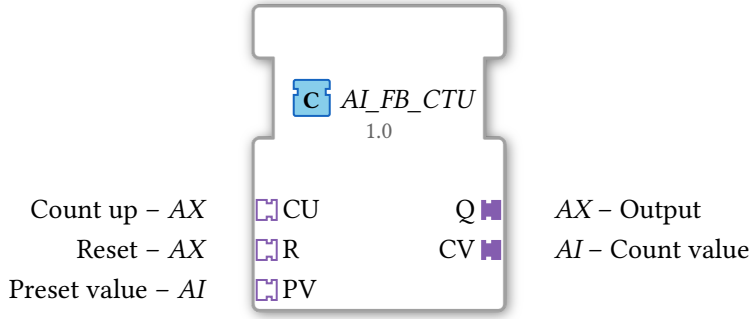
Application Scenarios

- **Inventory Counter**: Decrementing an inventory level upon removal (CD), resetting via LD after replenishment.
- **Event Counter with Threshold**: Counts events until 0 is reached, then triggers a signal (Q).
- **Time/Pulse Control**: Used as a pulse counter in conjunction with a clock (CD) and specifying the desired number of events (PV).
- **Adapter Integration**: In modular control systems where events and data are to be encapsulated via standardized adapter interfaces.

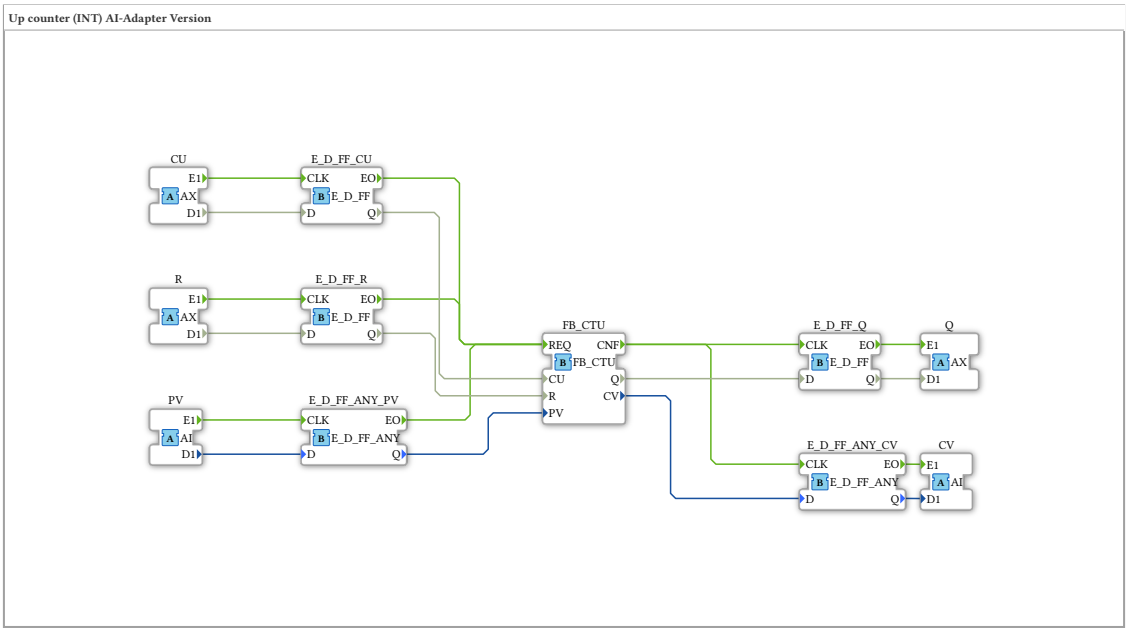
Comparison with Similar Components

Component	Counting Direction	Interfaces	Special Feature
AI_FB_CTD	Downward	Adapters only (AX, AI)	Output on every update
AI_FB_CTU	Upward	Adapters only (AX, AI)	Upward counter, analog structure
FB_CTD (Standard)	Downward	Direct Events/Data	Classic Variable Connection, without Adapter
FB_CTUD	Both	Direct	Combined Increment/Decrement Counter, Extended Logic

The **AI_FB_CTD** stands out due to its consistent use of adapters, making it ideal for hierarchical and reusable control models. Unlike the standard FB_CTD, separate data and event inputs are eliminated – everything is handled via the adapters.



Conclusion



The `AI_FB_CTD` is a flexible, adapter-based down counter for integer values that translates the proven counting logic from IEC 61131 into a modern, modular interface landscape. It is ideally suited for use in distributed control systems according to IEC 61499, where encapsulation and reusability are paramount. Its ease of use (three input events, two output adapters) and clear documentation make it a solid foundation for counter applications. For change detection, it is recommended to use a `AX_D_FF` upstream.

AI_FB_CTU

• – ○ • – ○ • – ○ •

Introduction

The **AI_FB_CTU** is an up counter for integers (INT) that encapsulates the IEC 61131-3 functionality of a CTU (Counter Up) in an adapter-based form factor. It is specifically designed for use in the 4diac IDE and allows for modular connection via unidirectional adapter interfaces. The block fires an acknowledgment event with each update of its inputs (CU, R, PV), making it suitable for time-controlled or event-driven counting tasks.

Interface Structure

Event Inputs

The block does not have direct event inputs. Event control is handled exclusively via the adapter sockets **CU**, **R**, and **PV**. Each of these sockets provides an event (E1) that triggers the internal process.

- **CU.E1** – Counting pulse (event from the counting-up adapter)
- **R.E1** – Reset (event from the reset adapter)
- **PV.E1** – Set preset value (event from the preset-value adapter)

Event Outputs

- **CNF** (Type: Event) – Confirmation event triggered after each successful processing of all three possible events.

The output adapters **Q** and **CV** are also served with the same event:

- **Q.E1** – Event for the output adapter (counter reading reaches or exceeds the preset value)
- **CV.E1** – Event for the current count value

Data Inputs

All data inputs are provided via the adapter sockets:

Adapter	Data Input	Type	Description
CU.D1	CU	INT	Count Up – Count pulse (increments with each event)
R.D1	R	INT	Reset – Value to which the counter is reset (typically 0)
PV.D1	PV	INT	Preset Value – Threshold at which output Q becomes active

Data Outputs

- **Q.D1** (via adapter Q, type AX) – Output signal (BOOL), becomes TRUE when the counter value is ≥ PV.
- **CV.D1** (via adapter CV, type AI) – Current counter value (INT).

Adapters

Name	Type	Direction	Description
CU	adapter::types::unidirectional::AX	Socket (Input)	Event and data adapter for the counter pulse
R	adapter::types::unidirectional::AX	Socket (Input)	Event and data adapter for the reset
PV	adapter::types::unidirectional::AI	Socket (Input)	Data adapter (value only, no event) for the preset value
Q	adapter::types::unidirectional::AX	Plug (Output)	Event and data adapter for the counter output
CV	adapter::types::unidirectional::AI	Plug (Output)	Data adapter (value only) for the current counter reading

Functionality

The **AI_FB_CTU** internally uses a standardized IEC 61131-3 CTU block (`iec61131::counters::FB_CTU`). Upon each incoming event (CU.E1, R.E1, or PV.E1), the internal CTU is processed by calling its REQ input. The data from the adapters (CU.D1, R.D1, PV.D1) is forwarded directly to the corresponding inputs of the internal CTU.

After processing, the result (current counter reading CV and output Q) is sent to the output adapters, and the acknowledgment event CNF is triggered simultaneously. Important: **The block performs a complete pass for each of the three events**, meaning that CU, R, and PV are always evaluated together. This behavior can lead to unexpected counting pulses if not all inputs are relevant at the same time. For change-only triggering, the use of an AX_D_FF (D flip-flop) as a filter is recommended.

Technical Features

- **Adapter-Based Interface**: All inputs and outputs are implemented as adapters, enabling flexible interconnection in composite function blocks or sub-applications.
- **IEC 61131-3 Encapsulation**: The module encapsulates the proven counter logic from IEC 61131-3 in a 4diac-compliant component.
- **Simultaneous Triggering**: Every event (CU, R, PV) triggers a complete recalculation – even if only one parameter has changed.
- **License**: Released under the Eclipse Public License 2.0.

State Overview

The internal state is determined by the IEC 61131-3 CTU:

- **CV** (Current Meter Reading) – Integer value that is incremented with each CU event (unless a reset occurs).
- **Q** (Output) – Boolean value that becomes TRUE as soon as CV >= PV.
- On a **Reset** (R), CV is set to the value of R.D1 (usually 0) and Q is reset.
- On a new **PV**, only the threshold is updated; Q can change immediately if CV >= new PV.

The function block has no sequential states beyond these data dependencies.

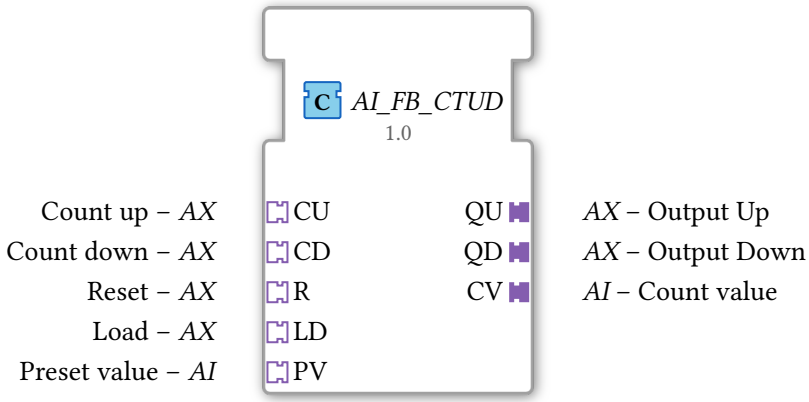
Application Scenarios

- **Production Counting**: Recording of workpieces on a conveyor belt (CU = pulse generator, PV = batch size, Q = batch end).
- **Event Counter**: Counting sensor signals in combination with time-based evaluation.
- **Batch Processes**: Control of dosing or filling processes with an adjustable setpoint (PV).
- **Modular Automation**: Integration into larger function blocks via standardized adapter interfaces (AX/AI).

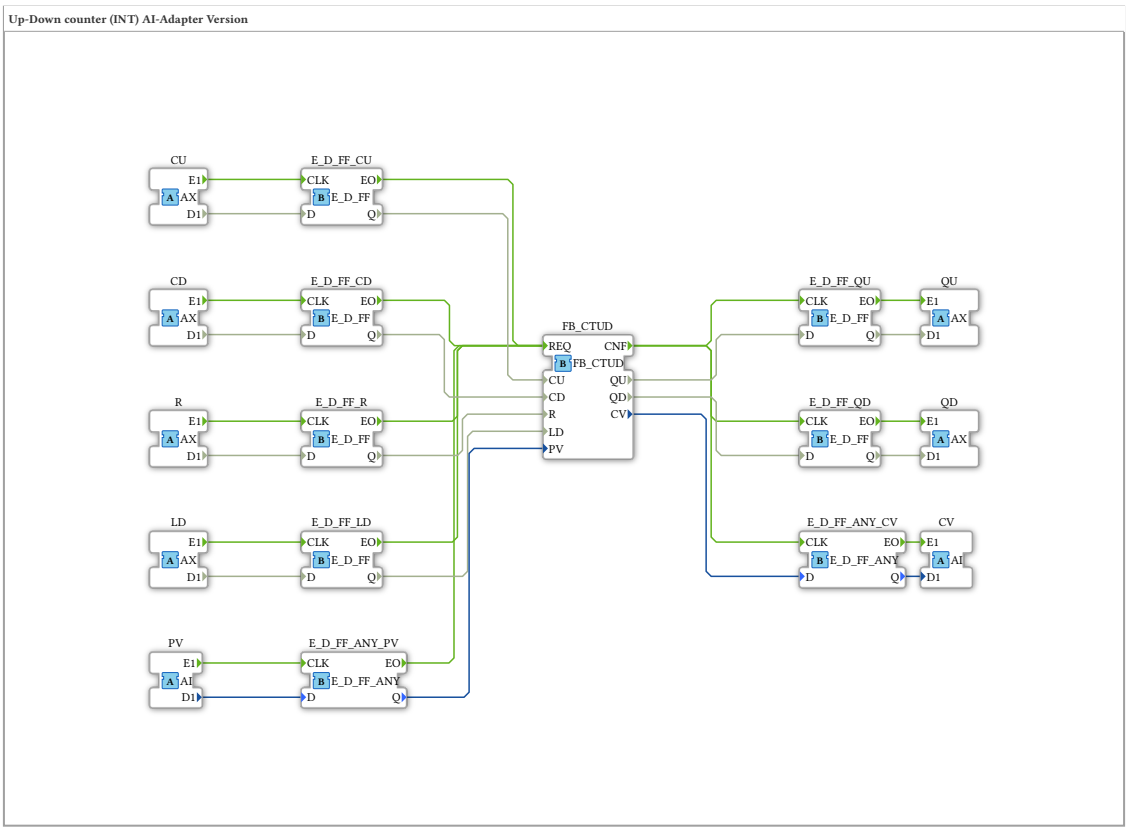
Comparison with Similar Function Blocks

Function Block	Properties
AI_FB_CTU	Adapter-based, uses IEC 61131-3 CTU, triggers on every input
Standard CTU (IEC 61131)	Inputs as events + data, no adapter concept, often directly bound to hardware
CTUD (Up/Down Counter)	Offers additional down counting, has a more complex interface
AX_CTU (hypothetical)	Could offer optimized event triggering (only on change)

The **AI_FB_CTU** impresses with its simple adapter connection, but may require an external filter to avoid unnecessary calls.



Conclusion



The **AI_FB_CTU** is a practical counter module for adapter-based automation with 4diac. It combines proven IEC 61131-3 logic with modern, modular interface technology. Its simple structure and clear functionality make it the first choice for all incrementing tasks where loose coupling via adapters is desired. Users should, however, be aware of the triggering on each event and implement differential filtering if necessary.

AI_FB_CTUD

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_FB_CTUD** implements an up/down counter of data type **INT** in an adapter-based variant. It encapsulates the IEC 61131-3 standard function block `FB_CTUD` and makes its functionality available to the 4diac IDE via the adapter interfaces (`AX` and `AI`). The function block is particularly suitable for use in industrial control systems that rely on event-driven communication.

Interface Structure

Event Inputs

The function block does not have separate event inputs in the traditional sense. Instead, events are received via the **Sockets** (adapters):

- **CU** (AX) – Count Up event
- **CD** (AX) – Count Down event
- **R** (AX) – Reset

- **LD** (AX) – Load preset value
- **PV** (AI) – Pass preset value

Each incoming event triggers an update of the internal counter.

Event Outputs

- **CNF** – Execution Confirmation, output with each update.
- **QU** (AX) – Up counter output
- **QD** (AX) – Down counter output
- **CV** (AI) – Current count value output

Data Inputs

All data is provided via the **sockets**:

- **CU.D** (BOOL) – Up counter pulse
- **CD.D** (BOOL) – Down counter pulse
- **R.D** (BOOL) – Reset signal
- **LD.D** (BOOL) – Enable preset value loading
- **PV.D** (INT) – Preset value

Data Outputs

- **QU.D** (BOOL) – Up counter flag (TRUE when counter reaches PV value)
- **QD.D** (BOOL) – Down counter flag (TRUE when counter reaches PV value) (has reached the value 0)
- **CV.D** (INT) – Current counter reading

Adapters

- **Sockets (Inputs):**
- `CU` (Type `adapter::types::unidirectional::AX`)
- `CD` (Type `adapter::types::unidirectional::AX`)
- `R` (Type `adapter::types::unidirectional::AX`)
- `LD` (Type `adapter::types::unidirectional::AX`)
- `PV` (Type `adapter::types::unidirectional::AI`)
- **Plugs (Outputs):**
- `QU` (Type `adapter::types::unidirectional::AX`)
- `QD` (Type `adapter::types::unidirectional::AX`)
- `CV` (Type `adapter::types::unidirectional::AI`)

Functionality

This function block operates as a pure **adapter wrapper** for the internal IEC 61131-3 FB `FB_CTUD`. Incoming adapter events (via the sockets) are aggregated at the event input `FB_CTUD.REQ`, while the corresponding data values (e.g., `CU.D`, `PV.D`) are forwarded to the corresponding inputs of the internal counter. During each execution of the internal function block, its outputs (`CV`, `QU`, `QD`) are read and output via the adapter plugs. Simultaneously, the event `CNF` is generated.

The internal counter behaves like a classic IEC 61131-3 up-down counter:

- A rising edge at `CU` increments the counter value by 1.
- A rising edge at `CD` decrements the counter value by 1.
- A rising edge at `R` resets the counter value to 0.
- A rising edge at `CU` increments the counter value by 1.
- A rising edge at `R` resets the counter value to 0. - The combination of `LD = TRUE` and an event at `PV` loads the current counter value to the value of `PV`.
- `QU` becomes TRUE when the counter value reaches or exceeds the preset value.
- `QD` becomes TRUE when the counter value reaches or falls below 0.

Technical Features

- **No Change Detection:** The function block outputs `CNF`, `QU`, `QD`, and `CV` **for every received event** (regardless of an actual value change). If a behavior is desired where the outputs only fire upon a change,

a preceding **AX_D_FF** (differentiator/filter) should be used. This is also explicitly recommended in the function block's source code.
- **Adapter Usage:** All communication takes place via unidirectional adapters (`AX` for Boolean events, `AI` for analog values). This enables loose coupling and reusability in different system topologies.
- **Unified Triggering:** All five event sources (CU, CD, R, LD, PV) trigger the execution of the internal counter via the common `REQ` input – there is no separate processing logic for each event.

State Overview

The component itself does not have an explicit state machine, but rather reflects the state of the internal `FB_CTUD`:

- **Counter Reading (INT):** Initial 0, changes via CU, CD, R, or LD.
- **Flags:** `QU` and `QD` are set based on a comparison of the counter reading and the preset value (or 0).
- **Preset Value:** Stored via the `PV` adapter and loaded with each `LD` event.

A detailed state machine description of the IEC 61131-3 counter can be found in the corresponding standard.

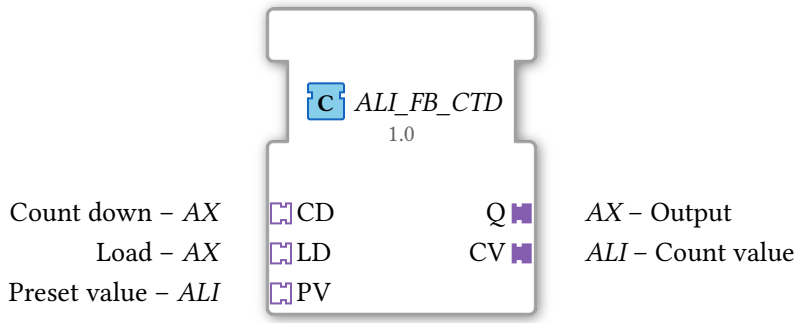
Application Scenarios

- **Bidirectional Event Counting:** E.g., detecting workpieces on a conveyor belt using sensors for infeed (CU) and outfeed (CD).
- **Inventory Management:** Adding and removing materials from a buffer.
- **Preset Positioning:** A system can be set to a predefined position (PV) and then tracked using CU/CD.
- **Resets After Cycle End:** Resetting the counter after reaching a specific quantity.

Comparison with Similar Function Blocks

- **FB_CTUD (Standard IEC 61131-3):** The `AI_FB_CTUD` is an **adapter version** of the same logic block. While the standard FB uses classic input/output pins, the adapter version communicates via event and data adapters. This simplifies integration into 4diac systems with adapter-based communication.
- **AI_FB_CTU / AI_FB_CTD:** Simple up and down counters without reverse direction. `AI_FB_CTUD` offers both counting directions in a single block.
- **AX_D_FF:** A differentiator/filter that fires only on changes. Can be used as a pre-function block to optimize the output behavior of `AI_FB_CTUD`.

Conclusion



The `AI_FB_CTUD` is a powerful, adapter-based up/down counter that transfers the established IEC 61131-3 functionality into the event-driven world of 4diac. Its clean encapsulation and use of unidirectional adapters make it flexible and easy to integrate into modular automation solutions. The explicit recommendation to use a `AX_D_FF`For change-driven output, this shows that the component was deliberately kept simple – a strength for transparent and predictable systems.

ALI_FB_CTD

• – ◦ • – ◦ • – ◦ •

The **ALI_FB_CTD** is a down counter for LINT values (64-bit integers) with adapter interfaces according to IEC 61499. It is specifically designed for use with the unidirectional adapters `AX` (event/boolean carrier) and `ALI` (LINT value carrier). The function block encapsulates the standard FB `FB_CTD_LINT` from the library `iec61131::counters` and extends it with an adapter-based connection that enables loose coupling between the function blocks. The function block fires its event outputs with every update – regardless of whether the counter value actually changes. For change-triggered processing, it is recommended to use a `AX_D_FF` as a filter.

None – all event and data information is transmitted via adapter sockets (CD, LD, PV).

- **CNF** (Event): Acknowledgement of the executed operation (sent after every update).

There are no separate data inputs. The input data is provided via the following adapter sockets:

- **CD** (Socket, type `adapter::types::unidirectional::AX`): Down count pulse (activates the counting process).
- **PV** (Socket, type `adapter::types::unidirectional::ALI`): Preset value (LINT); the value is adopted during loading (LD).

There are no separate data outputs. The output data is provided via the following adapter plugs:

- **Q** (Plug, type `adapter::types::unidirectional::AX`): Output signal (Bool) – indicates whether the counter reading has reached **zero**.
- **CV** (Plug, type `adapter::types::unidirectional::ALI`): Current counter value (LINT).
